

#### Description

The Atmel® | SMART™ SAM C20 is a microcontroller series optimized for industrial automation, appliances and other 5V applications using the 32-bit ARM® Cortex®-M0+ processor, and ranging from 32- to 64-pins with up to 256KB Flash and 32KB of SRAM. The SAM C20 devices operate at a maximum frequency of 48MHz and reach 2.46 Coremark/MHz. They are designed for simple and intuitive migration with identical peripheral modules, hex compatible code, identical linear address map and pin compatible migration paths between all devices in the product series. All devices include intelligent and flexible peripherals, Atmel Event System for inter-peripheral signaling, and support for capacitive touch button, slider and wheel user interfaces. SAM C20 devices are pin compatible to the SAM D family of general purpose microcontrollers.

The Atmel SAM C20 devices provide the following features: In-system programmable Flash, six-channel direct memory access (DMA) controller, six channel Event System, programmable interrupt controller, up to 52 programmable I/O pins, 32-bit real-time clock and calendar, up to five 16-bit Timer/Counters (TC) and one 24-bit Timer/Counter for Control (TCC), where each TC can be configured to perform frequency and waveform generation, accurate program execution timing or input capture with time and frequency measurement of digital signals. The TCs can operate in 8- or 16-bit mode, selected TCs can be cascaded to form a 32-bit TC, and one timer/counter has extended functions optimized for motor, lighting and other control applications. The series provide up to four Serial Communication Modules (SERCOM) that each can be configured to act as an USART, UART, SPI, I<sup>2</sup>C up to 3.4MHz, SMBus, PMBus, RS-485 and LIN master/slave; one 12-bit, 1Msps ADC with up to 12 channels, two analog comparators with window mode, Peripheral Touch Controller supporting up to 256 buttons, sliders, wheels and proximity sensing; programmable Watchdog Timer, brown-out detector and power-on reset and two-pin Serial Wire Debug (SWD) program and debug interface.

All devices have accurate and low-power external and internal oscillators. All oscillators can be used as a source for the system clock. Different clock domains can be independently configured to run at different frequencies, enabling power saving by running each peripheral at its optimal clock frequency, and thus maintaining a high CPU frequency while reducing power consumption.

The SAM C20 devices have three software-selectable sleep modes, idle, standby and off. In idle mode the CPU is stopped while all other functions can be kept running. In standby all clocks and functions are stopped except those selected to continue running. In this mode all RAMs and logic contents are retained. The device supports SleepWalking. This feature allows the peripheral to wake up from sleep based on predefined conditions, and thus allows some internal operation like DMA transfer and/or the CPU to wake up only when needed, e.g. when a threshold is crossed or a result is ready. The Event System supports synchronous and asynchronous events, allowing peripherals to receive, react to and send events even in standby mode.

The Flash program memory can be reprogrammed in-system through the SWD interface. The same interface can be used for non-intrusive on-chip debug of application code. A boot loader running in the device can use any communication interface to download and upgrade the application program in the Flash memory.

The Atmel SAM C20 devices are supported with a full suite of program and system development tools, including C compilers, macro assemblers, program debugger/simulators, programmers and evaluation kits.

## Features

---

- Processor
  - ARM Cortex-M0+ CPU running at up to 48MHz
    - Single-cycle hardware multiplier
    - Micro Trace Buffer
- Memories
  - 32/64/128/256KB in-system self-programmable Flash
  - 2/4/6/8KB independent self-programmable Flash for EEPROM emulation
  - 4/8/16/32KB SRAM Main Memory
- System
  - Power-on reset (POR) and brown-out detection (BOD)
  - Internal and external clock options with 48MHz to 96MHz Fractional Digital Phase Locked Loop (FDPLL96M)
  - External Interrupt Controller (EIC)
  - 16 external interrupts
  - One non-maskable interrupt
  - Two-pin Serial Wire Debug (SWD) programming, test and debugging interface
- Low Power
  - Idle, standby, and off sleep modes
  - SleepWalking peripherals
- Peripherals
  - Hardware Divide Accelerator (DIVA)
  - 6-channel Direct Memory Access Controller (DMAC)
  - 6-channel Event System
  - Up to five 16-bit Timer/Counters (TC), configurable as either:
    - One 16-bit TC with compare/capture channels
    - One 8-bit TC with compare/capture channels
    - One 32-bit TC with compare/capture channels, by using two TCs
  - One 24-bit Timer/Counter for Control (TCC), with extended functions:
    - Up to four compare channels with optional complementary output
    - Generation of synchronized pulse width modulation (PWM) pattern across port pins
    - Deterministic fault protection, fast decay and configurable dead-time between complementary output
    - Dithering that increase resolution with up to 5 bit and reduce quantization error
  - 32-bit Real Time Counter (RTC) with clock/calendar function
  - Watchdog Timer (WDT)
  - CRC-32 generator
  - Up to four Serial Communication Interfaces (SERCOM), each configurable to operate as either:
    - USART with full-duplex and single-wire half-duplex configuration
    - I<sup>2</sup>C up to 3.4MHz
    - SPI
    - LIN master/slave
    - RS-485
  - One Configurable Custom Logic (CCL)
  - One 12-bit, 1Msps Analog-to-Digital Converter (ADC) with up to 12 channels
    - Differential and single-ended input
    - Automatic offset and gain error compensation
    - Oversampling and decimation in hardware to support 13-, 14-, 15- or 16-bit resolution
  - Two Analog Comparators (AC) with window compare function
  - Peripheral Touch Controller (PTC)
    - 256-Channel capacitive touch and proximity sensing
- I/O
  - Up to 52 programmable I/O pins
- Drop in compatible with SAM D20 and SAM D21
- Packages
  - 64-pin TQFP, QFN
  - 48-pin TQFP, QFN
  - 32-pin TQFP, QFN
- Operating Voltage
  - 2.7V – 5.5V

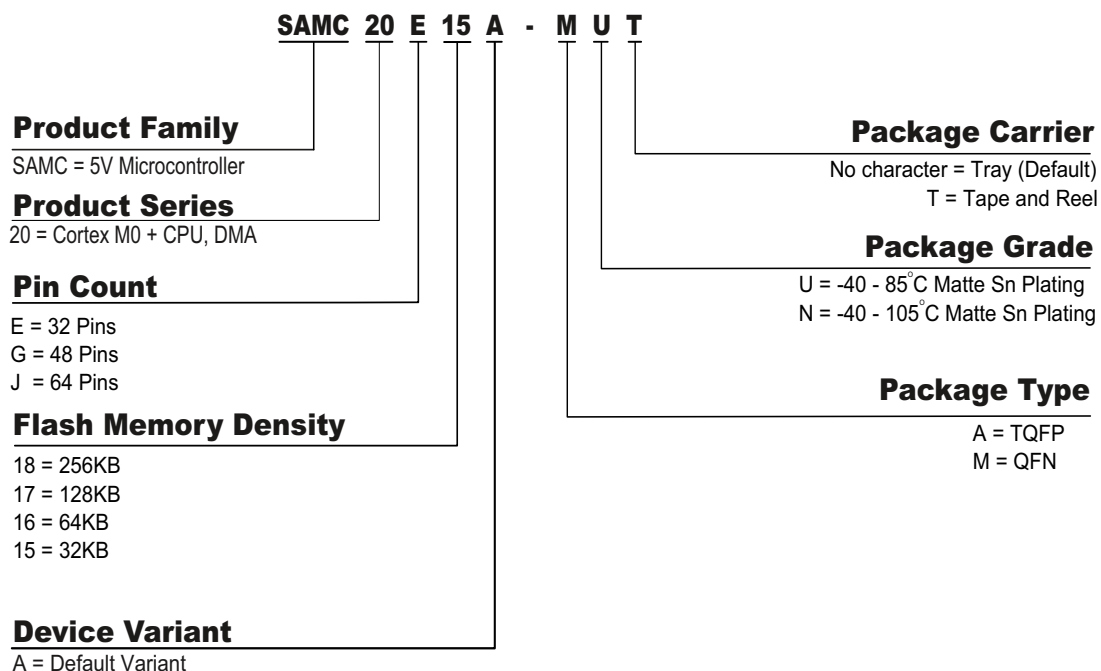

# 1. Configuration Summary

|  | SAM C20J                             | SAM C20G                             | SAM C20E                             |
|--|--------------------------------------|--------------------------------------|--------------------------------------|
| Pins   | 64                                   | 48                                   | 32                                   |
| General Purpose I/O-pins (GPIOs)                         | 52                                   | 38                                   | 26                                   |

## 2. Ordering Information

### 2.1 SAM C20E

| Ordering Code    | FLASH (bytes) | SRAM (bytes) | Package | Carrier Type |
|------------------|---------------|--------------|---------|--------------|
| ATSAMC20E15A-AUT | 32K           | 4K           | TQFP32  | Tape & Reel  |
| ATSAMC20E15A-MUT | 32K           | 4K           | QFN32   | Tape & Reel  |
| ATSAMC20E16A-AUT | 64K           | 8K           | TQFP32  | Tape & Reel  |
| ATSAMC20E16A-MUT | 64K           | 8K           | QFN32   | Tape & Reel  |
| ATSAMC20E17A-AUT | 128K          | 16K          | TQFP32  | Tape & Reel  |
| ATSAMC20E17A-MUT | 128K          | 16K          | QFN32   | Tape & Reel  |
| ATSAMC20E18A-AUT | 256K          | 32K          | TQFP32  | Tape & Reel  |
| ATSAMC20E18A-MUT | 256K          | 32K          | QFN32   | Tape & Reel  |

### 2.2 SAM C20G

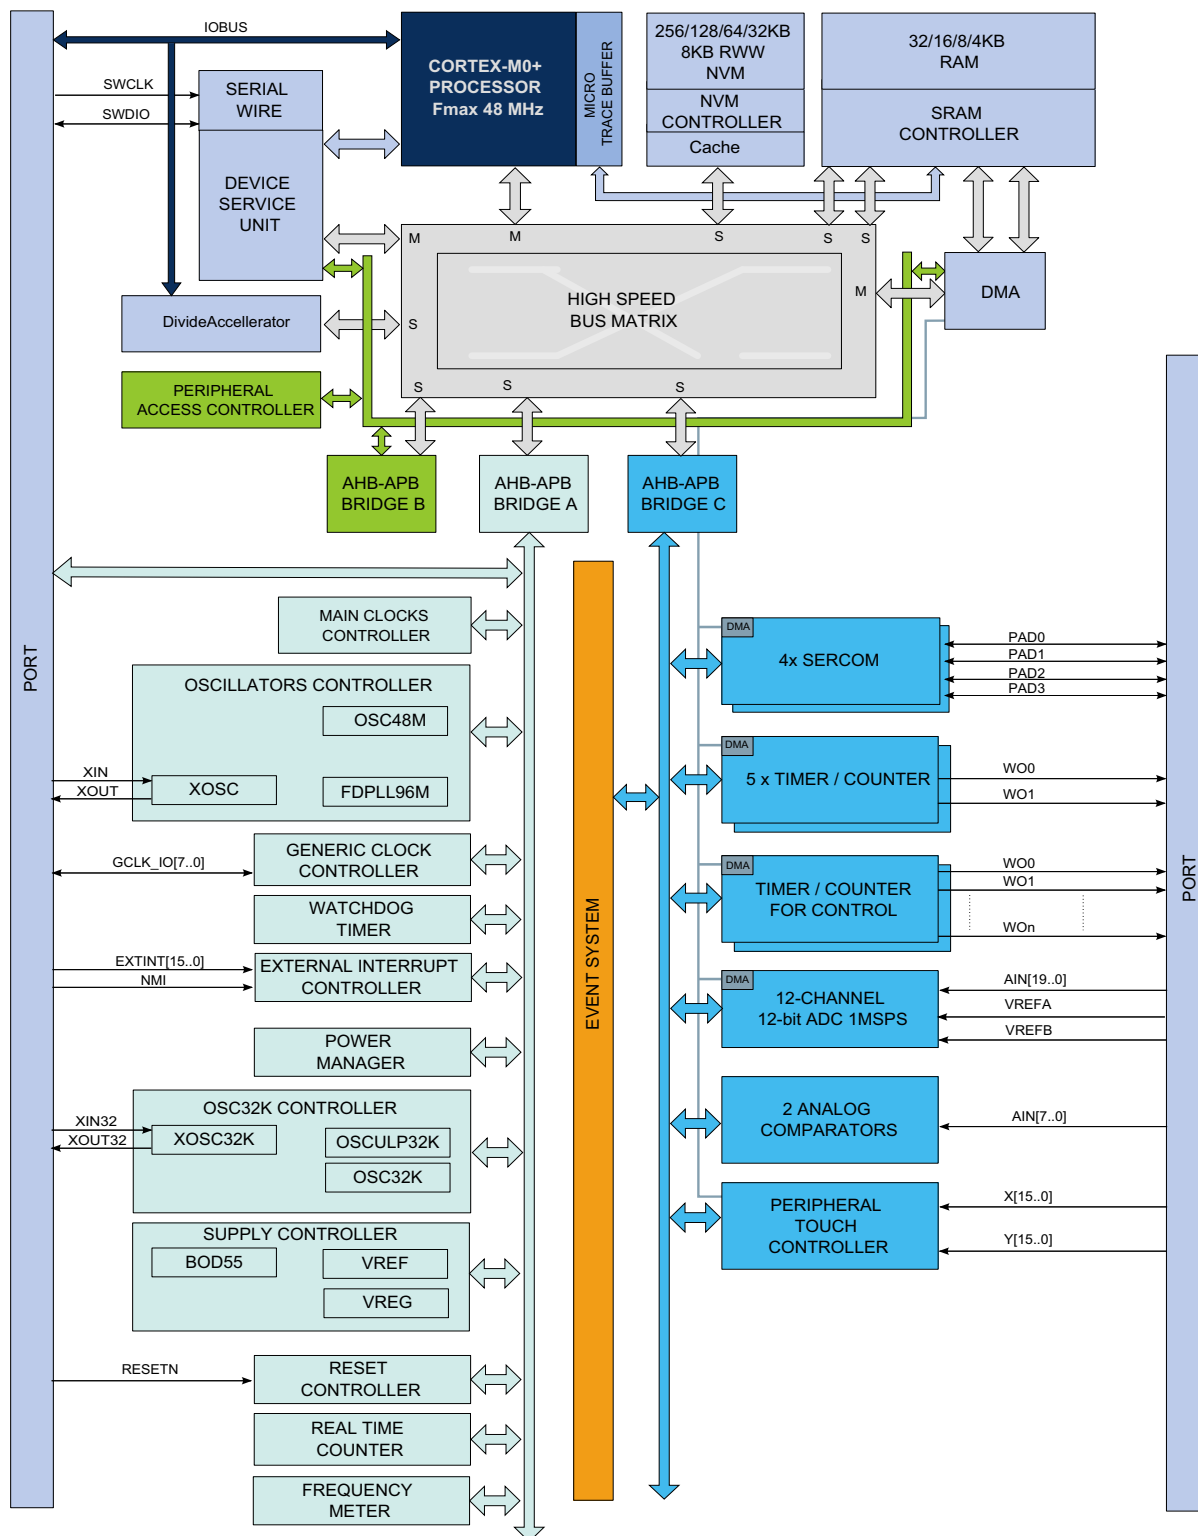

| Ordering Code    | FLASH (bytes) | SRAM (bytes) | Package | Carrier Type |
|------------------|---------------|--------------|---------|--------------|
| ATSAMC20G15A-AUT | 32K           | 4K           | TQFP48  | Tape & Reel  |
| ATSAMC20G15A-MUT | 32K           | 4K           | QFN48   | Tape & Reel  |
| ATSAMC20G16A-AUT | 64K           | 8K           | TQFP48  | Tape & Reel  |

| Ordering Code    | FLASH (bytes) | SRAM (bytes) | Package | Carrier Type |
|------------------|---------------|--------------|---------|--------------|
| ATSAMC20G16A-MUT | 64K           | 8K           | QFN48   | Tape & Reel  |
| ATSAMC20G17A-AUT | 128K          | 16K          | TQFP48  | Tape & Reel  |
| ATSAMC20G17A-MUT | 128K          | 16K          | QFN48   | Tape & Reel  |
| ATSAMC20G18A-AUT | 256K          | 32K          | TQFP48  | Tape & Reel  |
| ATSAMC20G18A-MUT | 256K          | 32K          | QFN48   | Tape & Reel  |

## 2.3 SAM C20J

| Ordering Code    | FLASH (bytes) | SRAM (bytes) | Package | Carrier Type |
|------------------|---------------|--------------|---------|--------------|
| ATSAMC20J15A-AUT | 32K           | 4K           | TQFP64  | Tape & Reel  |
| ATSAMC20J15A-MUT | 32K           | 4K           | QFN64   | Tape & Reel  |
| ATSAMC20J16A-AUT | 64K           | 8K           | TQFP64  | Tape & Reel  |
| ATSAMC20J16A-MUT | 64K           | 8K           | QFN64   | Tape & Reel  |
| ATSAMC20J17A-AUT | 128K          | 16K          | TQFP64  | Tape & Reel  |
| ATSAMC20J17A-MUT | 128K          | 16K          | QFN64   | Tape & Reel  |
| ATSAMC20J18A-AUT | 256K          | 32K          | TQFP64  | Tape & Reel  |
| ATSAMD20J18A-MUT | 256K          | 32K          | QFN64   | Tape & Reel  |

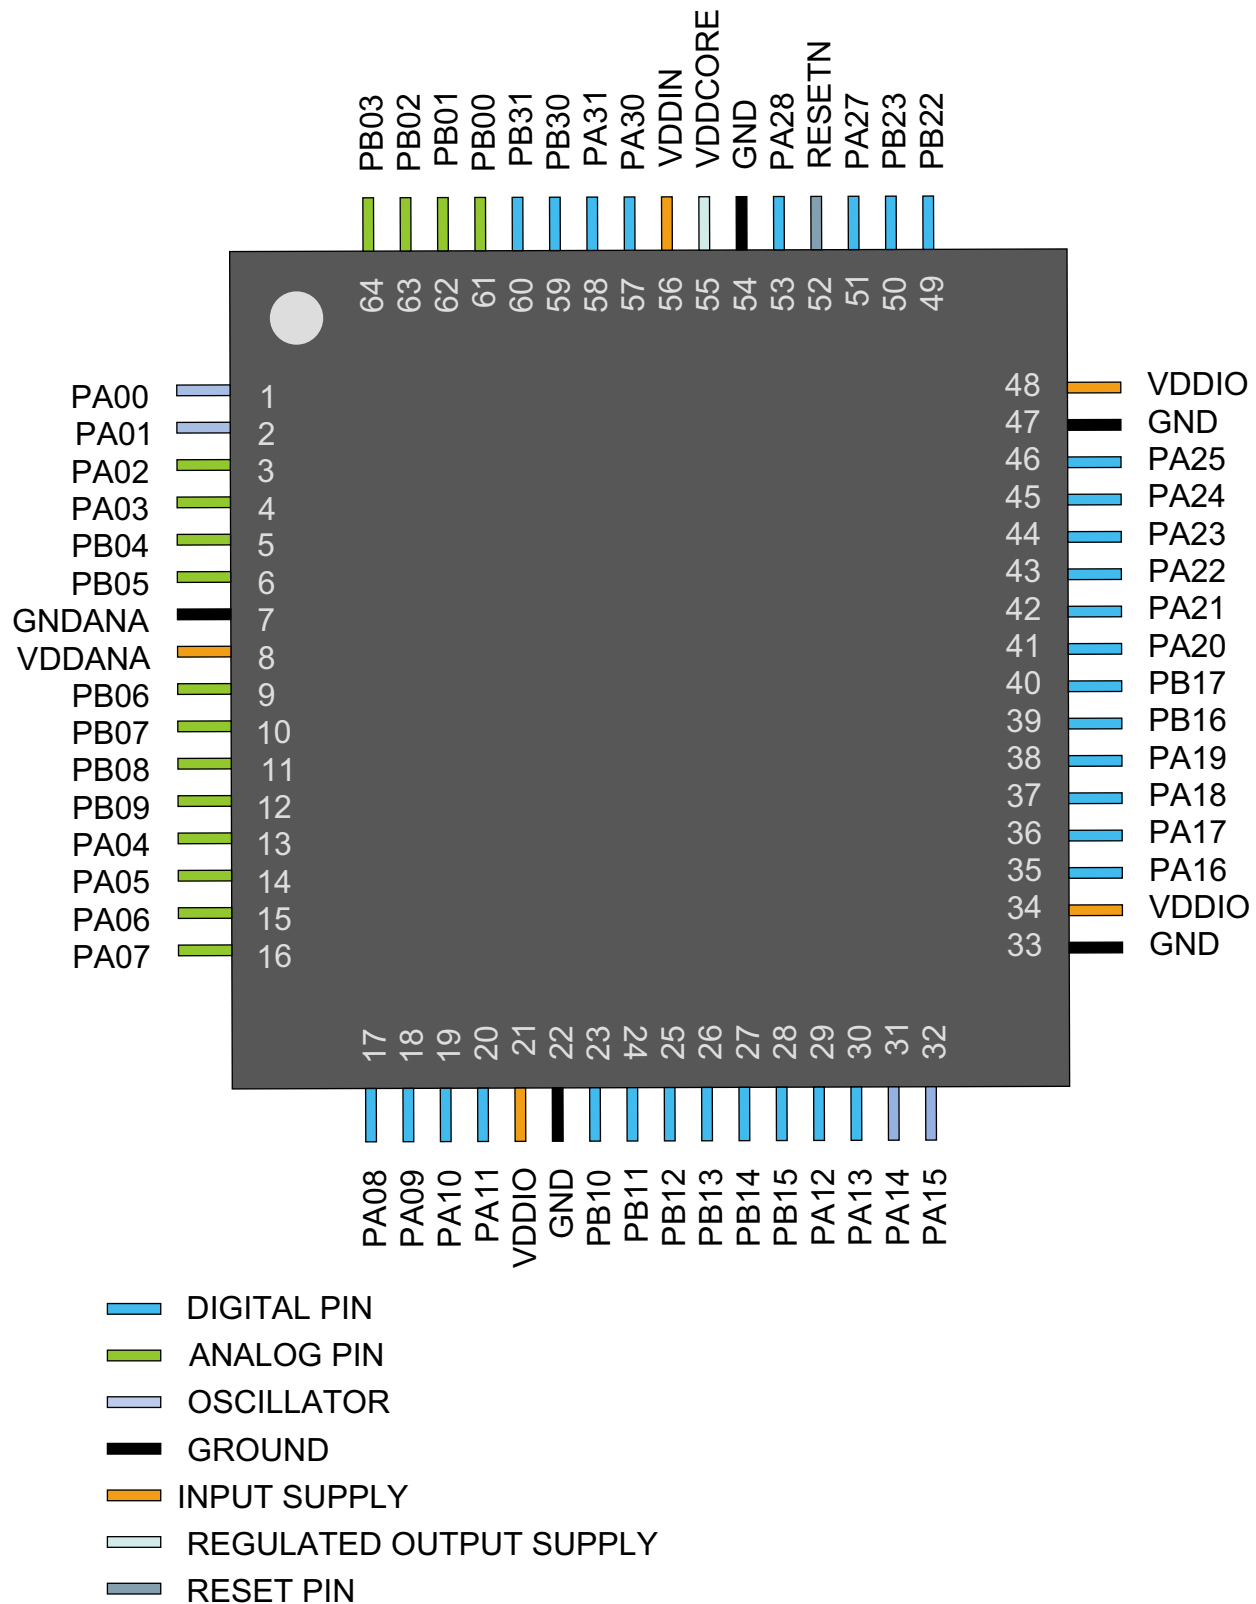

### 3. Block Diagram

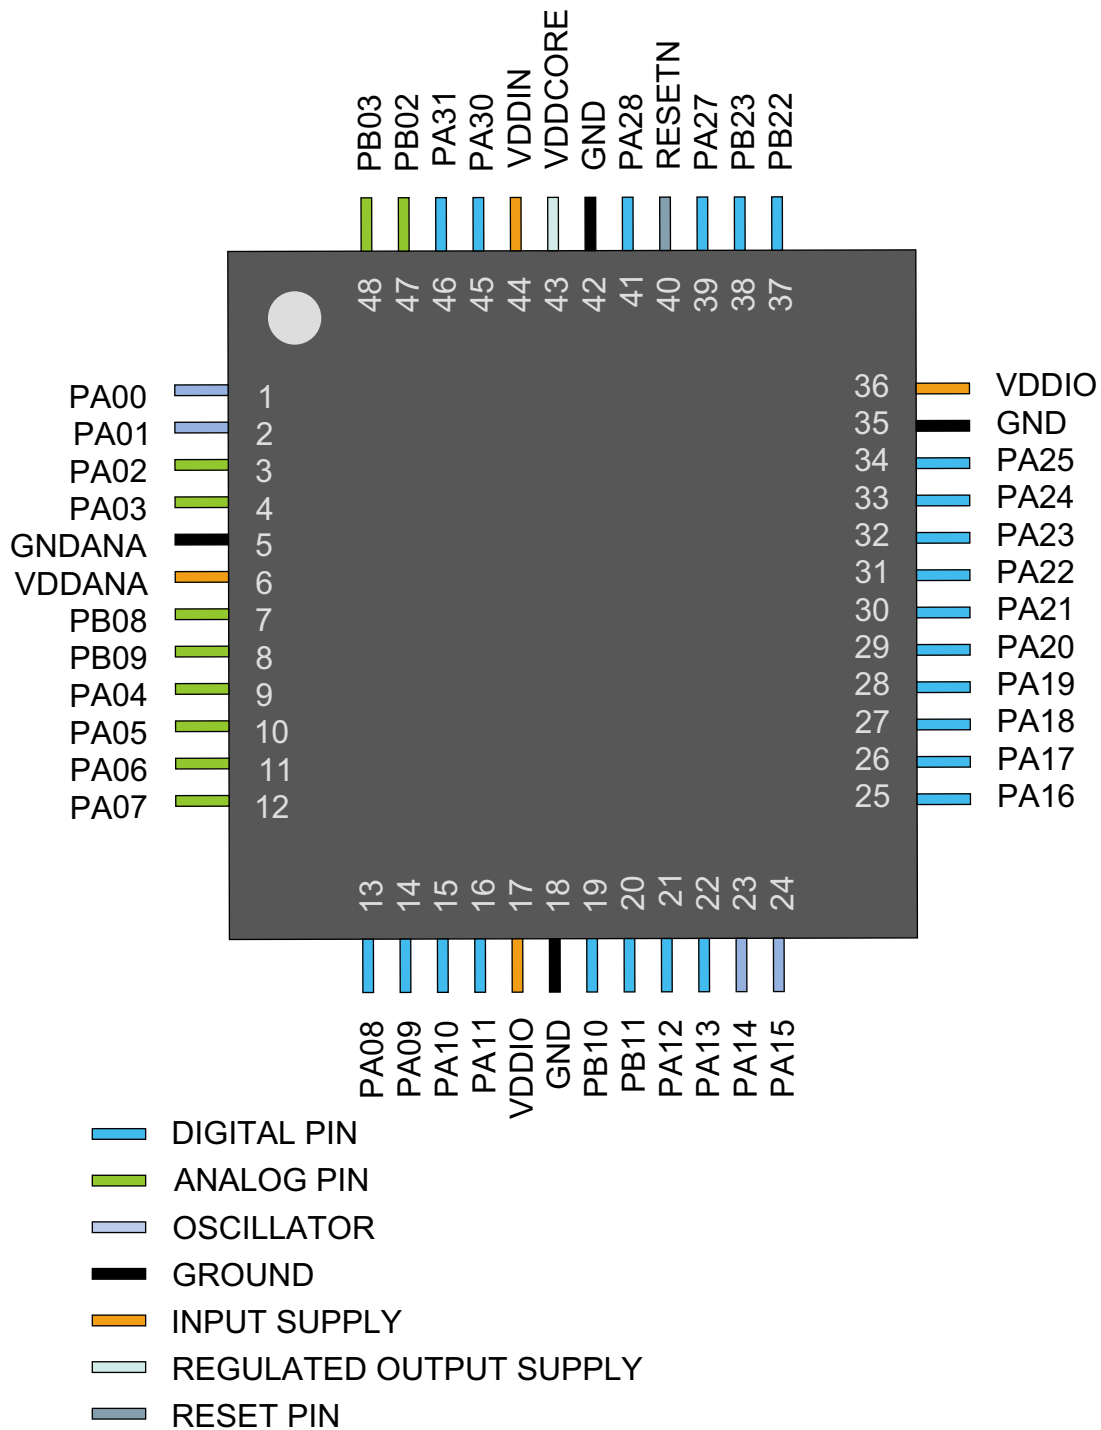

Notes: 1. Some products have different number of SERCOM instances, Timer/Counter instances, PTC signals and ADC signals. Refer to "Ordering Information" on page 4 for details.

## 4.2 SAM C20G

4.3 SAM C20E

## 5. Signal Descriptions List

The following table gives details on signal names classified by peripheral.

| Signal Name                                     | Function  | Type            | Active Level |
|---|---|-----------------|--------------|
| <b>Analog Comparators - AC</b>                  |   |                 |              |
| AIN[3:0]  | AC Analog Inputs  | Analog          |              |
| CMP[1:0]  | AC Comparator Outputs   | Digital         |              |
| <b>Analog Digital Converter - ADC</b>           |   |                 |              |
| AIN[11:0]                                       | ADC Analog Inputs   | Analog          |              |
| VREFA   | ADC Voltage External Reference A                                      | Analog          |              |
| <b>External Interrupt Controller - EIC</b>      |   |                 |              |
| EXTINT[15:0]                                    | External Interrupts inputs  | Digital         |              |
| NMI   | External Non-Maskable Interrupt input                                 | Digital         |              |
| <b>Generic Clock Generator - GCLK</b>           |   |                 |              |
| GCLK_IO[7:0]                                    | Generic Clock (source clock inputs or generic clock generator output) | Digital         |              |
| <b>Custom Control Logic - CCL</b>               |   |                 |              |
| IN[11:0]  | Logic Inputs  | Digital         |              |
| OUT[3:0]  | Logic Outputs   | Digital         |              |
| <b>Power Manager - PM</b>                       |   |                 |              |
| RESETN  | Reset input   | Digital         | Low          |
| <b>Serial Communication Interface - SERCOMx</b> |   |                 |              |
| PAD[3:0]  | SERCOM Inputs/Outputs Pads  | Digital         |              |

## 6. I/O Multiplexing and Considerations

### 6.1 Multiplexed Signals

Each pin is by default controlled by the PORT as a general purpose I/O and alternatively it can be assigned to one of the peripheral functions A, B, C, D, E, F, G; H or I. To enable a peripheral function on a pin, the Peripheral Multiplexer Enable bit in the Pin Configuration register corresponding to that pin (PINCFGn.PMUXEN, n = 0-31) in the PORT must be written to one. The selection of peripheral function A to H is done by writing to the Peripheral Multiplexing Odd and Even bits in the Peripheral Multiplexing register (PMUXn.PMUXE/O) in the PORT.

Table 5-1 on page 11 describes the peripheral signals multiplexed to the PORT I/O pins.

**Table 6-1. PORT Function Multiplexing**

| Pin      |          |          | I/O Pin | Supply | Type             | A         | B <sup>(1)(2)</sup> |        |        |            |  |  | C                           | D                         | E          | F   | G   | H       | I               |

|         |         | 61      | PB00    | VDDANA |                  | EXTINT[0]  |                     |      |  |    | Y[6]        |  |  |                             |                           | TC3/WO[0]  |                |   |            | CCL0<br>IN[1] |
|         |         | 62      | PB01    | VDDANA |                  | EXTINT[1]  |                     |      |  |    | Y[7]        |  |  |                             |                           | TC3/WO[1]  |                |   |            | CCL0<br>IN[2] |
|         | 47      | 63      | PB02    | VDDANA |                  | EXTINT[2]  |                     |      |  |    | Y[8]        |  |  |                             |                           | TC2/WO[0]  |                |   |            | CCL0<br>OUT   |
|         | 48      | 64      | PB03    | VDDANA |                  | EXTINT[3]  |                     |      |  |    | Y[9]        |  |  |                             |                           | TC2/WO[1]  |                |   |            |               |

- Notes:
1. All analog pin functions are on peripheral function B. Peripheral function B must be selected to disable the digital control of the pin.
  2. Only some pins can be used in SERCOM I<sup>2</sup>C mode. See the Type column for using a SERCOM pin in I<sup>2</sup>C mode.
  3. Note that SERCOM4 and SERCOM5 are not supported on SAM C20E.
  4. This function is only activated in the presence of a debugger.
  5. Pins of type HS and I<sup>2</sup>C have higher sink capabilities.

## 6.2 Other Functions

### 6.2.1 Oscillator Pinout

The oscillators are not mapped to the normal PORT functions and their multiplexing are controlled by registers in the Oscillator Controllers (OSCCTRL and OSC32KCTRL).

| Oscillator | Supply | Signal | I/O Pin |
|------------|--------|--------|---------|
| XOSC       | VDDIO  | XIN    | PA14    |
|            |        | XOUT   | PA15    |
| XOSC32K    | VDDANA | XIN32  | PA00    |
|            |        | XOUT32 | PA01    |

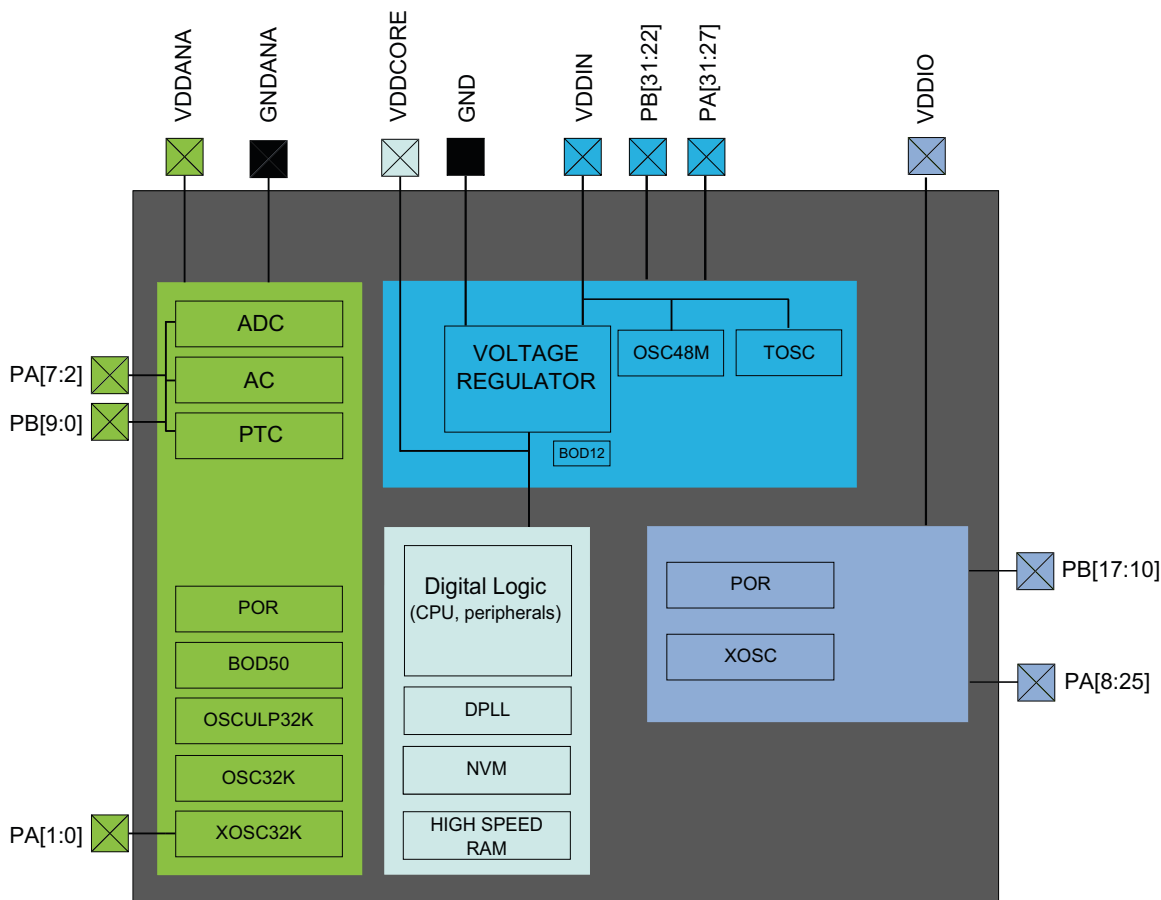

### 6.2.2 Serial Wire Debug Interface Pinout

Only the SWCLK pin is mapped to the normal PORT functions. A debugger cold-plugging or hot-plugging detection will automatically switch the SWDIO port to the SWDIO function.

| Signal | Supply | I/O Pin |
|--------|--------|---------|
| SWCLK  | VDDIN  | PA30    |
| SWDIO  | VDDIN  | PA31    |

## 7. Power Supply and Start-Up Considerations

### 7.1 Power Domain Overview

### 7.2 Power Supply Considerations

#### 7.2.1 Power Supplies

The Atmel® SAMC20 has several different power supply pins:

- VDDIO: Powers I/O lines and XOSC. Voltage is 2.70V to 5.50V.
- VDDIN: Powers I/O lines and the OSC48M, TOSC and internal regulator. Voltage is 2.70V to 5.50V.
- VDDANA: Powers I/O lines and the ADC, AC, PTC, OSCULP32K, OSC32K and XOSC32K. Voltage is 2.70V to 5.50V.
- VDDCORE: Internal regulated voltage output. Powers the core, memories, peripherals, and FDPLL96M. Voltage is 1.2V typical.

The same voltage must be applied to both VDDIN and VDDANA. This common voltage is referred to as  $V_{DD}$  in the datasheet. VDDIO must always be less than or equal to VDDIN.

The ground pins, GND, are common to VDDCORE, VDDIO and VDDIN. The ground pin for VDDANA is GNDANA.

For decoupling recommendations for the different power supplies, refer to the schematic checklist.

Refer to [“Schematic Checklist” on page 940](#) for details.

## 7.2.2 Voltage Regulator

The SAM C20 voltage regulator has two different modes:

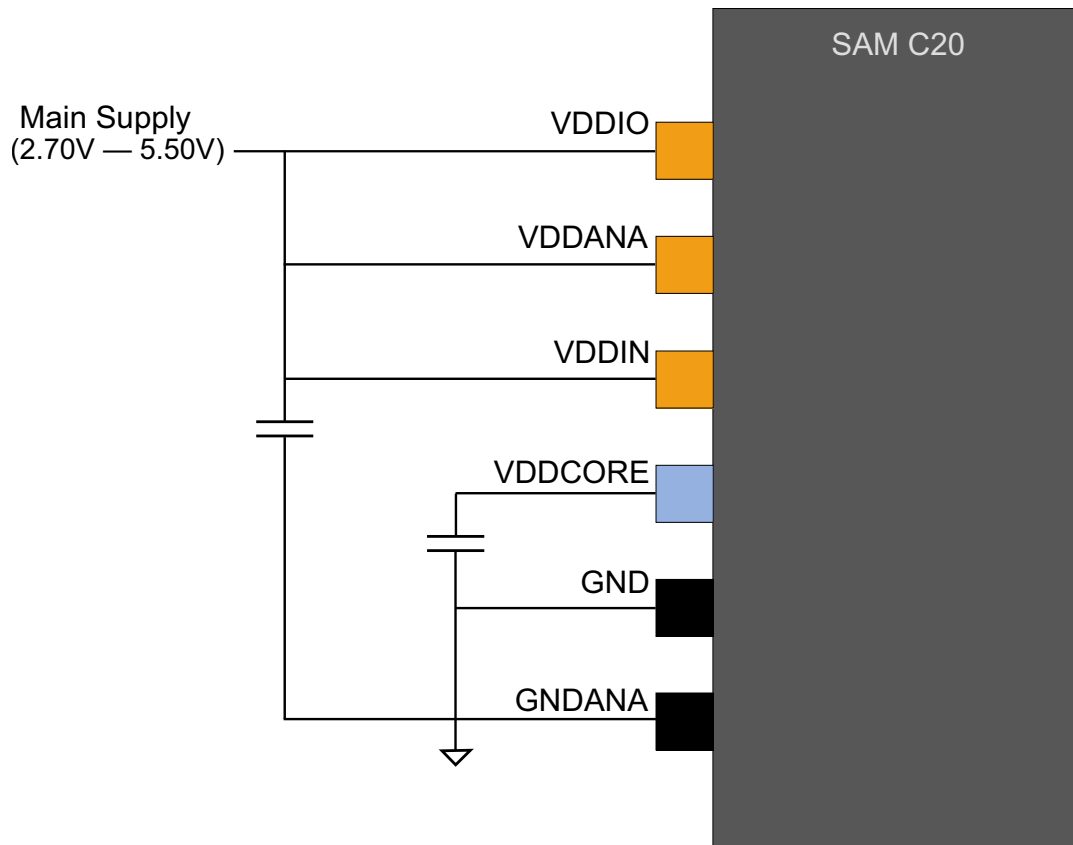

- Normal mode: This is the default mode when CPU and peripherals are running
- Low Power (LP) mode: This is the default mode used when the chip is in standby mode.

## 7.2.3 Typical Powering Schematics

The SAM C20 uses a single supply from 2.70V to 5.50V or dual supply mode where VDDIO is supplied separately from VDDIN.

The following figures show the recommended power supply connections.

**Figure 7-1. Power Supply Connection for single supply mode only**

**Figure 7-2. Power Supply Connection for dual supply mode**

## 7.2.4 Power-Up Sequence

### 7.2.4.1 Minimum Rise Rate

The integrated power-on reset (POR) circuitry monitoring the VDDIN power supply requires a minimum rise rate. Refer to the [“Electrical Characteristics” on page 903](#) for details.

### 7.2.4.2 Maximum Rise Rate

The rise rate of the power supply must not exceed the values described in Electrical Characteristics. Refer to the [“Electrical Characteristics” on page 903](#) for details.

## 7.3 Power-Up

This section summarizes the power-up sequence of the SAM C20. The behavior after power-up is controlled by the Power Manager. Refer to [“PM – Power Manager” on page 148](#) for details.

### 7.3.1 Starting of Clocks

After power-up, the device is set to its initial state and kept in reset, until the power has stabilized throughout the device. Once the power has stabilized, the device will use a 4MHz clock. This clock is derived from the 48MHz Internal Oscillator (OSC48M), which is configured to provide a 4MHz clock and used as a clock source for generic clock generator 0. Generic clock generator 0 is the main clock for the Power Manager (PM).

Some synchronous system clocks are active, allowing software execution.

Refer to the “Clock Mask Register” section in [“PM – Power Manager” on page 148](#) for the list of default peripheral clocks running. Synchronous system clocks that are running are by default not divided and receive a 4MHz clock through generic clock generator 0. Other generic clocks are disabled.

### 7.3.2 I/O Pins

After power-up, the I/O pins are tri-stated.

### 7.3.3 Fetching of Initial Instructions

After reset has been released, the CPU starts fetching PC and SP values from the reset address, which is 0x00000000. This address points to the first executable address in the internal flash. The code read from the internal flash is free to configure the clock system and clock sources. Refer to “PM – Power Manager” on page 148, “GCLK – Generic Clock Controller” on page 109, “OSCCTRL – Oscillators Controller” on page 157, and “OSC32KCTRL – 32k Oscillators Controller” on page 201 for details. Refer to the ARM Architecture Reference Manual for more information on CPU startup (<http://www.arm.com>).

## 7.4 Power-On Reset and Brown-Out Detector

The SAM C20 embeds three features to monitor, warn and/or reset the device:

- POR: Power-on reset on VDDIN and VDDIO
- BODVDD: Brown-out detector on VDDIN
- BODCORE: Voltage Regulator Internal Brown-out detector on VDDCORE. The Voltage Regulator Internal BOD is calibrated in production and its calibration configuration is stored in the NVM User Row. This configuration should not be changed if the user row is written to assure the correct behavior of the BODCORE.

### 7.4.1 Power-On Reset on VDDIN

POR monitors VDDIN. It is always activated and monitors voltage at startup and also during all the sleep modes. If VDDIN goes below the threshold voltage, the entire chip is reset.

### 7.4.2 Power-On Reset on VDDIO

POR monitors VDDIO. It is always activated and monitors voltage at startup and also during all the sleep modes. If VDDIO goes below the threshold voltage, all IOs supplied by VDDIO are reset.

### 7.4.3 Brown-Out Detector on VDDIN

BODVDD monitors VDDIN. Refer to “SUPC – Supply Controller” on page 228 for details.

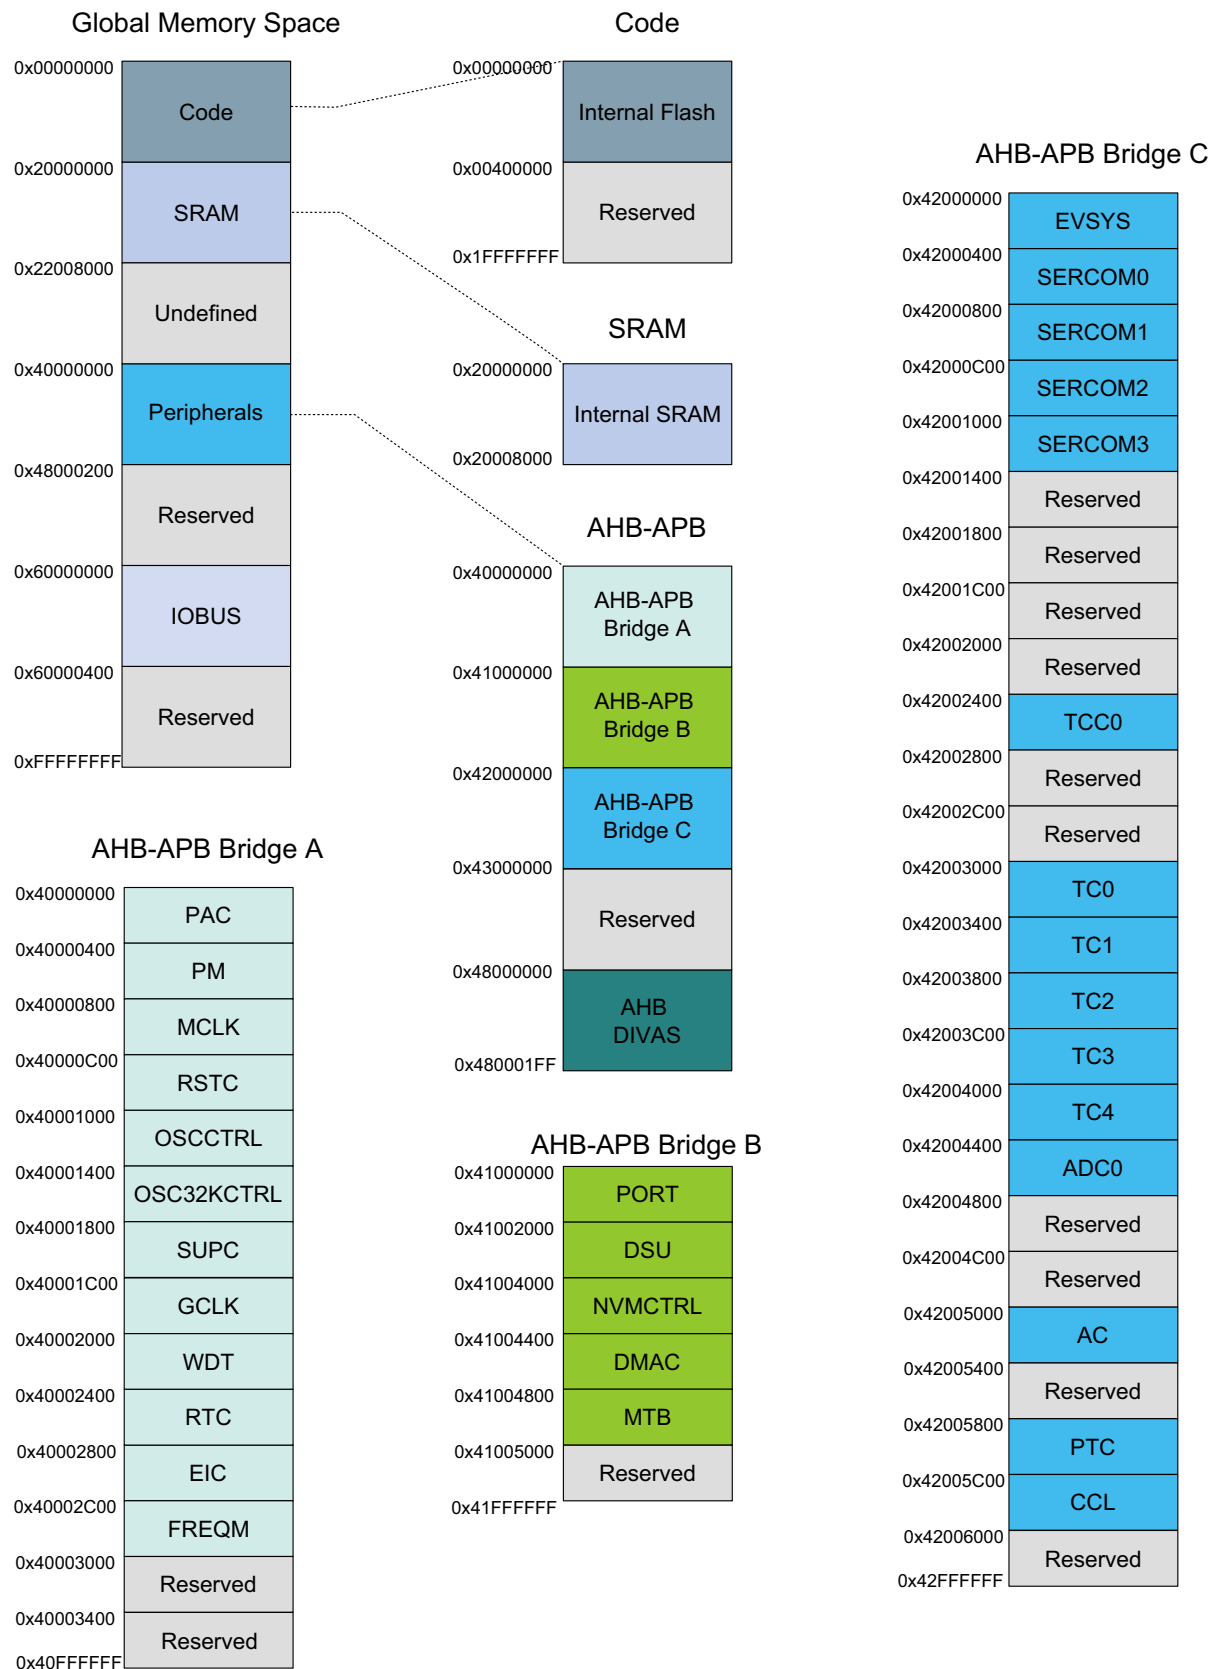

### 7.4.4 Brown-Out Detector on VDDCORE

Once the device has started up, BODCORE monitors the internal VDDCORE.

## 8. Product Mapping

**Figure 8-1. SAM C20 Product Mapping**

## 9. Memories

### 9.1 Embedded Memories

- Internal high-speed flash with Read-While-Write capability on section of the array
- Internal high-speed RAM, single-cycle access at full speed

### 9.2 Physical Memory Map

The High-Speed bus is implemented as a bus matrix. All High-Speed bus addresses are fixed, and they are never remapped in any way, even during boot. The 32-bit physical address space is mapped as follow:

**Table 9-1. SAM C20 physical memory map<sup>(1)</sup>**

| Memory                   | Start address | Size      |           |           |           |
|--------------------------|---------------|-----------|-----------|-----------|-----------|
|                          |               | SAMC20x18 | SAMC20x17 | SAMC20x16 | SAMC20x15 |
| Embedded Flash           | 0x00000000    | 256Kbytes | 128Kbytes | 64Kbytes  | 32Kbytes  |
| Embedded RWW section     | 0x00400000    | 8Kbytes   | 4Kbytes   | 2Kbytes   | 1Kbytes   |
| Embedded high-speed SRAM | 0x20000000    | 32Kbytes  | 16Kbytes  | 8Kbytes   | 4Kbytes   |
| Peripheral Bridge A      | 0x40000000    | 64Kbytes  | 64Kbytes  | 64Kbytes  | 64Kbytes  |
| Peripheral Bridge B      | 0x41000000    | 64Kbytes  | 64Kbytes  | 64Kbytes  | 64Kbytes  |
| Peripheral Bridge C      | 0x42000000    | 64Kbytes  | 64Kbytes  | 64Kbytes  | 64Kbytes  |

Note: 1. x = G, J or E.

**Table 9-2. Flash memory parameters<sup>(1)</sup>**

| Device    | Flash size (FLASH_PM) | Number of pages (FLASH_P) | Page size (FLASH_W) |
|-----------|-----------------------|---------------------------|---------------------|
| SAMC20x18 | 256Kbytes             | 4096                      | 64 bytes            |
| SAMC20x17 | 128Kbytes             | 2046                      | 64 bytes            |
| SAMC20x16 | 64Kbytes              | 1024                      | 64 bytes            |
| SAMC20x15 | 32Kbytes              | 512                       | 64 bytes            |

Note: 1. x = G, J or E.

**Table 9-3. RWW section parameters<sup>(1)</sup>**

| Device    | Flash size (FLASH_PM) | Number of pages (FLASH_P) | Page size (FLASH_W) |
|-----------|-----------------------|---------------------------|---------------------|
| SAMC20x18 | 8Kbytes               | 128                       | 64 bytes            |
| SAMC20x17 | 4Kbytes               | 64                        | 64 bytes            |
| SAMC20x16 | 2Kbytes               | 32                        | 64 bytes            |
| SAMC20x15 | 1Kbytes               | 16                        | 64 bytes            |

Note: 1. x = G, J or E.

## 9.3 NVM User Row Mapping

The NVM User Row contains calibration data that are automatically read at device power on.

The NVM User Row can be read at address 0x804000.

To write the NVM User Row refer to [“NVMCTRL – Non-Volatile Memory Controller” on page 409](#).

Note that when writing to the user row the values do not get loaded by the other modules on the device until a device reset occurs.

**Table 9-4. NVM User Row Mapping**

| Bit Position | Name              | Usage   |
|--------------|-------------------|---|
| 2:0          | BOOTPROT          | Used to select one of eight different bootloader sizes. Refer to <a href="#">“NVMCTRL – Non-Volatile Memory Controller” on page 409</a> .   |
| 3            | Reserved          |   |
| 6:4          | EEPROM            | Used to select one of eight different EEPROM sizes. Refer to <a href="#">“NVMCTRL – Non-Volatile Memory Controller” on page 409</a> .       |
| 7            | Reserved          |   |
| 13:8         | BODVDD Level      | BODVDD Threshold Level at power on. Refer to <a href="#">BODVDD</a> register.   |
| 14           | BODVDD Enable     | BODVDD Enable at power on. Refer to <a href="#">BODVDD</a> register.  |
| 16:15        | BODVDD Action     | BODVDD Action at power on. Refer to <a href="#">BODVDD</a> register.  |
| 25:17        | Reserved          | Voltage Regulator Internal BOD (BODCORE) configuration. These bits are written in production and must not be changed. Default value = 0x70. |
| 26           | WDT Enable        | WDT Enable at power on. Refer to WDT <a href="#">CTRLA</a> register.  |
| 27           | WDT Always-On     | WDT Always-On at power on. Refer to WDT <a href="#">CTRLA</a> register.   |
| 31:28        | WDT Period        | WDT Period at power on. Refer to WDT <a href="#">CONFIG</a> register.   |
| 35:32        | WDT Window        | WDT Window mode time-out at power on. Refer to WDT <a href="#">CONFIG</a> register.   |
| 39:36        | WDT EWOFFSET      | WDT Early Warning Interrupt Time Offset at power on. Refer to WDT <a href="#">EWCTRL</a> register.  |
| 40           | WDT WEN           | WDT Timer Window Mode Enable at power on. Refer to WDT <a href="#">CTRLA</a> register.  |
| 41           | BODVDD Hysteresis | BODVDD Hysteresis configuration at power on. Refer to <a href="#">BODVDD</a> register.  |
| 42           | Reserved          | Voltage Regulator Internal BOD (BODCORE) configuration. This bit is written in production and must not be changed. Default value = 0.       |
| 47:43        | Reserved          |   |
| 63:48        | LOCK              | NVM Region Lock Bits. Refer to <a href="#">“NVMCTRL – Non-Volatile Memory Controller” on page 409</a> .                                     |

## 9.4 NVM Software Calibration Area Mapping

The NVM Software Calibration Area contains calibration data that are measured and written during production test. These calibration values should be read by the application software and written back to the corresponding register.

The NVM Software Calibration Area can be read at address 0x806020.

The NVM Software Calibration Area can not be written.

**Table 9-5. NVM Software Calibration Area Mapping**

| Bit Position | Name           | Description  |
|--------------|----------------|--|
| 2:0          | ADC0 LINEARITY | ADC0 Linearity Calibration. Should be written to <a href="#">CALIB</a> register. |
| 5:3          | ADC0 BIASCAL   | ADC0 Bias Calibration. Should be written to <a href="#">CALIB</a> register.      |
| 11:6         | Reserved       |  |
| 18:12        | OSC32K CAL     | OSC32KCalibration. Should be written to <a href="#">OSC32K</a> register.         |
| 63:19        | Reserved       |  |

## 9.5 Serial Number

Each device has a unique 128-bit serial number which is a concatenation of four 32-bit words contained at the following addresses:

Word 0: 0x0080A00C

Word 1: 0x0080A040

Word 2: 0x0080A044

Word 3: 0x0080A048

The uniqueness of the serial number is guaranteed only when using all 128 bits.

## 10. Processor And Architecture

### 10.1 Cortex M0+ Processor

The Atmel SAM C20 implements the ARM® Cortex™-M0+ processor, based on the ARMv6 Architecture and Thumb®-2 ISA. The Cortex M0+ is 100% instruction set compatible with its predecessor, the Cortex-M0 core, and upward compatible to Cortex-M3 and M4 cores. For more information refer to [www.arm.com](http://www.arm.com).

#### 10.1.1 Cortex M0+ Configuration

Table 10-1. Cortex M0+ Configuration

| Features                         | Configurable option          | Atmel SMART SAM C20 configuration |
|----------------------------------|------------------------------|-----------------------------------|
| Interrupts                       | External interrupts 0-32     | 32                                |
| Data endianness                  | Little-endian or big-endian  | Little-endian                     |
| SysTick timer                    | Present or absent            | Present                           |
| Number of watchpoint comparators | 0, 1, 2                      | 2                                 |
| Number of breakpoint comparators | 0, 1, 2, 3, 4                | 4                                 |
| Halting debug support            | Present or absent            | Present                           |
| Multiplier                       | Fast or small                | Fast (single cycle)               |
| Single-cycle I/O port            | Present or absent            | Present                           |
| Wake-up interrupt controller     | Supported or not supported   | Not supported                     |
| Vector Table Offset Register     | Present or absent            | Present                           |
| Unprivileged/Privileged support  | Present or absent            | Present                           |
| Memory Protection Unit           | Not present or 8-region      | 8-region                          |
| Reset all registers              | Present or absent            | Absent                            |
| Instruction fetch width          | 16-bit only or mostly 32-bit | 32-bit                            |

The ARM Cortex-M0+ core has two bus interfaces:

- Single 32-bit AMBA-3 AHB-Lite system interface that provides connections to peripherals and all system memory, which includes flash and RAM
- Single 32-bit I/O port bus interfacing to the PORT and DIVAS with 1-cycle loads and stores

#### 10.1.2 Cortex-M0+ Peripherals

- System Control Space (SCS)
  - The processor provides debug through registers in the SCS. Refer to the Cortex-M0+ Technical Reference Manual for details ([www.arm.com](http://www.arm.com)).
- System Timer (SysTick)
  - The System Timer is a 24-bit timer clocked by CLK\_CPU that extends the functionality of both the processor and the NVIC. Refer to the Cortex-M0+ Technical Reference Manual for details ([www.arm.com](http://www.arm.com)).
- Nested Vectored Interrupt Controller (NVIC)
  - External interrupt signals connect to the NVIC, and the NVIC prioritizes the interrupts. Software can set the priority of each interrupt. The NVIC and the Cortex-M0+ processor core are closely coupled, providing low

latency interrupt processing and efficient processing of late arriving interrupts. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 and the Cortex-M0+ Technical Reference Manual for details ([www.arm.com](http://www.arm.com)).

- System Control Block (SCB)
  - The System Control Block provides system implementation information, and system control. This includes configuration, control, and reporting of the system exceptions. Refer to the Cortex-M0+ Devices Generic User Guide for details ([www.arm.com](http://www.arm.com)).
- Micro Trace Buffer (MTB)
  - The CoreSight MTB-M0+ (MTB) provides a simple execution trace capability to the Cortex-M0+ processor. Refer to section “[Micro Trace Buffer](#)” on page 29 and the CoreSight MTB-M0+ Technical Reference Manual for details ([www.arm.com](http://www.arm.com)).

### 10.1.3 Cortex-M0+ Address Map

**Table 10-2. Cortex-M0+ Address Map**

| Address  | Peripheral                                  |
|--|---|
| 0xE000E000   | System Control Space (SCS)                  |
| 0xE000E010   | System Timer (SysTick)                      |
| 0xE000E100   | Nested Vectored Interrupt Controller (NVIC) |
| 0xE000ED00   | System Control Block (SCB)                  |
| 0x41008000 (see also “ <a href="#">Product Mapping</a> ” on page 21) | Micro Trace Buffer (MTB)                    |

### 10.1.4 I/O Interface

#### 10.1.4.1 Overview

Because accesses to the AMBA® AHB-Lite™ and the single cycle I/O interface can be made concurrently, the Cortex-M0+ processor can fetch the next instructions while accessing the I/Os. This enables single cycle I/O accesses to be sustained for as long as needed. Refer to “[CPU Local Bus](#)” on page 440 for more information.

#### 10.1.4.2 Description

Direct access to PORT registers and DIVAS registers.

## 10.2 Nested Vector Interrupt Controller

### 10.2.1 Overview

The Nested Vectored Interrupt Controller (NVIC) in the SAM C20 supports 32 interrupt lines with four different priority levels. For more details, refer to the Cortex-M0+ Technical Reference Manual ([www.arm.com](http://www.arm.com)).

### 10.2.2 Interrupt Line Mapping

Each of the 28 interrupt lines is connected to one peripheral instance, as shown in the table below. Each peripheral can have one or more interrupt flags, located in the peripheral’s Interrupt Flag Status and Clear (INTFLAG) register. The interrupt flag is set when the interrupt condition occurs. Each interrupt in the peripheral can be individually enabled by writing a one to the corresponding bit in the peripheral’s Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the peripheral’s Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated from the peripheral when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt requests for one peripheral are ORed together on system level, generating one interrupt request for each peripheral. An

interrupt request will set the corresponding interrupt pending bit in the NVIC interrupt pending registers (SETPEND/CLRPEND bits in ISPR/ICPR). For the NVIC to activate the interrupt, it must be enabled in the NVIC interrupt enable register (SETENA/CLRENA bits in ISER/ICER). The NVIC interrupt priority registers IPR0-IPR7 provide a priority field for each interrupt.

**Table 10-3. Interrupt Line Mapping**

| Peripheral Source  | NVIC Line |
|--|-----------|
| EIC NMI – External Interrupt Controller  | NMI       |
| PM – Power Manager<br>MCLK - Main Clock<br>OSCCTRL - Oscillators Controller<br>OSC32KCTRL - 32kHz Oscillators Controller<br>SUPC - Supply Controller<br>PAC - Protection Access Controller | 0         |
| WDT – Watchdog Timer   | 1         |
| RTC – Real Time Clock  | 2         |
| EIC – External Interrupt Controller  | 3         |
| FREQM – Frequency Meter  | 4         |
| Reserved   | 5         |
| NVMCTRL – Non-Volatile Memory Controller   | 6         |
| DMAC - Direct Memory Access Controller   | 7         |
| EVSYS – Event System   | 8         |
| SERCOM0 – Serial Communication Controller 0  | 9         |
| SERCOM1 – Serial Communication Controller 1  | 10        |
| SERCOM2 – Serial Communication Controller 2  | 11        |
| SERCOM3 – Serial Communication Controller 3  | 12        |
| Reserved   | 13        |
| Reserved   | 14        |
| Reserved   | 15        |
| Reserved   | 16        |
| TCC0 – Timer Counter for Control 0   | 17        |
| Reserved   | 18        |
| Reserved   | 19        |
| TC0 – Timer Counter 0  | 20        |
| TC1 – Timer Counter 2  | 21        |

**Table 10-3. Interrupt Line Mapping (Continued)**

| Peripheral Source                    | NVIC Line |
|--------------------------------------|-----------|
| TC2 – Timer Counter 2                | 22        |
| TC3 – Timer Counter 3                | 23        |
| TC4 – Timer Counter 4                | 24        |
| ADC0 – Analog-to-Digital Converter 0 | 25        |
| Reserved                             | 26        |

| Reserved                             | 28        |
| Reserved                             | 29        |
| PTC – Peripheral Touch Controller    | 30        |
| Reserved                             | 31        |

## 10.3 Micro Trace Buffer

### 10.3.1 Features

- Program flow tracing for the Cortex-M0+ processor
- MTB SRAM can be used for both trace and general purpose storage by the processor
- The position and size of the trace buffer in SRAM is configurable by software
- CoreSight compliant

### 10.3.2 Overview

When enabled, the MTB records changes in program flow, reported by the Cortex-M0+ processor over the execution trace interface shared between the Cortex-M0+ processor and the CoreSight MTB-M0+. This information is stored as trace packets in the SRAM by the MTB. An off-chip debugger can extract the trace information using the Debug Access Port to read the trace information from the SRAM. The debugger can then reconstruct the program flow from this information.

The MTB simultaneously stores trace information into the SRAM, and gives the processor access to the SRAM. The MTB ensures that trace write accesses have priority over processor accesses.

The execution trace packet consists of a pair of 32-bit words that the MTB generates when it detects the processor PC value changes non-sequentially. A non-sequential PC change can occur during branch instructions or during exception entry. See the CoreSight MTB-M0+ Technical Reference Manual for more details on the MTB execution trace packet format.

Tracing is enabled when the MASTER.EN bit in the Master Trace Control Register is 1. There are various ways to set the bit to 1 to start tracing, or to 0 to stop tracing. See the CoreSight Cortex-M0+ Technical Reference Manual for more details on the Trace start and stop and for a detailed description of the MTB's MASTER register. The MTB can be programmed to stop tracing automatically when the memory fills to a specified watermark level or to start or stop tracing by writing directly to the MASTER.EN bit. If the watermark mechanism is not being used and the trace buffer overflows, then the buffer wraps around overwriting previous trace packets.

The base address of the MTB registers is 0x41006000; this address is also written in the CoreSight ROM Table. The offset of each register from the base address is fixed and as defined by the CoreSight MTB-M0+ Technical Reference Manual. The MTB has 4 programmable registers to control the behavior of the trace features:

- POSITION: Contains the trace write pointer and the wrap bit,
- MASTER: Contains the main trace enable bit and other trace control fields,

- FLOW: Contains the WATERMARK address and the AUTOSTOP and AUTOHALT control bits,
- BASE: Indicates where the SRAM is located in the processor memory map. This register is provided to enable auto discovery of the MTB SRAM location, by a debug agent.

See the CoreSight MTB-M0+ Technical Reference Manual for a detailed description of these registers.

## 10.4 High-Speed Bus System

### 10.4.1 Features

High-Speed Bus Matrix has the following features:

- Symmetric crossbar bus switch implementation
- Allows concurrent accesses from different masters to different slaves
- 32-bit data bus
- Operation at a 1-to-1 clock frequency with the bus masters

### 10.4.2 Configuration

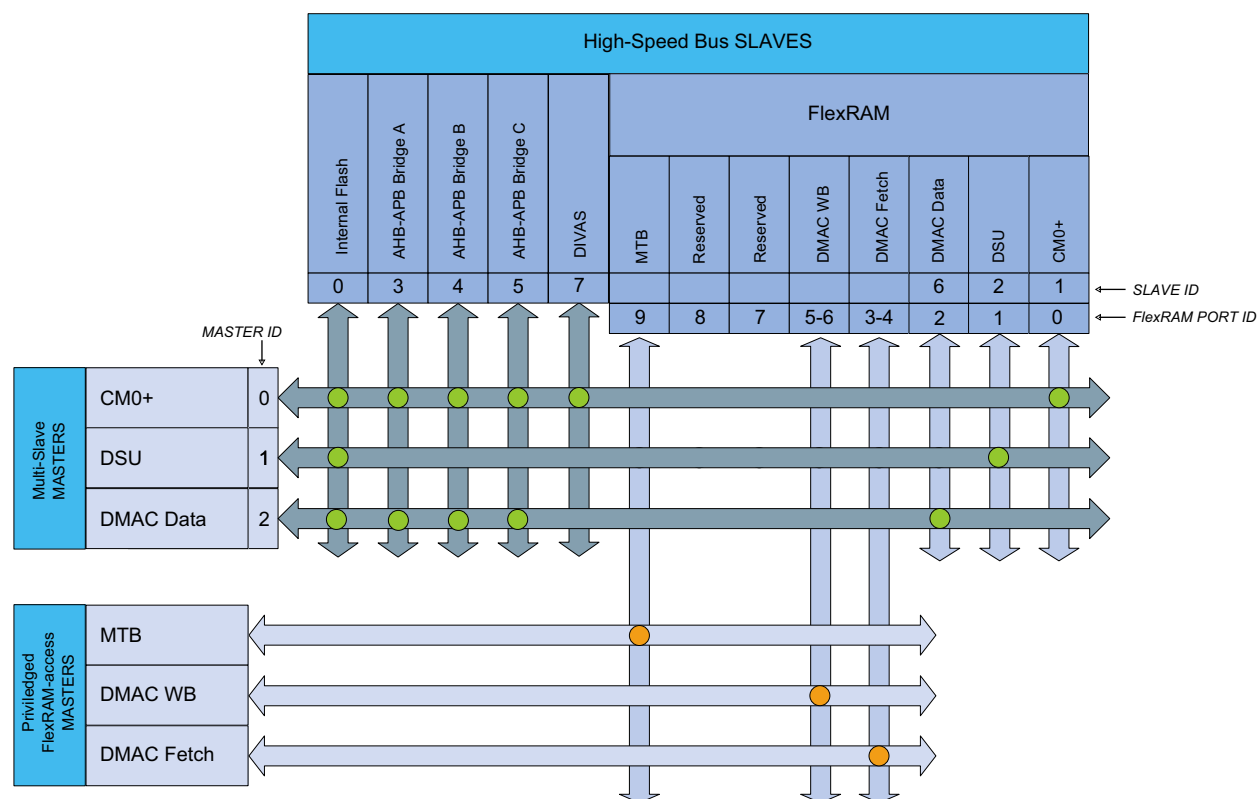

Table 10-4. Bus Matrix Masters

| Bus Matrix Masters                                   | Master ID |
|--|-----------|
| CM0+ - Cortex M0+ Processor                          | 0         |
| DSU - Device Service Unit                            | 1         |
| DMAC - Direct Memory Access Controller / Data Access | 2         |

**Table 10-5. Bus Matrix Slaves**

| Bus Matrix Slaves              | Slave ID |
|--------------------------------|----------|
| Internal Flash Memory          | 0        |
| SRAM Port 4 - CM0+ Access      | 1        |
| SRAM Port 6 - DSU Access       | 2        |
| AHB-APB Bridge A               | 3        |
| AHB-APB Bridge B               | 4        |
| AHB-APB Bridge C               | 5        |
| SRAM Port 5 - DMAC Data Access | 6        |
| DIVAS - Divide Accelerator     | 7        |

**Table 10-6. SRAM Port Connections**

| SRAM Port Connection   | Port ID | Connection Type |
|--|---------|-----------------|
| CM0+ - Cortex M0+ Processor                                  | 0       | Bus Matrix      |
| DSU - Device Service Unit                                    | 1       | Bus Matrix      |
| DMAC - Direct Memory Access Controller - Data Access         | 2       | Bus Matrix      |

| DMAC - Direct Memory Access Controller - Fetch Access 1      | 4       | Direct          |
| DMAC - Direct Memory Access Controller - Write-Back Access 0 | 5       | Direct          |
| DMAC - Direct Memory Access Controller - Write-Back Access 1 | 6       | Direct          |
| Reserved   | 7       | Direct          |
| Reserved   | 8       | Direct          |
| MTB - Micro Trace Buffer                                     | 9       | Direct          |

### 10.4.3 SRAM Quality of Service

To ensure that masters with latency requirements get sufficient priority when accessing RAM, the different masters can be configured to have a given priority for different type of access.

The Quality of Service (QoS) level is independently selected for each master accessing the RAM. For any access to the RAM the RAM also receives the QoS level. The QoS levels and their corresponding bit values for the QoS level configuration is shown in [Table 10-7](#).

**Table 10-7. Quality of Service**

| Value | Name    | Description                         |
|-------|---------|-------------------------------------|
| 00    | DISABLE | Background (no sensitive operation) |

| Value | Name   | Description         |
|-------|--------|---------------------|
| 01    | LOW    | Sensitive Bandwidth |
| 10    | MEDIUM | Sensitive Latency   |
| 11    | HIGH   | Critical Latency    |

If a master is configured with QoS level 0x00 or 0x01 there will be minimum one cycle latency for the RAM access.

The priority order for concurrent accesses are decided by two factors. First the QoS level for the master and then a static priority given by table nn-mm (table: SRAM port connection) where the lowest port ID has the highest static priority.

The MTB has fixed QoS level HIGH (0x3).

The CPU QoS level can be written/read at address 0x4100A114, bits [1:0]. Its reset value is 0x3.

Refer to different master registers for configuring QoS for the other masters (DMAC, DSU).

**Table 10-8. SRAM Port Connections Qos**

| Connection   | Port ID | Type       | QoS Configuration     | Default QoS |
|--------------|---------|------------|-----------------------|-------------|
| MTB          | 9       | Direct     | STATIC-3              | 0x3         |
| DMAC - WB    | 5, 6    | Direct     | IP-QOSCTRL.WRBQOS     | 0x2         |
| DMAC - Fetch | 3, 4    | Direct     | IP-QOSCTRL.FQOS       | 0x2         |
| DMAC - Data  | 2       | Bus Matrix | IP-QOSCTRL.DQOS       | 0x2         |
| DSU          | 1       | Bus Matrix | 0x4100201C, bits[1:0] | 0x2         |
| CM0+         | 0       | Bus Matrix | 0x4100A114, bits[1:0] | 0x3         |

## 11. PAC – Peripheral Access Control

### 11.1 Overview

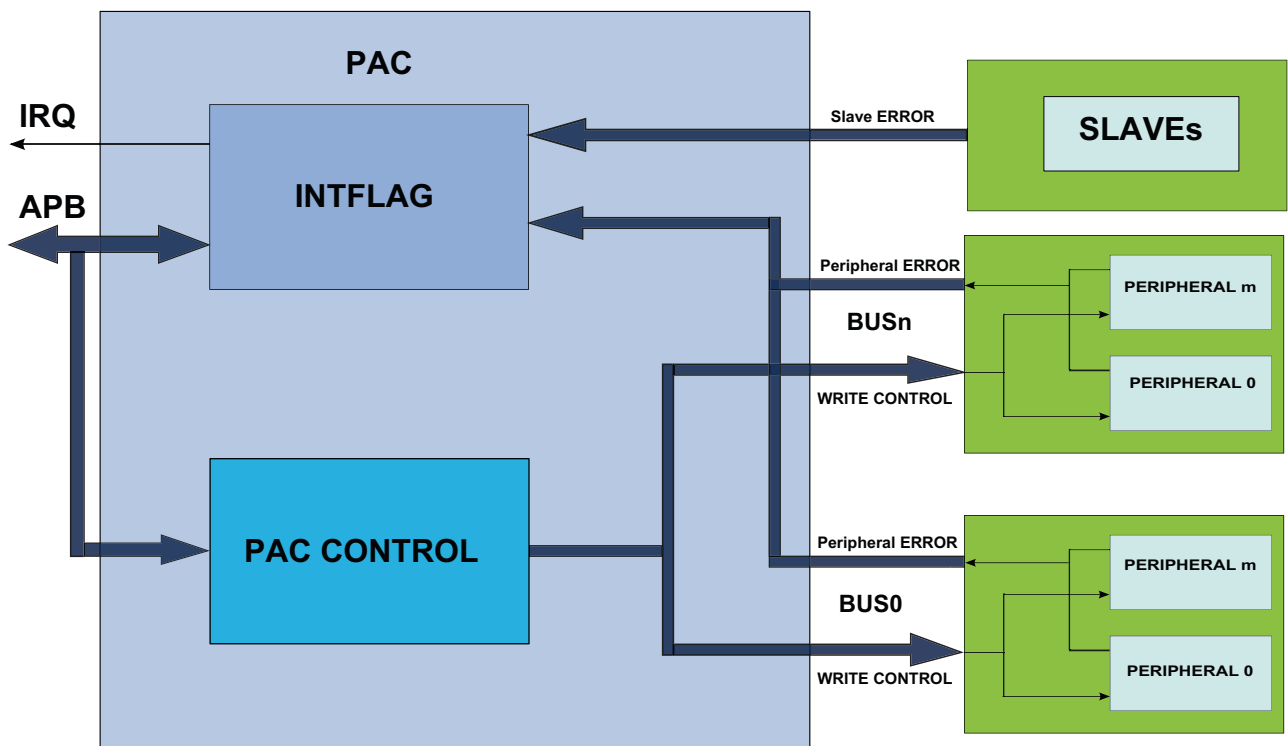

The Peripheral Access Controller provides write protection for registers of the peripherals and reports all violations that could happen when accessing a peripheral, write protected access, illegal access, enable protected access, access when clock synchronization or software reset is on going. These errors are reported in an unique interrupt flag for a peripheral. The PAC module reports also the errors occurring at a slave bus level, when an access to non-existing addresses is detected.

### 11.2 Features

- Manages write protection access and reports access errors for the peripheral modules or bridges.

### 11.3 Block Diagram

Figure 11-1. PAC Block Diagram.

### 11.4 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

#### 11.4.1 I/O Lines

Not Applicable

## 11.4.2 Power Management

The PAC can continue to operate in any sleep mode where the selected source clock is running. The PAC interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

## 11.4.3 Clocks

The PAC bus clock (CLK\_PAC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_PAC\_APB can be found in [Table 17-1](#).

## 11.4.4 DMA

Not applicable.

## 11.4.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the PAC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

## 11.4.6 Events

The events are connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

## 11.4.7 Debug Operation

When the CPU is halted in debug mode, write protection of all peripherals is disabled and the PAC continues normal operation. If the PAC is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

## 11.4.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Write Control (WRCTRL) register
- AHB Slave Bus Interrupt Flag Status and Clear (INTFLAGAHB) register
- Peripheral Interrupt Flag Status and Clear n (INTFLAG A/B/C...) registers

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

# 11.5 Functional Description

## 11.5.1 Principle of Operation

The Peripheral Access Control module allows the user to set a write protection on peripheral modules and generate an interrupt in case of a peripheral access violation. The peripheral's protection can be set, cleared or locked for user convenience. A set of Interrupt Flag and Status registers informs the user on the status of the violation in the peripherals. In addition, slaves bus errors can be also reported in the cases where reserved area is accessed by the application.

## 11.5.2 Basic Operation

### 11.5.2.1 Initialization

After reset, PAC is ready to operate.

### 11.5.2.2 Enabling and Resetting

The PAC is always enabled after reset.

Only a hardware reset will reset the PAC module.

### 11.5.2.3 Operations

The PAC module allows the user to set, clear or lock the write protection of all peripherals on all Peripheral Bridges.

Peripheral Interrupt Flag n registers (INTFLAGn) informs the user on the status of the violation in the peripherals connected to the Peripheral Bridge n (n = A,B,C ...), and the corresponding Peripheral Write Control Status n register (STATUSn) gives the state of the write protection for all peripherals connected to the corresponding Peripheral Bridge n. For further details, refer to [“Peripheral Access Errors” on page 35](#).

The PAC module reports also the errors occurring at slave bus level where an access to reserved area is detected. AHB Slave Bus Interrupt Flag register (INTFLAGAHB) informs the user on the status of the violation in the corresponding slave. For further details, refer to [“AHB Slave Bus Errors” on page 36](#).

### 11.5.2.4 Peripheral Access Errors

To avoid unexpected write to the registers of a peripheral, each peripheral can be write protected. Only the registers denoted as “Write Protected” in the module’s datasheet will be protected.

If a peripheral is not write protected, write data accesses are performed normally. If a peripheral is write protected and if a write access is done, data will not be written and peripheral returns an access error. The corresponding interrupt flag bit in the INTFLAGn register will be set.

A peripheral error will be also detected on illegal access, enable protected write, synchronized write, whether the peripheral is on an AHB or APB bus, and the access is from any master (CPU, DMA ...).

When any of the INTFLAGn registers bit is set, an interrupt will be requested if the PAC interrupt enable is set.

### 11.5.2.5 Write Access Protection Management

A peripheral access control can be enabled or disabled by writing to the WRCTRL register.

The data written to the WRCTRL register is composed of two fields, WRCTRL.PERID and WRCTRL.KEY. The WRCTRL.PERID is a unique identifier corresponding to a peripheral. The WRCTRL.KEY is a key value that defines the operation to be done on the control access bit. These operations can be “clear protection”, “set protection” and “set and lock protection bit”.

The “clear protection” operation will remove the write access protection for the peripheral selected by WRCTRL.PERID. Write accesses are allowed for the registers in this peripheral.

The “set protection” operation will set the write access protection for the peripheral selected by WRCTRL.PERID. Write accesses are not allowed for the registers with write protection property in this peripheral.

The “set and lock protection” operation will permanently set the write access protection for the peripheral selected by WRCTRL.PERID. The write access protection will only be cleared by a hardware reset.

The peripheral access control status can be read from the corresponding STATUSn register.

### 11.5.2.6 Write Access Protection Management Errors

Only word-wise write to the WRCTRL register will effectively change the access protection. Other type of accesses will have no effect and will cause a PAC write access error. This error is reported in the INTFLAGn.PAC bit corresponding to the PAC module.

PAC also offers an additional safety feature for correct program execution with an interruption generated on double write clear protection or double write set protection. If a peripheral is write protected and a subsequent set protection operation is detected then the PAC returns an error, and similarly for a double clear protection operation. In addition, an error is generated when writing a “set and lock” protection to a write-protected peripheral or when a write access is done to a locked set protection.

This can be used to ensure that the application follows the intended program flow by always following a write protect with an unprotect and conversely. However in applications where a write protected peripheral is used in several contexts, e.g. interrupt, care should be taken so that either the interrupt can not happen while the main application or other interrupt

levels manipulates the write protection status or when the interrupt handler needs to unprotect the peripheral based on the current protection status by reading the STATUS register.

The errors generated while accessing the PAC module registers (eg. key error, double protect error...) will set the INTFLAGn.PAC flag.

#### 11.5.2.7 AHB Slave Bus Errors

The PAC module reports errors occurring at a Slave bus level. These errors are generated when an access is performed at an address where no slave (bridge or peripheral) is mapped. These errors are reported in the INTFLAGAHB register.

#### 11.5.2.8 Generating events

The PAC module can also generate an event when any of the Interrupt Flag registers bit is set. To enable the PAC event generation, the control bit EVCTRL.ERREO must be set.

### 11.5.3 DMA Operation

Not applicable

### 11.5.4 Interrupts

The PAC has the following interrupt source:

- Error (ERR): Indicates that a peripheral access violation occurred in one of the peripherals under control of the PAC module or a bridge error occurred in one of the bridges reported by the PAC.
  - This interrupt is a synchronous wake-up source. See [Table 19-1](#) for details.

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAGAHB and INTFLAGn) registers is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the PAC is reset. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to <[“Nested Vector Interrupt Controller” on page 27](#)> for details. The user must read the INTFLAGAHB and INTFLAGn registers to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to <[“Nested Vector Interrupt Controller” on page 27](#)> for details.

### 11.5.5 Events

The PAC can generate the following output events:

- Error (ERR): Generated when one of the interrupt flag registers bits is set.

Writing a one to an Event Output bit in the Event Control Register (EVCTRL.ERREO) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to the Event System chapter for details on configuring the event system.

### 11.5.6 Sleep Mode Operation

In Sleep mode, the PAC is kept enabled if an available master (CPU, DMA) is running. The PAC will continue to catch access errors from module and generate interrupts or events.

### 11.5.7 Synchronization

Not applicable

## 11.6 Register Summary

| Offset      | Name      | Bit pos. |             |           |            |         |         |          |           |       |
|-------------|-----------|----------|-------------|-----------|------------|---------|---------|----------|-----------|-------|
| 0x00        | WRCTRL    | 7:0      | PERID[7:0]  |           |            |         |         |          |           |       |

## 11.7 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 34](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 36](#) for details.

Some registers are enable-protected, meaning they can only be written when the PAC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 11.7.1 Write control

**Name:** WRCTRL  
**Offset:** 0x0  
**Access:** Read/Write  
**Reset:** 0x00000000  
**Property:** –

- **Bits 31:24 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 23:16 – KEY: Peripheral Access Control Key**  
 These bits define the peripheral access control key, as shown in [Table 11-1](#):

**Table 11-1. Peripheral Access Control Key**

| Value | Name  | Description   |
|-------|-------|---|
| 0x0   | OFF   | No action   |
| 0x1   | CLEAR | Clear the peripheral write control                                      |
| 0x2   | SET   | Set the peripheral write control  |
| 0x3   | LOCK  | Set and lock until the next hardware reset the peripheral write control |

- **Bits 15-0 – PERID: Peripheral Identifier**

The PERID represents the peripheral whose control is changed using the WRCTRL.KEY. The Peripheral Identifier is calculated following formula:

$$PERID = 32 * BridgeNumber + N$$

Where BridgeNumber represents the Peripheral Bridge Number (0 for Peripheral Bridge A, 1 for Peripheral Bridge B, etc). N represents the peripheral index from the respective Bridge Number.

### 11.7.2 Event Control

**Name:** EVCTRL

**Offset:** 0x04

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|--------|---|---|---|---|---|---|---|-------|
|        |   |   |   |   |   |   |   | ERREO |
| Access | R | R | R | R | R | R | R | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0     |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – ERREO: Peripheral Access Error Event Output**

This bit indicates if the Peripheral Access Error Event Output is enabled or not. When enabled, an event will be generated when one of the interrupt flag registers bits (INTFLAGAHB, INTFLAGn) is set:

0: Peripheral Access Error Event Output is disabled.

1: Peripheral Access Error Event Output is enabled.

### 11.7.3 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x08

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
|--------|---|---|---|---|---|---|---|-----|
|        |   |   |   |   |   |   |   | ERR |
| Access | R | R | R | R | R | R | R | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – ERR: Peripheral Access Error Interrupt Enable**

This bit indicates that the Peripheral Access Error Interrupt is enabled and an interrupt request will be generated when one of the interrupt flag registers bits (INTFLAGAHB, INTFLAGn) is set:

0: Peripheral Access Error interrupt is disabled.

1: Peripheral Access Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Peripheral Access Error interrupt Enable bit and disables the corresponding interrupt request.

### 11.7.4 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x09

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
|--------|---|---|---|---|---|---|---|-----|
|        |   |   |   |   |   |   |   | ERR |
| Access | R | R | R | R | R | R | R | R   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – ERR: Peripheral Access Error Interrupt Enable**

This bit indicates that the Peripheral Access Error Interrupt is enabled and an interrupt request will be generated when one of the interrupt flag registers bits (INTFLAGAHB, INTFLAGn) is set:

0: Peripheral Access Error interrupt is disabled.

1: Peripheral Access Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Peripheral Access Error interrupt Enable bit and enables the corresponding interrupt request.

### 11.7.5 AHB Slave Bus Interrupt Flag Status and Clear

**Name:** INTFLAGAHB

**Offset:** 0x10

**Access:** Read/Write

**Reset:** 0x000000

**Property:** –

| Access | R/W          | R/W                   | R/W         | R/W         | R/W         | R/W             | R/W              | R/W          |
| Reset  | 0            | 0                     | 0           | 0           | 0           | 0               | 0                | 0            |

- **Bits 31:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 7:0 – Peripheral AHB Interrupt Flag n**

This flag is cleared by writing a one to the flag.

This flag is set when an access error is detected by the SLAVE n, and will generate an interrupt request if INTEN-CLR/SET.ERR is one.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the corresponding INTFLAGAHB interrupt flag.

## 11.7.6 Peripheral Interrupt Flag Status and Clear A

**Name:** INTFLAGA

**Offset:** 0x14

**Access:** Read/Write

**Reset:** 0x000000

**Property:** –

|        |      |      |            |         |       |      |     |     |

| Reset  | 0    | 0    | 0          | 0       | 0     | 0    | 0   | 0   |
| Bit    | 7    | 6    | 5          | 4       | 3     | 2    | 1   | 0   |
|        | GCLK | SUPC | OSC32KCTRL | OSCCTRL | RSTC  | MCLK | PM  | PAC |
| Access | R/W  | R/W  | R/W        | R/W     | R/W   | R/W  | R/W | R/W |
| Reset  | 0    | 0    | 0          | 0       | 0     | 0    | 0   | 0   |

- **Bits 31:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:0 – Peripheral APBA Interrupt Flag x**

This flag is cleared by writing a one to the flag.

This flag is set when a Peripheral Access Error occurs while accessing the peripheral associated with the respective INTFLAGA bit, and will generate an interrupt request if INTENCLR/SET.ERR is one.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the corresponding INTFLAGA interrupt flag.

### 11.7.7 Peripheral Interrupt Flag Status and Clear B

**Name:** INTFLAGB

**Offset:** 0x18

**Access:** Read/Write

**Reset:** 0x000000

**Property:** –

|        |    |    |           |     |      |         |     |      |
|--------|----|----|-----------|-----|------|---------|-----|------|
| Bit    | 31 | 30 | 29        | 28  | 27   | 26      | 25  | 24   |
|        |    |    |           |     |      |         |     |      |

| Bit    | 23 | 22 | 21        | 20  | 19   | 18      | 17  | 16   |
|        |    |    |           |     |      |         |     |      |
| Access | R  | R  | R         | R   | R    | R       | R   | R    |
| Reset  | 0  | 0  | 0         | 0   | 0    | 0       | 0   | 0    |
| Bit    | 15 | 14 | 13        | 12  | 11   | 10      | 9   | 8    |
|        |    |    |           |     |      |         |     |      |
| Access | R  | R  | R         | R   | R    | R       | R   | R    |
| Reset  | 0  | 0  | 0         | 0   | 0    | 0       | 0   | 0    |
| Bit    | 7  | 6  | 5         | 4   | 3    | 2       | 1   | 0    |
|        |    |    | HMATRIXHS | MTB | DMAC | NVMCTRL | DSU | PORT |
| Access | R  | R  | R/W       | R/W | R/W  | R/W     | R/W | R/W  |
| Reset  | 0  | 0  | 0         | 0   | 0    | 0       | 0   | 0    |

- **Bits 31:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – Peripheral APBB Interrupt Flag x**

This flag is cleared by writing a one to the flag.

This flag is set when a Peripheral Access Error occurs while accessing the peripheral associated with the respective INTFLAGB bit, and will generate an interrupt request if INTENCLR/SET.ERR is one.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the corresponding INTFLAGB interrupt flag.

## 11.7.8 Peripheral Interrupt Flag Status and Clear C

**Name:** INTFLAGC

**Offset:** 0x1C

**Access:** Read/Write

**Reset:** 0x000000

**Property:** –

- **Bits 31:24, 21, 19:18, 11:10, 8:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 23:22, 20, 17:12, 9, 4:0 – Peripheral APBC Interrupt Flag x**

This flag is cleared by writing a one to the flag.

This flag is set when a Peripheral Access Error occurs while accessing the peripheral associated with the respective INTFLAGC bit, and will generate an interrupt request if INTENCLR/SET.ERR is one.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the corresponding INTFLAGC interrupt flag.

### 11.7.9 Peripheral Write Protection Status A

**Name:** STATUSA

**Offset:** 0x34

**Access:** Read Only

**Reset:** 0x000000

**Property:** –

- **Bits 31:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:0 – Peripheral APBA Write Protection Status**

Writing to this register has no effect.

Reading STATUS register returns peripheral write protection status:

0: Peripheral is not write protected

1: Peripheral is write protected

### 11.7.10 Peripheral Write Protection Status B

**Name:** STATUSB

**Offset:** 0x38

**Access:** Read Only

**Reset:** 0x000000

**Property:** –

- **Bits 31:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – Peripheral APBB Write Protection Status**

Writing to this register has no effect.

Reading STATUS register returns peripheral write protection status:

0: Peripheral is not write protected

1: Peripheral is write protected

### 11.7.11 Peripheral Write Protection Status C

**Name:** STATUSC

**Offset:** 0x3C

**Access:** Read Only

**Reset:** 0x000000

**Property:** –

| Reset  | 0          | 0          | 0          | 0              | 0              | 0              | 0              | 0            |

- **Bits 31:24, 21, 19:18, 11:10, 8:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 23:22, 20, 17:12, 9, 4:0 – Peripheral APBC Write Protection Status**

Writing to this register has no effect.

Reading STATUS register returns peripheral write protection status:

0: Peripheral is not write protected

1: Peripheral is write protected

## 12. Peripherals Configuration Summary

Table 12-1. Peripherals Configuration Summary

| Peripheral Name  | Base Address | IRQ Line | AHB Clock |                  | APB Clock |                  | Generic Clock                               | PAC   |               | Events                |   | DMA            |               |
|------------------|--------------|----------|-----------|------------------|-----------|------------------|---|-------|---------------|-----------------------|---|----------------|---------------|

## 13. DSU – Device Service Unit

### 13.1 Overview

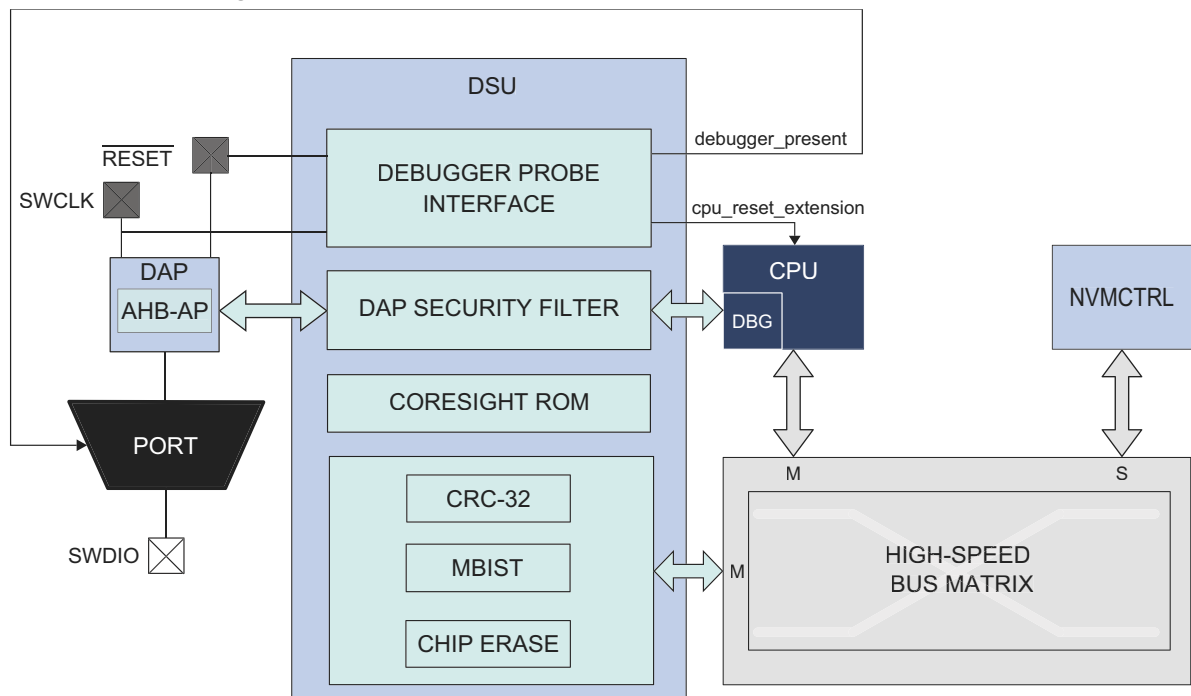

The Device Service Unit (DSU) provides a means to detect debugger probes. This enables the ARM Debug Access Port (DAP) to have control over multiplexed debug pads and CPU reset. The DSU also provides system-level services to debug adapters in an ARM debug system. It implements a CoreSight Debug ROM that provides device identification as well as identification of other debug components in the system. Hence, it complies with the ARM Peripheral Identification specification. The DSU also provides system services to applications that need memory testing, as required for IEC60730 Class B compliance, for example. The DSU can be accessed simultaneously by a debugger and the CPU, as it is connected on the High-Speed Bus Matrix. For security reasons, some of the DSU features will be limited or unavailable when the device is protected by the NVMCTRL security bit (refer to “[Security Bit](#)” on page 417).

### 13.2 Features

- CPU reset extension
- Debugger probe detection (Cold- and Hot-Plugging)
- Chip-Erase command and status
- 32-bit cyclic redundancy check (CRC32) of any memory accessible through the bus matrix
- ARM® CoreSight™ compliant device identification
- Two debug communications channels
- Debug access port security filter
- Onboard memory built-in self-test (MBIST)

### 13.3 Block Diagram

Figure 13-1. DSU Block Diagram

## 13.4 Signal Description

Table 13-1. Signal Description

| Signal Name               | Type          | Description               |
|---------------------------|---------------|---------------------------|
| $\overline{\text{RESET}}$ | Digital Input | External reset            |
| SWCLK                     | Digital Input | SW clock                  |
| SWDIO                     | Digital I/O   | SW bidirectional data pin |

Refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral.

## 13.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 13.5.1 I/O Lines

The SWCLK pin is by default assigned to the DSU module to allow debugger probe detection and the condition to stretch the CPU reset phase. For more information, refer to [“Debugger Probe Detection” on page 57](#). The Hot-Plugging feature depends on the PORT configuration. If the SWCLK pin function is changed in the PORT or if the PORT\_MUX is disabled, the Hot-Plugging feature is disabled until a power-reset or an external reset.

### 13.5.2 Power Management

The DSU will continue to operate in any sleep mode where the selected source clock is running.

Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 13.5.3 Clocks

The DSU bus clocks (CLK\_DSU\_APB and CLK\_DSU\_AHB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_DSU\_APB and CLK\_DSU\_AHB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

### 13.5.4 DMA

Not applicable.

### 13.5.5 Interrupts

Not applicable.

### 13.5.6 Events

Not applicable.

### 13.5.7 Register Access Protection

All registers with write access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Debug Communication Channel 0 register (DCC0)
- Debug Communication Channel 1 register (DCC1)

Write-protection is denoted by the Write-Protection property in the register description.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 13.5.8 Analog Connections

Not applicable.

## 13.6 Debug Operation

### 13.6.1 Principle of Operation

The DSU provides basic services to allow on-chip debug using the ARM Debug Access Port and the ARM processor debug resources:

- CPU reset extension
- Debugger probe detection

For more details on the ARM debug components, refer to the ARM Debug Interface v5Architecture Specification.

### 13.6.2 CPU Reset Extension

“CPU reset extension” refers to the extension of the reset phase of the CPU core after the external reset is released. This ensures that the CPU is not executing code at startup while a debugger connects to the system. It is detected on a RESET release event when SWCLK is low. At startup, SWCLK is internally pulled up to avoid false detection of a debugger if SWCLK is left unconnected. When the CPU is held in the reset extension phase, the CPU Reset Extension bit (CRSTEXT) of the Status A register (STATUSA.CRSTEXT) is set. To release the CPU, write a one to STATUSA.CRSTEXT. STATUSA.CRSTEXT will then be set to zero. Writing a zero to STATUSA.CRSTEXT has no effect. For security reasons, it is not possible to release the CPU reset extension when the device is protected by the NVMCTRL security bit (refer to “[Security Bit](#)” on page 417). Trying to do so sets the Protection Error bit (PERR) of the Status A register (STATUSA.PERR).

Figure 13-2. Typical CPU Reset Extension Set and Clear Timing Diagram

### 13.6.3 Debugger Probe Detection

#### 13.6.3.1 Cold-Plugging

Cold-Plugging is the detection of a debugger when the system is in reset. Cold-Plugging is detected when the CPU reset extension is requested, as described above.

#### 13.6.3.2 Hot-Plugging

Hot-Plugging is the detection of a debugger probe when the system is not in reset. Hot-Plugging is not possible under reset because the detector is reset when POR or RESET are asserted. Hot-Plugging is active when a SWCLK falling edge is detected. The SWCLK pad is multiplexed with other functions and the user must ensure that its default function is assigned to the debug system. If the SWCLK function is changed, the Hot-Plugging feature is disabled until a power-

reset or external reset occurs. Availability of the Hot-Plugging feature can be read from the Hot-Plugging Enable bit of the Status B register (STATUSB.HPE).

**Figure 13-3. Hot-Plugging Detection Timing Diagram**

The presence of a debugger probe is detected when either Hot-Plugging or Cold-Plugging is detected. Once detected, the Debugger Present bit of the Status B register (STATUSB.DBGPRES) is set. For security reasons, Hot-Plugging is not available when the device is protected by the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)).

This detection requires that pads are correctly powered. Thus, at cold startup, this detection cannot be done until POR is released. If the device is protected, Cold-Plugging is the only way to detect a debugger probe, and so the external reset timing must be longer than the POR timing. If external reset is deasserted before POR release, the user must retry the procedure above until it gets connected to the device.

## 13.7 Chip-Erase

Chip-Erase consists of removing all sensitive information stored in the chip and clearing the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)). Hence, all volatile memories and the flash array (including the EEPROM emulation area) will be erased. The flash auxiliary rows, including the user row, will not be erased. When the device is protected, the debugger must reset the device in order to be detected. This ensures that internal registers are reset after the protected state is removed. The Chip-Erase operation is triggered by writing a one to the Chip-Erase bit in the Control register (CTRL.CE). This command will be discarded if the DSU is protected by the Peripheral Access Controller (PAC). Once issued, the module clears volatile memories prior to erasing the flash array. To ensure that the Chip-Erase operation is completed, check the Done bit of the Status A register (STATUSA.DONE). The Chip-Erase operation depends on clocks and power management features that can be altered by the CPU. For that reason, it is recommended to issue a Chip-Erase after a Cold-Plugging procedure to ensure that the device is in a known and safe state.

The recommended sequence is as follows:

1. Issue the Cold-Plugging procedure (refer to [“Cold-Plugging” on page 57](#)). The device then:
  1. Detects the debugger probe
  2. Holds the CPU in reset
2. Issue the Chip-Erase command by writing a one to CTRL.CE. The device then:
  1. Clears the system volatile memories
  2. Erases the whole flash array (including the EEPROM emulation area, not including auxiliary rows)
  3. Erases the lock row, removing the NVMCTRL security bit protection
3. Check for completion by polling STATUSA.DONE (read as one when completed).
4. Reset the device to let the NVMCTRL update fuses.

## 13.8 Programming

Programming of the flash or RAM memories is available when the device is not protected by the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)).

1. At power up,  $\overline{\text{RESET}}$  is driven low by a debugger. The on-chip regulator holds the system in a POR state until the input supply is above the POR threshold (refer to “Power-on Reset Characteristics” on page 917). The system continues to be held in this static state until the internally regulated supplies have reached a safe operating state.
2. The PM starts, clocks are switched to the slow clock (Core Clock, System Clock, Flash Clock and any Bus Clocks that do not have clock gate control). Internal resets are maintained due to the external reset.
3. The debugger maintains a low level on SWCLK. Releasing  $\overline{\text{RESET}}$  results in a debugger Cold-Plugging procedure.
4. The debugger generates a clock signal on the SWCLK pin, the Debug Access Port (DAP) receives a clock.
5. The CPU remains in reset due to the Cold-Plugging procedure; meanwhile, the rest of the system is released.
6. A Chip-Erase is issued to ensure that the flash is fully erased prior to programming.
7. Programming is available through the AHB-AP.
8. After operation is completed, the chip can be restarted either by asserting  $\overline{\text{RESET}}$ , toggling power or writing a one to the Status A register CPU Reset Phase Extension bit (STATUSA.CRSTEXT). Make sure that the SWCLK pin is high when releasing  $\overline{\text{RESET}}$  to prevent extending the CPU reset.

## 13.9 Intellectual Property Protection

Intellectual property protection consists of restricting access to internal memories from external tools when the device is protected, and is accomplished by setting the NVMCTRL security bit (refer to “Security Bit” on page 417). This protected state can be removed by issuing a Chip-Erase (refer to “Chip-Erase” on page 58). When the device is protected, read/write accesses using the AHB-AP are limited to the DSU address range and DSU commands are restricted.

The DSU implements a security filter that monitors the AHB transactions generated by the ARM AHB-AP inside the DAP. If the device is protected, then AHB-AP read/write accesses outside the DSU external address range are discarded, causing an error response that sets the ARM AHB-AP sticky error bits (refer to the ARM Debug Interface v5 Architecture Specification on <http://www.arm.com>).

The DSU is intended to be accessed either:

- Internally from the CPU, without any limitation, even when the device is protected
- Externally from a debug adapter, with some restrictions when the device is protected

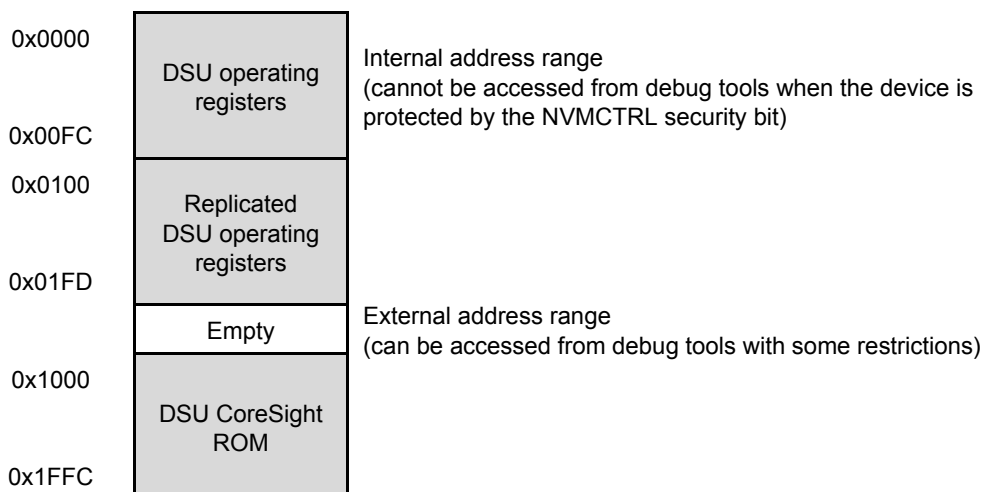

For security reasons, DSU features have limitations when used from a debug adapter. To differentiate external accesses from internal ones, the first 0x100 bytes of the DSU register map have been replicated at offset 0x100:

- The first 0x100 bytes form the internal address range
- The next 0x100 bytes form the external address range

When the device is protected, the DAP can only issue MEM-AP accesses in the DSU address range limited to the 0x100-0x2000 offset range.

The DSU operating registers are located in the 0x00-0xFF area and remapped in 0x100-0x1FF to differentiate accesses coming from a debugger and the CPU. If the device is protected and an access is issued in the region 0x100-0x1FF, it is subject to security restrictions. For more information, refer to [Table 13-2](#).

**Figure 13-4. APB Memory Mapping**

Some features not activated by APB transactions are not available when the device is protected:

**Table 13-2. Feature Availability Under Protection**

| Features               | Availability When the Device is Protected |
|------------------------|---|
| CPU reset extension    | Yes                                       |
| Debugger Cold-Plugging | Yes                                       |
| Debugger Hot-Plugging  | No  |

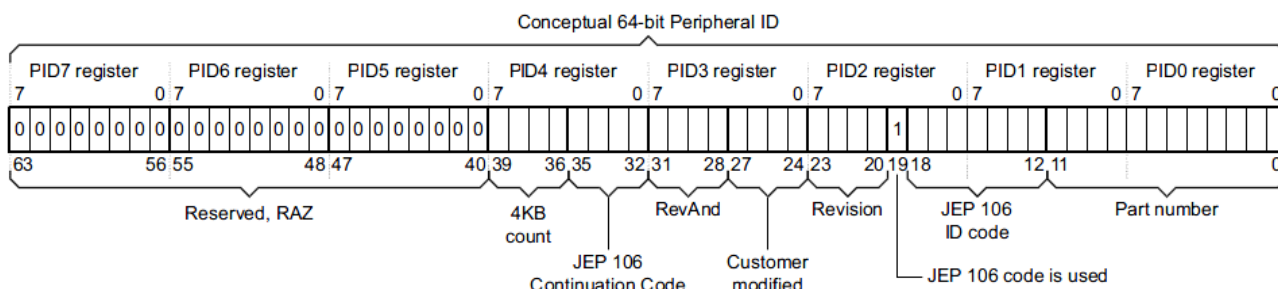

## 13.10 Device Identification

Device identification relies on the ARM CoreSight component identification scheme, which allows the chip to be identified as an ATMEL device implementing a DSU. The DSU contains identification registers to differentiate the device.

### 13.10.1 CoreSight Identification

A system-level ARM CoreSight ROM table is present in the device to identify the vendor and the chip identification method. Its address is provided in the MEM-AP BASE register inside the ARM Debug Access Port. The CoreSight ROM implements a 64-bit conceptual ID composed as follows from the PID0 to PID7 CoreSight ROM Table registers:

**Figure 13-5. Conceptual 64-Bit Peripheral ID**

**Table 13-3. Conceptual 64-Bit Peripheral ID Bit Descriptions**

| Field           | Size | Description   | Location  |
|-----------------|------|---|-----------|
| JEP-106 CC code | 4    | Atmel continuation code: 0x0  | PID4      |
| JEP-106 ID code | 7    | Atmel device ID: 0x1F   | PID1+PID2 |
| 4KB count       | 4    | Indicates that the CoreSight component is a ROM: 0x0  | PID4      |
| RevAnd          | 4    | Not used; read as 0   | PID3      |
| CUSMOD          | 4    | Not used; read as 0   | PID3      |
| PARTNUM         | 12   | Contains 0xCD0 to indicate that DSU is present  | PID0+PID1 |
| REVISION        | 4    | DSU revision (starts at 0x0 and increments by 1 at both major and minor revisions). Identifies DSU identification method variants. If 0x0, this indicates that device identification can be completed by reading the Device Identification register (DID) | PID3      |

For more information, refer to the ARM Debug Interface Version 5 Architecture Specification.

### 13.10.2 DSU Chip Identification Method:

The DSU DID register identifies the device by implementing the following information:

- Processor identification
- Family identification
- Subfamily identification
- Device select

## 13.11 Functional Description

### 13.11.1 Principle of Operation

The DSU provides memory services such as CRC32 or MBIST that require almost the same interface. Hence, the Address, Length and Data registers are shared. They must be configured first; then a command can be issued by writing the Control register. When a command is ongoing, other commands are discarded until the current operation is completed. Hence, the user must wait for the STATUSA.DONE bit to be set prior to issuing another one.

### 13.11.2 Basic Operation

#### 13.11.2.1 Initialization

The module is enabled by enabling its clocks. For more details, refer to [“Clocks” on page 56](#). The DSU registers can be write-protected. Refer to [“PAC – Peripheral Access Control” on page 33](#).

#### 13.11.2.2 Operation from a debug adapter

Debug adapters should access the DSU registers in the external address range 0x100 – 0x2000. If the device is protected by the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)), accessing the first 0x100 bytes causes the system to return an error (refer to [“Intellectual Property Protection” on page 59](#)).

#### 13.11.2.3 Operation from the CPU

There are no restrictions when accessing DSU registers from the CPU. However, the user should access DSU registers in the internal address range (0x0 – 0x100) to avoid external security restrictions (refer to [“Intellectual Property Protection” on page 59](#)).

### 13.11.3 32-bit Cyclic Redundancy Check (CRC32)

The DSU unit provides support for calculating a cyclic redundancy check (CRC32) value for a memory area (including flash and AHB RAM).

When the CRC32 command is issued from:

- The internal range, the CRC32 can be operated at any memory location
- The external range, the CRC32 operation is restricted; DATA, ADDR and LENGTH values are forced (see below)

**Table 13-4. AMOD Bit Descriptions when Operating CRC32**

| AMOD[1:0] | Short Name | External Range Restrictions   |
|-----------|------------|---|
| 0         | ARRAY      | CRC32 is restricted to the full flash array area (EEPROM emulation area not included)<br>DATA forced to 0xFFFFFFFF before calculation (no seed) |
| 1         | EEPROM     | CRC32 of the whole EEPROM emulation area<br>DATA forced to 0xFFFFFFFF before calculation (no seed)  |
| 2-3       | Reserved   |   |

The algorithm employed is the industry standard CRC32 algorithm using the generator polynomial 0xEDB88320 (reversed representation).

#### 13.11.3.1 Starting CRC32 Calculation

CRC32 calculation for a memory range is started after writing the start address into the Address register (ADDR) and the size of the memory range into the Length register (LENGTH). Both must be word-aligned.

The initial value used for the CRC32 calculation must be written to the Data register. This value will usually be 0xFFFFFFFF, but can be, for example, the result of a previous CRC32 calculation if generating a common CRC32 of separate memory blocks.

Once completed, the calculated CRC32 value can be read out of the Data register. The read value must be complemented to match standard CRC32 implementations or kept non-inverted if used as starting point for subsequent CRC32 calculations.

If the device is in protected state by the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)), it is only possible to calculate the CRC32 of the whole flash array. In most cases, this area will be the entire onboard non-volatile memory. The Address, Length and Data registers will be forced to predefined values once the CRC32 operation is started, and values written by the user are ignored. This allows the user to verify the contents of a protected device.

The actual test is started by writing a one in the 32-bit Cyclic Redundancy Check bit of the Control register (CTRL.CRC). A running CRC32 operation can be canceled by resetting the module (writing a one to CTRL.SWRST).

#### 13.11.3.2 Interpreting the Results

The user should monitor the Status A register. When the operation is completed, STATUSA.DONE is set. Then the Bus Error bit of the Status A register (STATUSA.BERR) must be read to ensure that no bus error occurred.

#### 13.11.4 Debug Communication Channels

The Debug Communication Channels (DCC0 and DCC1) consist of a pair of registers with associated handshake logic, accessible by both CPU and debugger even if the device is protected by the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)). The registers can be used to exchange data between the CPU and the debugger, during run time as well as in debug mode. This enables the user to build a custom debug protocol using only these registers. The DCC0 and DCC1 registers are accessible when the protected state is active. When the device is protected, however, it is not possible to connect a debugger while the CPU is running (STATUSA.CRSTEXT is not writable and the CPU is held under reset). Dirty bits in the status registers indicate whether a new value has been written in DCC0 or DCC1. These bits, DCC0D and DCC1D, are located in the STATUSB registers. They are automatically set on write and cleared on

read. The DCC0 and DCC1 registers are shared with the onboard memory testing logic (MBIST). Accordingly, DCC0 and DCC1 must not be used while performing MBIST operations.

### 13.11.5 Testing of Onboard Memories (MBIST)

The DSU implements a feature for automatic testing of memory also known as MBIST. This is primarily intended for production test of onboard memories. MBIST cannot be operated from the external address range when the device is protected by the NVMCTRL security bit (refer to [“Security Bit” on page 417](#)). If a MBIST command is issued when the device is protected, a protection error is reported in the Protection Error bit in the Status A register (STATUSA.PERR).

#### 1. Algorithm

The algorithm used for testing is a type of March algorithm called "March LR". This algorithm is able to detect a wide range of memory defects, while still keeping a linear run time. The algorithm is:

1. Write entire memory to 0, in any order.
2. Bit for bit read 0, write 1, in descending order.
3. Bit for bit read 1, write 0, read 0, write 1, in ascending order.
4. Bit for bit read 1, write 0, in ascending order.
5. Bit for bit read 0, write 1, read 1, write 0, in ascending order.
6. Read 0 from entire memory, in ascending order.

The specific implementation used has a run time of  $O(14n)$  where  $n$  is the number of bits in the RAM. The detected faults are:

- Address decoder faults
- Stuck-at faults
- Transition faults
- Coupling faults
- Linked Coupling faults
- Stuck-open faults

#### 2. Starting MBIST

To test a memory, you need to write the start address of the memory to the ADDR.ADDR bit group, and the size of the memory into the Length register. See [“Physical Memory Map” on page 23](#) to know which memories are available, and which address they are at.

For best test coverage, an entire physical memory block should be tested at once. It is possible to test only a subset of a memory, but the test coverage will then be somewhat lower.

The actual test is started by writing a one to CTRL.MBIST. A running MBIST operation can be canceled by writing a one to CTRL.SWRST.

#### 3. Interpreting the Results

The tester should monitor the STATUSA register. When the operation is completed, STATUSA.DONE is set.

There are three different modes:

- ADDR.AMOD=0: exit-on-error (default)

In this mode, the algorithm terminates either when a fault is detected or on successful completion. In both cases, STATUSA.DONE is set. If an error was detected, STATUSA.FAIL will be set. User then can read the DATA and ADDR registers to locate the fault. Refer to [“Locating Errors” on page 63](#).

- ADDR.AMOD=1: pause-on-error

In this mode, the MBIST algorithm is paused when an error is detected. In such a situation, only STATUSA.FAIL is asserted. The state machine waits for user to clear STATUSA.FAIL by writing a one in STATUSA.FAIL to resume. Prior to resuming, user can read the DATA and ADDR registers to locate the fault. Refer to [“Locating Errors” on page 63](#).

#### 4. Locating Errors

If the test stops with STATUSA.FAIL set, one or more bits failed the test. The test stops at the first detected error. The position of the failing bit can be found by reading the following registers:

- ADDR: Address of the word containing the failing bit.
- DATA: contains data to identify which bit failed, and during which phase of the test it failed. The DATA register will in this case contain the following bit groups:

**Table 13-5. DATA bits Description When MBIST Operation Returns An Error**

|     |    |    |    |           |    |       |    |    |
|-----|----|----|----|-----------|----|-------|----|----|
| Bit | 31 | 30 | 29 | 28        | 27 | 26    | 25 | 24 |
|     |    |    |    |           |    |       |    |    |
| Bit | 23 | 22 | 21 | 20        | 19 | 18    | 17 | 16 |
|     |    |    |    |           |    |       |    |    |
| Bit | 15 | 14 | 13 | 12        | 11 | 10    | 9  | 8  |
|     |    |    |    |           |    | phase |    |    |
| Bit | 7  | 6  | 5  | 4         | 3  | 2     | 1  | 0  |
|     |    |    |    | bit_index |    |       |    |    |

- bit\_index: contains the bit number of the failing bit
- phase: indicates which phase of the test failed and the cause of the error. See [Table 13-6 on page 64](#).

**Table 13-6. MBIST Operation Phases**

| Phase | Test Actions                                    |
|-------|---|
| 0     | Write all bits to zero. This phase cannot fail. |
| 1     | Read 0, write 1, increment address              |
| 2     | Read 1, write 0                                 |
| 3     | Read 0, write 1, decrement address              |
| 4     | Read 1, write 0, decrement address              |
| 5     | Read 0, write 1                                 |
| 6     | Read 1, write 0, decrement address              |
| 7     | Read all zeros. bit_index is not used           |

### 13.11.6 System Services Availability When Accessed Externally

External access: Access performed in the DSU address offset 0x200-0x1FFF range.

Internal access: Access performed in the DSU address offset 0x0-0x100 range.

**Table 13-7. Available Features When Operated From The External Address Range**

| Features                                  | Availability From The External Address Range      |
|---|---|
| Chip-Erase command and status             | Yes   |
| CRC32                                     | Yes, only full array or full EEPROM               |
| CoreSight Compliant Device identification | Yes   |
| Debug communication channels              | Yes   |
| Testing of onboard memories (MBIST)       | Yes   |
| STATUSA.CRSTEXT clearing                  | No (STATUSA.PERR is set when attempting to do so) |

## 13.12 Register Summary

Table 13-8. Register Summary

| Offset        | Name  | Bit Pos |                |  |             |      |               |       |         |       |
|---------------|---|---------|----------------|--|-------------|------|---------------|-------|---------|-------|
| 0x0000        | CTRL  | 7:0     |                |  |             | CE   | MBIST         | CRC   |         | SWRST |
| 0x0001        | STATUSA   | 7:0     |                |  |             | PERR | FAIL          | BERR  | CRSTEXT | DONE  |
| 0x0002        | STATUSB   | 7:0     |                |  |             | HPE  | DCCD1         | DCCD0 | DBGPRES | PROT  |
| 0x0003        | Reserved  |         |                |  |             |      |               |       |         |       |
| 0x0004        | ADDR  | 7:0     | ADDR[5:0]      |  |             |      |               |       |         |       |
| 0x0005        |   | 15:8    | ADDR[13:6]     |  |             |      |               |       |         |       |
| 0x0006        |   | 23:16   | ADDR[21:14]    |  |             |      |               |       |         |       |
| 0x0007        |   | 31:24   | ADDR[29:22]    |  |             |      |               |       |         |       |
| 0x0008        | LENGTH  | 7:0     | LENGTH[5:0]    |  |             |      |               |       |         |       |
| 0x0009        |   | 15:8    | LENGTH[13:6]   |  |             |      |               |       |         |       |
| 0x000A        |   | 23:16   | LENGTH[21:14]  |  |             |      |               |       |         |       |
| 0x000B        |   | 31:24   | LENGTH[29:22]  |  |             |      |               |       |         |       |
| 0x000C        | DATA  | 7:0     | DATA[7:0]      |  |             |      |               |       |         |       |
| 0x000D        |   | 15:8    | DATA[15:8]     |  |             |      |               |       |         |       |
| 0x000E        |   | 23:16   | DATA[23:16]    |  |             |      |               |       |         |       |
| 0x000F        |   | 31:24   | DATA[31:24]    |  |             |      |               |       |         |       |
| 0x0010        | DCC0  | 7:0     | DATA[7:0]      |  |             |      |               |       |         |       |
| 0x0011        |   | 15:8    | DATA[15:8]     |  |             |      |               |       |         |       |
| 0x0012        |   | 23:16   | DATA[23:16]    |  |             |      |               |       |         |       |
| 0x0013        |   | 31:24   | DATA[31:24]    |  |             |      |               |       |         |       |
| 0x0014        | DCC1  | 7:0     | DATA[7:0]      |  |             |      |               |       |         |       |

### 13.13 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write protection is denoted by the Write-Protected property in each individual register description. Refer to [“Register Access Protection” on page 56](#) for details.

### 13.13.1 Control

**Name:** CTRL

**Offset:** 0x0000

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4  | 3     | 2   | 1 | 0     |
|--------|---|---|---|----|-------|-----|---|-------|
|        |   |   |   | CE | MBIST | CRC |   | SWRST |
| Access | R | R | R | W  | W     | W   | R | W     |
| Reset  | 0 | 0 | 0 | 0  | 0     | 0   | 0 | 0     |

- **Bits 7:5 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 4 – CE: Chip Erase**  
Writing a zero to this bit has no effect.  
Writing a one to this bit starts the Chip-Erase operation.
- **Bit 3 – MBIST: Memory Built-In Self-Test**  
Writing a zero to this bit has no effect.  
Writing a one to this bit starts the memory BIST algorithm.
- **Bit 2 – CRC: 32-bit Cyclic Redundancy Check**  
Writing a zero to this bit has no effect.  
Writing a one to this bit starts the cyclic redundancy check algorithm.
- **Bit 1 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written.
- **Bit 0 – SWRST: Software Reset**  
Writing a zero to this bit has no effect.  
Writing a one to this bit resets the module.

### 13.13.2 Status A

**Name:** STATUSA  
**Offset:** 0x0001  
**Reset:** 0x00  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4           | 3           | 2           | 1              | 0           |
|--------|---|---|---|-------------|-------------|-------------|----------------|-------------|
|        |   |   |   | <b>PERR</b> | <b>FAIL</b> | <b>BERR</b> | <b>CRSTEXT</b> | <b>DONE</b> |
| Access | R | R | R | R/W         | R/W         | R/W         | R/W            | R/W         |
| Reset  | 0 | 0 | 0 | 0           | 0           | 0           | 0              | 0           |

- Bits 7:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 4 – PERR: Protection Error**  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Protection Error bit.  
 This bit is set when a command that is not allowed in protected state is issued.
- Bit 3 – FAIL: Failure**  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Failure bit.  
 This bit is set when a DSU operation failure is detected.
- Bit 2 – BERR: Bus Error**  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Bus Error bit.  
 This bit is set when a bus error is detected.
- Bit 1 – CRSTEXT: CPU Reset Phase Extension**  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the CPU Reset Phase Extension bit.  
 This bit is set when a debug adapter Cold-Plugging is detected, which extends the CPU reset phase.
- Bit 0 – DONE: Done**  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Done bit.  
 This bit is set when a DSU operation is completed.

### 13.13.3 Status B

**Name:** STATUSB  
**Offset:** 0x0002  
**Reset:** 0x1X  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4   | 3     | 2     | 1       | 0    |
|--------|---|---|---|-----|-------|-------|---------|------|
|        |   |   |   | HPE | DCCD1 | DCCD0 | DBGPRES | PROT |
| Access | R | R | R | R   | R     | R     | R       | R    |
| Reset  | 0 | 0 | 0 | 1   | 0     | 0     | X       | X    |

- **Bits 7:5 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 4 – HPE: Hot-Plugging Enable**  
Writing a zero to this bit has no effect.  
Writing a one to this bit has no effect.  
This bit is set when Hot-Plugging is enabled.  
This bit is cleared when Hot-Plugging is disabled. This is the case when the SWCLK function is changed. Only a power-reset or a external reset can set it again.
- **Bits 3:2 – DCCDx [x=1..0]: Debug Communication Channel x Dirty**  
Writing a zero to this bit has no effect.  
Writing a one to this bit has no effect.  
This bit is set when DCCx is written.  
This bit is cleared when DCCx is read.
- **Bit 1 – DBGPRES: Debugger Present**  
Writing a zero to this bit has no effect.  
Writing a one to this bit has no effect.  
This bit is set when a debugger probe is detected.  
This bit is never cleared.
- **Bit 0 – PROT: Protected**  
Writing a zero to this bit has no effect.  
Writing a one to this bit has no effect.  
This bit is set at powerup when the device is protected.  
This bit is never cleared.

### 13.13.4 Address

**Name:** ADDR  
**Offset:** 0x0004  
**Reset:** 0x00000000  
**Property:** Write-Protected

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  |

The information in this register is related to the ordering code. Refer to the [“Ordering Information” on page 5](#) for details.

- Bits 31:28 – PROCESSOR[3:0]: Processor**  
 The value of this field defines the processor used on the device. For this device, the value of this field is 0x1, corresponding to the ARM Cortex-M0+ processor.
- Bits 27:23 – FAMILY[4:0]: Product Family**  
 The value of this field corresponds to the Product Family part of the ordering code. For this device, the value of this field is 0x2, corresponding to the SAM C family of 5V microcontrollers.
- Bits 21:16 – SERIES[5:0]: Product Series**  
 The value of this field corresponds to the Product Series part of the ordering code. For this device, the value of this field is 0x0, corresponding to a product with the Cortex-M0+ processor with DMA features.
- Bits 15:12 – DIE[3:0]: Die Identification**  
 Identifies the die in the family.
- Bits 11:8 – REVISION[3:0]: Revision**  
 Identifies the die revision number.

- **Bits 7:0 – DEVSEL[7:0]: Device Selection**

DEVSEL is used to identify a device within a product family and product series. The value corresponds to the Flash memory density, pin count and device variant parts of the ordering code. Refer to [Table 13-9](#). for details.

**Table 13-9. Device Selection**

| DEVSEL   | Device     | Flash | RAM  | Pincount |
|----------|------------|-------|------|----------|
| 0x0      | SAMC20J18A | 256KB | 32KB | 64       |
| 0x1      | SAMC20J17A | 128KB | 16KB | 64       |
| 0x2      | SAMC20J16A | 64KB  | 8KB  | 64       |
| 0x3      | SAMC20J15A | 32KB  | 4KB  | 64       |

| Access | R             | R  | R  | R  | R  | R  | R   | R     |
| Reset  | 0             | 0  | 0  | 0  | 0  | 0  | 1   | X     |

- **Bits 31:12 – ADDOFF[19:0]: Address Offset**  
The base address of the component, relative to the base address of this ROM table.
- **Bits 11:2 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 1 – FMT: Format**  
Always read as one, indicates a 32-bit ROM table.
- **Bit 0 – EPRES: Entry Present**  
This bit indicates whether an entry is present at this location in the ROM table.  
This bit is set at powerup if the device is not protected indicating that the entry is not present.  
This bit is cleared at powerup if the device is not protected indicating that the entry is present.

### 13.13.10 CoreSight ROM Table End

**Name:** END  
**Offset:** 0x1008  
**Reset:** 0x00000000  
**Property:** -

|        |            |    |    |    |    |    |    |    |

|        |    |    |    |    |    |    |    |              |
| Access | R  | R  | R  | R  | R  | R  | R  | R            |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0            |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0            |
|        |    |    |    |    |    |    |    | <b>SMEMP</b> |
| Access | R  | R  | R  | R  | R  | R  | R  | R            |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | X            |

- Bits 31:1 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 – SMEMP: System Memory Present**  
 This bit indicates whether system memory is present on the bus that connects to the ROM table.  
 This bit is set at powerup if the device is not protected indicating that the system memory is accessible from a debug adapter.  
 This bit is cleared at powerup if the device is protected indicating that the system memory is not accessible from a debug adapter.

### 13.13.12 Peripheral Identification 4

**Name:** PID4  
**Offset:** 0x1FD0  
**Reset:** 0x00000000  
**Property:** -

|        |           |    |    |    |            |    |    |    |
|--------|-----------|----|----|----|------------|----|----|----|
| Bit    | 31        | 30 | 29 | 28 | 27         | 26 | 25 | 24 |
|        |           |    |    |    |            |    |    |    |
| Access | R         | R  | R  | R  | R          | R  | R  | R  |
| Reset  | 0         | 0  | 0  | 0  | 0          | 0  | 0  | 0  |
| Bit    | 23        | 22 | 21 | 20 | 19         | 18 | 17 | 16 |

| Access | R         | R  | R  | R  | R          | R  | R  | R  |
| Reset  | 0         | 0  | 0  | 0  | 0          | 0  | 0  | 0  |
| Bit    | 15        | 14 | 13 | 12 | 11         | 10 | 9  | 8  |
|        |           |    |    |    |            |    |    |    |
| Access | R         | R  | R  | R  | R          | R  | R  | R  |
| Reset  | 0         | 0  | 0  | 0  | 0          | 0  | 0  | 0  |
| Bit    | 7         | 6  | 5  | 4  | 3          | 2  | 1  | 0  |
|        | FKBC[3:0] |    |    |    | JEPCC[3:0] |    |    |    |
| Access | R         | R  | R  | R  | R          | R  | R  | R  |
| Reset  | 0         | 0  | 0  | 0  | 0          | 0  | 0  | 0  |

- Bits 31:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 7:4 – FKBC[3:0]: 4KB Count**  
 These bits will always return zero when read, indicating that this debug component occupies one 4KB block.
- Bits 3:0 – JEPCC[3:0]: JEP-106 Continuation Code**  
 These bits will always return zero when read, indicating a Atmel device.

### 13.13.13 Peripheral Identification 0

**Name:** PID0  
**Offset:** 0x1FE0  
**Reset:** 0x000000D0  
**Property:** -

|        |              |    |    |    |    |    |    |    |
|--------|--------------|----|----|----|----|----|----|----|
| Bit    | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |              |    |    |    |    |    |    |    |
| Access | R            | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        |              |    |    |    |    |    |    |    |
| Access | R            | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | PARTNBL[7:0] |    |    |    |    |    |    |    |
| Access | R            | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 1            | 1  | 0  | 1  | 0  | 0  | 0  | 0  |

- **Bits 31:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 7:0 – PARTNBL[7:0]: Part Number Low**  
 These bits will always return 0xD0 when read, indicating that this device implements a DSU module instance.

### 13.13.14 Peripheral Identification 1

**Name:** PID1  
**Offset:** 0x1FE4  
**Reset:** 0x000000FC  
**Property:** -

|        |              |    |    |    |              |    |    |    |
|--------|--------------|----|----|----|--------------|----|----|----|
| Bit    | 31           | 30 | 29 | 28 | 27           | 26 | 25 | 24 |

|        |              |    |    |    |              |    |    |    |
| Access | R            | R  | R  | R  | R            | R  | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0            | 0  | 0  | 0  |
| Bit    | 15           | 14 | 13 | 12 | 11           | 10 | 9  | 8  |
|        |              |    |    |    |              |    |    |    |
| Access | R            | R  | R  | R  | R            | R  | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0            | 0  | 0  | 0  |
| Bit    | 7            | 6  | 5  | 4  | 3            | 2  | 1  | 0  |
|        | JEPIDCL[3:0] |    |    |    | PARTNBH[3:0] |    |    |    |
| Access | R            | R  | R  | R  | R            | R  | R  | R  |
| Reset  | 1            | 1  | 1  | 1  | 1            | 1  | 0  | 0  |

- Bits 31:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 7:4 – JEPIDCL[3:0]: Low part of the JEP-106 Identity Code**  
 These bits will always return 0xF when read, indicating a Atmel device (Atmel JEP-106 identity code is 0x1F).
- Bits 3:0 – PARTNBH[3:0]: Part Number High**  
 These bits will always return 0xC when read, indicating that this device implements a DSU module instance.

### 13.13.15 Peripheral Identification 2

**Name:** PID2  
**Offset:** 0x1FE8  
**Reset:** 0x00000009  
**Property:** -

|        |               |    |    |    |      |              |    |    |
|--------|---------------|----|----|----|------|--------------|----|----|
| Bit    | 31            | 30 | 29 | 28 | 27   | 26           | 25 | 24 |

|        | REVISION[3:0] |    |    |    | JEPU | JEPIDCH[2:0] |    |    |
| Access | R             | R  | R  | R  | R    | R            | R  | R  |
| Reset  | 0             | 0  | 0  | 0  | 1    | 0            | 0  | 1  |

- Bits 31:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 7:4 – REVISION[3:0]: Revision Number**  
 Revision of the peripheral. Starts at 0x0 and increments by one at both major and minor revisions.
- Bit 3 – JEPU: JEP-106 Identity Code is used**  
 This bit will always return one when read, indicating that JEP-106 code is used.
- Bits 2:0 – JEPIDCH[2:0]: JEP-106 Identity Code High**  
 These bits will always return 0x1 when read, indicating an Atmel device (Atmel JEP-106 identity code is 0x1F).

### 13.13.16 Peripheral Identification 3

**Name:** PID3  
**Offset:** 0x1FEC  
**Reset:** 0x00000000  
**Property:** -

|        |             |    |    |    |             |    |    |    |

- Bits 31:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 7:0 – PREAMBLEB3[7:0]: Preamble Byte 3**  
 These bits will always return 0xB1 when read.

## 14. DIVAS – Divide and Square Root Accelerator

### 14.1 Overview

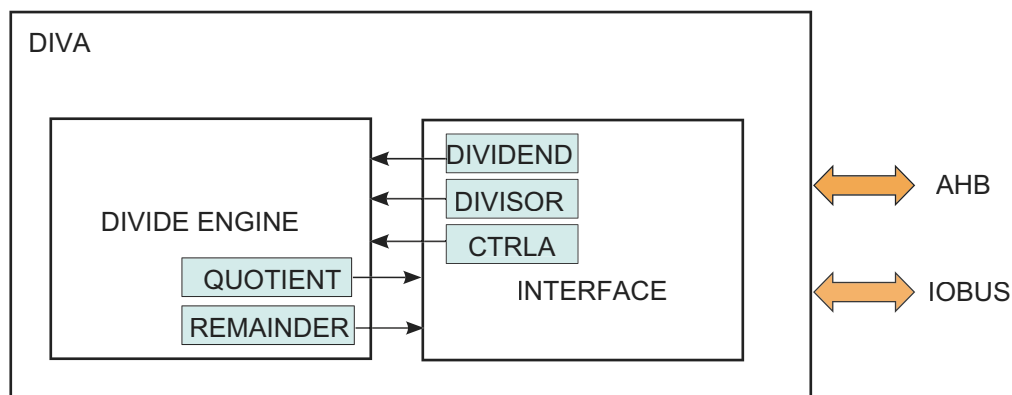

The Divide and Square Root Accelerator (DIVAS) is a programmable 32-bit signed or unsigned hardware divider and a 32-bit unsigned square root hardware engine. The DIVAS is connected to the high-speed bus matrix and may also be accessed using the low-latency CPU local bus (IOBUS; ARM® single-cycle I/O port). The DIVAS takes dividend and divisor values and returns the quotient and remainder when it is used as divider. The DIVAS takes unsigned input value and returns its square root and remainder when it is used as square root function.

### 14.2 Features

- Division accelerator for Cortex-M0+ systems
- 32-bit signed or unsigned integer division
- 32-bit unsigned square root
- 32-bit division in 2-16 cycles
- Programmable leading zero optimization
- Result includes quotient and remainder
- Result includes square root and remainder
- Busy and Divide-by-zero status
- Automatic start of operation when divisor or square root input is loaded

### 14.3 Block Diagram

Figure 14-1. DIVAS Block Diagram

### 14.4 Signal Description

Not applicable

### 14.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

#### 14.5.1 I/O Lines

Not applicable

### 14.5.2 Power Management

The DIVAS will not operate in any sleep mode .

### 14.5.3 Clocks

The DIVAS bus clock (CLK\_DIVAS\_AHB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_DIVAS\_AHB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

### 14.5.4 DMA

Not applicable

### 14.5.5 Interrupts

Not applicable

### 14.5.6 Events

Not applicable

### 14.5.7 Debug Operation

Not applicable

### 14.5.8 Register Access Protection

Certain registers cannot be modified while DIVAS is busy. The following registers are write-protected while busy:

- Control A ([CTRLA](#))
- Dividend ([DIVIDEND](#))
- Divisor ([DIVISOR](#))
- Square Number([SQRNUM](#))

Accessing these registers while protected will result in an error. Refer to “[PAC – Peripheral Access Control](#)” on [page 33](#) for details.

### 14.5.9 Analog Connections

Not applicable

### 14.5.10 CPU Local Bus

The CPU local bus (IOBUS) is an interface that connects the CPU directly to the DIVAS. It is a single-cycle bus interface, and does not support wait states. It supports byte, half word and word sizes. This bus is generally used for low latency. All registers can be read and written using this bus.

Since the IOBUS cannot wait for DIVAS to complete operation, the Quotient and Remainder registers must be only be read via the IOBUS while the Busy bit in the Status register (STATUS.BUSY) is zero to prevent incorrect data from being read.

## 14.6 Functional Description

### 14.6.1 Principle of Operation

The Divide and Square Root Accelerator (DIVAS) supports signed or unsigned hardware division of 32-bit values and unsigned square root of 32-bit value. It is accessible from the CPU via both the AHB bus and IOBUS. When the dividend and divide registers are programmed, the division starts and the result will be stored in the Result and Remainder registers. The Busy and Divide-by-zero status can be read from STATUS register.

When the square root input register (**SQRNUM**) is programmed, the square root function starts and the result will be stored in the Result and Remainder registers. The Busy status can be read from STATUS register.

## 14.6.2 Basic Operation

### 14.6.2.1 Initialization

The DIVAS configuration cannot be modified while a divide operation is ongoing. The following bits must be written prior to starting a division:

- Sign selection bit in Control A register (CTRLA.SIGNED)
- Leading zero mode bit in Control A register (CTRLA.DLZ)

### 14.6.2.2 Performing Division

First write the dividend to DIVIDEND register. Writing the divisor to DIVISOR register starts the division and sets the busy bit in the Status register (STATUS.BUSY). When the division has completed, the STATUS.BUSY bit is cleared and the result will be stored in RESULT and REMAINDER registers.

The RESULT and REMAINDER registers can be read directly via the high-speed bus without checking first STATUS.BUSY. Wait states will be inserted on the high-speed bus until the operation is complete. The IOBUS does not support wait states. For accesses via the IOBUS, the STATUS.BUSY bit must be polled before reading the result from the RESULT and REMAINDER registers.

### 14.6.2.3 Operand Size

#### Divide

The DIVAS can perform 32-bit signed and unsigned division and the operation follows the equation as below.

$$\begin{aligned}\text{RESULT}[31:0] &= \text{DIVIDEND}[31:0] / \text{DIVISOR}[31:0] \\ \text{REMAINDER}[31:0] &= \text{DIVIDEND}[31:0] \% \text{DIVISOR}[31:0]\end{aligned}$$

DIVAS completes 32-bit division in 2-16 cycles.

#### Square Root

The DIVAS can perform 32-bit unsigned division and the operation follows the equation as below.

$$\begin{aligned}\text{RESULT}[31:0] &= \sqrt{\text{SQRNUM}[31:0]} \\ \text{REMAINDER}[31:0] &= \text{SQRNUM}[31:0] - \text{RESULT}[31:0]^2\end{aligned}$$

### 14.6.2.4 Signed Division

When CTRLA.SIGNED is one, both the input and the result will be in 2's complement format. The results of signed division are such that the remainder and dividend have the same sign and the quotient is negative if the dividend and divisor have opposite signs. 16-bit results are sign extended to 32-bits. Note that when the maximum negative number is divided by the minimum negative number, the resulting quotient overflows the signed integer range and will return the maximum negative number with no indication of the overflow. This occurs for 0x80000000 / 0xFFFFFFFF in 32-bit operation and 0x8000 / 0xFFFF in 16-bit operation.

### 14.6.2.5 Divide By Zero

A divide by zero fault occurs if the DIVISOR is programmed to zero. QUOTIENT will be zero and the REMAINDER is equal to DIVIDEND. Divide by zero sets the Divide-by-zero bit in the Status register (STATUS.DBZ) to one. STATUS.DBZ must be cleared by writing a one to it.

### 14.6.2.6 Leading Zero Optimization

Leading zero optimization can reduce the time it takes to complete a division by skipping leading zeros in the DIVIDEND (or leading ones in signed mode). Leading zero optimization is enabled by default and can be disabled by the Disable Leading Zero bit in the Control A register (CTRLA.DLZ). When CTRLA.DLZ is zero, 16-bit division completes in 2-8

cycles and 32-bit division completes in 2-16 cycles, depending on the dividend value. If deterministic timing is required, setting CTRLA.DLZ to one forces 16-bit division to always take 8 cycles and 32-bit division to always take 16 cycles.

#### 14.6.2.7 Unsigned Square Root

When the square root input register ([SQRNUM](#)) is programmed, the square root function starts and the result will be stored in the Result and Remainder registers. The Busy status can be read from STATUS register.

## 14.7 Register Summary

| Offset | Name      | Bit Pos. |                  |  |  |  |  |  |     |        |
|--------|-----------|----------|------------------|--|--|--|--|--|-----|--------|
| 0x00   | CTRLA     | 7:0      |                  |  |  |  |  |  | DLZ | SIGNED |
| 0x01   | Reserved  |          |                  |  |  |  |  |  |     |        |

| 0x1A   |           | 23:16    | SQRNUM[23:16]    |  |  |  |  |  |     |        |
| 0x1B   |           | 31:24    | SQRNUM[31:24]    |  |  |  |  |  |     |        |

## 14.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

### 14.8.1 Control Register

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00

**Property:** -

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1   | 0      |
|--------|---|---|---|---|---|---|-----|--------|
|        |   |   |   |   |   |   | DLZ | SIGNED |
| Access | R | R | R | R | R | R | R/W | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0   | 0      |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1– DLZ: Disable Leading Zero Optimization**

0: Enable leading zero optimization; 32-bit division takes 2-16 cycles.

1: Disable leading zero optimization; 32-bit division takes 16 cycles.

- **Bit 0– SIGNED: Signed Division Enable**

0: Unsigned division.

1: Signed division.

## 14.8.2 Status

**Name:** STATUS

**Offset:** 0x04

**Reset:** 0x00

**Property:** -

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1   | 0    |
|--------|---|---|---|---|---|---|-----|------|
|        |   |   |   |   |   |   | DBZ | BUSY |
| Access | R | R | R | R | R | R | R/W | R    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0   | 0    |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1 – DBZ: divide-by-zero**

0: A divide-by-zero fault has not occurred

1: A divide-by-zero fault has occurred

Writing a zero to this bit has no effect.

Writing a one to this bit clears DBZ to zero.

- **Bits 0 – BUSY: DIVAS Accelerator Busy**

0: DIVAS is idle

1: DIVAS is busy with an ongoing division

This bit is set when a value is written to the DIVISOR or SQRNUM registers.

This bit is cleared when either division or square root function completes and results are ready in the RESULT and REMAINDER registers.

### 14.8.3 DIVIDEND

**Name:** DIVIDEND

**Offset:** 0x08

**Property:** -

|        |                 |     |     |     |     |     |     |     |
|--------|-----------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31              | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIVIDEND[31:24] |     |     |     |     |     |     |     |
| Access | R/W             | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23              | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | DIVIDEND[23:16] |     |     |     |     |     |     |     |
| Access | R/W             | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15              | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | DIVIDEND[15:8]  |     |     |     |     |     |     |     |
| Access | R/W             | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 31              | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIVIDEND[7:0]   |     |     |     |     |     |     |     |
| Access | R/W             | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bit 31:0 – DIVIDEND[31:0]: Dividend Value**

Holds the 32-bit dividend for the divide operation. If the Signed bit in Control A register (CTRLA.SIGNED) is zero, DIVIDEND is unsigned. If CTRLA.SIGNED = 1, DIVIDEND is signed two's complement. Refer to [“Performing Division” on page 93](#), [“Operand Size” on page 93](#) and [“Signed Division” on page 93](#).

## 14.8.4 DIVISOR

**Name:** DIVISOR

**Offset:** 0x0C

**Property:** -

|        |                |     |     |     |     |     |     |     |
|--------|----------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31             | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIVISOR[31:24] |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23             | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | DIVISOR[23:16] |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15             | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | DIVISOR[15:8]  |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 31             | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIVISOR[7:0]   |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bit 31:0 – DIVISOR[31:0]: Divisor Value**

Holds the 32-bit divisor for the divide operation. If the Signed bit in Control A register (CTRLA.SIGNED) is zero, DIVISOR is unsigned. If CTRLA.SIGNED = 1, DIVISOR is signed two's complement. Writing the DIVISOR register will start the divide function. Refer to [“Performing Division” on page 93](#), [“Operand Size” on page 93](#) and [“Signed Division” on page 93](#).

## 14.8.5 RESULT

**Name:** RESULT

**Offset:** 0x10

**Property:** -

|        |               |    |    |    |    |    |    |    |
|--------|---------------|----|----|----|----|----|----|----|
| Bit    | 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | RESULT[31:24] |    |    |    |    |    |    |    |
| q      | R             | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0             | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        | RESULT[23:16] |    |    |    |    |    |    |    |
| Access | R             | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0             | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | RESULT[15:8]  |    |    |    |    |    |    |    |
| Access | R             | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0             | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | RESULT[7:0]   |    |    |    |    |    |    |    |
| Access | R             | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0             | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

- **Bit 31:0 – RESULT[31:0]: Result of Operation**

Holds the 32-bit result of the last performed operation. For a divide operation this is the quotient. If the Signed bit in Control A register (CTRLA.SIGNED) is zero, the quotient is unsigned. If CTRLA.SIGNED = 1, the quotient is signed two's complement. For a square root operation this is the square root. Refer to [“Performing Division” on page 93](#), [“Operand Size” on page 93](#) and [“Signed Division” on page 93](#).

## 14.8.6 REMAINDER

**Name:** REMAINDER

**Offset:** 0x14

**Property:** -

|        |                   |    |    |    |    |    |    |    |
|--------|-------------------|----|----|----|----|----|----|----|
| Bit    | 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | REMAINDER[31:24]  |    |    |    |    |    |    |    |
| q      | R                 | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 23                | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        | REMAINDER[[23:16] |    |    |    |    |    |    |    |
| Access | R                 | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 15                | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | REMAINDER[[15:8]  |    |    |    |    |    |    |    |
| Access | R                 | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | REMAINDER[[7:0]   |    |    |    |    |    |    |    |
| Access | R                 | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

- **Bit 31:0 – REMAINDER[31:0]: Remainder of Operation**

Holds the 32-bit remainder of the last performed operation. For a divide operation this is the division remainder. If the Signed bit in Control A register (CTRLA.SIGNED) is zero, the quotient is unsigned. If CTRLA.SIGNED = 1, the quotient is signed two's complement. For a square root operation this is the square root remainder. Refer to [“Performing Division” on page 93](#), [“Operand Size” on page 93](#) and [“Signed Division” on page 93](#).

## 14.8.7 SQUARE ROOT INPUT

**Name:** SQRNUM

**Offset:** 0x18

**Property:** -

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | SQRNUM[31:24] |     |     |     |     |     |     |     |
| q      | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | SQRNUM[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | SQRNUM[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | SQRNUM[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bit 31:0 – SQRNUM[[31:0]**

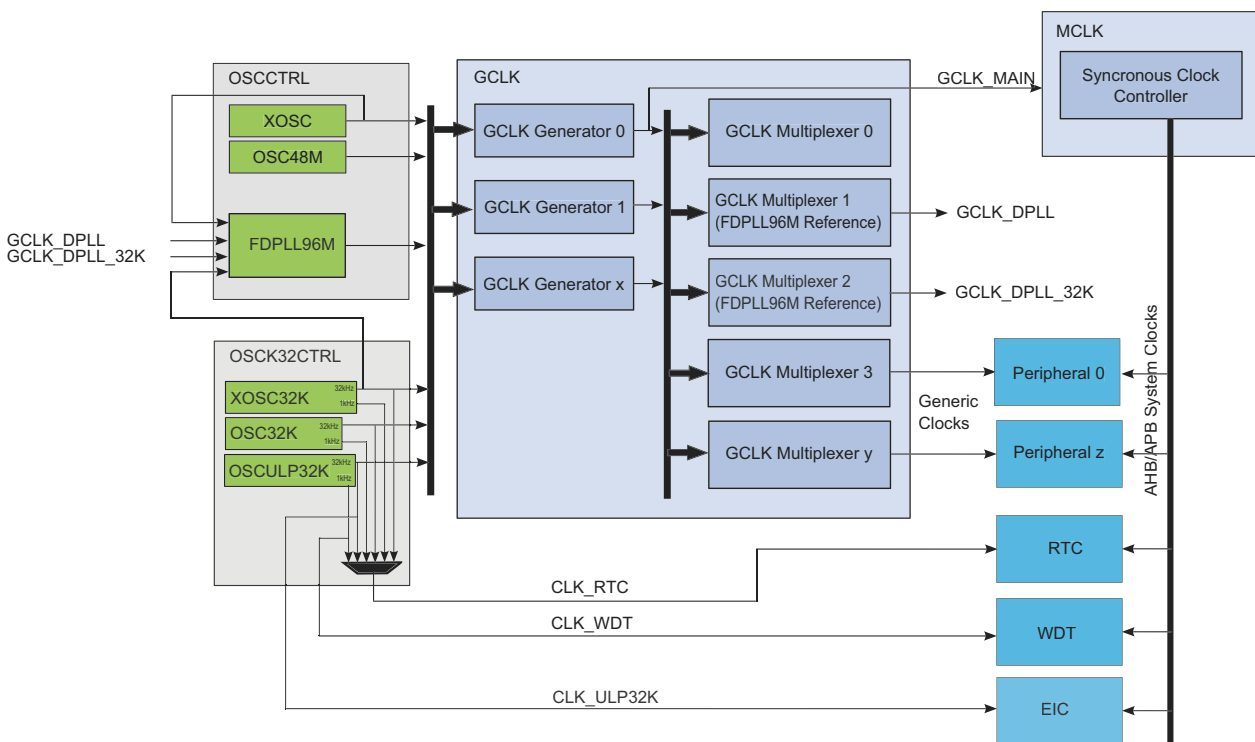

Holds the 32-bit unsigned input for the square root operation. Writing the SQRNUM register will start the square root function. Refer to [“Unsigned Square Root” on page 94](#).

## 15. Clock System

This chapter only aims to summarize the clock distribution and terminology in the SAM C20 device. It will not explain every detail of its configuration. For in-depth documentation, see the referenced module chapters.

### 15.1 Clock Distribution

Figure 15-1. Clock distribution

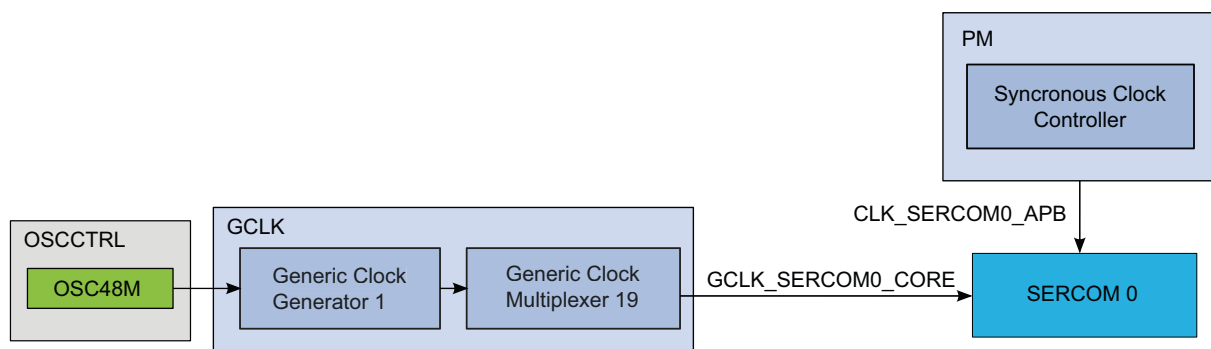

The clock system on the SAM C20 consists of:

- **Clock sources**, controlled by OSCCTRL and OSC32KCTRL
  - A Clock source is the base clock signal used in the system. Example clock sources are the internal 48MHz oscillator (OSC48M), External crystal oscillator (XOSC) and the Digital phase locked loop (FDPLL96M).
- **Generic Clock Controller (GCLK)** which controls the clock distribution system, made up of:
  - **Generic Clock generators:** A programmable prescaler, that can use any of the system clock sources as its source clock. The Generic Clock Generator 0, also called GCLK\_MAIN, is the clock feeding the Power Manager used to generate synchronous clocks.
  - **Generic Clocks:** Typically the clock input of a peripheral on the system. The generic clocks, through the Generic Clock Multiplexer, can use any of the Generic Clock generators as its clock source. Multiple instances of a peripheral will typically have a separate generic clock for each instance.
- **Main Clock controller (MCLK)**
  - The MCLK controls synchronous clocks on the system. This includes the CPU, bus clocks (APB, AHB) as well as the synchronous (to the CPU) user interfaces of the peripherals. It contains clock masks that can turn on/off the user interface of a peripheral as well as prescalers for the CPU and bus clocks.

Figure 15-2 shows an example where SERCOM0 is clocked by the OSC48M. The OSC48M is enabled, the Generic Clock Generator 1 uses the OSC48M as its clock source, and the generic clock 19, also called GCLK\_SERCOM0\_CORE, that is connected to SERCOM0 uses generator 1 as its source. The SERCOM0 interface, clocked by CLK\_SERCOM0\_APB, has been unmasked in the APBC Mask register in the MCLK.

**Figure 15-2. Example of SERCOM clock**

## 15.2 Synchronous and Asynchronous Clocks

As the CPU and the peripherals can be clocked from different clock sources, possibly with widely different clock speeds, some peripheral accesses by the CPU needs to be synchronized between the different clock domains. In these cases the peripheral includes a SYNCBUSY status register that can be used to check if a sync operation is in progress. As the nature of the synchronization might vary between different peripherals, detailed description for each peripheral can be found in the sub-chapter “synchronization” for each peripheral where this is necessary.

In the datasheet references to synchronous clocks are referring to the CPU and bus clocks, while asynchronous clocks are clock generated by generic clocks.

## 15.3 Register Synchronization

### 15.3.1 Overview

All peripherals are composed of one digital bus interface, which is connected to the APB or AHB bus and clocked using a corresponding synchronous clock, and one core clock, which is clocked using a generic clock. Access between these clock domains must be synchronized. As this mechanism is implemented in hardware the synchronization process takes place even if the different clocks domains are clocked from the same source and on the same frequency. All registers in the bus interface are accessible without synchronization. All core registers in the generic clock domain must be synchronized when written. Some core registers must be synchronized when read. Registers that need synchronization has this denoted in each individual register description.

### 15.3.2 General Write synchronization

Inside the same module, each core register, denoted by the Write-Synchronized property, use its own synchronization mechanism so that writing to different core registers can be done without waiting for the end of synchronization of previous core register access.

However a second write access to the same core register, while synchronization is on going, is discarded and an error is reported through the PAC. To write again to the same core register in the same module, user must wait for the end of synchronization.

For each core register, that can be written, a synchronization status bit is associated

#### Example:

REGA, REGB are 8-bit core registers. REGC is 16-bit core register.

| Offset | Register |
|--------|----------|
| 0x00   | REGA     |
| 0x01   | REGB     |

|      |      |
|------|------|
| 0x02 | REGC |
| 0x03 |      |

Since synchronization is per register, user can write REGA (8-bit access) then immediately write REGB (8-bit access) without error.

User can write REGC (16-bit access) without affecting REGA or REGB. But if user writes REGC in two consecutive 8-bit accesses, second write will be discarded and generate an error.

When user makes a 32-bit access to offset 0x00, all registers are written but REGA, REGB, REGC can be updated at a different time because of independent write synchronization

### 15.3.3 General read synchronization

Before any read of a core register, the user must check that the related bit in SYNCBUSY register is cleared.

Read access to core register is always immediate but the return value is reliable only if a synchronization of this core register is not going.

### 15.3.4 Completion of synchronization

The user can either poll SYNCBUSY register or use the Synchronisation Ready interrupt (if available) to check when the synchronization is complete.

### 15.3.5 Enable Write-Synchronization

Writing to the Enable bit in the Control register (CTRL.ENABLE) will also trigger write-synchronization and set SYNCBUSY.ENABLE. CTRL.ENABLE will read its new value immediately after being written. The Synchronisation Ready interrupt (if available) cannot be used for Enable write-synchronization.

### 15.3.6 Software Reset Write-Synchronization

Writing a one to the Software Reset bit in CTRL (CTRL.SWRST) will also trigger write-synchronization and set SYNCBUSY.SWRST. When writing a one to the CTRL.SWRST bit it will immediately read as one. CTRL.SWRST and SYNCBUSY.SWRST will be cleared by hardware when the peripheral has been reset. Writing a zero to the CTRL.SWRST bit has no effect. The Synchronisation Ready interrupt (if available) cannot be used for Software Reset write-synchronization.

### 15.3.7 Synchronization Delay

The synchronization will delay the write or read access duration by a delay D, given by the equation:

$$5 \cdot P_{GCLK} + 2 \cdot P_{APB} < D < 6 \cdot P_{GCLK} + 3 \cdot P_{APB}$$

Where  $P_{GCLK}$  is the period of the generic clock and  $P_{APB}$  is the period of the peripheral bus clock. A normal peripheral bus register access duration is  $2 \cdot P_{APB}$ .

## 15.4 Enabling a Peripheral

To enable a peripheral clocked by a generic clock, the following parts of the system needs to be configured:

- A running clock source.
- A clock from the Generic Clock Generator must be configured to use one of the running clock sources, and the generator must be enabled.
- The generic clock, through the Generic Clock Multiplexer, that connects to the peripheral needs to be configured with a running clock from the Generic Clock Generator, and the generic clock must be enabled.
- The user interface of the peripheral needs to be unmasked in the PM. If this is not done the peripheral registers will read as all 0's and any writes to the peripheral will be discarded.

## 15.5 On-demand, Clock Requests

Figure 15-3. Clock request routing

All the clock sources in the system can be run in an on-demand mode, where the clock source is in a stopped state when no peripherals are requesting the clock source. Clock requests propagate from the peripheral, via the GCLK, to the clock source. If one or more peripheral is using a clock source, the clock source will be started/kept running. As soon as the clock source is no longer needed and no peripheral have an active request the clock source will be stopped until requested again. For the clock request to reach the clock source, the peripheral, the generic clock and the clock from the Generic Clock Generator in-between must be enabled. The time taken from a clock request being asserted to the clock source being ready is dependent on the clock source startup time, clock source frequency as well as the divider used in the Generic Clock Generator. The total startup time from a clock request to the clock is available for the peripheral is:

$$\text{Delay\_start\_max} = \text{Clock source startup time} + 2 * \text{clock source periods} + 2 * \text{divided clock source periods}$$

$$\text{Delay\_start\_min} = \text{Clock source startup time} + 1 * \text{clock source period} + 1 * \text{divided clock source period}$$

The delay for shutting down the clock source when there is no longer an active request is:

$$\text{Delay\_stop\_min} = 1 * \text{divided clock source period} + 1 * \text{clock source period}$$

$$\text{Delay\_stop\_max} = 2 * \text{divided clock source periods} + 2 * \text{clock source periods}$$

The On-Demand principle can be disabled individually for each clock source by clearing the ONDEMAND bit located in each clock source controller. The clock is always running whatever is the clock request. This has the effect to remove the clock source startup time at the cost of the power consumption.

In standby mode, the clock request mechanism is still working if the modules are configured to run in standby mode (RUNSTDBY bit).

## 15.6 Power Consumption vs Speed

Due to the nature of the asynchronous clocking of the peripherals there are some considerations that needs to be taken if either targeting a low-power or a fast-acting system. If clocking a peripheral with a very low clock, the active power consumption of the peripheral will be lower. At the same time the synchronization to the synchronous (CPU) clock domain is dependent on the peripheral clock speed, and will be longer with a slower peripheral clock; giving lower response time and more time waiting for the synchronization to complete.

## 15.7 Clocks after Reset

On any reset the synchronous clocks start to their initial state:

- OSC48M is enabled and divided by 12
- GCLK\_MAIN uses OSC48M as source
- CPU and BUS clocks are undivided

On a power reset the GCLK starts to their initial state:

- All generic clock generators disabled except:
  - The generator 0 (GCLK\_MAIN) using OSC48M as source, with no division
- All generic clocks disabled

On a user reset the GCLK starts to their initial state, except for:

- Generic clocks that are write-locked (WRTLOCK is written to one prior to reset)

On any reset the clock sources are reset to their initial state except the 32KHz clock sources which are reset only by a power reset.

## 16. GCLK – Generic Clock Controller

### 16.1 Overview

Depending on the application, peripherals may require specific clock frequencies to operate correctly. The GCLK provides a number of generic clock generators that can provide a wide range of clock frequencies. Generators can be set to use different external and internal clock sources. The clock in each generator can be divided. The outputs from the generators are used as clock sources for the peripheral channels, which select one of the sources to generate a generic clock (GCLK\_PERIPH), as shown in [Figure 16-2](#). The number of generic clocks,  $m$ , depends on how many peripherals the device has. The main GCLK clock (GCLK\_MAIN) is generated by generator 0.

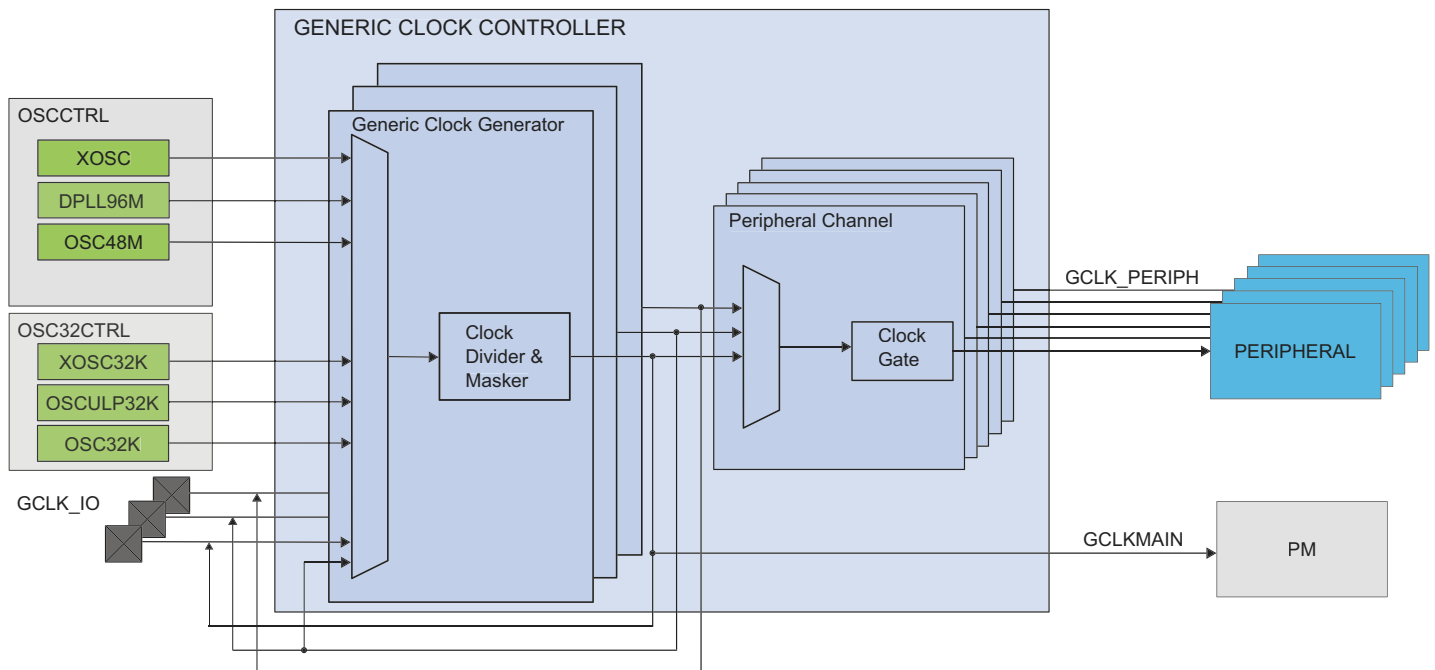

### 16.2 Features

- Provides a device-defined number of generic clocks
- Wide frequency range

### 16.3 Block Diagram

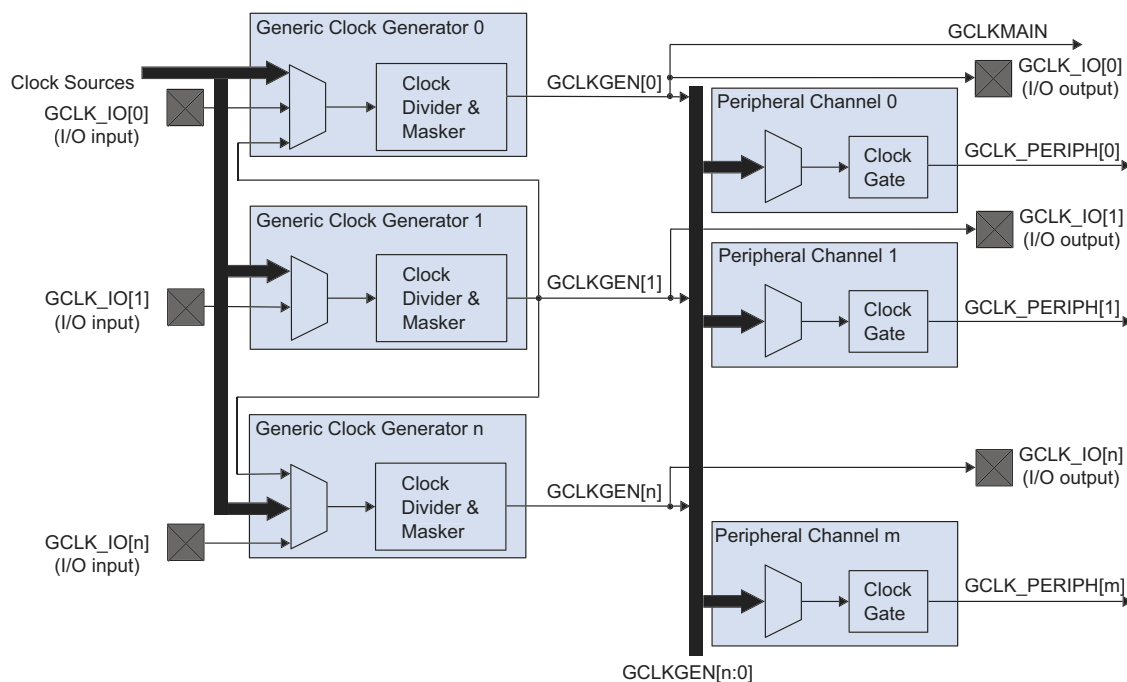

The peripheral and main GCLK clocks can be seen in the clocking diagram, which is shown in [Figure 16-1](#).

Figure 16-1. Device Clocking Diagram

The GCLK block diagram is shown in [Figure 16-2](#).

**Figure 16-2. Generic Clock Controller Block Diagram**

## 16.4 Signal Description

| Signal Name   | Type        | Description  |
|---------------|-------------|--|
| GCLK_IO[n..0] | Digital I/O | Source clock when input<br>Generic clock when output |

Please refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 16.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 16.5.1 I/O Lines

Using the GCLK’s I/O lines requires the I/O pins to be configured. Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

### 16.5.2 Power Management

The GCLK can operate in all sleep modes, if required. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 16.5.3 Clocks

The GCLK bus clock (CLK\_GCLK\_APB) can be enabled and disabled in the Main Clock Controller, and the default state of CLK\_GCLK\_APB can be found in the Peripheral Clock Masking section in [“MCLK – Main Clock” on page 126](#).

#### 16.5.4 DMA

Not applicable.

#### 16.5.5 Interrupts

Not applicable.

#### 16.5.6 Events

Not applicable.

#### 16.5.7 Debug Operation

When the CPU is halted in debug mode the GCLK continues normal operation. If the GCLK is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

#### 16.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC).

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to the [“PAC – Peripheral Access Control” on page 33](#) chapter for details.

#### 16.5.9 Analog Connections

Not applicable.

### 16.6 Functional Description

#### 16.6.1 Principle of Operation

The GCLK module is comprised of nine Generic Clock Generators (Generator) sourcing m Peripheral Channels.

A clock source selected as input to one of the generators can be used directly, or it can be prescaled in the generator before the generator output is used as input to one or more of the peripheral channels. A Peripheral Channel provides a peripheral generic clock to the peripherals (GCLK\_PERIPHERAL).

#### 16.6.2 Basic Operation

##### 16.6.2.1 Initialization

Before a generator is enabled, the corresponding clock source should be enabled. The peripheral clock must be configured as outlined by the following steps:

1. Generator must be enabled (GENCTRL.GENEN) and division factor must be set (GENCTRL.DIV) by performing a single 32-bit write to the Generator Control register (GENCTRL).
2. The generic clock for a peripheral must be configured by performing a write to the Peripheral Channel Control register (PCHCTRL). The generator used as the source of peripheral clock must be written to the GEN bits group in the Peripheral Channel Control register (PCHCTRL.GEN).

##### 16.6.2.2 Enabling, Disabling and Resetting

The GCLK module has no enable/disable bit to enable or disable the whole module.

The GCLK is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the GCLK will be reset to their initial state, except for Peripheral Channels and associated Generators that have their Write Lock bit written to one (PCHCTRL.WRTLOCK). For further details, refer to [“Configuration Lock” on page 114](#).

### 16.6.2.3 Generic Clock Generator

Each generator (GCLKGEN) can be set to run from one of nine different clock sources except GCLKGEN[1] which can be set to run from one of eight sources. GCLKGEN[1] is the only generator that can be selected as source to others generators.

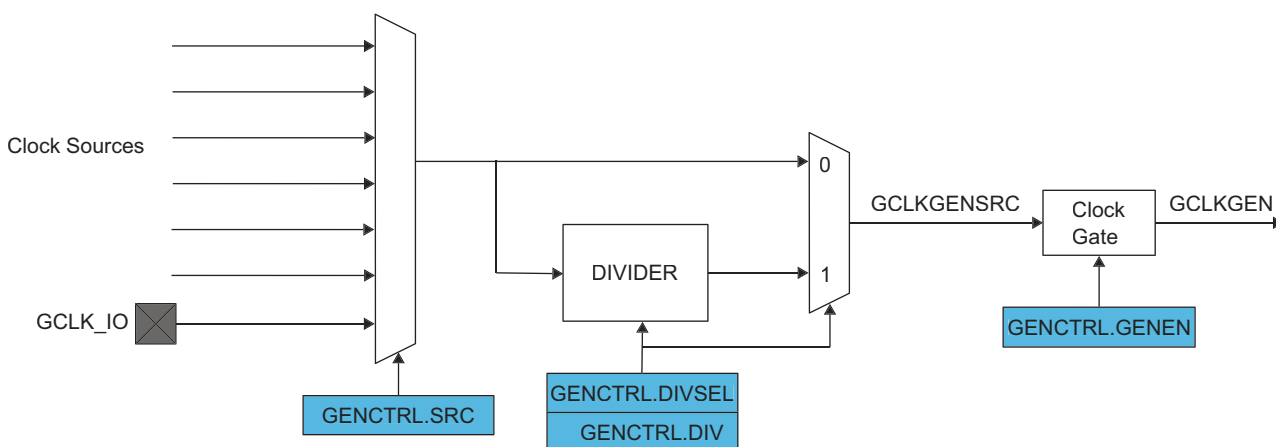

Each generator GCLKGEN[x] can be connected to one specific pin (GCLK\_IO[x]). The GCLK\_IO[x] can be set to act as source to GCLKGEN[x] or to output the clock generated by GCLKGEN[x].

The selected source (GCLKGENSRC in Figure 16-3 can be divided. Each generator can be independently enabled or disabled.

Each GCLKGEN clock can then be used as a clock source for Peripheral Channels. Each generator output clock is allocated to one or several peripherals.

GCLKGEN[0], is used as GCLKMAIN for the synchronous clock controller inside the Main Clock Controller. Refer to “MCLK – Main Clock” on page 126 for details on the synchronous clock generation.

**Figure 16-3. Generic Clock Generator**

### 16.6.2.4 Enabling a Generator

A generator is enabled by writing a one to the Generator Enable bit in the Generator Control register (GENCTRL.GENEN).

### 16.6.2.5 Disabling a Generator

A generator is disabled by writing a zero to GENCTRL.GENEN. When GENCTRL.GENEN is read as zero, the GCLKGEN clock is disabled and clock gated.

### 16.6.2.6 Selecting a Clock Source for the Generator

Each generator can individually select a clock source by writing to the Source Select bit group in Generator Control register (GENCTRL.SRC). Changing from one clock source, A, to another clock source, B, can be done on the fly. If clock source B is not ready, the generator will continue running with clock source A. As soon as clock source B is ready, generator will switch to it. During the switching operation, generator holds clock requests to clock sources A and B and then releases the clock source A request when the switch is done. The bit in SYNCHBUSY register (SYNCHBUSY.GENCTRLn) associated to the generator that is switching from one clock to another will remain at one until the switch operation is completed.

The available clock sources are device dependent (usually the oscillators, RC oscillators, DPLL and DFLL clocks). Only GCLKGEN[1] can be used as a common source for all other generators.

### 16.6.2.7 Changing the Clock Frequency

The selected source for a generator can be divided by writing a division factor in the Division Factor bit group in the Generator Control register (GENCTRL.DIV). Depending on the value of the Divide Selection bit in Generator Control register (GENCTRL.DIVSEL), it can be interpreted in two ways by the integer divider, as shown in Table 16-1.

Note that the number of DIV bits for each generator is device dependent. Refer to Table 16-2 for details.

**Table 16-1. Division Factor**

| GENCTRL.DIVSEL | Division Factor              |
|----------------|------------------------------|
| 0              | GENCTRL.DIV                  |
| 1              | $2^{(\text{GENCTRL.DIV}+1)}$ |

If GENCTRL.DIVSEL is zero and GENCTRL.DIV is zero or one, the output clock will be undivided.

### 16.6.2.8 Duty Cycle

When dividing a clock with an odd division factor, the duty-cycle will not be 50/50. Writing a one to the Improve Duty Cycle bit in Generator Control register (GENCTRL.IDC) will result in a 50/50 duty cycle.

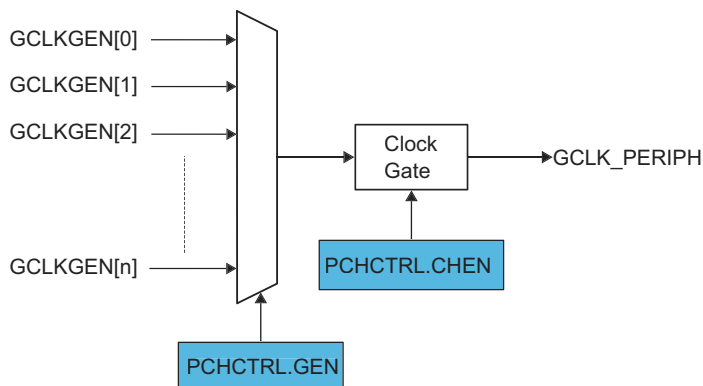

### 16.6.2.9 External Clock

The output clock (GCLKGEN) of each generator can be sent to I/O pins (GCLK\_IO). If the Output Enable bit in the Generator Control register (GENCTRL.OE) is set to one and the generator is enabled (GENCTRL.GENEN is one), the generator requests its clock source and the GCLKGEN clock is output to an I/O pin. If GENCTRL.OE is zero, I/O pin is set according to the Output Off Value bit value in Generator Control register (GENCTRL.OOV). If the Output Off Value bit is zero, the output clock will be low when turned off. If the bit value is one, the output clock will be high when turned off.

In standby mode, if the clock is output (GENCTRL.OE is one), the clock on the I/O pin is frozen to the OOV value if the Run In Standby bit in Generic Control register (GENCTRL.RUNSTDBY) is zero. If GENCTRL.RUNSTDBY is one, the GCLKGEN clock is kept running and output to the I/O pin.

## 16.6.3 Peripheral Clock

**Figure 16-4. Peripheral Clock**

### 16.6.3.1 Enabling a Peripheral Clock

Before a peripheral clock is enabled, one of the generators must be enabled (GENCTRL.GEN) and selected as source for the Peripheral Channel, by setting Generator Selection bits in Peripheral Channel Control register (PCHCTRL.GEN). Any available generator can be selected as clock source for each peripheral.

When a generator has been selected, the peripheral clock is enabled by writing a one to the Channel Enable bit in the Peripheral Channel Control register (PCHCTRL.CHEN). The PCHCTRL.CHEN bit must be synchronized to the generic clock domain. PCHCTRL.CHEN will continue to read as its previous state until the synchronization is complete.

#### 16.6.3.2 Disabling a Peripheral Clock

A peripheral clock is disabled by writing a zero to PCHCTRL.CHEN. The PCHCTRL.CHEN bit must be synchronized to the generic clock domain. PCHCTRL.CHEN will continue to read as its previous state until the synchronization is complete. The peripheral clock is gated when disabled.

#### 16.6.3.3 Selecting a Clock Source for the Peripheral

When changing a peripheral clock source by writing to PCHCTRL.GEN, the peripheral clock must be disabled before being re-enabled with the new clock source setting. This prevents glitches during the transition:

- a. Write a zero to PCHCTRL.CHEN
- b. Wait until PCHCTRL.CHEN reads as zero
- c. Change the source of the generic clock by writing PCHCTRL.GEN
- d. Re-enable the generic clock by writing a one to PCHCTRL.CHEN

#### 16.6.3.4 Configuration Lock

The peripheral clock configuration is locked for further write accesses by writing a one to the Write Lock bit in the Peripheral Channel Control register (PCHCTRL.WRTLOCK). All writes to the PCHCTRL register will be ignored. It can only be unlocked by a power reset.

The generator source of a “locked” Peripheral Channel is also locked. The corresponding GENCTRL register is locked, and can be unlocked only by a power reset.

There is one exception concerning the GCLKGEN[0]. As it is used as GCLKMAIN, it can not be locked. It is reset by any reset, to startup with a known configuration.

The software reset (CTRLA.SWRST) can not unlock the registers.

### 16.6.4 Additional Features

#### 16.6.4.1 Peripheral Clock Enable after Reset

The Generic Clock Controller must be able to provide a generic clock to some specific peripherals after a reset. That means that the configuration of the generators and peripheral channels after reset is device-dependent.

Refer to [Table 16-4](#) and [Table 16-5](#) for details on GENCTRL reset.

Refer to [Table 16-7](#) for details on PCHCTRL reset.

### 16.6.5 Sleep Mode Operation

#### 16.6.5.1 SleepWalking

The GCLK module supports the SleepWalking feature. During a sleep mode where the generic clocks are stopped, a peripheral that needs its clock to execute a process must request it from the Generic Clock Controller.

The Generic Clock Controller will receive this request and then determine which Generic Clock Generator is involved and which clock source needs to be awakened. It then wakes up the clock source, enables the generator and peripheral channel stages successively and delivers the clock to the peripheral.

The RUNSTDBY bit in Generator Control register controls clock output to pin during standby sleep mode. If the bit is cleared, the generator clock output on pin is not available. When set, the GCLK can continuously output the generator output to GCLK\_IO. Refer to [“External Clock” on page 113](#) for details.

### 16.6.6 Synchronization

Due to the asynchronicity between the main clock domain (CLK\_GCLK\_APB) and the peripheral clock domain (GCLKGENSRC) some registers are synchronized when written. When a write-synchronized register is written, the

corresponding bit in the Synchronization Busy register (SYNCBUSY) is set immediately. When the write-synchronization is complete, this bit is cleared. Reading a write-synchronized register while the synchronization is ongoing will return the value written, and not the current value in the peripheral clock domain. To read the current value in the peripheral clock domain after writing a register, the user must wait for the corresponding SYNCBUSY bit to be cleared before reading the value.

If a register is written while the corresponding bit in SYNCBUSY is one, the write is discarded and an error is generated.

An exception is made for Channel Enable bit in the Peripheral Channel Control register (PCHCTRL.CHEN). When changing the bit value, the bit value must be read-back to ensure the synchronization is complete and glitch free internal operation. Changing the bit value while the synchronization is not completed will not trigger any error generation.

The following registers need synchronization when written:

- Generic Clock Generator Control register (GENCTRL)
- Control A register (CTRLA)

Write-synchronization is denoted by the Write-Synchronization property in the register description.

## 16.7 Register Summary

### 16.7.1 Common Register

| Offset | Name     | Bit Pos. |          |          |          |          |          |          |          |          |
|--------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|
| 0x0    | CTRLA    | 7:0      |          |          |          |          |          |          |          | SWRST    |
| 0x1    | Reserved |          |          |          |          |          |          |          |          |          |
| 0x2    | Reserved |          |          |          |          |          |          |          |          |          |
| 0x3    | Reserved |          |          |          |          |          |          |          |          |          |
| 0x4    | SYNCBUSY | 7:0      | GENCTRL5 | GENCTRL4 | GENCTRL3 | GENCTRL2 | GENCTRL1 | GENCTRL0 |          | SWRST    |
| 0x5    |          | 15:8     |          |          |          |          |          | GENCTRL8 | GENCTRL7 | GENCTRL6 |
| 0x6    |          | 23:16    |          |          |          |          |          |          |          |          |
| 0x7    |          | 31:24    |          |          |          |          |          |          |          |          |

### 16.7.2 Generic Clock Generator n

| Offset <sup>(1)</sup> | Name     | Bit Pos. |           |  |          |          |    |     |     |       |
|-----------------------|----------|----------|-----------|--|----------|----------|----|-----|-----|-------|
| 0x20 + 0x4*n          | GENCTRLn | 7:0      |           |  |          | SRC[4:0] |    |     |     |       |
| 0x21 + 0x4*n          |          | 15:8     |           |  | RUNSTDBY | DIVSEL   | OE | OOV | IDC | GENEN |
| 0x22 + 0x4*n          |          | 23:16    | DIV[7:0]  |  |          |          |    |     |     |       |
| 0x23 + 0x4*n          |          | 31:24    | DIV[15:8] |  |          |          |    |     |     |       |

### 16.7.3 Peripheral Channel Control m

| Offset <sup>(2)</sup> | Name     | Bit Pos. |         |      |  |  |          |  |  |  |
|-----------------------|----------|----------|---------|------|--|--|----------|--|--|--|
| 0x80 + 0x4*m          | PCHCTRLm | 7:0      | WRTLOCK | CHEN |  |  | GEN[3:0] |  |  |  |
| 0x81 + 0x4*m          |          | 15:8     |         |      |  |  |          |  |  |  |
| 0x82 + 0x4*m          |          | 23:16    |         |      |  |  |          |  |  |  |
| 0x83 + 0x4*m          |          | 31:24    |         |      |  |  |          |  |  |  |

(1) n is clock generator number

(2) m is generic clock number

## 16.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-protected property in each individual register description. Please refer to [“Register Access Protection” on page 111](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 114](#) for details.

### 16.8.1 Control A

**Name:** CTRLA

**Offset:** 0x0

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0            |
|--------|---|---|---|---|---|---|---|--------------|
|        |   |   |   |   |   |   |   | <b>SWRST</b> |
| Access | R | R | R | R | R | R | R | R/W          |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0            |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: There is a reset operation ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the GCLK to their initial state after a power reset, except for generic clocks and associated generators that have their WRTLOCK bit in [PCHCTRLm](#) read as one.

Refer to [Table 16-4](#) for details on GENCTRL register reset.

Refer to [Table 16-7](#) for details on PCHCTRL register reset.

Due to synchronization, there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

## 16.8.2 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** –

|        |          |          |          |          |          |          |          |          |
|--------|----------|----------|----------|----------|----------|----------|----------|----------|
| Bit    | 31       | 30       | 29       | 28       | 27       | 26       | 25       | 24       |
|        |          |          |          |          |          |          |          |          |
| Access | R        | R        | R        | R        | R        | R        | R        | R        |
| Reset  | 0        | 0        | 0        | 0        | 0        | 0        | 0        | 0        |
| Bit    | 23       | 22       | 21       | 20       | 19       | 18       | 17       | 16       |
|        |          |          |          |          |          |          |          |          |
| Access | R        | R        | R        | R        | R        | R        | R        | R        |
| Reset  | 0        | 0        | 0        | 0        | 0        | 0        | 0        | 0        |
| Bit    | 15       | 14       | 13       | 12       | 11       | 10       | 9        | 8        |
|        |          |          |          |          |          | GENCTRL8 | GENCTRL7 | GENCTRL6 |
| Access | R        | R        | R        | R        | R        | R        | R        | R        |
| Reset  | 0        | 0        | 0        | 0        | 0        | 0        | 0        | 0        |
| Bit    | 7        | 6        | 5        | 4        | 3        | 2        | 1        | 0        |
|        | GENCTRL5 | GENCTRL4 | GENCTRL3 | GENCTRL2 | GENCTRL1 | GENCTRL0 |          | SWRST    |
| Access | R        | R        | R        | R        | R        | R        | R        | R        |
| Reset  | 0        | 0        | 0        | 0        | 0        | 0        | 0        | 0        |

- Bits 31:11 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 10:2 – GENCTRLx: Generator Control x Synchronization Busy**  
 This bit is cleared when the synchronization of the Generator Control x register between the clock domains is complete or when clock switching operation is complete.  
 This bit is set when the synchronization of Generator Control x register between clock domains is started.
- Bit 1 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 0 – SWRST: SWRST Synchronization Busy**  
 This bit is cleared when the synchronization of SWRST register bit between the clock domains is complete.  
 This bit is set when the synchronization of SWRST register bit between clock domains is started.

### 16.8.3 Generator Control

**Name:** GENCTRLn

**Offset:** 0x20+4\*n, (n=0..15)

**Reset:** [Table 16-4](#)

**Property:** Write-protected, Write-Synchronized

|        |           |     |          |          |     |     |     |       |
|--------|-----------|-----|----------|----------|-----|-----|-----|-------|
| Bit    | 31        | 30  | 29       | 28       | 27  | 26  | 25  | 24    |
|        | DIV[15:8] |     |          |          |     |     |     |       |
| Access | R/W       | R/W | R/W      | R/W      | R/W | R/W | R/W | R/W   |
| Reset  | 0         | 0   | 0        | 0        | 0   | 0   | 0   | 0     |

- Bits 31:16 – DIV[15:0]: Division Factor**

These bits apply a division on the corresponding generator. The number of DIV bits each generator has can be seen in [Table 16-2](#). Writes to bits above the specified number will be ignored.

**Table 16-2. Division Factor**

| Generic Clock Generator | Division Factor Bits                |
|-------------------------|-------------------------------------|
| Generator 0             | 8 division factor bits - DIV[7:0]   |
| Generator 1             | 16 division factor bits - DIV[15:0] |
| Generator 2             | 5 division factor bits - DIV[4:0]   |
| Generator 3 - 7         | 8 division factor bits - DIV[7:0]   |

- Bits 15:14 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 21 – RUNSTDBY: Run in Standby**  
 This bit is used to keep generator running when it is configured to be output to its dedicated GCLK\_IO pin. If GENCTRL.OE is zero, this bit has no effect and the generator will only be running if a peripheral requires the clock.  
 0: The generator is stopped in standby and the GCLK\_IO pin state (one or zero) will be dependent on the setting in GENCTRL.OOV.  
 1: The generator is kept running and output to its dedicated GCLK\_IO pin during standby mode.
- **Bit 20 – DIVSEL: Divide Selection**  
 This bit is used to decide how the clock source used by the generator will be divided. If the clock source should not be divided, the DIVSEL bit must be zero and the GENCTRL.DIV value must be zero or one.  
 0: Generator clock equals the clock source divided by GENCTRL.DIV.  
 1: Generator clock equals the clock source divided by  $2^{(GENCTRL.DIV+1)}$ .
- **Bit 19 – OE: Output Enable**  
 This bit is used to output the generator clock output to the corresponding pin (GCLK\_IO), when GCLK\_IO is not selected as a generator source in the GENCTRL.SRC bit group.  
 0: Generator clock is not output.  
 1: Generator clock is output to the corresponding GCLK\_IO, unless the corresponding GCLK\_IO is selected as a generator source in the GENCTRL.SRC bit group.
- **Bit 18 – OOV: Output Off Value**  
 This bit is used to control the clock output value on pin (GCLK\_IO), when GCLK\_IO is not selected as a generator source in the GENCTRL.SRC bit group.  
 0: The GCLK\_IO will be zero when generator is turned off or when the OE bit is zero.  
 1: The GCLK\_IO will be one when generator is turned off or when the OE bit is zero.
- **Bit 17 – IDC: Improve Duty Cycle**  
 This bit is used to improve the duty cycle of the generator output clock, when odd division factors are used.  
 0: Generator output clock duty cycle is not 50/50 for odd division factors.  
 1: Generator output clock duty cycle is 50/50.
- **Bit 16 – GENEN: Generator Enable**  
 This bit is used to enable and disable the generator.  
 0: Generator is disabled.  
 1: Generator is enabled.
- **Bits 7:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 4:0 – SRC[4:0]: Generator Clock Source Selection**  
 These bits define the generator clock source, as shown in [Table 16-3](#).

**Table 16-3. Generator Clock Source Selection**

| Value     | Name      | Description                      |
|-----------|-----------|----------------------------------|
| 0x00      | XOSC      | XOSC oscillator output           |
| 0x01      | GCLKIN    | Generator input pad (GCLK_IO)    |
| 0x02      | GCLKGEN1  | Generic clock generator 1 output |
| 0x03      | OSCULP32K | OSCULP32K oscillator output      |
| 0x04      | OSC32K    | OSC32K oscillator output         |
| 0x05      | XOSC32K   | XOSC32K oscillator output        |
| 0x06      | OSC48M    | OSC48M oscillator output         |
| 0x07      | DPLL96M   | DPLL96M output                   |
| 0x08-0x1F | Reserved  | Reserved for future use          |

A power reset will reset all GENCTRL registers. If a generator other than generator 0 is not a source of a “locked” peripheral clock, a user reset will reset the associated GENCTRL register.

After a power reset, the reset value of the GENCTRL register is as shown in [Table 16-4](#).

**Table 16-4. GENCTRL Reset Value after a Power Reset**

| GCLK Generator | Reset Value after a Power Reset |
|----------------|---------------------------------|
| 0              | 0x00000106                      |
| others         | 0x00000000                      |

After a user reset, the reset value of the GENCTRL register is as shown in [Table 16-5](#).

**Table 16-5. GENCTRL Reset Value after a User Reset**

| GCLK Generator | Reset Value after a User Reset   |
|----------------|--|
| 0              | 0x00000106   |
| others         | No change if the generator is used by a GCLK with a WRTLOCK set at one,<br>else 0x00000000 |

## 16.8.4 Peripheral Channel Control

**Name:** PCHCTRLm

**Offset:** 0x80 + 4\*m, (m= 0..36)

**Reset:** 0x00000000

**Property:** Write-Protected

|        |                |             |    |    |                 |     |     |     |
|--------|----------------|-------------|----|----|-----------------|-----|-----|-----|

|        |                |             |    |    |                 |     |     |     |
| Access | R              | R           | R  | R  | R               | R   | R   | R   |
| Reset  | 0              | 0           | 0  | 0  | 0               | 0   | 0   | 0   |
| Bit    | 23             | 22          | 21 | 20 | 19              | 18  | 17  | 16  |
|        |                |             |    |    |                 |     |     |     |
| Access | R              | R           | R  | R  | R               | R   | R   | R   |
| Reset  | 0              | 0           | 0  | 0  | 0               | 0   | 0   | 0   |
| Bit    | 15             | 14          | 13 | 12 | 11              | 10  | 9   | 8   |
|        |                |             |    |    |                 |     |     |     |
| Access | R              | R           | R  | R  | R               | R   | R   | R   |
| Reset  | 0              | 0           | 0  | 0  | 0               | 0   | 0   | 0   |
| Bit    | 7              | 6           | 5  | 4  | 3               | 2   | 1   | 0   |
|        | <b>WRTLOCK</b> | <b>CHEN</b> |    |    | <b>GEN[3:0]</b> |     |     |     |
| Access | R/W            | R/W         | R  | R  | R/W             | R/W | R/W | R/W |
| Reset  | 0              | 0           | 0  | 0  | 0               | 0   | 0   | 0   |

- Bit 7– WRTLOCK: Write Lock**  
 When this bit is written, further writes to the PCHCTRL register will be discarded. The generator (GENCTRLx) pointed to in PCHCTRL.GEN will also be locked. It can only be unlocked by a power reset.  
 One exception to this is generator 0, which cannot be locked.  
 0: The peripheral channel and the associated generator registers are not locked.  
 1: The peripheral channel and the associated generator registers are locked.
- Bit 6– CHEN: Channel Enable**  
 This bit is used to enable and disable a peripheral channel.  
 0: The peripheral channel is disabled.  
 1: The peripheral channel is enabled.
- Bits 5:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 3:0 – GEN[3:0]: Generator Selection**  
 These bits select the generator to be used as the source of a peripheral clock, as shown in [Table 16-6](#):

**Table 16-6. Generator Selection**

| Value   | Description               |
|---------|---------------------------|
| 0x0     | Generic clock generator 0 |
| 0x1     | Generic clock generator 1 |
| 0x2     | Generic clock generator 2 |
| 0x3     | Generic clock generator 3 |
| 0x4     | Generic clock generator 4 |
| 0x5     | Generic clock generator 5 |
| 0x6     | Generic clock generator 6 |
| 0x7     | Generic clock generator 7 |
| 0x8     | Generic clock generator 8 |
| 0x9-0xF | Reserved                  |

A power reset will reset all the PCHCTRL registers. If the WRTLOCK bit is zero, a user reset will also reset the PCHCTRL register.

A user reset will reset PCHCTRL if the WRTLOCK bit is zero, else PCHCTRL value remains unchanged.

PCHCTRL register reset value is shown in [Table 16-7](#).

**Table 16-7. PCHCTRL Reset Value after a User Reset or Power Reset**

| Reset       | PCHCTRL.GEN                                | PCHCTRL.CHEN                               | PCHCTRL.WRTLOCK |
|-------------|--|--|-----------------|
| Power Reset | 0x0  | 0x0  | 0x0             |
| User Reset  | 0x0 if WRTLOCK=0<br>No change if WRTLOCK=1 | 0x0 If WRTLOCK=0<br>No change if WRTLOCK=1 | No change       |

**Table 16-8. PCHCTRLm mapping**

| index(m) | Name                 | Description   |
|----------|----------------------|---|
| 0        | GCLK_DPLL            | FDPLL96M input clock source for reference             |
| 1        | GCLK_DPLL_32K        | FDPLL96M 32kHz clock for FDPLL96M internal lock timer |
| 2        | GCLK_EIC             | EIC   |
| 3        | GCLK_FREQM_MSR       | FREQM Measure   |

## 17. MCLK – Main Clock

### 17.1 Overview

The Main Clock (MCLK) controls the synchronous clock generation of the microcontroller.

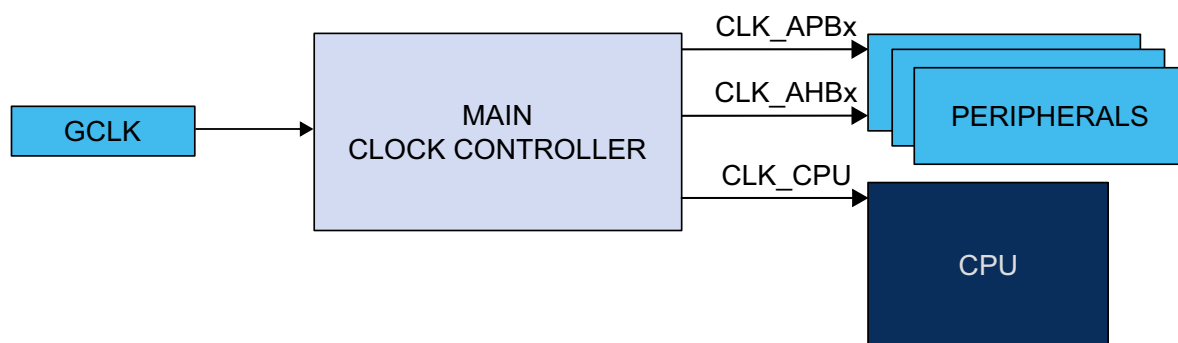

Utilizing a main clock chosen from a large number of clock sources from the GCLK, the clock controller provides synchronous system clocks to the CPU and the modules connected to the AHBx and the APBx bus. The synchronous system clocks are divided into a number of clock domains. Each clock domains can run at different frequencies, enabling the user to save power by running peripherals at a relatively low clock frequency, while maintaining high CPU performance or vice versa. The clock can be masked for individual modules.

### 17.2 Features

- Generates CPU, AHB and APB system clocks
  - Multiple clock sources and division factor from GCLK
  - Clock prescaler with 1x to 128x division
- Safe run-time clock switching from GCLK
- Module-level clock gating through maskable peripheral clocks

### 17.3 Block Diagram

Figure 17-1. MCLK Block Diagram

### 17.4 I/O Lines Description

Not applicable

### 17.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

#### 17.5.1 I/O Lines

Not applicable.

#### 17.5.2 Power Management

The MCLK will operate in all sleep modes if a synchronous clock is required in these modes.

Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 17.5.3 Clocks

The MCLK bus clock (CLK\_MCLK\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_MCLK\_APB can be found in [Table 17-1](#). If this clock is disabled, it can only be re-enabled by a reset.

A generic clock (GCLKMAIN) is required to generate the main clock. This clock is configured by default in the Generic Clock Controller, and can be re-configured by the user if needed. Please refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

#### 17.5.3.1 Main Clock

The main clock (CLK\_MAIN) is the common source for the synchronous clocks. This is fed into the common 8-bit prescaler that is used to generate synchronous clocks to the CPU, AHBx and APBx modules.

#### 17.5.3.2 CPU Clock

The CPU clock (CLK\_CPU) is routed to the CPU. Halting the CPU clock inhibits the CPU from executing instructions.

#### 17.5.3.3 APBx and AHBx Clock

The APBx clocks (CLK\_APBx) and the AHBx clocks (CLK\_AHBx) are the root clock source used by modules requiring a clock on the APBx and the AHBx bus. These clocks are always synchronous to the CPU clock, but can be divided by a prescaler, and can run even when the CPU clock is turned off in sleep mode. A clock gater is inserted from the common APB clock to any APBx clock of a module on APBx bus, as well as the AHBx clock.

#### 17.5.3.4 Clock domains

There is one synchronous clock domain:

- CPU synchronous clock domain (CPU Clock Domain). Frequency is  $f_{\text{CPU}}$

[Table 17-1](#) describes the clock domain partitioning.

### 17.5.4 DMA

Not applicable.

### 17.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the MCLK interrupt requires the Interrupt Controller to be configured first.

### 17.5.6 Events

Not applicable.

### 17.5.7 Debug Operation

When the CPU is halted in debug mode, the MCLK continues normal operation. In sleep mode, the clocks generated from the MCLK are kept running to allow the debugger accessing any modules. As a consequence, power measurements are meaningless in debug mode.

### 17.5.8 Register Access Protection

All registers with write access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag register (INTFLAG)

Write-protection is denoted by the Write-Protection property in the register description.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

## 17.5.9 Analog Connections

Not applicable.

## 17.6 Functional Description

### 17.6.1 Principle of Operation

The GCLKMAIN clock from GCLK module provides the source for the main clock, which is the common root for the synchronous clocks for the CPU, APBx and AHBx modules. The main clock is divided by an 8-bit prescaler, and each of the derived clocks can run from any divided or undivided main clock, to provide synchronous clocks source for each clock domain. The clock domain (CPU) can be changed on the fly to respond to variable load in the application. The clocks for each module in clock domain can be individually masked to avoid power consumption in inactive modules. Depending on the sleep mode, some clock domains can be turned off.

### 17.6.2 Basic Operation

#### 17.6.2.1 Initialization

After reset, the default clock source of the GCLKMAIN clock is started and calibrated before the CPU starts running. The GCLKMAIN clock is selected as the main clock without any prescaler division.

By default, only the necessary clocks are enabled (please refer to [Table 17-1](#)).

#### 17.6.2.2 Enabling, Disabling and Resetting

The MCLK module is always enabled and cannot be reset.

#### 17.6.2.3 Selecting the Main Clock Source

Refer to “[GCLK – Generic Clock Controller](#)” on page 109 for details on how to configure the clock source of the GCLKMAIN clock.

#### 17.6.2.4 Selecting the Synchronous Clock Division Ratio

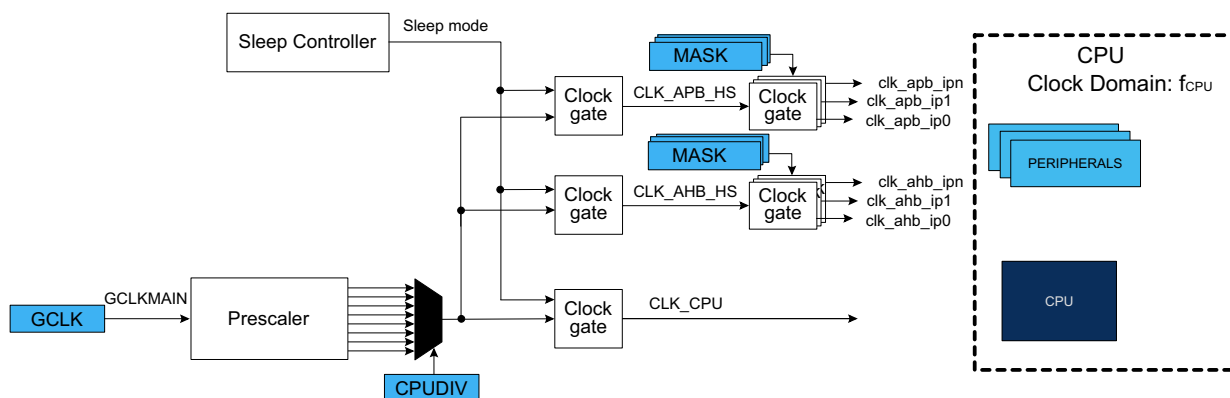

The main clock feeds an 8-bit prescaler, which can be used to generate the synchronous clocks. By default, the synchronous clocks run on the undivided main clock. The user can select a prescaler division for the CPU clock domain by writing the Division (DIV) bits in the CPU Clock Division register (CPUDIV), resulting in a CPU clock domain frequency determined by this equation:

$$f_{CPU} = \frac{f_{main}}{2^{CPUDIV}}$$

If the application attempts to write forbidden value in CPUDIV register, registers are not written, these bad values are not taken into account and a violation is reported to the PAC module. Refer to “[PAC – Peripheral Access Control](#)” on page 33 for details.

Division bits (DIV) can be written without halting or disabling peripheral modules. Writing DIV bits allows a new clock setting to be written to all synchronous clocks belonging to the corresponding clock domain at the same time. It is possible to keep one or more clock domains unchanged.

**Figure 17-2. Synchronous Clock Selection and Prescaler**

#### 17.6.2.5 Clock Ready Flag

There is a slight delay from when CPUDIV is written and until the new clock setting becomes effective. During this interval, the Clock Ready flag in the Interrupt Flag Status and Clear register (INTFLAG.CKRDY) will be read zero. If CKRDY in the INTENSET register is written to one, the Clock Ready interrupt can be triggered when the new clock setting is effective. CLKCFG must not be re-written while CKRDY is zero. The system may become unstable or hang, and a violation is reported to the PAC module. Please refer to “[PAC – Peripheral Access Control](#)” on page 33 for details.

#### 17.6.2.6 Peripheral Clock Masking

It is possible to disable or enable the AHB or APB clock for a peripheral by writing the corresponding MASK bit in the AHBMASK or APBMASK registers. Refer to [Table 17-1](#) for the default state of each peripheral clock.

**Table 17-1. Peripheral Clock Default State**

| Peripheral Clock  | Default State | Clock Domain     |
|-------------------|---------------|------------------|
| CLK_AC_APB        | Disabled      | CPU Clock Domain |
| CLK_ADC0_APB      | Disabled      | CPU Clock Domain |
| CLK_BRIDGE_A_AHB  | Enabled       | CPU Clock Domain |
| CLK_BRIDGE_B_AHB  | Enabled       | CPU Clock Domain |
| CLK_BRIDGE_C_AHB  | Enabled       | CPU Clock Domain |
| CLK_CCL_APB       | Disabled      | CPU Clock Domain |
| CLK_DIVAS_AHB     | Enabled       | CPU Clock Domain |
| CLK_DMAC_AHB      | Enabled       | CPU Clock Domain |
| CLK_DMAC_APB      | Enabled       | CPU Clock Domain |
| CLK_DSU_AHB       | Enabled       | CPU Clock Domain |
| CLK_DSU_APB       | Enabled       | CPU Clock Domain |
| CLK_EIC_APB       | Enabled       | CPU Clock Domain |
| CLK_EVSYS_APB     | Disabled      | CPU Clock Domain |
| CLK_FREQM_APB     | Enabled       | CPU Clock Domain |
| CLK_GCLK_APB      | Enabled       | CPU Clock Domain |
| CLK_HMATRIXHS_APB | Disabled      | CPU Clock Domain |

**Table 17-1. Peripheral Clock Default State (Continued)**

| Peripheral Clock   | Default State | Clock Domain     |
|--------------------|---------------|------------------|
| CLK_MCLK_APB       | Enabled       | CPU Clock Domain |
| CLK_MTB_APB        | Enabled       | CPU Clock Domain |
| CLK_NVMCTRL_AHB    | Enabled       | CPU Clock Domain |
| CLK_NVMCTRL_APB    | Enabled       | CPU Clock Domain |
| CLK_OSCCTRL_APB    | Enabled       | CPU Clock Domain |
| CLK_OSC32KCTRL_APB | Enabled       | CPU Clock Domain |
| CLK_PAC_AHB        | Enabled       | CPU Clock Domain |
| CLK_PAC_APB        | Enabled       | CPU Clock Domain |
| CLK_PM_APB         | Enabled       | CPU Clock Domain |
| CLK_PORT_APB       | Enabled       | CPU Clock Domain |
| CLK_PTC_APB        | Disabled      | CPU Clock Domain |
| CLK_RSTC_APB       | Enabled       | CPU Clock Domain |
| CLK_RTC_APB        | Enabled       | CPU Clock Domain |
| CLK_SERCOM0_APB    | Disabled      | CPU Clock Domain |
| CLK_SERCOM1_APB    | Disabled      | CPU Clock Domain |
| CLK_SERCOM2_APB    | Disabled      | CPU Clock Domain |
| CLK_SERCOM3_APB    | Disabled      | CPU Clock Domain |
| CLK_SUPC_APB       | Enabled       | CPU Clock Domain |
| CLK_TCC0_APB       | Disabled      | CPU Clock Domain |
| CLK_TC0_APB        | Disabled      | CPU Clock Domain |
| CLK_TC1_APB        | Disabled      | CPU Clock Domain |
| CLK_TC2_APB        | Disabled      | CPU Clock Domain |
| CLK_TC3_APB        | Disabled      | CPU Clock Domain |
| CLK_TC4_APB        | Disabled      | CPU Clock Domain |
| CLK_WDT_APB        | Enabled       | CPU Clock Domain |

When a module is not clocked, it will cease operation, and its registers cannot be read or written. The module can be re-enabled later by writing the corresponding mask bit to one.

A module may be connected to several clock domains (for instance, AHB and APB), in which case it will have several mask bits.

Note that clocks should only be switched off if that module will never be used. Switching off the clock for the NVM Controller (NVMCTRL) will cause an issue if the CPU needs to read from the flash memory. Switching off the clock to the MCLK module, which contains the mask registers, or the corresponding APBx bridge, will make impossible to write the mask registers again. In this case, they can only be re-enabled by a system reset.

### 17.6.3 DMA Operation

Not applicable.

### 17.6.4 Interrupts

The peripheral has the following interrupt sources:

- Clock Ready (CKRDY): indicates CPU clocks are ready

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the peripheral is reset. An interrupt flag is cleared by writing a one to the corresponding bit in the INTFLAG register. Each peripheral can have one interrupt request line per interrupt source or one common interrupt request line for all the interrupt sources. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details. If the peripheral has one common interrupt request line for all the interrupt sources, the user must read the INTFLAG register to determine which interrupt condition is present.

### 17.6.5 Events

Not applicable.

### 17.6.6 Sleep Mode Operation

In all IDLE sleep modes, the MCLK is still running on the selected main clock.

In STANDBY sleep mode, the MCLK is frozen.

## 17.7 Register Summary

| Offset | Name     | Bit Pos. |        |               |                |           |         |         |         |       |
|--------|----------|----------|--------|---------------|----------------|-----------|---------|---------|---------|-------|
| 0x00   | Reserved |          |        |               |                |           |         |         |         |       |

## 17.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16-, and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 127](#) for details.

### 17.8.1 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set (INTENSET) register.

**Name:** INTENCLR

**Offset:** 0x01

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2   | 1   | 0     |
|--------|---|---|---|---|---|-----|-----|-------|
|        |   |   |   |   |   |     |     | CKRDY |
| Access | R | R | R | R | R | R/W | R/W | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0   | 0   | 0     |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – CKRDY: Clock Ready Interrupt Enable**

0: The Clock Ready interrupt is disabled.

1: The Clock Ready interrupt is enabled and will generate an interrupt request when the Clock Ready Interrupt Flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Clock Ready Interrupt Enable bit and the corresponding interrupt request.

## 17.8.2 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear (INTENCLR) register.

**Name:** INTENSET

**Offset:** 0x02

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2   | 1   | 0     |
|--------|---|---|---|---|---|-----|-----|-------|
|        |   |   |   |   |   |     |     | CKRDY |
| Access | R | R | R | R | R | R/W | R/W | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0   | 0   | 0     |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – CKRDY: Clock Ready Interrupt Enable**

0: The Clock Ready interrupt is disabled.

1: The Clock Ready interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Clock Ready Interrupt Enable bit and enable the Clock Ready interrupt.

### 17.8.3 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x03

**Reset:** 0x01

**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3 | 2   | 1   | 0     |
|--------|---|---|---|---|---|-----|-----|-------|
|        |   |   |   |   |   |     |     | CKRDY |
| Access | R | R | R | R | R | R/W | R/W | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0   | 0   | 1     |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – CKRDY: Clock Ready**

This flag is cleared by writing a one to the flag.

This flag is set when the synchronous CPU, APBx and AHBx clocks have frequencies as indicates in the CLKCFG registers and will generate an interrupt if INTENCLR/SET.CKRDY is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Clock Ready interrupt flag.

## 17.8.4 CPU Clock Division

**Name:** CPUDIV

**Offset:** 0x04

**Reset:** 0x01

**Property:** Write-Protected

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | CPUDIV[7:0] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 1   |

- Bits 7:0 – CPUDIV[2:0]: CPU Clock Division Factor**

These bits define the division ratio of the main clock prescaler ( $2^n$ ) related to the CPU clock domain. To ensure correct operation, frequencies must be selected so that  $BUPDIV \geq LPDIV \geq HSDIV$ . Also, frequencies must never exceed the specified maximum frequency for each clock domain.

**Table 17-2. Division**

| Value  | Name   | Description   |
|--------|--------|---------------|
| 0x01   | DIV1   | Divide by 1   |
| 0x02   | DIV2   | Divide by 2   |
| 0x04   | DIV4   | Divide by 4   |
| 0x08   | DIV8   | Divide by 8   |
| 0x10   | DIV16  | Divide by 16  |
| 0x20   | DIV32  | Divide by 32  |
| 0x40   | DIV64  | Divide by 64  |
| 0x80   | DIV128 | Divide by 128 |
| others | -      | Reserved      |

## 17.8.5 AHB Mask

**Name:** AHBMASK

**Offset:** 0x10

**Reset:**

**Property:** Write-Protected

|        |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |    |    |    |    |    |    |    |    |
| Access | R  | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

|        |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|
| Bit    | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        |    |    |    |    |    |    |    |    |
| Access | R  | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

|        |    |    |    |       |                      |     |   |   |
|--------|----|----|----|-------|----------------------|-----|---|---|

- **Bits 31:24,21,19:18,11:10,8:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 23:22,20,17:12,9,4:0 – Peripheral APBC Clock Enable**

For any bit:

0: The APBC clock for the corresponding peripheral is stopped.

1: The APBC clock for the corresponding peripheral is enabled.

## 18. RSTC – Reset Controller

### 18.1 Overview

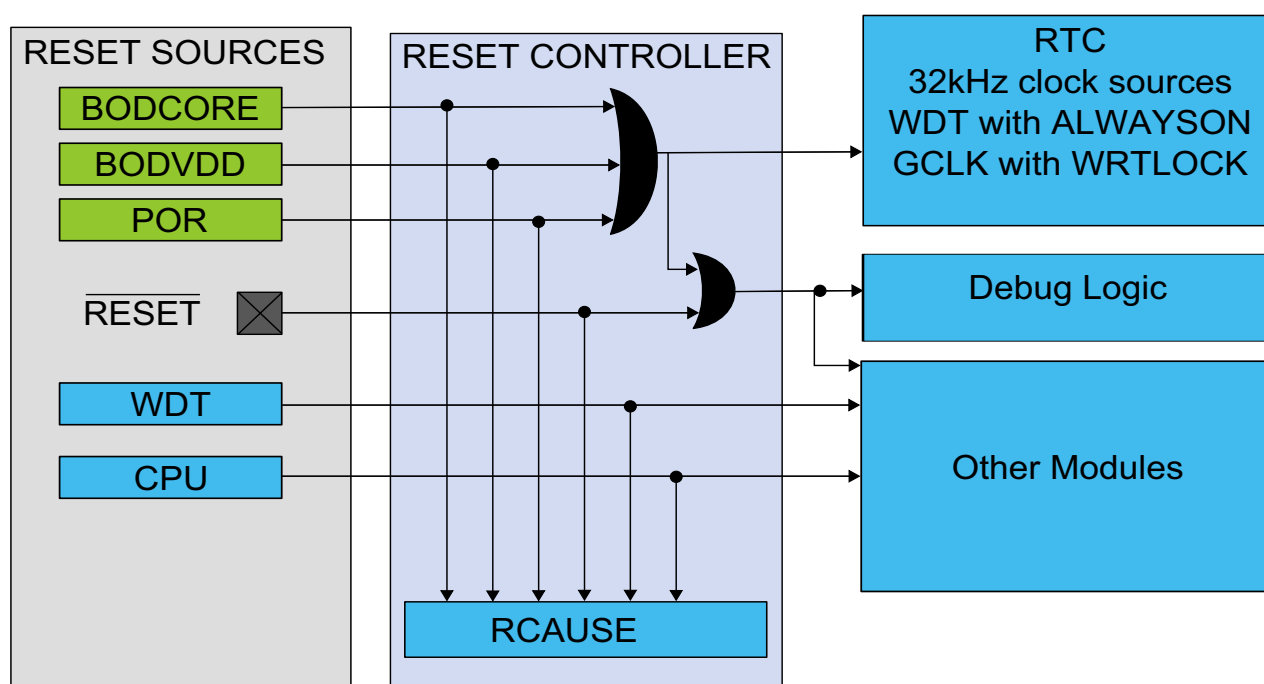

The Reset Controller (RSTC) manages the reset of the microcontroller. It issues a microcontroller reset, sets the device to its initial state and allows the reset source to be identified by software.

### 18.2 Features

- Reset the microcontroller and set it to an initial state according to the reset source
- Reset cause register for reading the reset source from the application code
- Multiple reset sources
  - Power supply reset sources: POR, BODCORE, BODVDD
  - User reset sources: External reset (RESET), Watchdog reset, System Reset Request.

### 18.3 Block Diagram

Figure 18-1. Reset System

### 18.4 Signal Description

| Signal Name | Type          | Description    |
|-------------|---------------|----------------|
| RESET       | Digital input | External reset |

Please refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

### 18.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 18.5.1 I/O Lines

Not applicable.

### 18.5.2 Power Management

The Reset Controller module is always on.

### 18.5.3 Clocks

The RSTC bus clock (CLK\_RSTC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_RSTC\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

### 18.5.4 DMA

Not applicable.

### 18.5.5 Interrupts

Not Applicable.

### 18.5.6 Events

Not applicable.

### 18.5.7 Debug Operation

When the CPU is halted in debug mode, the RSTC continues normal operation.

### 18.5.8 Register Access Protection

All registers with write access are optionally write-protected by the Peripheral Access Controller (PAC).

Write-protection is denoted by the Write-Protection property in the register description.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 18.5.9 Analog Connections

Not applicable.

## 18.6 Functional Description

### 18.6.1 Principle of Operation

The Reset Controller collects the various reset sources and generates reset for the device.

### 18.6.2 Basic Operation

#### 18.6.2.1 Initialization

After a power-on reset, the RSTC is enabled and the Reset Cause (RCAUSE) register indicates the POR source.

#### 18.6.2.2 Enabling, Disabling and Resetting

The RSTC module is always enabled.

#### 18.6.2.3 Reset causes and effects

The latest reset cause is available in RCAUSE register, and can be read during the application boot sequence in order to determine proper action.

There are three groups of reset sources:

- Power supply reset: Resets caused by an electrical issue. It covers POR and BODs reset.
- User reset: Resets caused by the application. It covers external reset, system reset request and watchdog reset.

The table below lists the parts of the device that are reset, depending on the reset type.

**Table 18-1. Effects of the Different Reset Events**

|  | Power Supply Reset |         | User Reset     |                                 |
|--|--------------------|---------|----------------|---------------------------------|
|  | POR, BODVDD        | BODCORE | External Reset | WDT Reset, System Reset Request |
| RTC, OSC32KCTRL, RSTC<br>GCLK with WRLOCK<br>Write Access Protection of PAC. | Y                  | N       | N              | N                               |
| Debug logic  | Y                  | Y       | Y              | N                               |
| Others   | Y                  | Y       | Y              | Y                               |

The external reset is generated when pulling the  $\overline{\text{RESET}}$  pin low.

The POR, BODCORE and BODVDD reset sources are generated by their corresponding module in the Supply Controller Interface (SUPC). Please refer to “SUPC – Supply Controller” on page 228 for details.

The WDT reset is generated by the Watchdog Timer.

The System Reset Request is a reset generated by the CPU when asserting the SYSRESETREQ bit located in the Reset Control register of the CPU (for details refer to the ARM® Cortex™ Technical Reference Manual on <http://www.arm.com>).

### 18.6.3 Additional Features

### 18.6.4 DMA Operation

Not applicable.

### 18.6.5 Interrupts

Not applicable

### 18.6.6 Events

Not applicable.

### 18.6.7 Sleep Mode Operation

The RSTC module is active in all sleep modes.

## 18.7 Register Summary

| Offset | Name                   | Bit Pos. |  |      |     |     |  |        |         |     |
|--------|------------------------|----------|--|------|-----|-----|--|--------|---------|-----|
| 0x00   | <a href="#">RCAUSE</a> | 7:0      |  | SYST | WDT | EXT |  | BODVDD | BODCORE | POR |
| 0x01   | Reserved               |          |  |      |     |     |  |        |         |     |
| 0x02   | Reserved               |          |  |      |     |     |  |        |         |     |
| 0x03   | Reserved               |          |  |      |     |     |  |        |         |     |

## 18.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 143](#) for details.

### 18.8.1 Reset Cause

**Name:** RCAUSE

**Offset:** 0x00

**Reset:** Latest Reset Source

|--------|---|------|-----|-----|---|--------|---------|-----|
|        |   | SYST | WDT | EXT |   | BODVDD | BODCORE | POR |
| Access | R | R    | R   | R   | R | R      | R       | R   |
| Reset  | 0 | X    | X   | X   | 0 | X      | X       | X   |

When a reset occurs, the bit corresponding to the reset source is set to one, the other bits are set to zero.

- **Bit 7 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bit 6 – SYST: System Reset Request**  
This bit is set if a system reset request has been performed. Refer to the Cortex processor documentation for more details.
- **Bit 5 – WDT: Watchdog Reset**  
This bit is set if a Watchdog Timer reset occurs.
- **Bit 4 – EXT: External Reset**  
This bit is set if an external reset occurs.
- **Bit 3 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bit 2 – BODVDD: VDD Brown Out Detector Reset**  
This bit is set if a BODVDD reset occurs.
- **Bit 1 – BODCORE: VDDCORE Brown Out Detector Reset**  
This bit is set if a BODCORE reset occurs.
- **Bit 0 – POR: Power On Reset**  
This bit is set if a POR occurs.

## 19. PM – Power Manager

### 19.1 Overview

The Power Manager (PM) controls the sleep modes of the microcontroller.

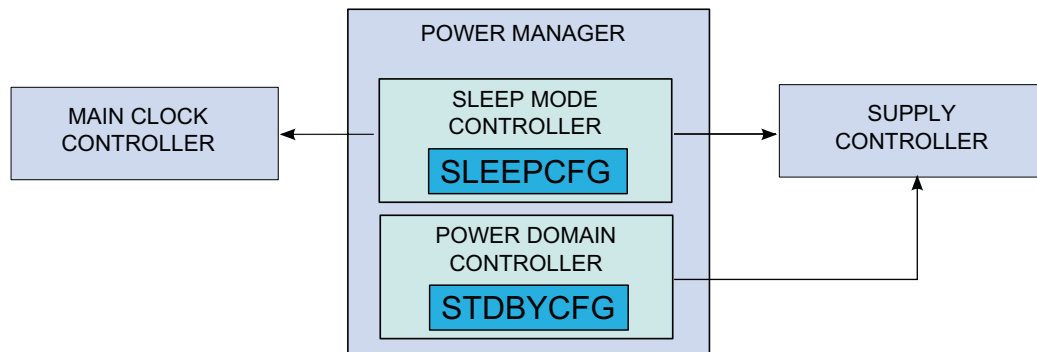

Various sleep modes are provided in order to fit power consumption requirements. This enables the microcontroller to stop unused modules to save power. In ACTIVE mode, the CPU is executing application code. When the device enters a sleep mode, program execution is stopped and some modules and clock domains are automatically switched off by the PM according to sleep mode. The application code decides which sleep mode to enter and when. Interrupts from enabled peripherals and all enabled reset sources can restore the microcontroller from a sleep mode to ACTIVE mode.

### 19.2 Features

- Power management control
  - Sleep modes: IDLE, STANDBY

### 19.3 Block Diagram

Figure 19-1. PM Block Diagram

### 19.4 Signal Description

Not applicable.

### 19.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

#### 19.5.1 I/O Lines

Not applicable.

#### 19.5.2 Power Management

Not applicable.

#### 19.5.3 Clocks

The PM bus clock (CLK\_PM\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_PM\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

#### 19.5.4 DMA

Not applicable.

### 19.5.5 Interrupts

Not applicable

### 19.5.6 Events

Not applicable.

### 19.5.7 Debug Operation

When the CPU is halted in debug mode, the PM continues normal operation. If a STANDBY mode is requested by the system while in debug mode, the regulator does not enter in Low Power mode (LPVREG). As a consequence, power measurements results are not relevant.

### 19.5.8 Register Access Protection

All registers with write access are optionally write-protected by the Peripheral Access Controller (PAC).

Write-protection is denoted by the Write-Protection property in the register description.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 19.5.9 Analog Connections

Not applicable.

## 19.6 Functional Description

### 19.6.1 Definitions

- Sleep modes:
  - IDLE mode: The CPU is stopped. Several synchronous clock domains are stopped, depending on the IDLE level. All logic and analog cells are active. The main voltage regulator is running.
  - STANDBY mode: The CPU is stopped. All clock sources are stopped except if required by a peripheral. All logic and analog cells are in static mode except if required by a peripheral. The LP voltage regulator (LPVREG) is running.

### 19.6.2 Principle of Operation

In active mode, all clock domains and power domains are active, allowing software execution and peripheral operation. The PM Sleep Mode Controller allows to save power by choosing between different sleep modes depending on application requirements.

The PM Power Domain Controller allows to reduce the power consumption in standby mode even further.

### 19.6.3 Basic Operation

#### 19.6.3.1 Initialization

After a power-on reset, the PM is enabled, the device is in ACTIVE mode.

#### 19.6.3.2 Enabling, Disabling and Resetting

The PM is always enabled and can not be reset.

#### 19.6.3.3 Sleep Mode Controller

A Sleep mode is entered by executing the Wait For Interrupt instruction (WFI). The Sleep Mode bits in the Sleep Configuration register (SLEEP\_CFG.SLEEPMOD) select the level of the sleep mode. [Figure](#) illustrates the possible transitions.

Note: A small latency happens between the store instruction and actual writing of the SLEEP\_CFG register due to bridges. Software must ensure that the SLEEP\_CFG register reads the desired value before issuing a WFI instruction.

**Table 19-1. Sleep Mode Entry and Exit Table**

| Mode    | Mode Entry                     | Wake-Up Sources  |
|---------|--------------------------------|--|
| IDLE    | SLEEP_CFG.SLEEP_MODE = IDLE_n  | Synchronous <sup>(2)</sup> (APB, AHB), Asynchronous <sup>(1)</sup> |
| STANDBY | SLEEP_CFG.SLEEP_MODE = STANDBY | Synchronous <sup>(3)</sup> , Asynchronous                          |

- Notes:
1. Asynchronous: interrupt generated on generic clock, external clock, or external event; synchronous: interrupt generated on the APB clock.
  2. Synchronous: interrupt generated on the APB clock
  3. Synchronous interrupt only for peripherals configured to run in standby

| SLEEP Mode | CPU Clock | AHB Clock           | APB Clock           | Main Clock | GCLK Clock          | Oscillators                    |                  | Regulator              | RAM                      |
|------------|-----------|---------------------|---------------------|------------|---------------------|--------------------------------|------------------|------------------------|--------------------------|
|            |           |                     |                     |            |                     | ONDEMAND=0                     | ONDEMAND=1       |                        |                          |
| IDLE 0     | Stop      | Run                 | Run                 | Run        | Run <sup>(1)</sup>  | Run                            | Run if requested | Main                   | Normal                   |
| IDLE 1     | Stop      | Stop <sup>(2)</sup> | Run                 | Run        | Run <sup>(1)</sup>  | Run                            | Run if requested | Main                   | Normal                   |
| IDLE 2     | Stop      | Stop <sup>(2)</sup> | Stop <sup>(2)</sup> | Run        | Run <sup>(1)</sup>  | Run                            | Run if requested | Main                   | Normal                   |
| STANDBY    | Stop      | Stop <sup>(2)</sup> | Stop <sup>(2)</sup> | Stop       | Stop <sup>(2)</sup> | Run if requested or RUNSTDBY=1 | Run if requested | LP VREG <sup>(3)</sup> | Low power <sup>(4)</sup> |

- Notes:
1. Running if requested by peripheral
  2. Running during SleepWalking
  3. Regulator state is programmable by using STDBY\_CFG.VREGSMOD bits
  4. RAM state is programmable by using STDBY\_CFG.BBIASHS bit

## IDLE Mode

The IDLE mode allows power optimization with the fastest wake-up time.

The CPU is stopped. To further reduce power consumption, the user can disable the clocking of modules and clock sources by configuring the SLEEP\_CFG bit group to IDLE level 1 or 2. The peripheral will be halted regardless of the bit settings of the mask registers in the MCLK (MCLK.AHBMASK, MCLK.APBxMASK).

- Entering IDLE mode: The IDLE mode is entered by executing the WFI instruction. Additionally, if the SLEEPONEXIT bit in the ARM Cortex System Control register (SCR) is set, the IDLE mode will also be entered when the CPU exits the lowest priority ISR. This mechanism can be useful for applications that only require the processor to run when an interrupt occurs. Before entering the IDLE mode, the user must configure the Sleep Configuration register.
- Exiting IDLE mode: The processor wakes the system up when it detects any non-masked interrupt with sufficient priority to cause exception entry. The system goes back to the ACTIVE mode. The CPU and affected modules are restarted.

Regulator operates in normal mode.

## STANDBY Mode

The STANDBY mode is the lowest power configuration while keeping the state of the logic and the RAMs content.

In this mode, all clocks are stopped except those which are kept running if requested by a running peripheral or have the ONDEMAND bit set to zero. For example, the RTC can operate in STANDBY mode. In this case, its GCLK clock source will also be enabled.

All features that don't require CPU intervention are supported in STANDBY mode. Here are examples:

- Autonomous peripherals features
- Features relying on Event System allowing autonomous communication between peripherals
- Features relying on on-demand clock
- DMA transfers
- Entering STANDBY mode: This mode is entered by executing the WFI instruction with the SLEEPCFG register written to STANDBY. The SLEEPONEXIT feature is also available as in IDLE mode.
- Exiting STANDBY mode: Any peripheral able to generate an asynchronous interrupt can wake up the system. For example, a peripheral running on a GCLK clock can trigger an interrupt. When the enabled asynchronous wake-up event occurs and the system is woken up, the device will either execute the interrupt service routine or continue the normal program execution according to the Priority Mask Register (PRIMASK) configuration of the CPU.

Depending on the configuration of these modules, the current consumption of the device in STANDBY mode can be slightly different.

The regulator operates in low-power mode (LP VREG) by default and can switch automatically to the main regulator if a task required by a peripheral requires more power. It returns automatically in the low power mode as soon as the task is completed.

#### 19.6.4 DMA Operation

Not applicable.

#### 19.6.5 Interrupts

Not applicable.

#### 19.6.6 Events

Not applicable.

#### 19.6.7 Sleep Mode Operation

The Power Manager is always active.

#### 19.6.8 Advanced Features

##### 19.6.8.1 RAM Automatic Low Power Mode

The RAM is by default put in low power mode (back-biased) if the device is in standby sleep mode. This behavior can be changed by configuring the Back Bias bit in STDBYCFG (STDBYCFG.BBIASHS), refer to the table below for details.

| STDBYCFG.BBIASHS | Mode                 | RAM   |
|------------------|----------------------|---|
| 0x0              | No Back Biasing      | RAM is not back-biased if the device is in standby sleep mode |
| 0x1              | Standby Back Biasing | RAM is back-biased if the device is in standby sleep mode     |

##### 19.6.8.2 Regulator Automatic Low Power Mode

In standby mode, the PM selects either the main or the low power voltage regulator to supply the VDDCORE. By default the low power voltage regulator is used. If a sleepwalking task is working on either asynchronous clocks (generic clocks) or synchronous clock (APB/AHB clocks), the main voltage regulator is used. This behavior can be changed by writing the Voltage Regulator Standby Mode bits in the Standby Configuration register (STDBYCFG.VREGSMOD). Refer to the following table for details.

| Sleep Mode | STDBYCFG.VREGSMOD | SleepWalking | Regulator state for VDDCORE |
|------------|-------------------|--------------|-----------------------------|
| Active     | –                 | –            | main voltage regulator      |
| Idle x     | –                 | –            | main voltage regulator      |
| Standby    | 0x0: AUTO         | NO           | low power regulator         |
|            |                   | YES          | main voltage regulator      |
|            | 0x1: PERFORMANCE  | –            | main voltage regulator      |
|            | 0x2: LP           | –            | low power regulator         |

## 19.7 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 149](#) for details.

### 19.7.1 Sleep Configuration

**Name:** SLEPCFG

**Offset:** 0x01

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2              | 1   | 0   |
|--------|---|---|---|---|---|----------------|-----|-----|
|        |   |   |   |   |   | SLEEPMODE[2:0] |     |     |
| Access | R | R | R | R | R | R/W            | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0              | 0   | 0   |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:0 – SLEEPMODE[2:0]: Sleep Mode**

**Table 19-2. Sleep Mode**

| Value   | Name     | Definition          |
|---------|----------|---------------------|
| 0x0     | IDLE0    | CPU clock is OFF    |
| 0x1     | IDLE1    | AHB clock is OFF    |
| 0x2     | IDLE2    | APBx clocks are OFF |
| 0x3     | Reserved | Reserved            |
| 0x4     | STANDBY  | ALL clocks are OFF  |
| 0x7-0x5 | Reserved | Reserved            |

## 19.7.2 Standby Configuration

**Name:** STDBYCFG

**Offset:** 0x08

**Reset:** 0x0400

**Property:** Write-Protected

|        |                      |     |    |    |    |                |   |   |
|--------|----------------------|-----|----|----|----|----------------|---|---|
| Bit    | 15                   | 14  | 13 | 12 | 11 | 10             | 8 | 9 |
|        |                      |     |    |    |    | <b>BBIASHS</b> |   |   |
| Access | R                    | R   | R  | R  | R  | R/W            | R | R |
| Reset  | 0                    | 0   | 0  | 0  | 0  | 1              | 0 | 0 |
| Bit    | 7                    | 6   | 5  | 4  | 3  | 2              | 1 | 0 |
|        | <b>VREGSMOD[1:0]</b> |     |    |    |    |                |   |   |
| Access | R/W                  | R/W | R  | R  | R  | R              | R | R |
| Reset  | 0                    | 0   | 0  | 0  | 0  | 0              | 0 | 0 |

- **Bits 15:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 10 – BBIASHS: Back Bias for HMC RAMCHS**

0 - No Back Biasing Mode

1 - Standby Back Biasing Mode

- **Bits 9:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 7:6 – VREGSMOD[1:0]: VREG Switching Mode**

**Table 19-3. VREG SwitchingMode**

| Value | Name        | Definition                     |
|-------|-------------|--------------------------------|
| 0x0   | AUTO        | Automatic Mode                 |
| 0x1   | PERFORMANCE | Performance oriented           |
| 0x2   | LP          | Low power consumption oriented |
| 0x3   | Reserved    | Reserved                       |

- **Bits 5:0 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

## 19.8 Register Summary

| Offset | Name     | Bit Pos. |               |  |  |  |  |                |  |  |
|--------|----------|----------|---------------|--|--|--|--|----------------|--|--|
| 0x00   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x01   | SLEEPCFG | 7:0      |               |  |  |  |  | SLEEPMODE[2:0] |  |  |
| 0x02   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x03   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x04   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x05   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x06   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x07   | Reserved |          |               |  |  |  |  |                |  |  |
| 0x08   | STDBYCFG | 7:0      | VREGSMOD[1:0] |  |  |  |  |                |  |  |
| 0x09   |          | 15:8     |               |  |  |  |  | BBIASHS        |  |  |

## 20. OSCCTRL – Oscillators Controller

### 20.1 Overview

The Oscillators Controller (OSCCTRL) provides a user interface to the XOSC, OSC48M, and DPLL96M.

Through the interface registers, it is possible to enable, disable, calibrate and monitor the OSCCTRL sub-peripherals.

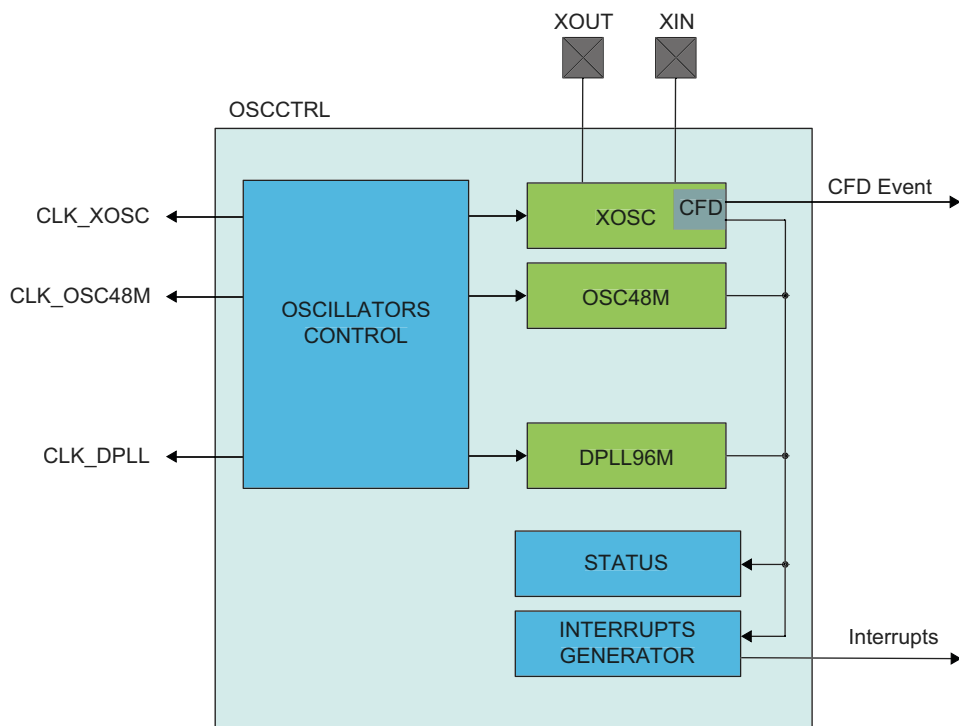

All sub-peripheral statuses are collected in the Status register (STATUS). They can additionally trigger interrupts upon status changes via the INTENSET, INTENCLR and INTFLAG registers.

### 20.2 Features

- 0.4-32MHz Crystal Oscillator (XOSC)
  - Tunable gain control
  - Programmable start-up time
  - Crystal or external input clock on XIN I/O
  - Clock failure detection with safe clock switch
  - Clock failure event output
- 48MHz Internal Oscillator (OSC48M)
  - Fast startup
  - Programmable start-up time
  - 4-bit linear divider available
- Digital Phase Locked Loop (DPLL)
  - 48MHz to 96MHz output frequency from a 32 kHz to 2 MHz reference clock
  - Three selectable reference clock
  - Three selectable output clocks
  - Adjustable proportional integral controller
  - Fractional part used to achieve 1/16th of reference clock step

## 20.3 Block Diagram

Figure 20-1. OSCCTRL Block Diagram

## 20.4 Signal Description

| Signal | Description   | Type          |
|--------|---|---------------|
| XIN    | Multipurpose Crystal Oscillator or external clock generator input | Analog input  |
| XOUT   | Multipurpose Crystal Oscillator output                            | Analog output |

The I/O lines are automatically selected when XOSC is enabled.

## 20.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 20.5.1 I/O Lines

I/O lines are configured by OSCCTRL when XOSC is enabled, and need no user configuration.

### 20.5.2 Power Management

The OSCCTRL can continue to operate in any sleep mode where the selected source clock is running. The OSCCTRL interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 20.5.3 Clocks

The OSCCTRL gathers controls for all device oscillators and provides clock sources to the Generic Clock Controller (GCLK). The available clock sources are: XOSC, OSC48M, and DPLL96M.

The OSCCTRL bus clock (CLK\_OSCCTRL\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_OSCCTRL\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

The OSC48M control logic uses the oscillator output, which is also asynchronous to the user interface clock (CLK\_OSCCTRL\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 167](#) for further details.

### 20.5.4 DMA

Not applicable.

### 20.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the OSCCTRL interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 20.5.6 Events

Not applicable.

### 20.5.7 Debug Operation

When the CPU is halted in debug mode the OSCCTRL continues normal operation. If the OSCCTRL is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

### 20.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag Status and Clear register (INTFLAG)

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 20.5.9 Analog Connections

The 0.4-32MHz crystal must be connected between the XIN and XOUT pins, along with any required load capacitors.

## 20.6 Functional Description

### 20.6.1 Principle of Operation

XOSC, OSC48M, and DPLL96M are configured via OSCCTRL control registers. Through this interface, the sub-peripherals are enabled, disabled or have their calibration values updated.

The Status register gathers different status signals coming from the sub-peripherals controlled by the OSCCTRL. The status signals can be used to generate system interrupts, and in some cases wake up the system from standby mode, provided the corresponding interrupt is enabled.

### 20.6.2 External Multipurpose Crystal Oscillator (XOSC) Operation

The XOSC can operate in two different modes:

- External clock, with an external clock signal connected to the XIN pin
- Crystal oscillator, with an external 0.4-32MHz crystal

The XOSC can be used as a clock source for generic clock generators, as described in the “[GCLK – Generic Clock Controller](#)” on page 109.

At reset, the XOSC is disabled, and the XIN/XOUT pins can be used as General Purpose I/O (GPIO) pins or by other peripherals in the system. When XOSC is enabled, the operating mode determines the GPIO usage. When in crystal oscillator mode, the XIN and XOUT pins are controlled by the OSCCTRL, and GPIO functions are overridden on both pins. When in external clock mode, the only XIN pin will be overridden and controlled by the OSCCTRL, while the XOUT pin can still be used as a GPIO pin.

The XOSC is enabled by writing a one to the Enable bit in the External Multipurpose Crystal Oscillator Control register (XOSCCTRL.ENABLE). To enable the XOSC as a crystal oscillator, the XTAL Enable bit (XOSCCTRL.XTALEN) must be written to one. If XOSCCTRL.XTALEN is zero, external clock input will be enabled.

When in crystal oscillator mode (XOSCCTRL.XTALEN is one), the External Multipurpose Crystal Oscillator Gain (XOSCCTRL.GAIN) must be set to match the external crystal oscillator frequency. If the External Multipurpose Crystal Oscillator Automatic Amplitude Gain Control (XOSCCTRL.AMPGC) is one, the oscillator amplitude will be automatically adjusted, and in most cases result in a lower power consumption.

The XOSC will behave differently in different sleep modes based on the settings of XOSCCTRL.RUNSTDBY, XOSCCTRL.ONDEMAND and XOSCCTRL.ENABLE, see [Table 20-1](#).

**Table 20-1. XOSC Sleep Behavior**

| XOSCCTRL.RUNSTDBY | XOSCCTRL.ONDEMAND | XOSCCTRL.ENABLE | Sleep Behavior  |
|-------------------|-------------------|-----------------|---|
| -                 | -                 | 0               | Disabled  |
| 0                 | 0                 | 1               | Always run in IDLE sleep modes. Run in STANDBY sleep mode if requested by a peripheral. |
| 0                 | 1                 | 1               | Only run in IDLE or STANDBY sleep modes if requested by a peripheral.                   |
| 1                 | 0                 | 1               | Always run in IDLE and STANDBY sleep modes.   |
| 1                 | 1                 | 1               | Only run in IDLE or STANDBY sleep modes if requested by a peripheral.                   |

After a hard reset, or when waking up from a sleep mode where the XOSC was disabled, the XOSC will need a certain amount of time to stabilize on the correct frequency. This start-up time can be configured by changing the Oscillator Start-Up Time bit group (XOSCCTRL.STARTUP) in the External Multipurpose Crystal Oscillator Control register. During the start-up time, the oscillator output is masked to ensure that no unstable clock propagates to the digital logic. The External Multipurpose Crystal Oscillator Ready bit in the Status register (STATUS.XOSCRDY) is set when the external clock or crystal oscillator is stable and ready to be used as a clock source. An interrupt is generated on a zero-to-one transition on STATUS.XOSCRDY if the External Multipurpose Crystal Oscillator Ready bit in the Interrupt Enable Set register (INTENSET.XOSCRDY) is set.

### 20.6.3 Clock Failure Detector operation

The Clock Failure Detector (CFD) allows the user to monitor the external clock or crystal oscillator clock signal provided by the External Multipurpose Crystal Oscillator (XOSC). It detects failing operation of the XOSC clock, and allows to switch to a safe clock in case of clock failure. The user can also switch from the safe clock to the XOSC clock in case of

clock recovery. The safe clock is derived from the OSC48M oscillator with a configurable prescaler. This allows to configure the safe clock in order to fulfill the operative conditions of the microcontroller. The CFD operation is automatically disabled when the XOSC clock is not requested in ONDEMAND mode or halted in STANDBY.

The user interface registers allow to enable, disable and configure the CFD. The Status register gives status on failure and clock switch conditions. The Clock Failure Detector can optionally trigger an interrupt or an event when a failure is detected.

### Clock Failure Detection

At reset the CFD is disabled. The CFD does not monitor the XOSC clock when the oscillator is disabled (XOSCCTRL.ENABLE = 0).

Before starting the CFD operation, the user must start and enable the safe clock source (OSC48M oscillator).

To start the CFD operation, the user must write a one to the CFD Enable bit in the External Oscillator Control register (XOSCCTRL.CFDEN). After the start or restart of the XOSC, the CFD does not detect failure until the start-up time, as configured by the Oscillator Start-Up Time (XOSCCTRL.STARTUP) in the External Multipurpose Crystal Oscillator Control register, is elapsed. Once the XOSC Start-Up Time is elapsed, the XOSC clock is constantly monitored.

During a period of 4 safe clocks, the CFD watches for a clock activity from the XOSC. There must be one rising and one falling XOSC clock edges during a 4 safe clock periods to meet a non failure status. If no activity is detected, the failure status is asserted. The Clock Failure status bit in the Status register (STATUS.CLKFAIL) is set. The Clock Failure interrupt flag bit in the Interrupt Flag register (INTFLAG.CLKFAIL) is set. If the CLKFAIL bit in the Interrupt Enable Set register (INTENSET.CLKFAIL) is set, an interrupt is generated. An output event is generated as well, if the Event Output enable bit in the Event Control register (EVCTRL.CFDEO) is set.

The XOSC clock continues to be monitored after a clock failure. The Clock Failure status bit in the Status register (STATUS.CLKFAIL) reflects the current XOSC clock activity.

### Clock Switch

When a clock failure is detected, the XOSC clock is replaced by the safe clock in order to maintain an active clock during the XOSC clock failure. The safe clock source is the OSC48M oscillator clock. The safe clock source can be downscaled with a configurable prescaler to ensure that the safe clock frequency does not exceed the operating conditions selected by the application. When the XOSC clock is switched to the safe clock, the Clock Switch bit (STATUS.CLKSW) in the Status register is set.

When the CFD has switched to the safe clock, the XOSC is not disabled. The application must take the necessary actions to disable the oscillator. The application must also take the necessary actions to configure the system clocks to continue normal operations.

In the case the application can recover the XOSC, it can switch back to the XOSC clock by writing a one to Switch Back bit (XOSCCTRL.SWBCK) in the External Oscillator Control register. Once the XOSC clock is switched back, the Switch Back bit (XOSCCTRL.SWBCK) is cleared by the hardware.

### Prescaler

The CFD has an internal configurable prescaler (CFDPRESC.CFDPRESC) to generate the safe clock from the OSC48M clock. The prescaler size allows to scale down the OSC48M clock such that the safe clock is not higher than the XOSC clock frequency monitored by the CFD. The frequency divider is  $2^{\text{CFDPRESC}}$  where CFDPRESC range from 0 to 7.

Example : for an external crystal oscillator at .4 mHz and the OSC48M internal oscillator configured to generate a 16 mHz clock, the prescaler should select a downscale value above 80 (16/.4), eg. 128.

### Event

If the Event Output enable bit in the Event Control register (EVCTRL.CFDEO) is set, the CFD clock failure will be output on the Event Output. When the CFD is switched to the safe clock, the CFD clock failure will not be output on the Event Output.

### Sleep mode

The CFD is halted depending on configuration of the XOSC and the peripheral clock request. For further details, refer to [Table 20-1](#). The CFD interrupt can be used to wake up the device from sleep modes.

#### 20.6.4 48MHz Internal Oscillator (OSC48M) Operation

OSC48M is an internal oscillator operating in open-loop mode and generating 48MHz frequency. Write to Division Factor field in OSC48MDIV register (OSC48MDIV.DIV) to select the OSC48M frequency. OSC48M is enabled by writing a one to the Oscillator Enable bit (OSC48MCTRL.ENABLE) in the OSC48M Control register, and disabled by writing a zero to this bit. Frequency selection may be done when OSC48M is enabled.

When enabling OSC48M, OSC48M clock is output when oscillator is ready (STATUS.OSC48MRDY=1). User must ensure that the OSC48M is fully disabled before enabling it by reading STATUS.OSC48MRDY=0.

After reset, OSC48M is the default clock source enabled and configured at 4MHz.

The OSC48M will behave differently in different sleep modes based on the settings of OSC48MCTRL.RUNSTDBY, OSC48MCTRL.ONDEMAND and OSC48MCTRL.ENABLE, see [Table 20-2](#).

**Table 20-2. OSC48M Sleep Behavior**

| OSC48MCTRL.RUNSTDBY | OSC48MCTRL.ONDEMAND | OSC48MCTRL.ENABLE | Sleep Behavior  |
|---------------------|---------------------|-------------------|---|
| -                   | -                   | 0                 | Disabled  |
| 0                   | 0                   | 1                 | Always run in IDLE sleep modes. Run in STANDBY sleep mode if requested by a peripheral. |
| 0                   | 1                   | 1                 | Only run in IDLE or STANDBY sleep modes if requested by a peripheral.                   |
| 1                   | 0                   | 1                 | Always run in IDLE and STANDBY sleep modes.   |
| 1                   | 1                   | 1                 | Only run in IDLE or STANDBY sleep modes if requested by a peripheral.                   |

After a hard reset, or when waking up from a sleep mode where the OSC48M was disabled, the OSC48M will need a certain amount of time to stabilize on the correct frequency. This start-up time can be configured by changing the Oscillator Start-Up Delay bit group (OSC48MSTUP.STARTUP) in the OSC48M Startup register. During the start-up time, the oscillator output is masked to ensure that no unstable clock propagates to the digital logic. The OSC48M Ready bit in the Status register (STATUS.OSC48MRDY) is set when the oscillator is stable and ready to be used as a clock source. An interrupt is generated on a zero-to-one transition on STATUS.OSC48MRDY if the OSC48M Ready bit in the Interrupt Enable Set register (INTENSET.OSC48MRDY) is set.

Faster start-up times are achievable by selecting shorter delays. However, the oscillator frequency may not stabilize within tolerances when short delays are used. If a fast start-up time is desired at the expense of initial accuracy, the division factor should be set to two or higher (OSC48MDIV.DIV > 0).

The OSC48M is used as a clock source for the generic clock generators, as described in the [“GCLK – Generic Clock Controller” on page 109](#) chapter.

#### 20.6.5 Digital Phase Locked Loop (DPLL) Operation

The task of the DPLL is to maintain coherence between the input (reference) signal and the respective output frequency CLK\_DPLL via phase comparison. The DPLL controller supports three independent sources of reference clocks:

- XOSC32K: this clock is provided by the 32K External Crystal Oscillator (XOSC32K). For further details, refer to [“OSC32KCTRL – 32k Oscillators Controller” on page 201](#).

The frequency of the DPLL output clock CK is stable when the module is enabled and when the LOCK bit is set. When DPLLCTRLB.LTIME is different from 0, a user defined lock time is used to validate the lock operation. In that case the lock time is constant. If DPLLCTRLB.LTIME is zero, the lock signal is linked with the status bit of the DPLL, the lock time vary depending on the filter selection and final target frequency. When DPLLCTRLB.WUF is set the wake up fast mode is activated. In that mode the clock gating cell is enabled at the end of the startup time. At that time the final frequency is not stable as it is still the acquisition period, but it allows to save several milliseconds. After First acquisition, DPLLCTRLB.LBYPASS indicates if the Lock signal is discarded from the control of the clock gater (CG) generating the output clock CLK\_DPLL.

**Table 20-3. CLK\_DPLL behavior from startup to first edge detection.**

| WUF | LTIME             | CLK_DPLL Behavior  |
|-----|-------------------|--|
| 0   | 0                 | Normal Mode: First Edge when lock is asserted                        |
| 0   | Not Equal To Zero | Lock Timer Timeout mode: First Edge when the timer down-counts to 0. |
| 1   | X                 | Wake Up Fast Mode: First Edge when CK is active (startup time)       |

**Table 20-4. CLK\_DPLL behavior after First Edge detection.**

| LBYPASS | CLK_DPLL Behavior   |
|---------|---|
| 0       | Normal Mode: the CLK_DPLL is turned off when lock signal is low.      |
| 1       | Lock Bypass Mode: the CLK_DPLL is always running, lock is irrelevant. |

**Figure 20-4. CK and CLK\_DPLL output from DPLL off mode to running mode**

**Figure 20-5. CK and CLK\_DPLL output from DPLL off mode to running mode when wake up fast is activated**

**Figure 20-6. CK and CLK\_DPLL output from running mode to DPLL off mode.**

### Reference Clock Switching

When a software operation requires reference clock switching, the normal operation is to turn the DPLL into the standby mode, modify the DPLLCTRLB.REFCLK to select the desired reference source and activate the DPLL again.

### Output Clock Prescaler

The DPLL controller includes an output prescaler. This prescaler provides three selectable output clocks CK, CKDIV2 and CKDIV4. The DPLLCTRLB.PRESC[1:0] field is used to select a new output clock prescaler. When the prescaler field is modified the DPLLSYNCBUSY.PRESC bit is set, it is cleared by hardware when the synchronization is over.

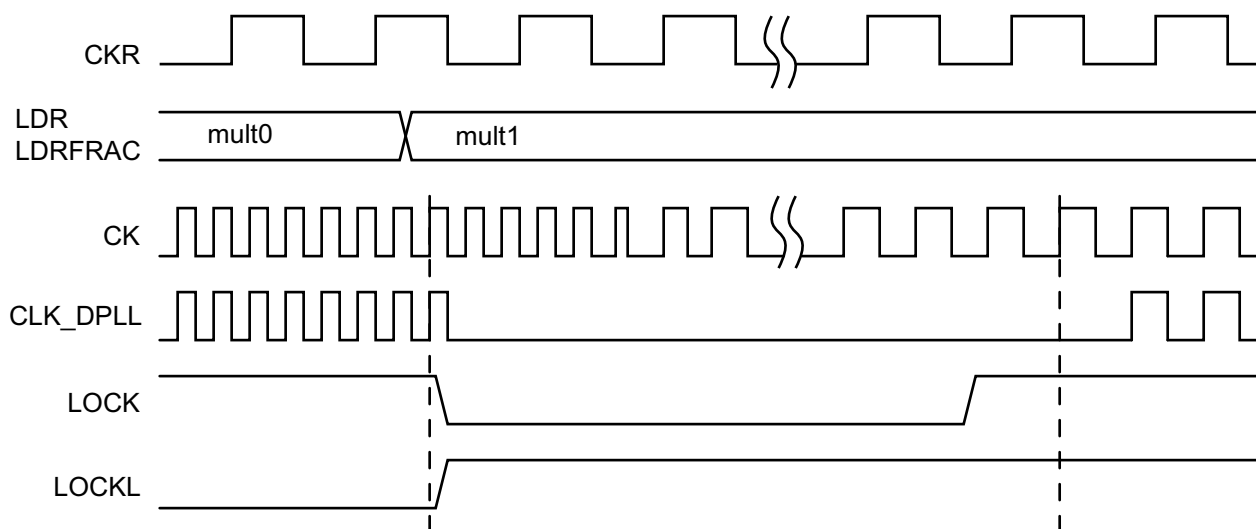

**Figure 20-7. Output Clock Switching Operation**

### Loop Divider Ratio Updates

The DPLL Controller supports on-the-fly update of the DPLL\_RATIO register, so it is allowed to modify the loop divider ratio and the loop divider ratio fractional part when the DPLL is enabled. STATUS.DPLLLDRTO is set when the DPLL\_RATIO register has been modified and the DPLL analog cell has successfully sampled the updated value. At that time the DPLLSTATUS.LOCK bit is cleared and set again by hardware when the output frequency reached a stable state.

**Figure 20-8. RATIOCTRL register update operation**

### Digital Filter Selection

The PLL digital filter (PI controller) is automatically adjusted in order to provide a good compromise between stability and jitter. Nevertheless a software operation can override the filter setting using the DPLLCTRLB.FILTER field. The DPLLCTRLB.LPEN field can be used to bypass the Time to Digital Converter (TDC) module.

## 20.6.6 DMA Operation

Not applicable.

## 20.6.7 Interrupts

The OSCCTRL has the following interrupt sources:

- XOSCRDY - Multipurpose Crystal Oscillator Ready: A “0-to-1” transition on the STATUS.XOSCRDY bit is detected
- CLKFAIL - Clock Failure: A “0-to-1” transition on the STATUS.CLKFAIL bit is detected.
- OSC48MRDY - 48MHz Internal Oscillator Ready: A “0-to-1” transition on the STATUS.OSC48MRDY bit is detected
- DPLLLOCKR - DPLL Lock Rise: A “0-to-1” transition on the STATUS.DPLLLOCKR bit is detected
- DPLLLOCKF - DPLL Lock Fall: A “0-to-1” transition on the STATUS.DPLLLOCKF bit is detected
- DPLLLTTO - DPLL Lock Timer Time-out: A “0-to-1” transition on the STATUS.DPLLLTTO bit is detected
- DPLLLDRTO - DPLL Loop Divider Ratio Update Complete. A “0-to-1” transition on the STATUS.DPLLLDRTO bit is detected

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the OSCCTRL is reset. See the [INTFLAG](#) register for details on how to clear interrupt flags.

The OSCCTRL has one common interrupt request line for all the interrupt sources. The user must read the INTFLAG register to determine which interrupt condition is present. Refer to the [INTFLAG](#) register for details.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to the [“Nested Vector Interrupt Controller” on page 27](#) for details.

## 20.6.8 Events

The CFD can generate the following output event:

- Clock Failure (CLKFAIL): Generated when the Clock Failure status bit is set in the Status register (STATUS.CLKFAIL). The CFD event is not generated when the Clock Switch bit (STATUS.CLKSW) in the Status register is set.

Writing a one to an Event Output bit in the Event Control register (EVCTRL.CFDEO) enables the CFD output event.

Writing a zero to this bit disables the CFD output event.

Refer to the Event System chapter for details on configuring the event system.

## 20.6.9 Synchronization

Due to the multiple clock domains, some registers in the OSC48M must be synchronized when accessed. A register can require:

- Synchronization when written
- No synchronization

When executing an operation that requires synchronization, the relevant synchronization bit in the Synchronization Busy register (OSC48MSYNCBUSY) will be set immediately, and cleared when synchronization is complete.

The following registers need synchronization when written:

- OSC48M Divider register (OSC48MDIV)

Due to the multiple clock domains (XOSC32K, XOSC, GCLK and CK), some registers in the DPLL must be synchronized when accessed. A register can require:

- Synchronization when written
- No synchronization

When executing an operation that requires synchronization, the relevant synchronization bit in the Synchronization Busy register (DPLLSYNCBUSY) will be set immediately, and cleared when synchronization is complete.

The following bits need synchronization when written:

- Enable bit in control register A (DPLLCTRLA.ENABLE)
- DPLL Ratio register (DPLLRATIO)
- DPLL Prescaler register (DPLLPRESC)

## 20.7 Register Summary

Table 20-5. OSCCTRL Register Summary

| Offset | Name               | Bit Pos. |              |          |  |           |              |               |          |          |
|--------|--------------------|----------|--------------|----------|--|-----------|--------------|---------------|----------|----------|
| 0x00   | INTENCLR           | 7:0      |              |          |  | OSC48MRDY |              |               |          | XOSCRDY  |
| 0x01   |                    | 15:8     |              |          |  |           | DPLLLDRTO    | DPLLLTO       | DPLLLCKF | DPLLLCKR |

## 20.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to the Register Access Protection section and the PAC chapter for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Synchronized property in each individual register description. Refer to [“Synchronization” on page 167](#) for details.

## 20.8.1 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x00

**Reset:** 0x00000000

**Property:** Write-Protected

- **Bits 31:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 11 – DPLLLDRTO: DPLL Loop Divider Ratio Update Complete Interrupt Enable**

0: The DPLL Loop Divider Ratio Update Complete interrupt is disabled.

1: The DPLL Loop Divider Ratio Update Complete interrupt is enabled, and an interrupt request will be generated when the DPLL Loop Divider Ratio Update Complete Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the DPLL Loop Divider Ratio Update Complete Interrupt Enable bit, which disables the DPLL Loop Divider Ratio Update Complete interrupt.

- **Bit 10 – DPLLLTO: DPLL Lock Timeout Interrupt Enable**

0: The DPLL Lock Timeout interrupt is disabled.

1: The DPLL Lock Timeout interrupt is enabled, and an interrupt request will be generated when the DPLL Lock Timeout Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the DPLL Lock Timeout Interrupt Enable bit, which disables the DPLL Lock Timeout interrupt.

- **Bit 9 – DPLLLCKF: DPLL Lock Fall Interrupt Enable**

0: The DPLL Lock Fall interrupt is disabled.

1: The DPLL Lock Fall interrupt is enabled, and an interrupt request will be generated when the DPLL Lock Fall Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the DPLL Lock Fall Interrupt Enable bit, which disables the DPLL Lock Fall interrupt.

- **Bit 8 – DPLLLCKR: DPLL Lock Rise Interrupt Enable**

0: The DPLL Lock Rise interrupt is disabled.

1: The DPLL Lock Rise interrupt is enabled, and an interrupt request will be generated when the DPLL Lock Rise Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the DPLL Lock Rise Interrupt Enable bit, which disables the DPLL Lock Rise interrupt.

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 – OSC48MRDY: OSC48M Ready Interrupt Enable**

0: The OSC48M Ready interrupt is disabled.

1: The OSC48M Ready interrupt is enabled, and an interrupt request will be generated when the OSC48M Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the OSC48M Ready Interrupt Enable bit, which disables the OSC48M Ready interrupt.

- **Bits 3:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – CLKFAIL: Clock Failure Interrupt Enable**

0: The XOSC Clock Failure interrupt is disabled.

1: The XOSC Clock Failure interrupt is enabled, and an interrupt request will be generated when the XOSC Clock Failure Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the XOSC Clock Failure Interrupt Enable bit, which disables the XOSC Clock Failure interrupt.

- **Bit 0 – XOSCRDY: XOSC Ready Interrupt Enable**

0: The XOSC Ready interrupt is disabled.

1: The XOSC Ready interrupt is enabled, and an interrupt request will be generated when the XOSC Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the XOSC Ready Interrupt Enable bit, which disables the XOSC Ready interrupt.

## 20.8.2 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |           |           |         |          |          |
|--------|----|----|----|-----------|-----------|---------|----------|----------|
| Bit    | 31 | 30 | 29 | 28        | 27        | 26      | 25       | 24       |
|        |    |    |    |           |           |         |          |          |
| Access | R  | R  | R  | R         | R         | R       | R        | R        |

| Access | R  | R  | R  | R         | R/W       | R/W     | R/W      | R/W      |
| Reset  | 0  | 0  | 0  | 0         | 0         | 0       | 0        | 0        |
| Bit    | 7  | 6  | 5  | 4         | 3         | 2       | 1        | 0        |
|        |    |    |    | OSC48MRDY |           |         | CLKFAIL  | XOSCRDY  |
| Access | R  | R  | R  | R/W       | R         | R       | R        | R/W      |
| Reset  | 0  | 0  | 0  | 0         | 0         | 0       | 0        | 0        |

- **Bits 31:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 11 – DPLLLDRTO: DPLL Loop Divider Ratio Update Complete Interrupt Enable**

0: The DPLL Loop Divider Ratio Update Complete interrupt is disabled.

1: The DPLL Loop Ratio Update Complete interrupt is enabled, and an interrupt request will be generated when the DPLL Loop Ratio Update Complete Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the DPLL Loop Ratio Update Complete Interrupt Enable bit, which enables the DPLL Loop Ratio Update Complete interrupt.

- **Bit 10 – DPLLLTO: DPLL Lock Timeout Interrupt Enable**

0: The DPLL Lock Timeout interrupt is disabled.

1: The DPLL Lock Timeout interrupt is enabled, and an interrupt request will be generated when the DPLL Lock Timeout Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the DPLL Lock Timeout Interrupt Enable bit, which enables the DPLL Lock Timeout interrupt.

- **Bit 9 – DPLLLCKF: DPLL Lock Fall Interrupt Enable**

0: The DPLL Lock Fall interrupt is disabled.

1: The DPLL Lock Fall interrupt is enabled, and an interrupt request will be generated when the DPLL Lock Fall Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the DPLL Lock Fall Interrupt Enable bit, which enables the DPLL Lock Fall interrupt.

- **Bit 8 – DPLLLCKR: DPLL Lock Rise Interrupt Enable**

0: The DPLL Lock Rise interrupt is disabled.

1: The DPLL Lock Rise interrupt is enabled, and an interrupt request will be generated when the DPLL Lock Rise Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the DPLL Lock Rise Interrupt Enable bit, which enables the DPLL Lock Rise interrupt.

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 – OSC48MRDY: OSC48M Ready Interrupt Enable**

0: The OSC48M Ready interrupt is disabled.

1: The OSC48M Ready interrupt is enabled, and an interrupt request will be generated when the OSC48M Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the OSC48M Ready Interrupt Enable bit, which enables the OSC48M Ready interrupt.

- **Bits 3:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – CLKFAIL: Clock Failure Interrupt Enable**

0: The XOSC Clock Failure interrupt is disabled.

1: The XOSC Clock Failure interrupt is enabled, and an interrupt request will be generated when the XOSC Clock Failure Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the XOSC Clock Failure Interrupt Enable bit, which enables the XOSC Clock Failure interrupt.

- **Bit 0 – XOSCRDY: XOSC Ready Interrupt Enable**

0: The XOSC Ready interrupt is disabled.

1: The XOSC Ready interrupt is enabled, and an interrupt request will be generated when the XOSC Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the XOSC Ready Interrupt Enable bit, which enables the XOSC Ready interrupt.

### 20.8.3 Interrupt Flag Status and Clear

**Name:** INTFLAG

- Bits 31:12 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 11 – DPLLLDRTO: DPLL Loop Divider Ratio Update Complete**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the DPLL Loop Divider Ratio Update Complete bit in the Status register (STATUS.DPLLLDRTO) and will generate an interrupt request if INTENSET.DPLLLDRTO is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the DPLL Loop Divider Ratio Update Complete interrupt flag.
- Bit 10 – DPLLLTO: DPLL Lock Timeout**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the DPLL Lock Timeout bit in the Status register (STATUS.DPLLLTO) and will generate an interrupt request if INTENSET.DPLLLTO is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the DPLL Lock Timeout interrupt flag.

- **Bit 9 – DPLLLCKF: DPLL Lock Fall**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the DPLL Lock Fall bit in the Status register (STATUS.DPLLLCKF) and will generate an interrupt request if INTENSET.DPLLLCKF is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the DPLL Lock Fall interrupt flag.
- **Bit 8 – DPLLLCKR: DPLL Lock Rise**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the DPLL Lock Rise bit in the Status register (STATUS.DPLLLCKR) and will generate an interrupt request if INTENSET.DPLLLCKR is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the DPLL Lock Rise interrupt flag.
- **Bits 7:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 4 – OSC48MRDY: OSC48M Ready**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the OSC48M Ready bit in the Status register (STATUS.OSC48MRDY) and will generate an interrupt request if INTENSET.OSC48MRDY is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the OSC48M Ready interrupt flag.
- **Bits 3:2 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 1 – CLKFAIL: XOSC Clock Failure**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the XOSC Clock Failure bit in the Status register (STATUS.CLKFAIL) and will generate an interrupt request if INTENSET.CLKFAIL is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the XOSC Clock Failure interrupt flag.
- **Bit 0 – XOSCRDY: XOSC Ready**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the XOSC Ready bit in the Status register (STATUS.XOSCRDY) and will generate an interrupt request if INTENSET.XOSCRDY is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the XOSC Ready interrupt flag.

## 20.8.4 Status

- **Bits 31:12 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 11 – DPLLLDRTO: DPLL Loop Divider Ratio Update Complete**  
 0: DPLL Loop Divider Ratio Update Complete not detected.  
 1: DPLL Loop Divider Ratio Update Complete detected.
- **Bit 10 – DPLLLTO: DPLL Lock Timeout**  
 0: DPLL Lock time-out not detected.  
 1: DPLL Lock time-out detected.
- **Bit 9 – DPLLLCKF: DPLL Lock Fall**  
 0: DPLL Lock fall edge not detected.  
 1: DPLL Lock fall edge detected.
- **Bit 8 – DPLLLCKR: DPLL Lock Rise**  
 0: DPLL Lock rise edge not detected.  
 1: DPLL Lock fall edge detected.

- **Bits 7:5 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 4 – OSC48MRDY: OSC48M Ready**  
0: OSC48M is not ready.  
1: OSC48M is stable and ready to be used as a clock source.
- **Bit 3 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bit 2 – CLKSW: XOSC Clock Switch**  
0: XOSC is not switched and provides the external clock or crystal oscillator clock.  
1: XOSC is switched and provides the safe clock.
- **Bit 1 – CLKFAIL: XOSC Clock Failure**  
0: XOSC failure not detected.  
1: XOSC failure detected.
- **Bit 0 – XOSCRDY: XOSC Ready**  
0: XOSC is not ready.  
1: XOSC is stable and ready to be used as a clock source.

## 20.8.5 External Multipurpose Crystal Oscillator (XOSC) Control

**Name:** XOSCCTRL

**Offset:** 0x10

**Reset:** 0x0080

**Property:** Write-Protected

|        |              |          |     |       |       |           |        |     |

| Access | R/W          | R/W      | R   | R     | R     | R/W       | R/W    | R   |
| Reset  | 1            | 0        | 0   | 0     | 0     | 0         | 0      | 0   |

- Bits 15:12 – STARTUP[3:0]: Start-Up Time**

These bits select start-up time for the oscillator according to [Table 20-6](#).

The OSCULP32K oscillator is used to clock the start-up counter.

**Table 20-6. Start-UpTime for External Multipurpose Crystal Oscillator**

| STARTUP[3:0] | Number of OSCULP32K Clock Cycles | Number of XOSC Clock Cycles | Approximate Equivalent Time <sup>(1)(2)</sup> |
|--------------|----------------------------------|-----------------------------|---|
| 0x0          | 1                                | 3                           | 31μs  |
| 0x1          | 2                                | 3                           | 61μs  |
| 0x2          | 4                                | 3                           | 122μs   |
| 0x3          | 8                                | 3                           | 244μs   |
| 0x4          | 16                               | 3                           | 488μs   |
| 0x5          | 32                               | 3                           | 977μs   |

**Table 20-6. Start-UpTime for External Multipurpose Crystal Oscillator (Continued)**

| STARTUP[3:0] | Number of OSCULP32K Clock Cycles | Number of XOSC Clock Cycles | Approximate Equivalent Time <sup>(1)(2)</sup> |
|--------------|----------------------------------|-----------------------------|---|
| 0x6          | 64                               | 3                           | 1953μs  |
| 0x7          | 128                              | 3                           | 3906μs  |
| 0x8          | 256                              | 3                           | 7813μs  |
| 0x9          | 512                              | 3                           | 15625μs                                       |
| 0xA          | 1024                             | 3                           | 31250μs                                       |
| 0xB          | 2048                             | 3                           | 62500μs                                       |
| 0xC          | 4096                             | 3                           | 125000μs                                      |
| 0xD          | 8192                             | 3                           | 250000μs                                      |
| 0xE          | 16384                            | 3                           | 500000μs                                      |
| 0xF          | 32768                            | 3                           | 1000000μs                                     |

- Notes:
1. Actual startup time is 1 OSCULP32K cycle + 3 XOSC cycles.
  2. The given time neglects the 3 XOSC cycles before OSCULP32K cycle.

- **Bit 11 – AMPGC: Automatic Amplitude Gain Control**

0: The automatic amplitude gain control is disabled.

1: The automatic amplitude gain control is enabled. Amplitude gain will be automatically adjusted during Crystal Oscillator operation.

- **Bits 10:8 – GAIN[2:0]: Oscillator Gain**

These bits select the gain for the oscillator, given in table <Table 20-7>. The listed maximum frequencies are recommendations, and might vary based on capacitive load and crystal characteristics. Setting this bit group has no effect when the Automatic Amplitude Gain Control is active.

**Table 20-7. External Multipurpose Crystal Oscillator Gain Settings**

| GAIN[2:0] | Recommended Max Frequency |
|-----------|---------------------------|
| 0x0       | 2MHz                      |
| 0x1       | 4MHz                      |
| 0x2       | 8MHz                      |
| 0x3       | 16MHz                     |
| 0x4       | 30MHz                     |
| 0x5-0x7   | Reserved                  |

- **Bit 7 – ONDEMAND: On Demand Control**

The On Demand operation mode allows the oscillator to be enabled or disabled, depending on peripheral clock requests.

In On Demand operation mode, i.e., if the ONDEMAND bit has been previously written to one, the oscillator will be running only when requested by a peripheral. If there is no peripheral requesting the oscillator's clock source, the oscillator will be in a disabled state.

If On Demand is disabled, the oscillator will always be running when enabled.

In standby sleep mode, the On Demand operation is still active.

0: The oscillator is always on, if enabled.

1: The oscillator is enabled when a peripheral is requesting the oscillator to be used as a clock source. The oscillator is disabled if no peripheral is requesting the clock source.

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit controls how the XOSC behaves during standby sleep mode:

0: The XOSC is disabled in standby sleep mode if no peripheral requests the clock.

1: The XOSC is not stopped in standby sleep mode. If ONDEMAND is one, the XOSC will be running when a peripheral is requesting the clock. If ONDEMAND is zero, the clock source will always be running in standby sleep mode.

- **Bit 5 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 4 – SWBCK: Clock Switch Back**

This bit controls the XOSC output clock switch back to the external clock or crystal oscillator in case of clock recovery :

0: The clock switch back is disabled.

1: The clock switch back is enabled. This bit is reset once the XOSC output clock is switched back to the external clock or crystal oscillator.

- **Bit 3 – CFDEN: Clock Failure Detector Enable**

This bit controls the clock failure detector :

0: the Clock Failure Detector is disabled.

1: the Clock Failure Detector is enabled.

- **Bit 2 – XTALEN: Crystal Oscillator Enable**

This bit controls the connections between the I/O pads and the external clock or crystal oscillator:

0: External clock connected on XIN. XOUT can be used as general-purpose I/O.

1: Crystal connected to XIN/XOUT.

- **Bit 1 – ENABLE: Oscillator Enable**

0: The oscillator is disabled.

1: The oscillator is enabled.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

20.8.6 Clock Failure Detector Prescaler

**Name:** CFDPRESC  
**Offset:** 0x12  
**Reset:** 0x00  
**Property:** Write-Protected

|        |    |    |    |    |    |               |     |     |
|--------|----|----|----|----|----|---------------|-----|-----|
| Bit    | 15 | 14 | 13 | 12 | 11 | 10            | 9   | 8   |
|        |    |    |    |    |    | CFDPRESC[2:0] |     |     |
| Access | R  | R  | R  | R  | R  | R/W           | R/W | R/W |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0             | 0   | 0   |

- Bits 2:0 – CFDPRESC[2:0]: Clock Failure Detector Prescaler**  
These bits select the prescaler for the clock failure detector.  
The OSC48M oscillator is used to clock the CFD prescaler.  
The CFD safe clock frequency is the OSC48M frequency divided by  $2^{CFDPRESC}$ .

20.8.7 Event Control

**Name:** EVCTRL  
**Offset:** 0x13  
**Reset:** 0x00  
**Property:** Write-Protected

|        |    |    |    |    |    |    |   |       |
|--------|----|----|----|----|----|----|---|-------|
| Bit    | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8     |
|        |    |    |    |    |    |    |   | CFDEO |
| Access | R  | R  | R  | R  | R  | R  | R | R/W   |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0     |

- Bits 0 – CFDEO: Clock Failure Detector Event Out**  
This bit indicates whether the Clock Failure detector event output is enabled or not and an output event will be generated when the Clock Failure detector detects a clock failure.  
0: Clock Failure detector event output is disabled and an event will not be generated.  
1: Clock Failure detector event output is enabled and an event will be generated.

## 20.8.8 48MHz Internal Oscillator (OSC48M) Control

**Name:** OSC48MCTRL

**Offset:** 0x14

**Reset:** 0x82

**Property:** Write-Protected

| Bit    | 7               | 6               | 5 | 4 | 3 | 2 | 1             | 0 |
|--------|-----------------|-----------------|---|---|---|---|---------------|---|
|        | <b>ONDEMAND</b> | <b>RUNSTDBY</b> |   |   |   |   | <b>ENABLE</b> |   |
| Access | R/W             | R/W             | R | R | R | R | R/W           | R |
| Reset  | 1               | 0               | 0 | 0 | 0 | 0 | 1             | 0 |

- **Bit 7 – ONDEMAND: On Demand Control**

The On Demand operation mode allows the oscillator to be enabled or disabled depending on peripheral clock requests.

In On Demand operation mode, i.e., if the ONDEMAND bit has been previously written to one, the oscillator will only be running when requested by a peripheral. If there is no peripheral requesting the oscillator's clock source, the oscillator will be in a disabled state.

If On Demand is disabled the oscillator will always be running when enabled.

In standby sleep mode, the On Demand operation is still active.

0: The oscillator is always on, if enabled.

1: The oscillator is enabled when a peripheral is requesting the oscillator to be used as a clock source. The oscillator is disabled if no peripheral is requesting the clock source.

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit controls how the OSC48M behaves during standby sleep mode:

0: The OSC48M is disabled in standby sleep mode if no peripheral requests the clock.

1: The OSC48M is not stopped in standby sleep mode. If ONDEMAND is one, the OSC48M will be running when a peripheral is requesting the clock. If ONDEMAND is zero, the clock source will always be running in standby sleep mode.

- **Bits 5:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Oscillator Enable**

0: The oscillator is disabled.

1: The oscillator is enabled.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 20.8.9 48MHz Internal Oscillator (OSC48M) Divider

**Name:** OSC48MDIV

**Offset:** 0x15

**Reset:** 0x0B

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|--------|---|---|---|---|----------|-----|-----|-----|
|        |   |   |   |   | DIV[3:0] |     |     |     |
| Access | R | R | R | R | R/W      | R/W | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 1        | 0   | 1   | 1   |

- Bits 7:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 3:0 – DIV[3:0]: Oscillator Divider Selection**  
 These bits control the oscillator frequency range by adjusting the division ratio. The oscillator frequency is 48MHz divided by DIV+1.

**Table 20-8. Oscillator Division Selection**

| DIV[3:0] | Description |
|----------|-------------|
| 0000     | 48MHz       |
| 0001     | 24MHz       |
| 0010     | 16MHz       |
| 0011     | 12MHz       |
| 0100     | 9.6MHz      |
| 0101     | 8MHz        |
| 0110     | 6.86MHz     |
| 0111     | 6MHz        |
| 1000     | 5.33MHz     |
| 1001     | 4.8MHz      |
| 1010     | 4.36MHz     |
| 1011     | 4MHz        |
| 1100     | 3.69MHz     |
| 1101     | 3.43MHz     |
| 1110     | 3.2MHz      |
| 1111     | 3MHz        |

### 20.8.10 48MHz Internal Oscillator (OSC48M) Startup

**Name:** OSC48MSTUP

**Offset:** 0x16

**Reset:** 0x0B

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2            | 1   | 0   |
|--------|---|---|---|---|---|--------------|-----|-----|
|        |   |   |   |   |   | STARTUP[2:0] |     |     |
| Access | R | R | R | R | R | R/W          | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0            | 1   | 1   |

- Bits 7:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 2:0 – STARTUP[2:0]: Oscillator Startup Delay**  
 These bits select the oscillator start-up delay in oscillator cycles

**Table 20-9. Oscillator Division Selection**

| STARTUP[2:0] | Number of OSC48M Clock Cycles | Approximate Equivalent Time <sup>(1)(2)</sup> |
|--------------|-------------------------------|---|
| 0x0          | 8                             | 166ns   |
| 0x1          | 16                            | 333ns   |
| 0x2          | 32                            | 667ns   |
| 0x3          | 64                            | 1.333µs                                       |
| 0x4          | 128                           | 2.667µs                                       |
| 0x5          | 256                           | 5.333µs                                       |
| 0x6          | 512                           | 10.667µs                                      |
| 0x7          | 1024                          | 21.333µs                                      |

- Notes:
- Start-up delay is in addition to time to first clock edge.
  - Actual delay will be less as the oscillator generally starts with higher frequency before settling.

### 20.8.11 48MHz Internal Oscillator (OSC48M) Synchronization Busy

**Name:** OSC48MSYNCBUSY

**Offset:** 0x18

**Reset:** 0x00000000

**Property:** –

|        |    |    |    |    |     |           |     |     |
|--------|----|----|----|----|-----|-----------|-----|-----|
| Bit    | 31 | 30 | 29 | 28 | 27  | 26        | 25  | 24  |
|        |    |    |    |    |     |           |     |     |
| Access | R  | R  | R  | R  | R   | R         | R   | R   |
| Reset  | 0  | 0  | 0  | 0  | 0   | 0         | 0   | 0   |
| Bit    | 23 | 22 | 21 | 20 | 19  | 18        | 17  | 16  |
|        |    |    |    |    |     |           |     |     |
| Access | R  | R  | R  | R  | R   | R         | R   | R   |
| Reset  | 0  | 0  | 0  | 0  | 0   | 0         | 0   | 0   |
| Bit    | 15 | 14 | 13 | 12 | 11  | 10        | 9   | 8   |
|        |    |    |    |    |     |           |     |     |
| Access | R  | R  | R  | R  | R/W | R/W       | R/W | R/W |
| Reset  | 0  | 0  | 0  | 0  | 1   | 1         | 0   | 0   |
| Bit    | 7  | 6  | 5  | 4  | 3   | 2         | 1   | 0   |
|        |    |    |    |    |     | OSC48MDIV |     |     |
| Access | R  | R  | R  | R  | R   | R         | R   | R   |
| Reset  | 1  | 0  | 0  | 0  | 0   | 0         | 0   | 0   |

- Bits 31:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 2 – OSC48MDIV: Oscillator Divider Synchronization Status**  
 0: No synchronized access.  
 1: Synchronized access is ongoing.  
 This bit is set when OSC48MDIV register is written.  
 This bit is cleared when OSC48MDIV synchronization is completed.
- Bits 1:0 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

## 20.8.12 DPLL Control A

**Name:** DPLLCTRLA

**Offset:** 0x1C

**Reset:** 0x80

**Property:** Write-Protected, Write-Synchronized (ENABLE)

| Bit    | 7               | 6               | 5 | 4 | 3 | 2 | 1             | 0 |
|--------|-----------------|-----------------|---|---|---|---|---------------|---|
|        | <b>ONDEMAND</b> | <b>RUNSTDBY</b> |   |   |   |   | <b>ENABLE</b> |   |
| Access | R/W             | R/W             | R | R | R | R | R/W           | R |
| Reset  | 1               | 0               | 0 | 0 | 0 | 0 | 0             | 0 |

- **Bit 7 – ONDEMAND: On Demand Clock Activation**

The On Demand operation mode allows the DPLL to be enabled or disabled depending on peripheral clock requests.

In On Demand operation mode, i.e., if the ONDEMAND bit has been previously written to one, the DPLL will only be running when requested by a peripheral. If there is no peripheral requesting the DPLL's clock source, the DPLL will be in a disabled state.

If On Demand is disabled the DPLL will always be running when enabled.

In standby sleep mode, the On Demand operation is still active.

0: The DPLL is always on, if enabled.

1: The DPLL is enabled when a peripheral is requesting the DPLL to be used as a clock source. The DPLL is disabled if no peripheral is requesting the clock source.

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit controls how the DPLL behaves during standby sleep mode:

0: The DPLL is disabled in standby sleep mode if no peripheral requests the clock.

1: The DPLL is not stopped in standby sleep mode. If ONDEMAND is one, the DPLL will be running when a peripheral is requesting the clock. If ONDEMAND is zero, the clock source will always be running in standby sleep mode.

- **Bits 5:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: DPLL Enable**

0: The DPLL is disabled.

1: The DPLL is enabled.

The software operation of enabling or disabling the DPLL takes a few clock cycles, so the DPLLSYNC-BUSY.ENABLE status bit indicates when the DPLL is successfully enabled or disabled.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 20.8.13 DPLL Ratio Control

Refer to the Synchronization section in the Clock System Overview chapter for details on the functionality of this register.

**Name:** DPLLRATIO

**Offset:** 0x20

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

|        |          |     |     |     |              |     |     |     |
|--------|----------|-----|-----|-----|--------------|-----|-----|-----|
| Bit    | 31       | 30  | 29  | 28  | 27           | 26  | 25  | 24  |
|        |          |     |     |     |              |     |     |     |
| Access | R        | R   | R   | R   | R            | R   | R   | R   |
| Reset  | 0        | 0   | 0   | 0   | 0            | 0   | 0   | 0   |
| Bit    | 23       | 22  | 21  | 20  | 19           | 18  | 17  | 16  |
|        |          |     |     |     | LDRFRAC[3:0] |     |     |     |
| Access | R        | R   | R   | R   | R/W          | R/W | R/W | R/W |
| Reset  | 0        | 0   | 0   | 0   | 0            | 0   | 0   | 0   |
| Bit    | 15       | 14  | 13  | 12  | 11           | 10  | 9   | 8   |
|        |          |     |     |     | LDR[11:8]    |     |     |     |
| Access | R        | R   | R   | R   | R/W          | R/W | R/W | R/W |
| Reset  | 0        | 0   | 0   | 0   | 0            | 0   | 0   | 0   |
| Bit    | 7        | 6   | 5   | 4   | 3            | 2   | 1   | 0   |
|        | LDR[7:0] |     |     |     |              |     |     |     |
| Access | R/W      | R/W | R/W | R/W | R/W          | R/W | R/W | R/W |
| Reset  | 0        | 0   | 0   | 0   | 0            | 0   | 0   | 0   |

- **Bits 31:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 19:16 – LDRFRAC[3:0]: Loop Divider Ratio Fractional Part**

Write these bits to set the fractional part of the frequency multiplier. Due to synchronization there is a delay between writing to DPLLRATIO.LDRFRAC[3:0] and the effect on the DPLL output clock. The value written DPLLRATIO.LDRFAC[3:0] will be read back immediately and the DPLLRATIO bit in the synchronization busy register, DPLLSYNCBUSY.DPLLRATIO, will be set. DPLLSYNCBUSY.DPLLRATIO will be cleared when the operation is completed.

- **Bits 15:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:0 – LDR[11:0]: Loop Divider Ratio**

Write these bits to set the integer part of the frequency multiplier. The value written DPLLratio.LDR[3:0] will be read back immediately and the DPLLratio bit in the synchronization busy register, DPLLsyncbusy.DPLLratio, will be set. DPLLsyncbusy.DPLLratio will be cleared when the operation is completed.

## 20.8.14 DPLL Control B

**Name:** DPLLCTRLB

**Offset:** 0x24

**Reset:** 0x00

**Property:** Write-Protected

|        |          |     |             |         |     |            |             |     |
|--------|----------|-----|-------------|---------|-----|------------|-------------|-----|
| Bit    | 31       | 30  | 29          | 28      | 27  | 26         | 25          | 24  |
|        |          |     |             |         |     | DIV[10:8]  |             |     |
| Access | R        | R   | R           | R       | R   | R/W        | R/W         | R/W |
| Reset  | 0        | 0   | 0           | 0       | 0   | 0          | 0           | 0   |
| Bit    | 23       | 22  | 21          | 20      | 19  | 18         | 17          | 16  |
|        | DIV[7:0] |     |             |         |     |            |             |     |
| Access | R/W      | R/W | R/W         | R/W     | R/W | R/W        | R/W         | R/W |
| Reset  | 0        | 0   | 0           | 0       | 0   | 0          | 0           | 0   |
| Bit    | 15       | 14  | 13          | 12      | 11  | 10         | 9           | 8   |
|        |          |     |             | LBYPASS |     | LTIME[2:0] |             |     |
| Access | R        | R   | R           | R/W     | R   | R/W        | R/W         | R/W |
| Reset  | 0        | 0   | 0           | 0       | 0   | 0          | 0           | 0   |
| Bit    | 7        | 6   | 5           | 4       | 3   | 2          | 1           | 0   |
|        |          |     | REFCLK[1:0] |         | WUF | LPEN       | FILTER[1:0] |     |
| Access | R        | R   | R/W         | R/W     | R/W | R/W        | R/W         | R/W |
| Reset  | 0        | 0   | 0           | 0       | 0   | 0          | 0           | 0   |

- **Bits 31:27 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 26:16 – DIV[10:0]: Clock Divider**

These bits are used to set the XOSC clock division factor and can be calculated with following formula:

$$f_{DIV} = \frac{f_{XOSC}}{2 \times (DIV + 1)}$$

- **Bits 15:13 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 12 – LBYPASS: Lock Bypass**

0: DPLL Lock signal drives the DPLL controller internal logic.

1: DPLL Lock signal is always asserted.

- **Bit 11 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 10:8 – LTIME[2:0]: Lock Time**

Write these bits to select the lock time-out value, as shown in <Table 20-10>:

**Table 20-10. Lock Time**

| Value | Name     | Description                      |
|-------|----------|----------------------------------|
| 0x0   | Default  | No time-out. Automatic lock.     |
| 0x1   | Reserved |                                  |
| 0x2   | Reserved |                                  |
| 0x3   | Reserved |                                  |
| 0x4   | 8MS      | Time-out if no lock within 8 ms  |
| 0x5   | 9MS      | Time-out if no lock within 9 ms  |
| 0x6   | 10MS     | Time-out if no lock within 10 ms |
| 0x7   | 11MS     | Time-out if no lock within 11 ms |

- **Bits 7:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:4 – REFCLK[1:0]: Reference Clock Selection**

Write these bits to select the DPLL clock reference, as shown in <Table 20-11>:

**Table 20-11. Reference Clock Selection**

| Value | Name     | Description             |
|-------|----------|-------------------------|
| 0x0   | XOSC32K  | XOSC32K clock reference |
| 0x1   | XOSC     | XOSC clock reference    |
| 0x2   | GCLK     | GCLK clock reference    |
| 0x3   | Reserved |                         |

- **Bit 3 – WUF: Wake Up Fast**

0: DPLL clock is output after startup and lock time.

1: DPLL clock is output after startup time.

- **Bit 2 – LPEN: Low-Power Enable**

0: The low-power mode is disabled. Time to Digital Converter is enabled.

1: The low-power mode is enabled. Time to Digital Converter is disabled. This will improve power consumption but increase the output jitter.

- **Bits 1:0 – FILTER[1:0]: Proportional Integral Filter Selection**

These bits select the DPLL filter type, as shown in <Table 20-12>:

**Table 20-12. Proportional Integral Filter selection**

| Value | Name    | Description           |
|-------|---------|-----------------------|
| 0x0   | DEFAULT | Default filter mode   |
| 0x1   | LBFILT  | Low bandwidth filter  |
| 0x2   | HBFILT  | High bandwidth filter |
| 0x3   | HDFILT  | High damping filter   |

20.8.15 DPLL Prescaler

**Name:** DPLLPRESC  
**Offset:** 0x28  
**Reset:** 0x00  
**Property:** Write-Protected, Write-Synchronized

|        |   |   |   |   |   |   |            |     |
|--------|---|---|---|---|---|---|------------|-----|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1          | 0   |
|        |   |   |   |   |   |   | PRESC[1:0] |     |
| Access | R | R | R | R | R | R | R/W        | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0          | 0   |

- Bits 7:2 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 1:0 – PRESC[1:0]: Output Clock Prescaler**  
These bits define the output clock prescaler setting.

Table 20-13.Output Clock Prescaler

| Value | Name     | Description                 |
|-------|----------|-----------------------------|
| 0x0   | DIV1     | DPLL output is divided by 1 |
| 0x1   | DIV2     | DPLL output is divided by 2 |
| 0x2   | DIV4     | DPLL output is divided by 4 |
| 0x3   | Reserved |                             |

## 20.8.16 DPLL Synchronization Busy

**Name:** DPLLSYNCBUSY

**Offset:** 0x2C

**Reset:** 0x00

**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3         | 2         | 1      | 0 |
|--------|---|---|---|---|-----------|-----------|--------|---|
|        |   |   |   |   | DPLLPRESC | DPLLRATIO | ENABLE |   |
| Access | R | R | R | R | R         | R         | R      | R |
| Reset  | 0 | 0 | 0 | 0 | 0         | 0         | 0      | 0 |

- Bits 7:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 3 – DPLLPRESC: DPLL Prescaler Synchronization Status**  
 0: The DPLLRESC register has been synchronized.  
 1: The DPLLRESC register value has changed and its synchronization is in progress.
- Bit 2 – DPLLRATIO: DPLL Loop Divider Ratio Synchronization Status**  
 0: The DPLLRATIO register has been synchronized.  
 1: The DPLLRATIO register value has changed and its synchronization is in progress.
- Bit 1 – ENABLE: DPLL Enable Synchronization Status**  
 0: The DPLLCTRLA.ENABLE bit has been synchronized.  
 1: The DPLLCTRLA.ENABLE bit value has changed and its synchronization is in progress.
- Bit 0 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 20.8.17 DPLL Status

**Name:** DPLLSTATUS

**Offset:** 0x30

**Reset:** 0x00

**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0    |
|--------|---|---|---|---|---|---|--------|------|
|        |   |   |   |   |   |   | CLKRDY | LOCK |
| Access | R | R | R | R | R | R | R      | R    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0      | 0    |

- Bits 7:2 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 1 – CLKRDY: Output Clock Ready**  
 0: The DPLL output clock is off.  
 1: The DPLL output clock is on.
- Bit 0 – LOCK: DPLL Lock status bit**  
 0: The DPLL Lock signal is cleared, when the DPLL is disabled or when the DPLL is trying to reach the target frequency.  
 1: The DPLL Lock signal is asserted when the desired frequency is reached.

## 21. OSC32KCTRL – 32k Oscillators Controller

### 21.1 Overview

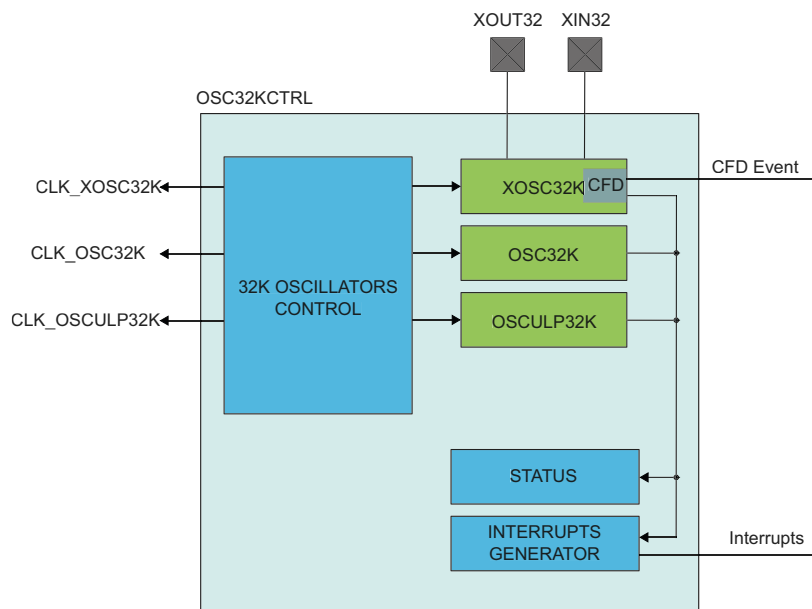

The 32K oscillators Controller (OSC32KCTRL) provides a user interface to the XOSC32K, OSC32K and OSCULP32K. Through the interface registers, it is possible to enable, disable, calibrate or monitor the OSC32KCTRL sub-peripherals. All sub-peripheral status are collected in the Status register (STATUS). They can additionally trigger interrupts upon status changes via the INTENSET, INTENCLR and INTFLAG registers.

### 21.2 Features

- 32.768kHz Crystal Oscillator (XOSC32K)
  - Programmable start-up time
  - Crystal or external input clock on XIN32 I/O
  - Clock failure detection with safe clock switch
  - Clock failure event output
- 32.768kHz High Accuracy Internal Oscillator (OSC32K)
  - Frequency fine tuning
  - Programmable start-up time
- 32.768kHz Ultra Low Power Internal Oscillator (OSCULP32K)
  - Ultra low power, always-on oscillator
  - Frequency fine tuning
- Calibration value loaded from Flash Factory Calibration at reset

### 21.3 Block Diagram

Figure 21-1. OSC32KCTRL Block Diagram.

## 21.4 Signal Description

| Signal | Description   | Type   |
|--------|---------------|--|
| XIN32  | Analog Input  | 32kHz Crystal Oscillator or external clock generator input |
| XOUT32 | Analog Output | 32kHz Crystal Oscillator output                            |

The I/O lines are automatically selected when XOSC32K is enabled.

## 21.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 21.5.1 I/O Lines

I/O lines is configured by OSC32KCTRL when XOSC32K is enabled, and needs no user configuration.

### 21.5.2 Power Management

The OSC32KCTRL will continue to operate in any sleep mode where the selected source clock is running. The OSC32KCTRL's interrupts can be used to wake up the device from sleep modes. Refer to the Power Manager chapter for details on the different sleep modes.

### 21.5.3 Clocks

The OSC32KCTRL gathers controls for all 32K oscillators and provides clock sources to the Generic Clock Controller (GCLK), Real-Time Counter (RTC) and Watchdog Timer (WDT). The available clock sources are: XOSC32K, OSC32K and OSCULP32K.

The OSC32KCTRL bus clock (CLK\_OSC32KCTRL\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_OSC32KCTRL\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

### 21.5.4 Interrupts

The interrupt request lines are connected to the interrupt controller. Using the OSC32KCTRL interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 21.5.5 Events

The event is connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

### 21.5.6 Debug Operation

When the CPU is halted in debug mode the OSC32KCTRL continues normal operation. If the OSC32KCTRL is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

### 21.5.7 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag Status and Clear (INTFLAG) register

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to the Peripheral Access Controller chapter for details.

## 21.5.8 Analog Connections

The 32.768kHz crystal must be connected between the XIN32 and XOUT32 pins, along with any required load capacitors. For details on recommended oscillator characteristics and capacitor load, refer to the [“Electrical Characteristics” on page 903](#) for details.

## 21.5.9 Calibration

The OSC32K calibration value from the production test must be loaded from the NVM Software Calibration Area into the OSC32K register (OSC32K.CALIB) by software to achieve specified accuracy.

Refer to [“NVM Software Calibration Area Mapping” on page 25](#) for further details.

## 21.6 Functional Description

### 21.6.1 Principle of Operation

XOSC32K, OSC32K and OSCULP32K are configured via OSC32KCTRL control registers. Through this interface, the sub-peripherals are enabled, disabled or have their calibration values updated.

The STATUS register gathers different status signals coming from the sub-peripherals controlled by the OSC32KCTRL. The status signals can be used to generate system interrupts, and in some cases wake up the system from standby mode, provided the corresponding interrupt is enabled.

### 21.6.2 32kHz External Crystal Oscillator (XOSC32K) Operation

The XOSC32K can operate in two different modes:

- External clock, with an external clock signal connected to XIN32
- Crystal oscillator, with an external 32.768kHz crystal connected between XIN32 and XOUT32

The XOSC32K will be reset only at power-on (POR).

When the XOSC32K is disabled, the XIN32/XOUT32 pins can be used as General Purpose I/O (GPIO) pins or by other peripherals in the system. When XOSC32K is enabled, the operating mode determines the GPIO usage. When in crystal oscillator mode, the XIN32 and XOUT32 pins are controlled by the OSC32KCTRL, and GPIO functions are overridden on both pins. When in external clock mode, the only XIN32 pin will be overridden and controlled by the OSC32KCTRL, while the XOUT32 pin can still be used as a GPIO pin.

The XOSC32K is enabled by writing a one to the Enable bit in the 32kHz External Crystal Oscillator Control register (XOSC32K.ENABLE). The XOSC32K is disabled by writing a zero to the Enable bit in the 32kHz External Crystal Oscillator Control register (XOSC32K.ENABLE).

To enable the XOSC32K as a crystal oscillator, XTALEN bit in the 32kHz External Crystal Oscillator Control register must be written to one (XOSC32K.XTALEN). If XOSC32K.XTALEN is zero, external clock input will be enabled.

The XOSC32K has a 32.768kHz output enabled by writing a one to the 32kHz Output Enable bit in the 32kHz External Crystal Oscillator Control register (XOSC32K.EN32K). The XOSC32K also has a 1.024kHz clock output enabled by writing a one to the 1kHz Output Enable bit in the 32kHz External Crystal Oscillator Control register (XOSC32K.EN1K).

It is also possible to lock the XOSC32K configuration by writing a one to Write Lock bit in the 32kHz External Crystal Oscillator Control register (XOSC32K.WRTLOCK). If set, the XOSC32K configuration is locked until a power-on reset (POR) is detected.

The XOSC32K will behave differently in different sleep modes based on the settings of XOSC32K.RUNSTDBY, XOSC32K.ONDEMAND and XOSC32K.ENABLE, as shown in [Table 21-1](#):

**Table 21-1. XOSC32K Sleep Behavior**

| XOSC32K.RUNSTDBY | XOSC32K.ONDEMAND | XOSC32K.ENABLE | Sleep Behavior   |
|------------------|------------------|----------------|--|
| -                | -                | 0              | Disabled   |
| 0                | 0                | 1              | Always run in IDLE sleep modes.<br>In STANDBY sleep mode: only running if requested by a peripheral. |
| 1                | 0                | 1              | Always run in both IDLE and STANDBY sleep modes.   |
| -                | 1                | 1              | In IDLE or STANDBY sleep modes: only running if requested by a peripheral.                           |

As a crystal oscillator usually requires a very long start-up time, the 32KHz External Crystal Oscillator will keep running across resets when XOSC32K.ONDEMAND=0, except for power-on reset (POR).

After such a reset or when waking up from a sleep mode where the XOSC32K was disabled, the XOSC32K will need a certain amount of time to stabilize on the correct frequency.

This start-up time can be configured by changing the Oscillator Start-Up Time bit group (XOSC32K.STARTUP) in the 32KHz External Crystal Oscillator Control register. During the start-up time, the oscillator output is masked to ensure that no unstable clock propagates to the digital logic.

Once the external clock or crystal oscillator is stable and ready to be used as a clock source, the XOSC32K Ready bit in the Status register is set (STATUS.XOSC32KRDY=1). The transition of STATUS.XOSC32KRDY from '0' to '1' generates an interrupt if the XOSC32K Ready bit in the Interrupt Enable Set register is set (INTENSET.XOSC32KRDY=1).

The XOSC32K can be used as a source for Generic Clock Generators (GCLK) or for the Real-Time Counter (RTC). Before enabling the GCLK or the RTC module, the corresponding oscillator output must be enabled (XOSC32K.EN32K or XOSC32K.EN1K) in order to ensure proper operation. In the same way, the GCLK or RTC modules must be disabled before the clock selection is changed. For further details on how to configure these modules, refer to the [“GCLK – Generic Clock Controller” on page 109](#) and [“RTC – Real-Time Counter” on page 268](#). For details on RTC clock configuration, refer to the [“Real-Time Counter Clock Selection” on page 207](#).

### 21.6.3 Clock Failure Detector operation

The Clock Failure Detector (CFD) allows the user to monitor the external clock or crystal oscillator signal provided by the external oscillator (XOSC32K). It detects failing operation of the XOSC32K clock with a reduced latency, and allows to switch to a safe clock in case of clock failure. The user can also switch from the safe clock to the XOSC32K clock in case of clock recovery. The safe clock is derived from the OSCULP32K oscillator with a configurable prescaler. This allows to configure the safe clock in order to fulfill the operative conditions of the microcontroller. The CFD operation is automatically disabled when the oscillator is not requested in ONDEMAND mode or halted in STANDBY.

The user interface registers allow to enable, disable and configure the CFD. The Status register gives status on failure and clock switch conditions. The Clock Failure Detector can optionally trigger an interrupt or an event when a failure is detected.

#### Clock Failure Detection

The CFD will be reset only at power-on (POR). The CFD does not monitor the XOSC32K clock when the oscillator is disabled (XOSC32K.ENABLE=0).

Before starting the CFD operation, the user must start and enable the safe clock source (OSCULP32K oscillator).

To start the CFD operation, the user must write a one to the CFD Enable bit in the External Oscillator Control register (CFDCTRL.CFDEN). After the start or restart of the XOSC32K, the CFD does not detect failure until the start-up time, as

configured by the Oscillator Start-Up Time (XOSC32K.STARTUP) in the External Multipurpose Crystal Oscillator Control register, is elapsed. Once the XOSC32K Start-Up Time is elapsed, the XOSC32K clock is constantly monitored.

During a period of 4 safe clocks (monitor period), the CFD watches for a clock activity from the XOSC32K. There must be one rising and one falling XOSC32K clock edges during a 4 safe clock periods to meet a non failure status. If no activity is detected, the failure status is asserted. The Clock Failure Detector status bit is set in the Status register (STATUS.CLKFAIL). The Clock Failure Detector interrupt flag bit is set in the Interrupt Flag register (INTFLAG.CLKFAIL). If the CLKFAIL bit in the Interrupt Enable Set register (INTENSET.CLKFAIL) is set, an interrupt is generated. An output event is generated as well if the Event Output enable bit in the Event Control register (EVCTRL.CFDEO) is set.

The XOSC32K clock continues to be monitored after a clock failure. The Clock Failure Detector status bit in the Status register (STATUS.CLKFAIL) reflects the current XOSC32K activity.

### Clock Switch

When a clock failure is detected, the XOSC32K clock is replaced by the safe clock in order to maintain an active clock during the XOSC32K clock failure. The safe clock source is the OSCULP32K oscillator clock. Both 32kHz and 1kHz outputs of the XOSC32K are replaced respectively by the OSCULP32K 32kHz and 1kHz outputs. The safe clock source can be downscaled with a configurable prescaler to ensure that the safe clock frequency does not exceed the operating conditions selected by the application. When the XOSC32K clock is switched to the safe clock, the Clock Switch bit (STATUS.CLKSW) in the Status register is set.

When the CFD has switched to the safe clock, the XOSC32K is not disabled. The application must take the necessary actions to disable the oscillator. The application must also take the necessary actions to configure the system clocks to continue normal operations.

In the case the application can recover the XOSC32K, it can switch back to the XOSC32K clock by writing a one to Switch Back Enable bit (XOSC32K.SWBEN) in the External Oscillator Control register. Once the XOSC32K clock is switched back, the Switch Back bit (CFDCTRL.SWBEN) is cleared by the hardware.

### Prescaler

The CFD has an internal configurable prescaler to generate the safe clock from the OSCULP32K clock. The prescaler size allows to scale down the OSCULP32K clock such that the safe clock is not higher than the XOSC32K clock frequency monitored by the CFD. The maximum division factor is 2.

The prescaler is applied on both outputs (32kHz and 1kHz) of the safe clock.

Example : for an external crystal oscillator at 32 kHz and the OSCULP32K frequency is 32kHz, the XOSC32K.CFDPRESC should be set to 0 for a safe clock of equal frequency.

### Event

If the Event Output Enable bit in the Event Control register (EVCTRL.CFDEO) is set, the CFD clock failure will be output on the Event Output. When the CFD is switched to the safe clock, the CFD clock failure will not be output on the Event Output.

### Sleep mode

The CFD is halted depending on configuration of the XOSC32K and the peripheral clock request. For further details, please refer to [Table 21-1](#). The CFD interrupt can be used to wake up the device from sleep modes.

## 21.6.4 32kHz Internal Oscillator (OSC32K) Operation

The OSC32K provides a tunable, low-speed and low-power clock source.

At reset, the OSC32K is disabled. The OSC32K is enabled by writing a one to the Enable bit in the 32kHz Internal Oscillator Control register (OSC32K.ENABLE). The OSC32K is disabled by writing a zero to the Enable bit in the 32kHz Internal Oscillator Control register (OSC32K.ENABLE).

The frequency of the OSC32K oscillator is controlled by the calibration value in the 32kHz Internal Oscillator Calibration bits (OSC32K.CALIB) in the 32kHz Internal Oscillator Control register. The CALIB value must be written by the user. Flash Factory Calibration values are stored in the non-volatile memory. When writing to the Calibration bits, the user must wait for the STATUS.OSC32KRDY bit to go high before the value is committed to the oscillator.

The OSC32K has a 32.768kHz output enabled by writing a one to the 32kHz Output Enable bit in the 32kHz Internal Oscillator Control register (OSC32K.EN32K). The OSC32K also has a 1.024kHz clock output enabled by writing a one to the 1kHz Output Enable bit in the 32kHz Internal Oscillator Control register (OSC32K.EN1K).

It is also possible to lock the OSC32K configuration by writing a one to Write Lock bit in the 32kHz Internal Oscillator Control register (OSC32K.WRTLOCK). If set, the OSC32K configuration is locked until a power-on reset (POR) is detected.

The OSC32K will behave differently in different sleep modes based on the settings of OSC32K.RUNSTDBY, OSC32K.ONDEMAND and OSC32K.ENABLE, as shown in [Table 21-2](#):

**Table 21-2. OSC32K Sleep Behavior**

| OSC32K.RUNSTDBY | OSC32K.ONDEMAND | OSC32K.ENABLE | Sleep Behavior   |
|-----------------|-----------------|---------------|--|
| -               | -               | 0             | Disabled   |
| 0               | 0               | 1             | Always run in IDLE sleep modes. Run in STANDBY sleep mode only if requested by peripheral. |
| 1               | 0               | 1             | Always run in IDLE and STANDBY sleep modes.  |
| -               | 1               | 1             | Run in IDLE or STANDBY sleep modes only if requested by a peripheral.                      |

The OSC32K requires a start-up time. For this reason, OSC32K will keep running across resets when OSC32K.ONDEMAND=0, except for power-on reset (POR).

After such a reset, or when waking up from a sleep mode where the OSC32K was disabled, the OSC32K will need a certain amount of time to stabilize on the correct frequency.

This startup time can be configured by changing the Oscillator Start-Up Time bit group (OSC32K.STARTUP) in the OSC32K Control register. During the start-up time, the oscillator output is masked to ensure that no unstable clock propagates to the digital logic.

Once the external clock or crystal oscillator is stable and ready to be used as a clock source, the OSC32K Ready bit in the Status register is set (STATUS.OSC32KRDY=1). The transition of STATUS.OSC32KRDY from '0' to '1' generates an interrupt if the OSC32K Ready bit in the Interrupt Enable Set register is set (INTENSET.OSC32KRDY=1).

The OSC32K can be used as a source for Generic Clock Generators (GCLK) or for the Real-Time Counter (RTC). Before enabling the GCLK or the RTC module, the corresponding oscillator output must be enabled (OSC32K.EN32K or OSC32K.EN1K) in order to ensure proper operation. In the same way, the GCLK or RTC modules must be disabled before the clock selection is changed. For further details on how to configure these modules, refer to the [“GCLK – Generic Clock Controller” on page 109](#) and [“RTC – Real-Time Counter” on page 268](#). For details on RTC clock configuration, refer to the [“Real-Time Counter Clock Selection” on page 207](#).

### 21.6.5 32kHz Ultra Low Power Internal Oscillator (OSCULP32K) Operation

The OSCULP32K provides a tunable, low-speed and ultra-low-power clock source. The OSCULP32K is factory-calibrated under typical voltage and temperature conditions. The OSCULP32K should be preferred to the OSC32K whenever the power requirements are prevalent over frequency stability and accuracy.

The OSCULP32K is enabled by default after a power-on reset (POR) and will always run except during POR. The frequency of the OSCULP32K oscillator is controlled by the value in the 32kHz Ultra Low Power Internal Oscillator Calibration bits (OSCULP32K.CALIB) in the 32kHz Ultra Low Power Internal Oscillator Control register.

OSCULP32K.CALIB is automatically loaded from Flash Factory Calibration during startup, and is used to compensate for

process variation, as described in the [“Electrical Characteristics” on page 903](#). The calibration value can be overridden by the user by writing to OSCULP32K.CALIB.

The OSCULP32K has a 32kHz output enabled by writing a one to the 32kHz Output Enable bit in the 32kHz Ultra Low Power Internal Oscillator Control register (OSCULP32K.EN32K). The OSC32K also has a 1kHz clock output enabled by writing a one to the 1kHz Output Enable bit in 32kHz Ultra Low Power Internal Oscillator Control register (OSC32K.EN1K).

It is also possible to lock the OSCULP32K configuration by writing a one to Write Lock bit in the 32kHz Ultra Low Power Internal Oscillator Control register (OSCULP32K.WRTLOCK). If set, the OSCULP32K configuration is locked until a power-on reset (POR) is detected.

The OSCULP32K can be used as a source for Generic Clock Generators (GCLK) or for the Real-Time Counter (RTC). Before enabling the GCLK or the RTC module, the corresponding oscillator output must be enabled (OSCULP32K.EN32K or OSC32K.EN1K). In the same way, to ensure a proper operation, the GCLK or RTC modules must be disabled before the clock selection is changed. For further details on how to configure these modules, refer to the [“GCLK – Generic Clock Controller” on page 109](#) and [“RTC – Real-Time Counter” on page 268](#). For details on RTC clock configuration, refer to the [“Real-Time Counter Clock Selection” on page 207](#).

### 21.6.6 Watchdog Timer Clock Selection

The Watchdog Timer (WDT) uses an internal 1kHz OSCULP32K output clock. This clock is running all the time and internally enabled when requested by the WDT module. For further details on WDT, refer to [“WDT – Watchdog Timer” on page 249](#).

### 21.6.7 Real-Time Counter Clock Selection

Before enabling the RTC module, the RTC clock must be selected first. All oscillators outputs are available as RTC clock selection. The selection is available in RTC Control register (RTCCTRL). To ensure a proper operation, it is highly recommended to disable the RTC module first, before changing the RTC clock source selection. For further details on how to enable/disable the RTC, refer to [“RTC – Real-Time Counter” on page 268](#).

### 21.6.8 Interrupts

The OSC32KCTRL has the following interrupt sources:

- XOSC32KRDY - 32kHz Crystal Oscillator Ready: A “0-to-1” transition on the STATUS.XOSC32KRDY bit is detected
- CLKFAIL - Clock Failure Detector: A “0-to-1” transition on the STATUS.CLKFAIL is detected
- OSC32KRDY - 32kHz Internal Oscillator Ready: A “0-to-1” transition on the STATUS.OSC32KRDY bit is detected

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the OSC32KCTRL is reset. See the [INTFLAG](#) register for details on how to clear interrupt flags.

The OSC32KCTRL has one common interrupt request line for all the interrupt sources. The user must read the INTFLAG register to determine which interrupt condition is present. Refer to the [INTFLAG](#) register for details.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to the [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 21.6.9 Events

The CFD can generate the following output event:

- Clock Failure Detector (CLKFAIL): Generated when the Clock Failure Detector status bit is set in the Status register (STATUS.CLKFAIL). The CFD event is not generated when the Clock Switch bit (STATUS.SWBACK) in the Status register is set.

Writing a one to an Event Output bit in the Event Control register (EVCTRL.CFDEO) enables the CFD output event. Writing a zero to this bit disables the CFD output event. Refer to the Event System chapter for details on configuring the event system.

## 21.7 Register Summary

Table 21-3. OSC32KCTRL Register Summary

| Offset | Name      | Bit Pos. |          |            |            |         |         |              |            |            |  |
|--------|-----------|----------|----------|------------|------------|---------|---------|--------------|------------|------------|--|
| 0x00   | INTENCLR  | 7:0      |          |            |            |         |         | CLKFAIL      | OSC32KRDY  | XOSC32KRDY |  |
| 0x01   |           | 15:8     |          |            |            |         |         |              |            |            |  |
| 0x02   |           | 23:16    |          |            |            |         |         |              |            |            |  |
| 0x03   |           | 31:24    |          |            |            |         |         |              |            |            |  |
| 0x04   | INTENSET  | 7:0      |          |            |            |         |         | CLKFAIL      | OSC32KRDY  | XOSC32KRDY |  |
| 0x05   |           | 15:8     |          |            |            |         |         |              |            |            |  |
| 0x06   |           | 23:16    |          |            |            |         |         |              |            |            |  |
| 0x07   |           | 31:24    |          |            |            |         |         |              |            |            |  |
| 0x08   | INTFLAG   | 7:0      |          |            |            |         |         | CLKFAIL      | OSC32KRDY  | XOSC32KRDY |  |

## 21.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to the Register Access Protection section and the PAC chapter for details.

## 21.8.1 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x00

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |    |    |         |           |            |

|        |    |    |    |    |    |         |           |            |
| Access | R  | R  | R  | R  | R  | R       | R         | R          |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10      | 9         | 8          |
|        |    |    |    |    |    |         |           |            |
| Access | R  | R  | R  | R  | R  | R       | R         | R          |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2       | 1         | 0          |
|        |    |    |    |    |    | CLKFAIL | OSC32KRDY | XOSC32KRDY |
| Access | R  | R  | R  | R  | R  | R/W     | R/W       | R/W        |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – CLKFAIL : XOSC32K Clock Failure Detector Interrupt Enable**

0: The XOSC32K Clock Failure Detector interrupt is disabled.

1: The XOSC32K Clock Failure Detector is enabled, and an interrupt request will be generated when the XOSC32K Clock Failure Detector interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the XOSC32K Clock Failure Detector Interrupt Enable bit, which disables the XOSC32K Clock Failure Detector interrupt.

- 
- **Bit 1 – OSC32KRDY: OSC32K Ready Interrupt Enable**
  - 0: The OSC32K Ready interrupt is disabled.
  - 1: The OSC32K Ready interrupt is enabled.
  - Writing a zero to this bit has no effect.
  - Writing a one to this bit will clear the OSC32K Ready Interrupt Enable bit, which disables the OSC32K Ready interrupt.
- **Bit 0 – XOSC32KRDY: XOSC32K Ready Interrupt Enable**
  - 0: The XOSC32K Ready interrupt is disabled.
  - 1: The XOSC32K Ready interrupt is enabled.
  - Writing a zero to this bit has no effect.
  - Writing a one to this bit will clear the XOSC32K Ready Interrupt Enable bit, which disables the XOSC32K Ready interrupt.

## 21.8.2 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x04

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |    |    |         |           |            |
|--------|----|----|----|----|----|---------|-----------|------------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26      | 25        | 24         |
|        |    |    |    |    |    |         |           |            |
| Access | R  | R  | R  | R  | R  | R       | R         | R          |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18      | 17        | 16         |
|        |    |    |    |    |    |         |           |            |
| Access | R  | R  | R  | R  | R  | R       | R         | R          |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10      | 9         | 8          |
|        |    |    |    |    |    |         |           |            |
| Access | R  | R  | R  | R  | R  | R       | R         | R          |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2       | 1         | 0          |
|        |    |    |    |    |    | CLKFAIL | OSC32KRDY | XOSC32KRDY |
| Access | R  | R  | R  | R  | R  | R/W     | R/W       | R/W        |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – CLKFAIL : XOSC32K Clock Failure Detector Interrupt Enable**

0: The XOSC32K Clock Failure Detector interrupt is disabled.

1: The XOSC32K Clock Failure Detector is enabled, and an interrupt request will be generated when the XOSC32K Clock Failure Detector interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the XOSC32K Clock Failure Detector Interrupt Enable bit, which enables the XOSC32K Clock Failure Detector interrupt.

- **Bit 1 – OSC32KRDY: OSC32K Ready Interrupt Enable**

0: The OSC32K Ready interrupt is disabled.

1: The OSC32K Ready interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the OSC32K Ready Interrupt Enable bit, which enables the OSC32K Ready interrupt.

- **Bit 0 – XOSC32KRDY: XOSC32K Ready Interrupt Enable**

0: The XOSC32K Ready interrupt is disabled.

1: The XOSC32K Ready interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the XOSC32K Ready Interrupt Enable bit, which enables the XOSC32K Ready interrupt.

### 21.8.3 Interrupt Flag Status and Clear

**Name:** INTFLAG

| Reset  | 0  | 0  | 0  | 0  | 0  | 0       | 0         | 0          |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – CLKFAIL : XOSC32K Clock Failure Detector**

This flag is cleared by writing a one to it.

This flag is set on a zero-to-one transition of the XOSC32K Clock Failure Detector bit in the Status register (STATUS.CLKFAIL) and will generate an interrupt request if INTENSET.CLKFAIL is one.

Writing a zero to this bit has no effect .

Writing a one to this bit clears the XOSC Clock Failure Detector interrupt flag.

- **Bit 1 – OSC32KRDY: OSC32K Ready**

This flag is cleared by writing a one to it.

This flag is set on a zero-to-one transition of the OSC32K Ready bit in the Status register (STATUS.OSC32KRDY) and will generate an interrupt request if INTENSET.OSC32KRDY is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the OSC32K Ready interrupt flag.

- **Bit 0 – XOSC32KRDY: XOSC32K Ready**

This flag is cleared by writing a one to it.

This flag is set on a zero-to-one transition of the XOSC32K Ready bit in the Status register (STATUS.XOSC32KRDY) and will generate an interrupt request if INTENSET.XOSC32KRDY is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the XOSC32K Ready interrupt flag.

## 21.8.4 Status

- Bits 31:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 3– CLKSW : XOSC32K Clock Switch**  
 0 : XOSC32K is not switched and provides the crystal oscillator clock.  
 1 : XOSC32K is switched and provides the safe clock.
- Bit 2 – CLKFAIL : XOSC32K Clock Failure Detector**  
 0 : XOSC32k is passing failure detection.  
 1 : XOSC32K is not passing failure detection.
- Bit 1 – OSC32KRDY: OSC32K Ready**  
 0: OSC32K is not ready.  
 1: OSC32K is stable and ready to be used as a clock source.
- Bit 0 – XOSC32KRDY: XOSC32K Ready**  
 0: XOSC32K is not ready.

1: XOSC32K is stable and ready to be used as a clock source.

### 21.8.5 RTC Clock Selection Control

**Name:** RTCCTRL

**Offset:** 0x10

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |    |    |             |     |     |

|        |    |    |    |    |    |             |     |     |
| Access | R  | R  | R  | R  | R  | R           | R   | R   |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0           | 0   | 0   |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2           | 1   | 0   |
|        |    |    |    |    |    | RTCSEL[2:0] |     |     |
| Access | R  | R  | R  | R  | R  | R/W         | R/W | R/W |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0           | 0   | 0   |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:0 – RTCSEL[2:0]: RTC Clock Source Selection**

These bits select the source for the RTC according to the [Table 21-4](#):

**Table 21-4. RTC Clock Source Selection**

| Value | Name     | Description  |
|-------|----------|--|
| 0x0   | ULP1K    | 1kHz from 32kHz internal ULP oscillator              |
| 0x1   | ULP32K   | 32kHz from 32kHz internal ULP oscillator             |
| 0x2   | OSC1K    | 1.024kHz from 32.768kHz internal oscillator          |
| 0x3   | OSC32K   | 32.768kHz from 32.768kHz internal oscillator         |
| 0x4   | XOSC1K   | 1.024kHz from 32.768kHz internal oscillator          |
| 0x5   | XOSC32K  | 32.768kHz from 32.768kHz external crystal oscillator |
| 0x6   | Reserved |  |
| 0x7   | Reserved |  |

## 21.8.6 32kHz External Crystal Oscillator (XOSC32K) Control

**Name:** XOSC32K

**Offset:** 0x14

**Access:** Read/Write

**Reset:** 0x0080

**Property:** Write-Protected

|        |          |          |    |         |       |              |        |     |
|--------|----------|----------|----|---------|-------|--------------|--------|-----|
| Bit    | 15       | 14       | 13 | 12      | 11    | 10           | 9      | 8   |
|        |          |          |    | WRTLOCK |       | STARTUP[2:0] |        |     |
| Access | R        | R        | R  | R/W     | R     | R/W          | R/W    | R/W |
| Reset  | 0        | 0        | 0  | 0       | 0     | 0            | 0      | 0   |
| Bit    | 7        | 6        | 5  | 4       | 3     | 2            | 1      | 0   |
|        | ONDEMAND | RUNSTDBY |    | EN1K    | EN32K | XTALEN       | ENABLE |     |
| Access | R/W      | R/W      | R  | R/W     | R/W   | R/W          | R/W    | R   |
| Reset  | 1        | 0        | 0  | 0       | 0     | 0            | 0      | 0   |

- Bits 15:13 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 12 – WRTLOCK: Write Lock**  
 This bit locks the XOSC32K register for future writes, to freeze the XOSC32K configuration:  
 0: The XOSC32K configuration is not locked.  
 1: The XOSC32K configuration is locked.
- Bit 11 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bits 10:8 – STARTUP[2:0]: Oscillator Start-Up Time**  
 These bits select the start-up time for the oscillator according to [Table 21-5](#).  
 The OSCULP32K oscillator is used to clock the start-up counter.

**Table 21-5. Start-Up Time for 32kHz External Crystal Oscillator**

| STARTUP[2:0] | Number of OSCULP32K Clock Cycles | Number of XOSC32K Clock Cycles | Approximate Equivalent Time (OSCULP = 32kHz) <sup>(1)(2)</sup> |
|--------------|----------------------------------|--------------------------------|--|
| 0x0          | 1                                | 3                              | 122μs  |
| 0x1          | 32                               | 3                              | 1068μs   |
| 0x2          | 2048                             | 3                              | 62592μs  |
| 0x3          | 4096                             | 3                              | 125092μs   |
| 0x4          | 16384                            | 3                              | 500092μs   |
| 0x5          | 32768                            | 3                              | 1000092μs  |
| 0x6          | 65536                            | 3                              | 2000092μs  |
| 0x7          | 131072                           | 3                              | 4000092μs  |

Notes: 1. Actual startup time is 1 OSCULP32K cycle + 3 XOSC32K cycles.  
2. The given time assumes an XTAL frequency of 32.768kHz.

- **Bit 7 – ONDEMAND: On Demand Control**

This bit controls how the XOSC32K behaves when a peripheral clock request is detected. For details, refer to [Table 21-1](#).

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit controls how the XOSC32K behaves during standby sleep mode. For details, refer to [Table 21-1](#).

- **Bit 5 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 4 – EN1K: 1kHz Output Enable**

0: The 1kHz output is disabled  
1: The 1kHz output is enabled.

- **Bit 3 – EN32K: 32kHz Output Enable**

0: The 32kHz output is disabled  
1: The 32kHz output is enabled.

- **Bit 2 – XTALEN: Crystal Oscillator Enable**

This bit controls the connections between the I/O pads and the external clock or crystal oscillator:  
0: External clock connected on XIN32. XOUT32 can be used as general-purpose I/O.  
1: Crystal connected to XIN32/XOUT32.

- **Bit 1 – ENABLE: Oscillator Enable**

0: The oscillator is disabled.  
1: The oscillator is enabled.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 21.8.7 Clock Failure Detector Control

**Name:** CFDCtrl

**Offset:** 0x16

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2        | 1      | 0     |
|--------|---|---|---|---|---|----------|--------|-------|
|        |   |   |   |   |   | CFDPRESC | SWBACK | CFDEN |
| Access | R | R | R | R | R | R/W      | R/W    | R/W   |
| Reset  | 1 | 0 | 0 | 0 | 0 | 0        | 0      | 0     |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – CFDPRESC: Clock Failure Detector Prescaler**

This bit selects the prescaler for the clock failure detector.

The OSCULP32K oscillator is used to clock the CFD prescaler.

The CFD safe clock frequency is the OSCULP32K frequency divided by  $2^{CFDPRESC}$ .

- **Bit 1 – SWBACK: Clock Switch Back**

This bit controls the XOSC32K output clock switch back to the external clock or crystal oscillator in case of clock recovery :

0: The clock switch is disabled.

1: the clock switch is enabled. This bit is reset once the XOSC32K output clock is switched back to the external clock or crystal oscillator.

- **Bit 0 – CFDEN: Clock Failure Detector Enable**

This bit controls the clock failure detector:

0: The Clock Failure Detector is disabled.

1: The Clock Failure Detector is enabled.

### 21.8.8 Event Control

**Name:** EVCTRL

**Offset:** 0x17

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|--------|---|---|---|---|---|---|---|-------|
|        |   |   |   |   |   |   |   | CFDEO |
| Access | R | R | R | R | R | R | R | R/W   |
| Reset  | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0     |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – CFDEO: Clock Failure Detector Event Out**

This bit indicates whether the Clock Failure detector event output is enabled or not and an output event will be generated when the Clock Failure Detector detects a clock failure.

0 : Clock Failure Detector event output is disabled and an event will not be generated.

1 : Clock Failure Detector event output is enabled and an event will be generated.

### 21.8.9 32kHz Internal Oscillator (OSC32K) Control

**Name:** OSC32K

**Offset:** 0x18

**Reset:** Read/Write

**Reset:** 0x003F0080

**Property:** Write-Protected

|        |          |            |     |         |      |              |        |     |
|--------|----------|------------|-----|---------|------|--------------|--------|-----|
| Bit    | 31       | 30         | 29  | 28      | 27   | 26           | 25     | 24  |
|        |          |            |     |         |      |              |        |     |
| Access | R        | R          | R   | R       | R    | R            | R      | R   |
| Reset  | 0        | 0          | 0   | 0       | 0    | 0            | 0      | 0   |
| Bit    | 23       | 22         | 21  | 20      | 19   | 18           | 17     | 16  |

|        |          |            |     | WRTLOCK |      | STARTUP[2:0] |        |     |
| Access | R        | R          | R   | R/W     | R    | R/W          | R/W    | R/W |
| Reset  | 0        | 0          | 0   | 0       | 0    | 0            | 0      | 0   |
| Bit    | 7        | 6          | 5   | 4       | 3    | 2            | 1      | 0   |
|        | ONDEMAND | RUNSTDBY   |     |         | EN1K | EN32K        | ENABLE |     |
| Access | R/W      | R/W        | R   | R       | R/W  | R/W          | R/W    | R   |
| Reset  | 1        | 0          | 0   | 0       | 0    | 0            | 0      | 0   |

- Bits 31:23 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 22:16 – CALIB[6:0]: Oscillator Calibration**  
 These bits control the oscillator calibration and must be written by the user.  
 Factory calibration values can be loaded from the non-volatile memory. For details refer to [“NVM User Row Mapping” on page 24](#).
- Bits 15:13 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 12 – WRTLOCK: Write Lock**  
 This bit locks the OSC32K register for future writes, to freeze the OSC32K configuration.  
 0: The OSC32K configuration is not locked.  
 1: The OSC32K configuration is locked.

- **Bit 11 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 10:8 – STARTUP[2:0]: Oscillator Start-Up Time**

These bits select start-up time for the oscillator according to [Table 21-6](#).

The OSCULP32K oscillator is used as input clock to the startup counter.

**Table 21-6. Start-Up Time for 32kHz Internal Oscillator**

| STARTUP[2:0] | Number of OSC32K clock cycles | Approximate Equivalent Time (OSCULP= 32 kHz) <sup>(1)(2)</sup> |
|--------------|-------------------------------|--|
| 0x0          | 3                             | 92μs   |

| 0x6          | 66                            | 2014μs   |
| 0x7          | 130                           | 3967μs   |

Notes: 1. Start-up time is given by STARTUP + 3 OSC32K cycles.  
2. The given time assumes an XTAL frequency of 32.768kHz.

- **Bit 7 – ONDEMAND: On Demand Control**

This bit controls how the OSC32K behaves when a peripheral clock request is detected. For details, refer to [Table 21-2](#).

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit controls how the OSC32K behaves during standby sleep mode. For details, refer to [Table 21-2](#).

- **Bits 5:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3 – EN1K: 1kHz Output Enable**

0: The 1kHz output is disabled.

1: The 1kHz output is enabled.

- **Bit 2 – EN32K: 32kHz Output Enable**

0: The 32kHz output is disabled.

1: The 32kHz output is enabled.

- **Bit 1 – ENABLE: Oscillator Enable**

0: The oscillator is disabled.

1: The oscillator is enabled.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 21.8.10 32kHz Ultra Low Power Internal Oscillator (OSCULP32K) Control

**Name:** OSCULP32K  
**Offset:** 0x1C  
**Access:** Read/Write  
**Reset:** 0x0000XX06  
**Property:** Write-Protected

|        |                |    |    |                   |     |     |     |     |

- Bits 31:16 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 15 – WRTLOCK: Write Lock**  
 This bit locks the OSCULP32K register for future writes to fix the OSCULP32K configuration.  
 0: The OSCULP32K configuration is not locked.  
 1: The OSCULP32K configuration is locked.
- Bits 14:13 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 12:8 – CALIB[4:0]: Oscillator Calibration**  
 These bits control the oscillator calibration.  
 These bits are loaded from Flash Calibration at startup.

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

## 22. SUPC – Supply Controller

### 22.1 Overview

The Supply Controller (SUPC) manages the voltage reference, power supply and supply monitoring of the device.

The SUPC controls the voltage regulators for the core (VDDCORE). It sets the voltage regulators according to the sleep modes.

The SUPC embeds two Brown-Out Detectors. BODVDD monitors the voltage applied to the device (VDD) and BODCORE monitors the internal voltage to the core (VDDCORE). The BOD can monitor the supply voltage continuously (continuous mode) or periodically (sampling mode).

The SUPC generates also a selectable reference voltage which can be used by analog modules like the ADC.

### 22.2 Features

- Voltage Regulator System
  - Main voltage regulator: LDO in active mode
  - Low Power voltage regulator in standby mode
- Voltage Reference System
  - Reference voltage for ADC and AC
- VDD Brown-Out Detector (BODVDD)
  - Programmable threshold
  - Threshold value loaded from Flash User Calibration at startup
  - Triggers resets or interrupts
  - Operating modes:
    - Continuous mode
    - Sampled mode for low power applications with programmable sample frequency
  - Hysteresis
- VDDCORE Brown-Out Detector (BODCORE)
  - Internal non-configurable Brown-out detector
  - Threshold value loaded from Flash User Calibration at startup

## 22.3 Block Diagram

Figure 22-1. SUPC Block Diagram

## 22.4 Signal Description

Not applicable.

## 22.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 22.5.1 I/O Lines

Not applicable.

### 22.5.2 Power Management

The SUPC can operate in all sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 22.5.3 Clocks

The SUPC bus clock (CLK\_SUPC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_SUPC\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

A 32kHz clock, asynchronous to the user interface clock (CLK\_SUPC\_APB), is required to run BODVDD and BODCORE in sampled mode. For further details, refer to [“OSC32KCTRL – 32k Oscillators Controller” on page 201](#). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 233](#) for further details.

#### 22.5.4 DMA

Not applicable.

#### 22.5.5 Interrupts

The interrupt request lines are connected to the interrupt controller. Using the SUPC interrupts requires the interrupt controller to be configured first. Please refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

#### 22.5.6 Events

Not applicable.

#### 22.5.7 Debug Operation

When the CPU is halted in debug mode, the SUPC continues normal operation. If the SUPC is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

If a debugger connection is detected by the system, BODVDD and BODCORE resets will be blocked.

#### 22.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following register:

- Interrupt Flag Status and Clear register ([INTFLAG](#))

Write-protection is denoted by the Write-Protected property in the register description.

#### 22.5.9 Analog Connections

Not applicable.

### 22.6 Functional Description

#### 22.6.1 Voltage Regulator System Operation

##### 22.6.1.1 Initialization

The LDO voltage regulator supplying VDDCORE is enabled after reset.

##### 22.6.1.2 Enabling, Disabling and Resetting

The LDO voltage regulator is enabled after any reset. The main voltage regulator can be disabled by writing a zero to the Enable bit in the VREG register (VREG.ENABLE). The main voltage regulator output supply level is automatically defined by the sleep mode selected in the Power Manager module.

##### 22.6.1.3 Sleep Mode Operation

In standby mode, the LP voltage regulator (LPVREG) is used to supply VDDCORE. By writing a one to the Run in Standby bit in the VREG register (VREG.RUNSTDBY), VDDCORE is kept from the main voltage regulator and the VDDCORE level is kept to the one in active mode.

#### 22.6.2 Voltage Reference System Operation

##### 22.6.2.1 Initialization

The voltage reference output is disabled after any reset.

##### 22.6.2.2 Enabling, Disabling and Resetting

The voltage reference output is enabled (respectively disabled) by writing a one (respectively zero) to the Voltage Reference Output Enable bit in the Voltage Reference register (VREF.VREFOE).

### 22.6.2.3 Selecting a Voltage Reference

A Voltage Reference output can be selected between different values. Writing in the SEL bit group in the VREF register (VREF.SEL) selects the reference voltage to be applied to analog modules, such the ADC.

### 22.6.2.4 Sleep Mode Operation

In sleep mode, the Voltage Reference output can be used depending on the Run in Standby bit in the VREF register (VREF.RUNSTDBY) and the OnDemand bit in VREF (VREF.ONDEMAND).

**Table 22-1. VREF Sleep Mode Operation**

| VREF.RUNSTDBY | VREF.ONDEMAND | Sleep behavior   |
|---------------|---------------|--|
| -             | -             | Disable  |
| 0             | 1             | Run in all sleep modes except standby sleep mode, only if requested by the ADC |
| 1             | 0             | Always run in all sleep modes  |
| 1             | 1             | Run in all sleep modes, only if requested by the ADC                           |

## 22.6.3 Brown-Out Detectors

### 22.6.3.1 Initialization

The BODVDD registers are enable-protected except the ENABLE bit, meaning that they can only be written when the BOD is disabled (BODVDD.ENABLE and SYNCBUSY.BODVDDEN are zero). Any writes to the enable-protected register when ENABLE bit is one will be discarded and an APB error will be generated.

Before the BOD (BODVDD) is enabled, it must be configured, as outlined by the following steps:

- Set the BOD level
- Set the configuration in active, standby modes
- Set the prescaling value if the BOD will run in sampling mode
- Set the action and hysteresis

### 22.6.3.2 Enabling, Disabling and Resetting

After power or user reset, the BODVDD register value is loaded from the Flash User Row. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

The BOD (BODVDD) is enabled by writing a one to the ENABLE bit in the BOD control register (BODVDD). The BOD (BODVDD) is disabled by writing a zero to the ENABLE bit in the BOD control register (BODVDD).

### 22.6.3.3 VDD Brown-Out Detector (BODVDD)

The VDD Brown-Out Detector (BODVDD) monitors the VDD supply and compares the voltage with the brown-out threshold level set in the BODVDD Level field (BODVDD.LEVEL) in the BODVDD register. The BODVDD can generate either an interrupt or a reset when VDD crosses below the brown-out threshold level. The BODVDD detection status can be read from the BODVDD Detection bit (STATUS.BODVDDDET) in the STATUS register.

At startup or at power-on reset (POR), the BODVDD register values are loaded from the Flash User Row. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

### 22.6.3.4 Continuous Mode

In active mode, when the BODVDD Configuration bit (BODVDD.ACTCFG) in the BODVDD register is written to zero and the BODVDD is enabled (BODVDD.ENABLE is written to one), the BODVDD operates in continuous mode. In this configuration, the BODVDD is continuously monitoring the VDD supply voltage.

Continuous mode is the default mode.

### 22.6.3.5 Sampling Mode

The sampling mode is a low-power mode where the BODVDD is being repeatedly enabled on a sampling clock's ticks. The BODVDD will monitor the supply voltage for a short period of time and then go to a low-power disabled state until the next sampling clock tick.

Sampling mode is enabled by writing one to BODVDD.ACTCFG . The frequency of the clock ticks ( $F_{\text{clksampling}}$ ) is controlled by the BODVDD Prescaler Select bit group (BODVDD.PSEL) in the BODVDD register.

$$F_{\text{clksampling}} = \frac{F_{\text{clkprescaler}}}{2^{(\text{PSEL} + 1)}}$$

The prescaler signal ( $F_{\text{clkprescaler}}$ ) is a 1kHz clock, output from the 32kHz Ultra Low Power Oscillator, OSCULP32K.

As the sampling mode clock is different from the APB clock domain, synchronization among the clocks is necessary. Enable-protected mechanism allows to handle this synchronization. The BODVDD Synchronization Ready bit (STATUS.BVDDSRDY in the STATUS register) show the synchronization ready status.

### 22.6.3.6 Hysteresis

The hysteresis functionality can be used in both continuous and sampling mode. Writing a one to the BODVDD Hysteresis bit (BODVDD.HYST) in the BODVDD register will add hysteresis to the BODVDD threshold level.

### 22.6.3.7 Standby Mode Operation

The BODVDD can be used in standby mode if the BOD is enabled and the Run in Standby bit is written to one (BODVDD.RUNSTDBY). The BOD configuration in standby sleep mode bit (STDBYCFG) in the BODVDD register set the configuration of the BOD in standby mode. This configuration can be either continuous or sampling mode.

## 22.6.4 Interrupts

The SUPC has the following interrupt sources:

- BODVDD Ready
- BODVDD Detection
- BODVDD Synchronization Ready

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the SUPC is reset. See the INTFLAG register for details on how to clear interrupt flags. The SUPC has one common interrupt request line for all the interrupt sources. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to the [“Nested Vector Interrupt Controller” on page 27](#) chapter for details

## 22.6.5 Synchronization

The prescaler counter used to trigger one-shot brown-out detections operates asynchronously from the peripheral bus. As a consequence, the BODVDD ENABLE bit need synchronization when written. The other fields of the BODVDD register is enabled-protected.

The write-synchronization of the ENABLE bit is triggered by writing a one to the ENABLE bit of the BODVDD control register. The Synchronization Ready bit (STATUS.BVDDSRDY) in the STATUS register will be cleared when the write-synchronization starts and set when the write-synchronization is complete. When the write-synchronization is ongoing (STATUS.BVDDSRDY is zero), writing to the same register will generate an error without stalling the APB bus.

## 22.7 Register Summary

| Offset      | Name     | Bit Pos. |           |          |            |             |          |          |           |           |

## 22.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 230](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 233](#) for details.

## 22.8.1 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x00

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |    |    |          |           |           |

| Reset  | 0  | 0  | 0  | 0  | 0  | 0        | 0         | 0         |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – BVDDSRDY: BODVDD Synchronization Ready Interrupt Enable**

0: The BODVDD Synchronization Ready interrupt is disabled.

1: The BODVDD Synchronization Ready interrupt is enabled, and an interrupt request will be generated when the BODVDD Synchronization Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the BODVDD Synchronization Ready Interrupt Enable bit, which disables the BODVDD Synchronization Ready interrupt.

- **Bit 1 – BODVDDDET: BODVDD Detection Interrupt Enable**

0: The BODVDD Detection interrupt is disabled.

1: The BODVDD Detection interrupt is enabled, and an interrupt request will be generated when the BODVDD Detection Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the BODVDD Detection Interrupt Enable bit, which disables the BODVDD Detection interrupt.

- **Bit 0 – BODVDDRDY: BODVDD Ready Interrupt Enable**

0: The BODVDD Ready interrupt is disabled.

1: The BODVDD Ready interrupt is enabled, and an interrupt request will be generated when the BODVDD Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the BODVDD Ready Interrupt Enable bit, which disables the BODVDD Ready interrupt.

## 22.8.2 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected

| Access | R  | R  | R  | R  | R  | R/W      | R/W       | R/W       |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0        | 0         | 0         |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – BVDDSRDY: BODVDD Synchronization Ready Interrupt Enable**

0: The BODVDD Synchronization Ready interrupt is disabled.

1: The BODVDD Synchronization Ready interrupt is enabled, and an interrupt request will be generated when the BODVDD Synchronization Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the BODVDD Synchronization Ready Interrupt Enable bit, which enables the BODVDD Synchronization Ready interrupt.

- **Bit 1 – BODVDDDET: BODVDD Detection Interrupt Enable**

0: The BODVDD Detection interrupt is disabled.

1: The BODVDD Detection interrupt is enabled, and an interrupt request will be generated when the BODVDD Detection Interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the BODVDD Detection Interrupt Enable bit, which enables the BODVDD Detection interrupt.

- **Bit 0 – BODVDDRDY: BODVDD Ready Interrupt Enable**

0: The BODVDD Ready interrupt is disabled.

1: The BODVDD Ready interrupt is enabled, and an interrupt request will be generated when the BODVDD Ready Interrupt flag is set.

Writing a zero to this bit has no effect.

- Writing a one to this bit will set the BODVDD Ready Interrupt Enable bit, which enables the BODVDD Ready interrupt.

### 22.8.3 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x08  
**Reset:** 0x000001XX  
**Property:** -

| Bit    | 23 | 22 | 21 | 20 | 19 | 18       | 17        | 16        |
|        |    |    |    |    |    |          |           |           |
| Access | R  | R  | R  | R  | R  | R        | R         | R         |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0        | 0         | 0         |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10       | 9         | 8         |
|        |    |    |    |    |    |          |           |           |
| Access | R  | R  | R  | R  | R  | R        | R         | R         |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0        | 0         | 1         |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2        | 1         | 0         |
|        |    |    |    |    |    | BVDDSRDY | BODVDDDET | BODVDDRDY |
| Access | R  | R  | R  | R  | R  | R/W      | R/W       | R/W       |
| Reset  | 0  | 0  | 0  | 0  | X  | 0        | 0         | X         |

- Bits 31:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 2 – BVDDSRDY: BODVDD Synchronization Ready**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the BODVDD Synchronization Ready bit in the Status register (STATUS.BVDDSRDY) and will generate an interrupt request if INTENSET.BVDDSRDY is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the BODVDD Synchronization Ready interrupt flag.
- Bit 1 – BODVDDDET: BODVDD Detection**  
 This flag is cleared by writing a one to it.  
 This flag is set on a zero-to-one transition of the BODVDD Detection bit in the Status register (STATUS.BODVDDDET) and will generate an interrupt request if INTENSET.BODVDDDET is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the BODVDD Detection interrupt flag.

- **Bit 0 – BODVDDRDY: BODVDD Ready**

This flag is cleared by writing a one to it.

This flag is set on a zero-to-one transition of the BODVDD Ready bit in the Status register (STATUS.BODVDDRDY) and will generate an interrupt request if INTENSET.BODVDDRDY is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the BODVDD Ready interrupt flag.

The BODVDD can be enabled at startup from Flash User Row. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

## 22.8.4 Status

- Bits 31:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 2 – BVDDSRDY: BODVDD Synchronization Ready**  
 0: BODVDD synchronization is ongoing.  
 1: BODVDD synchronization is complete.
- Bit 1 – BODVDDDET: BODVDD Detection**  
 0: No BODVDD detection.  
 1: BODVDD has detected that the I/O power supply is going below the BODVDD reference value.
- Bit 0 – BODVDDRDY: BODVDD Ready**  
 0: BODVDD is not ready.  
 1: BODVDD is ready.  
 The BODVDD can be enabled at startup from Flash User Row. Refer to “NVM User Row Mapping” on page 24 for more details.

|        |           | RUNSTDBY | STDBYCFG   | ACTION[1:0] |     | HYST | ENABLE |        |
| Access | R         | R/W      | R/W        | R/W         | R/W | R/W  | R/W    | R      |
| Reset  | 0         | 0        | 0          | X           | X   | 0    | X      | 0      |

- **Bits 31:22 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 21:16 – LEVEL[5:0]: BODVDD Threshold Level on VDD**

This field sets the triggering voltage threshold for the BODVDD when the BODVDD monitors VDD except in backup sleep mode. See the “[Electrical Characteristics](#)” on page 903 chapter for actual voltage levels. Note that any change to the LEVEL field of the BODVDD register should be done when the BODVDD is disabled in order to avoid spurious resets or interrupts.

These bits are loaded from Flash User Row at startup. Refer to “[NVM User Row Mapping](#)” on page 24 for more details.

This field is not synchronized.

- **Bits 15:0 – PSEL[3:0]: Prescaler Select**

Selects the prescaler divide-by output for the BODVDD sampling mode, as given in [Table 22-2](#). The input clock comes from the OSCULP32K 1kHz output.

**Table 22-2. BODVDD Prescaler Select**

| Value | Name     | Description           |
|-------|----------|-----------------------|
| 0x0   | DIV2     | Divide clock by 2     |
| 0x1   | DIV4     | Divide clock by 4     |
| 0x2   | DIV8     | Divide clock by 8     |
| 0x3   | DIV16    | Divide clock by 16    |
| 0x4   | DIV32    | Divide clock by 32    |
| 0x5   | DIV64    | Divide clock by 64    |
| 0x6   | DIV128   | Divide clock by 128   |
| 0x7   | DIV256   | Divide clock by 256   |
| 0x8   | DIV512   | Divide clock by 512   |
| 0x9   | DIV1024  | Divide clock by 1024  |
| 0xA   | DIV2048  | Divide clock by 2048  |
| 0xB   | DIV4096  | Divide clock by 4096  |
| 0xC   | DIV8192  | Divide clock by 8192  |
| 0xD   | DIV16384 | Divide clock by 16384 |
| 0xE   | DIV32768 | Divide clock by 32768 |
| 0xF   | DIV65536 | Divide clock by 65536 |

- Bits 11:9 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 8 – ACTCFG: BODVDD Configuration in Active Sleep Mode**  
 0: In active mode, the BODVDD operates in continuous mode.  
 1: In active mode, the BODVDD operates in sampling mode.  
 This field is not synchronized.
- Bit 7 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 6 – RUNSTDBY: Run in Standby**  
 0: In standby sleep mode, the BODVDD is disabled.  
 1: In standby sleep mode, the BODVDD is enabled.  
 This bit is not synchronized.
- Bit 5 – STDBYCFG: BODVDD Configuration in Standby Sleep Mode**  
 If the RUNSTDBY bit is set to 1, the STDBYCFG bit sets the BODVDD configuration in standby sleep mode.  
 0: In standby sleep mode, the BODVDD is enabled and configured in continuous mode.  
 1: In standby sleep mode, the BODVDD is enabled and configured in sampling mode.  
 This field is not synchronized.

- **Bits 4:3 – ACTION: BODVDD Action**

These bits are used to select the BODVDD action when the supply voltage crosses below the BODVDD threshold, as shown in [Table 22-3](#).

These bits are loaded from Flash User Row at startup. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

This field is not synchronized.

**Table 22-3. BODVDD Action**

| Value | Name  | Description                       |
|-------|-------|-----------------------------------|
| 0x0   | NONE  | No action                         |
| 0x1   | RESET | The BODVDD generates a reset      |
| 0x2   | INT   | The BODVDD generates an interrupt |
| 0x3   | -     | Reserved                          |

- **Bit 2 – HYST: Hysteresis**

This bit indicates whether hysteresis is enabled for the BODVDD threshold voltage:

0: No hysteresis.

1: Hysteresis enabled.

This field is not synchronized.

- **Bit 1 – ENABLE: Enable**

0: BODVDD is disabled.

1: BODVDD is enabled.

This bit is loaded from Flash User Row at startup. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

This bit is not enable-protected.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

## 22.8.6 Voltage Regulator System (VREG) Control

**Name:** VREG

**Offset:** 0x18

**Reset:** 0x0002

**Property:** Write-Protected

|        |    |          |    |    |    |     |        |     |
|--------|----|----------|----|----|----|-----|--------|-----|
| Bit    | 31 | 30       | 29 | 28 | 27 | 26  | 25     | 24  |
|        |    |          |    |    |    |     |        |     |
| Access | R  | R        | R  | R  | R  | R   | R      | R   |
| Reset  | 0  | 0        | 0  | 0  | 0  | 0   | 0      | 0   |
| Bit    | 23 | 22       | 21 | 20 | 19 | 18  | 17     | 16  |
|        |    |          |    |    |    |     |        |     |
| Access | R  | R        | R  | R  | R  | R/W | R/W    | R/W |
| Reset  | 0  | 0        | 0  | 0  | 0  | 0   | 0      | 0   |
| Bit    | 15 | 14       | 13 | 12 | 11 | 10  | 9      | 8   |
|        |    |          |    |    |    |     |        |     |
| Access | R  | R        | R  | R  | R  | R   | R      | R   |
| Reset  | 0  | 0        | 0  | 0  | 0  | 0   | 0      | 0   |
| Bit    | 7  | 6        | 5  | 4  | 3  | 2   | 1      | 0   |
|        |    | RUNSTDBY |    |    |    |     | ENABLE |     |
| Access | R  | R/W      | R  | R  | R  | R   | R/W    | R   |
| Reset  | 0  | 0        | 0  | 0  | 0  | 0   | 1      | 0   |

- Bits 31:7 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 6 – RUNSTDBY: Run in Standby**  
 0: The voltage regulator is in low power mode in Standby sleep mode.  
 1: The voltage regulator is in normal mode in Standby sleep mode.
- Bits 5:2 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 1 – ENABLE: Enable**  
 0: The voltage regulator is disabled.  
 1: The voltage regulator is enabled.
- Bit 0 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

## 22.8.7 Voltage References System (VREF) Control

**Name:** VREF

**Offset:** 0x1C

**Reset:** 0x00000000

**Property:** Write-Protected

|        |          |          |    |    |          |        |     |     |
|--------|----------|----------|----|----|----------|--------|-----|-----|
| Bit    | 31       | 30       | 29 | 28 | 27       | 26     | 25  | 24  |
|        |          |          |    |    |          |        |     |     |
| Access | R        | R        | R  | R  | R        | R      | R   | R   |
| Reset  | 0        | 0        | 0  | 0  | 0        | 0      | 0   | 0   |
| Bit    | 23       | 22       | 21 | 20 | 19       | 18     | 17  | 16  |
|        |          |          |    |    | SEL[3:0] |        |     |     |
| Access | R        | R        | R  | R  | R/W      | R/W    | R/W | R/W |
| Reset  | 0        | 0        | 0  | 0  | 0        | 0      | 0   | 0   |
| Bit    | 15       | 14       | 13 | 12 | 11       | 10     | 9   | 8   |
|        |          |          |    |    |          |        |     |     |
| Access | R        | R        | R  | R  | R        | R      | R   | R   |
| Reset  | 0        | 0        | 0  | 0  | 0        | 0      | 0   | 0   |
| Bit    | 7        | 6        | 5  | 4  | 3        | 2      | 1   | 0   |
|        | ONDEMAND | RUNSTDBY |    |    |          | VREFOE |     |     |
| Access | R/W      | R/W      | R  | R  | R        | R/W    | R   | R   |
| Reset  | 0        | 0        | 0  | 0  | 0        | 0      | 0   | 0   |

- **Bits 31:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 19:16 – SEL: Voltage Reference Selection**

These bits select the Voltage Reference for the ADC and AC, as shown in [Table 22-4](#):

**Table 22-4. Voltage Reference Selection**

| Value  | Name  | Description                            |
|--------|-------|--|
| 0x0    | 1V024 | 1.024V voltage reference typical value |
| 0x2    | 2V048 | 2.048V voltage reference typical value |
| 0x3    | 4V096 | 4.096V voltage reference typical value |
| others |       | Reserved                               |

- **Bits 15:8 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 7 – ONDEMAND: On Demand Control**  
The On Demand operation mode allows the voltage reference to be enabled or disabled, depending on other peripheral requests.  
In On Demand operation mode, i.e. if the VREF.ONDEMAND bit has been previously written to one, the voltage reference will be running only when requested by a peripheral. If there is no peripheral requesting the voltage reference, the voltage reference will be disabled.  
If On Demand is disabled, the voltage reference will always be running when enabled.  
In standby sleep mode, the On Demand operation is still active if the VREF.RUNSTDBY bit is one. If the VREF.RUNSTDBY is zero, the voltage reference is disabled.  
0: The voltage reference is always on, if enabled.  
1: The voltage reference is enabled, when a peripheral is requesting it. The voltage reference is disabled if no peripheral is requesting it.
- **Bit 6 – RUNSTDBY: Run In Standby**  
The bit controls how the voltage reference behaves during standby sleep mode.  
0: The voltage reference is halted during standby sleep mode.  
1: The voltage reference is not stopped in standby sleep mode. If VREF.ONDEMAND is one, the voltage reference will be running when a peripheral is requesting it. If VREF.ONDEMAND is zero, the voltage reference will always be running in standby sleep mode.
- **Bits 5:3 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 2 – VREFOE: Voltage Reference Output Enable**  
0: The Voltage Reference output is not available as an ADC input channel.  
1: The Voltage Reference output is routed to an ADC input channel.
- **Bits 1:0 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

## 23. WDT – Watchdog Timer

### 23.1 Overview

The Watchdog Timer (WDT) is a system function for monitoring correct program operation. It makes it possible to recover from error situations such as runaway or deadlocked code. The WDT is configured to a predefined time-out period, and is constantly running when enabled. If the WDT is not cleared within the time-out period, it will issue a system reset. An early-warning interrupt is available to indicate an upcoming watchdog time-out condition.

The window mode makes it possible to define a time slot (or window) inside the total time-out period during which the WDT must be cleared. If the WDT is cleared outside this window, either too early or too late, a system reset will be issued. Compared to the normal mode, this can also catch situations where a code error causes the WDT to be cleared frequently.

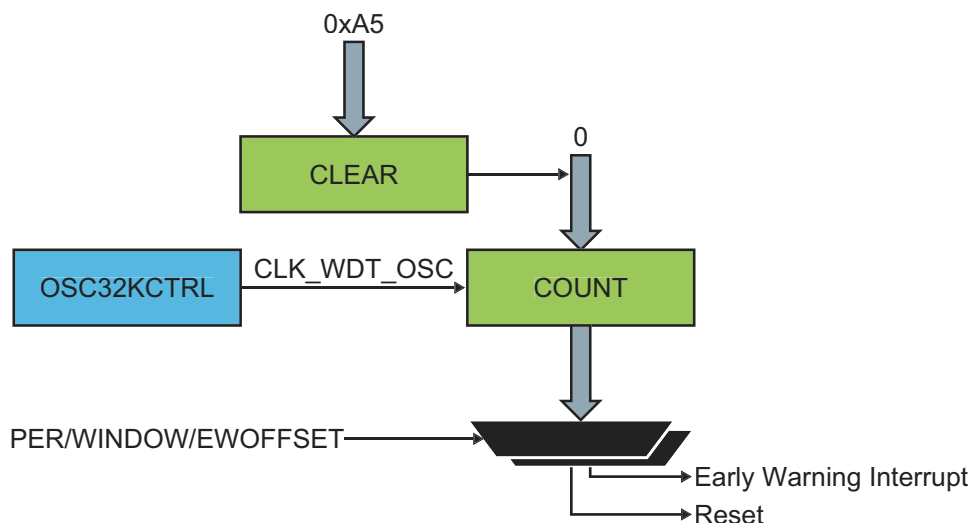

When enabled, the WDT will run in active mode and all sleep modes. It is asynchronous and runs from a CPU-independent clock source. The WDT will continue operation and issue a system reset or interrupt even if the main clocks fail.

### 23.2 Features

- Issues a system reset if the Watchdog Timer is not cleared before its time-out period
- Early Warning interrupt generation
- Asynchronous operation from dedicated oscillator
- Two types of operation:
  - Normal mode
  - Window mode
- Selectable time-out periods, from 8 cycles to 16,384 cycles in normal mode or 16 cycles to 32,768 cycles in window mode
- Always-on capability

### 23.3 Block Diagram

Figure 23-1. WDT Block Diagram

### 23.4 Signal Description

Not applicable.

## 23.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 23.5.1 I/O Lines

Not applicable.

### 23.5.2 Power Management

The WDT can continue to operate in any sleep mode where the selected source clock is running. The WDT interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 23.5.3 Clocks

The WDT bus clock (CLK\_WDT\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_WDT\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

A 1kHz oscillator clock (CLK\_WDT\_OSC) is required to clock the WDT internal counter. This clock must be configured and enabled in the 32kHz Oscillator Controller (OSC32KCTRL) before using the WDT. Refer to [“OSC32KCTRL – 32k Oscillators Controller” on page 201](#) chapter for details.

CLK\_WDT\_OSC is normally sourced from the clock of the internal ultra-low-power (ULPOSC32K) oscillator. Due to the ultra-low-power design, the oscillator is not very accurate, and so the exact time-out period may vary from device to device. This variation must be kept in mind when designing software that uses the WDT to ensure that the time-out periods used are valid for all devices. For more information on ULPOSC32K oscillator accuracy, consult the [“Ultra Low Power Internal 32kHz RC Oscillator \(OSCULP32K\) Characteristics” on page 930](#).

The counter clock (CLK\_WDT\_OSC) is asynchronous to the bus clock (CLK\_WDT\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 254](#) for further details.

### 23.5.4 DMA

Not applicable.

### 23.5.5 Interrupts

The interrupt request line is connected to the interrupt controller. Using the WDT interrupt(s) requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 23.5.6 Events

Not applicable.

### 23.5.7 Debug Operation

When the CPU is halted in debug mode the WDT will halt normal operation.

### 23.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag Status and Clear (INTFLAG) register

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) chapter for details.

## 23.5.9 Analog Connections

Not applicable.

## 23.6 Functional Description

### 23.6.1 Principle of Operation

The Watchdog Timer (WDT) is a system for monitoring correct program operation, making it possible to recover from error situations such as runaway code by issuing a reset. When enabled, the WDT is a constantly running timer that is configured to a predefined time-out period. Before the end of the time-out period, the WDT should be reconfigured.

The WDT has two modes of operation, normal and window. Additionally, the user can enable Early Warning interrupt generation in each of the modes. The description for each of the basic modes is given below. The settings in the Control A register (CTRLA) and the Interrupt Enable register (INTENCLR/SET) determine the mode of operation, as illustrated in [Table 23-1](#).

**Table 23-1. WDT Operating Modes**

| ENABLE | WEN | Interrupt Enable | Mode                                |
|--------|-----|------------------|-------------------------------------|
| 0      | x   | x                | Stopped                             |
| 1      | 0   | 0                | Normal                              |
| 1      | 0   | 1                | Normal with Early Warning interrupt |
| 1      | 1   | 0                | Window                              |
| 1      | 1   | 1                | Window with Early Warning interrupt |

### 23.6.2 Basic Operation

#### 23.6.2.1 Initialization

The following bits are enable-protected, meaning that they can only be written when the WDT is disabled (CTRLA.ENABLE is zero):

- Control A register (CTRLA), except the Enable bit (CTRLA.ENABLE)
- Configuration register (CONFIG)
- Early Warning Interrupt Control register (EWCTRL)

Enable-protected bits in the CTRLA register can be written at the same time as CTRLA.ENABLE is written to one, but not at the same time as CTRLA.ENABLE is written to zero.

Enable-protection is denoted by the Enable-Protected property in the register description.

Configuration of the WDT can be done only while the WDT is disabled. The WDT is configured by defining the required Time-Out Period bits in the Configuration register (CONFIG.PER). If window-mode operation is required, the Window Enable bit in the Control A register (CTRLA.WEN) must be written to one and the Window Period bits in the Configuration register (CONFIG.WINDOW) must be defined.

#### 23.6.2.2 Configurable Reset Values

On a power-on reset, some registers will be loaded with initial values from the NVM User Row. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

This encompasses the following bits and bit groups:

- Enable bit in the Control A register (CTRLA.ENABLE)
- Always-On bit in the Control A register (CTRLA.ALWAYSON)
- Watchdog Timer Windows Mode Enable bit in the Control A register (CTRLA.WEN)

- Watchdog Timer Windows Mode Time-Out Period bits in the Configuration register (CONFIG.WINDOW)
- Time-Out Period in the Configuration register (CONFIG.PER)
- Early Warning Interrupt Time Offset bits in the Early Warning Interrupt Control register (EWCTRL.EWOFFSET)

For more information about fuse locations, see [“NVM User Row Mapping” on page 24](#).

### 23.6.2.3 Enabling, Disabling and Resetting

The WDT is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The WDT is disabled by writing a zero to CTRLA.ENABLE.

The WDT can be disabled only while the Always-On bit in the Control A register (CTRLA.ALWAYSON) is zero.

### 23.6.2.4 Normal Mode

In normal-mode operation, the length of a time-out period is configured in CONFIG.PER. The WDT is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). Once enabled, if the WDT is not cleared from the application code before the time-out occurs, the WDT will issue a system reset. There are 12 possible WDT time-out ( $TO_{WDT}$ ) periods, selectable from 8ms to 16s, and the WDT can be cleared at any time during the time-out period. A new WDT time-out period will be started each time the WDT is cleared by writing 0xA5 to the Clear register (CLEAR). Writing any value other than 0xA5 to CLEAR will issue an immediate system reset.

By default, WDT issues a system reset upon a time-out, and the early warning interrupt is disabled. If an early warning interrupt is required, the Early Warning Interrupt Enable bit in the Interrupt Enable register (INTENSET.EW) must be enabled. Writing a one to the Early Warning Interrupt bit in the Interrupt Enable Set register (INTENSET.EW) enables the interrupt, and writing a one to the Early Warning Interrupt bit in the Interrupt Enable Clear register (INTENCLR.EW) disables the interrupt. If the Early Warning Interrupt is enabled, an interrupt is generated prior to a watchdog time-out condition. In normal mode, the Early Warning Offset bits in the Early Warning Interrupt Control register (EWCTRL.EWOFFSET) define the time where the early warning interrupt occurs. The normal-mode operation is illustrated in [Figure 23-2](#).

**Figure 23-2. Normal-Mode Operation**

### 23.6.2.5 Window Mode

In window-mode operation, the WDT uses two different time-out periods, a closed window time-out period ( $TO_{WDTW}$ ) and the normal, or open, time-out period ( $TO_{WDT}$ ). The closed window time-out period defines a duration from 8ms to 16s where the WDT cannot be reset. If the WDT is cleared during this period, the WDT will issue a system reset. The normal WDT time-out period, which is also from 8ms to 16s, defines the duration of the open period during which the WDT can be cleared. The open period will always follow the closed period, and so the total duration of the time-out period is the sum of the closed window and the open window time-out periods. The closed window is defined by the Window Period bits in the Configuration register (CONFIG.WINDOW), and the open window is defined by the Period bits in the Configuration register (CONFIG.PER).

By default, the WDT issues a system reset upon a time-out and the Early Warning interrupt is disabled. If an Early Warning interrupt is required, INTENCLR/SET.EW must be set. Writing a one to INTENSET.EW enables the interrupt, and writing a one to INTENCLR.EW disables the interrupt. If the Early Warning interrupt is enabled in window mode, the interrupt is generated at the start of the open window period.

The window mode operation is illustrated in [Figure 23-3](#).

**Figure 23-3. Window-Mode Operation**

### 23.6.3 DMA Operation

Not applicable.

### 23.6.4 Interrupts

The WDT has the following interrupt source:

- Early Warning (EW): Indicates that the counter is approaching the time-out condition.

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the WDT is reset. See [INTFLAG](#) for details on how to clear interrupt flags. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 23.6.5 Events

Not applicable.

### 23.6.6 Sleep Mode Operation

The WDT will continue to operate in any sleep mode where the source clock is active except backup mode. The WDT interrupts can be used to wake up the device from a sleep mode. An interrupt request will be generated after the wake-up if the Interrupt Controller is configured accordingly. Otherwise the CPU will wake up directly, without triggering an interrupt. In this case, the CPU will continue executing from the instruction following the entry into sleep.

## 23.6.7 Synchronization

Due to the asynchronicity between CLK\_WDT\_APB and CLK\_WDT\_OSC some registers must be synchronized when accessed. When a write-synchronized register is written, the corresponding bit in the Synchronization Busy register (SYNCBUSY) is set immediately. When the write-synchronization is complete, this bit is cleared. Reading a write-synchronized register while the synchronization is ongoing will return the value written, and not the current value in the peripheral clock domain. To read the current value in the peripheral clock domain after writing a register, the user must wait for the corresponding SYNCBUSY bit to be cleared before reading the value.

If a register is written while the corresponding bit in SYNCBUSY is one, the write is discarded and an error is generated.

The following bits need synchronization when written:

- Enable bit in Control A register (CTRLA.ENABLE)
- Window Enable bit in Control A register (CTRLA.WEN)
- Always-On bit in control Control A (CTRLA.ALWAYSON)

The following registers need synchronization when written:

- Watchdog Clear register (CLEAR)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

## 23.6.8 Additional Features

### 23.6.8.1 Always-On Mode

The always-on mode is enabled by writing a one to the Always-On bit in the Control A register (CTRLA.ALWAYSON). When the always-on mode is enabled, the WDT runs continuously, regardless of the state of CTRLA.ENABLE. Once written, the Always-On bit can only be cleared by a power-on reset. The Configuration (CONFIG) and Early Warning Control (EWCTRL) registers are read-only registers while the CTRLA.ALWAYSON bit is set. Thus, the time period configuration bits (CONFIG.PER, CONFIG.WINDOW, EWCTRL.EWOFFSET) of the WDT cannot be changed.

Enabling or disabling window-mode operation by writing the Window Enable bit (CTRLA.WEN) is allowed while in the always-on mode, but note that CONFIG.PER cannot be changed.

The Interrupt Clear and Interrupt Set registers are accessible in the always-on mode. The Early Warning interrupt can still be enabled or disabled while in the always-on mode, but note that EWCTRL.EWOFFSET cannot be changed.

Table 23-2 shows the operation of the WDT when CTRLA.ALWAYSON is set.

**Table 23-2. WDT Operating Modes With Always-On**

| WEN | Interrupt Enable | Mode   |
|-----|------------------|--|
| 0   | 0                | Always-on and normal mode                              |
| 0   | 1                | Always-on and normal mode with Early Warning interrupt |
| 1   | 0                | Always-on and window mode                              |
| 1   | 1                | Always-on and window mode with Early Warning interrupt |

### 23.6.8.2 Early Warning

The Early Warning interrupt provides notification that the WDT is approaching the time-out condition. The Early Warning interrupt behaves differently in normal mode and in window mode.

In normal mode, the Early Warning interrupt generation is defined by the Early Warning Offset in the Early Warning Control register (EWCTRL.EWOFFSET). The Early Warning Offset bits define the number of CLK\_WDT\_OSC clocks before the interrupt is generated, relative to the start of the watchdog time-out period. For example, if the WDT is operating in normal mode with CONFIG.PER = 0x2 and EWCTRL.EWOFFSET = 0x1, the Early Warning interrupt is generated 16 CLK\_WDT\_OSC clock cycles from the start of the watchdog time-out period, and the watchdog time-out system reset is generated 32 CLK\_WDT\_OSC clock cycles from the start of the watchdog time-out period. The user

must take caution when programming the Early Warning Offset bits. If these bits define an Early Warning interrupt generation time greater than the watchdog time-out period, the watchdog time-out system reset is generated prior to the Early Warning interrupt. Thus, the Early Warning interrupt will never be generated.

In window mode, the Early Warning interrupt is generated at the start of the open window period. In a typical application where the system is in sleep mode, it can use this interrupt to wake up and clear the Watchdog Timer, after which the system can perform other tasks or return to sleep mode.

## 23.7 Register Summary

**Table 23-3. Register Summary**

| Offset | Name     | Bit Pos. |             |  |  |       |               |     |        |    |
|--------|----------|----------|-------------|--|--|-------|---------------|-----|--------|----|
| 0x00   | CTRLA    | 7:0      | ALWAYSON    |  |  |       |               | WEN | ENABLE |    |
| 0x01   | CONFIG   | 7:0      | WINDOW[3:0] |  |  |       | PER[3:0]      |     |        |    |
| 0x02   | EWCTRL   | 7:0      |             |  |  |       | EWOFFSET[3:0] |     |        |    |
| 0x03   | Reserved |          |             |  |  |       |               |     |        |    |
| 0x04   | INTENCLR | 7:0      |             |  |  |       |               |     |        | EW |
| 0x05   | INTENSET | 7:0      |             |  |  |       |               |     |        | EW |
| 0x06   | INTFLAG  | 7:0      |             |  |  |       |               |     |        | EW |
| 0x07   | Reserved |          |             |  |  |       |               |     |        |    |
| 0x08   | SYNCBUSY | 7:0      |             |  |  | CLEAR | ALWAYSON      | WEN | ENABLE |    |
| 0x09   |          | 15:8     |             |  |  |       |               |     |        |    |
| 0x0A   |          | 23:16    |             |  |  |       |               |     |        |    |
| 0x0B   |          | 31:24    |             |  |  |       |               |     |        |    |
| 0x0C   | CLEAR    | 7:0      | CLEAR[7:0]  |  |  |       |               |     |        |    |

## 23.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 250](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 254](#) for details.

Some registers are enable-protected, meaning they can only be written when the WDT is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 23.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** Loaded from NVM User Row startup

**Property:** -

| Bit    | 7        | 6 | 5 | 4 | 3 | 2   | 1      | 0 |
|--------|----------|---|---|---|---|-----|--------|---|
|        | ALWAYSON |   |   |   |   | WEN | ENABLE |   |
| Access | R/W      | R | R | R | R | R/W | R/W    | R |
| Reset  | -        | 0 | 0 | 0 | 0 | -   | -      | 0 |

- **Bit 7 - ALWAYSON: Always-On**

This bit allows the WDT to run continuously. After being written to one, this bit cannot be written to zero, and the WDT will remain enabled until a power-on reset is received. When this bit is one, the Control A register (CTRLA), the Configuration register (CONFIG) and the Early Warning Control register (EWCTRL) will be read-only, and any writes to these registers are not allowed. Writing a zero to this bit has no effect.

0: The WDT is enabled and disabled through the ENABLE bit.

1: The WDT is enabled and can only be disabled by a power-on reset (POR).

This bit is not enable-protected.

These bits are loaded from NVM User Row at startup. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

- **Bits 6:3 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 - WEN: Watchdog Timer Window Mode Enable**

This bit enables window mode. This bit can only be written when CTRLA.ENABLE is zero or CTRLA.ALWAYSON is one:

- When CTRLA.ALWAYSON=0, this bit is enable-protected by CTRLA.ENABLE.
- When CTRLA.ALWAYSON=1, this bit is not enable-protected by CTRLA.ENABLE.

The initial value of this bit is loaded from Flash Calibration.

0: Window mode is disabled (normal operation).

1: Window mode is enabled.

This bit is loaded from NVM User Row at startup. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

- **Bit 1 - ENABLE: Enable**

This bit enables or disables the WDT. Can only be written while CTRLA.ALWAYSON is zero.

0: The WDT is disabled.

1: The WDT is enabled.

Due to synchronization, there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately, and the Enable bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

This bit is not enable-protected.

This bit is loaded from NVM User Row at startup. Refer to [“NVM User Row Mapping” on page 24](#) for more details.

- **Bit 0 - Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

## 23.8.2 Configuration

**Name:** CONFIG

**Offset:** 0x01

**Reset:** Loaded from NVM User Row startup

**Property:** Write-Protected, Enable-Protected

|        |             |     |     |     |          |     |     |     |
|--------|-------------|-----|-----|-----|----------|-----|-----|-----|
| Bit    | 7           | 6   | 5   | 4   | 3        | 2   | 1   | 0   |
|        | WINDOW[3:0] |     |     |     | PER[3:0] |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W      | R/W | R/W | R/W |
| Reset  | -           | -   | -   | -   | -        | -   | -   | -   |

- Bits 7:4 - WINDOW[3:0]: Window Mode Time-Out Period**

In window mode, these bits determine the watchdog closed window period as a number of oscillator cycles. The closed window periods are defined in [Table 23-4](#).

These bits are loaded from NVM User Row at startup. Refer to “[NVM User Row Mapping](#)” on page 24 for more details.

**Table 23-4. Window Mode Time-Out Period**

| Value     | Name     | Description        |
|-----------|----------|--------------------|
| 0x0       | CYC8     | 8 clock cycles     |
| 0x1       | CYC16    | 16 clock cycles    |
| 0x2       | CYC32    | 32 clock cycles    |
| 0x3       | CYC64    | 64 clock cycles    |
| 0x4       | CYC128   | 128 clock cycles   |
| 0x5       | CYC256   | 256 clock cycles   |
| 0x6       | CYC512   | 512 clock cycles   |
| 0x7       | CYC1024  | 1024 clock cycles  |
| 0x8       | CYC2048  | 2048 clock cycles  |
| 0x9       | CYC4096  | 4096 clock cycles  |
| 0xA       | CYC8192  | 8192 clock cycles  |
| 0xB       | CYC16384 | 16384 clock cycles |
| 0xC - 0xF | -        | Reserved           |

- Bits 3:0 - PER[3:0]: Time-Out Period**

These bits determine the watchdog time-out period as a number of GCLK\_WDT clock cycles. In window mode operation, these bits define the open window period. The different typical time-out periods are found in [Table 23-5](#).

These bits are loaded from NVM User Row at startup. Refer to “[NVM User Row Mapping](#)” on page 24 for more details.

**Table 23-5. Time-Out Period**

| Value     | Name     | Description        |
|-----------|----------|--------------------|
| 0x0       | CYC8     | 8 clock cycles     |
| 0x1       | CYC16    | 16 clock cycles    |
| 0x2       | CYC32    | 32 clock cycles    |
| 0x3       | CYC64    | 64 clock cycles    |
| 0x4       | CYC128   | 128 clock cycles   |
| 0x5       | CYC256   | 256 clock cycles   |
| 0x6       | CYC512   | 512 clock cycles   |
| 0x7       | CYC1024  | 1024 clock cycles  |
| 0x8       | CYC2048  | 2048 clock cycles  |
| 0x9       | CYC4096  | 4096 clock cycles  |
| 0xA       | CYC8192  | 8192 clock cycles  |
| 0xB       | CYC16384 | 16384 clock cycles |
| 0xC - 0xF | -        | Reserved           |

### 23.8.3 Early Warning Control

**Name:** EWCTRL

**Offset:** 0x02

**Reset:** Loaded from NVM User Row startup

**Property:** Write-Protected, Enable-Protected

|        |   |   |   |   |          |     |     |     |
|--------|---|---|---|---|----------|-----|-----|-----|
| Bit    | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|        |   |   |   |   | PER[3:0] |     |     |     |
| Access | R | R | R | R | R/W      | R/W | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | -        | -   | -   | -   |

- **Bits 7:4 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 3:0 - EWOFFSET[3:0]: Early Warning Interrupt Time Offset**

These bits determine the number of GCLK\_WDT clocks in the offset from the start of the watchdog time-out period to when the Early Warning interrupt is generated. The Early Warning Offset is defined in [Table 23-6](#). These bits are loaded from NVM User Row at startup. Refer to “[NVM User Row Mapping](#)” on [page 24](#) for more details.

**Table 23-6. Early Warning Interrupt Time Offset**

| Value     | Name     | Description        |
|-----------|----------|--------------------|
| 0x0       | CYC8     | 8 clock cycles     |
| 0x1       | CYC16    | 16 clock cycles    |
| 0x2       | CYC32    | 32 clock cycles    |
| 0x3       | CYC64    | 64 clock cycles    |
| 0x4       | CYC128   | 128 clock cycles   |
| 0x5       | CYC256   | 256 clock cycles   |
| 0x6       | CYC512   | 512 clock cycles   |
| 0x7       | CYC1024  | 1024 clock cycles  |
| 0x8       | CYC2048  | 2048 clock cycles  |
| 0x9       | CYC4096  | 4096 clock cycles  |
| 0xA       | CYC8192  | 8192 clock cycles  |
| 0xB       | CYC16384 | 16384 clock cycles |
| 0xC - 0xF | -        | Reserved           |

23.8.4 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set (INTENSET) register.

**Name:** INTENCLR  
**Offset:** 0x04  
**Reset:** 0x00  
**Property:** Write-Protected

|        |   |   |   |   |   |   |   |     |
|--------|---|---|---|---|---|---|---|-----|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
|        |   |   |   |   |   |   |   | EW  |
| Access | R | R | R | R | R | R | R | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   |

- Bits 7:1 - Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 - EW: Early Warning Interrupt Enable**  
0: The Early Warning interrupt is disabled.  
1: The Early Warning interrupt is enabled.  
Writing a zero to this bit has no effect.  
Writing a one to this bit clears the Early Warning Interrupt Enable bit, which disables the Early Warning interrupt.

23.8.5 Interrupt Enable Set

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear (INTENCLR) register.

**Name:** INTENSET  
**Offset:** 0x05  
**Reset:** 0x00  
**Property:** Write-Protected

|        |   |   |   |   |   |   |   |     |
|--------|---|---|---|---|---|---|---|-----|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
|        |   |   |   |   |   |   |   | EW  |
| Access | R | R | R | R | R | R | R | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   |

- Bits 7:1 - Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 - EW: Early Warning Interrupt Enable**  
0: The Early Warning interrupt is disabled.  
1: The Early Warning interrupt is enabled.  
Writing a zero to this bit has no effect.  
Writing a one to this bit sets the Early Warning Interrupt Enable bit, which enables the Early Warning interrupt.

23.8.6 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x06  
**Reset:** 0x00  
**Property:** -

|        |   |   |   |   |   |   |   |     |
|--------|---|---|---|---|---|---|---|-----|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
|        |   |   |   |   |   |   |   | EW  |
| Access | R | R | R | R | R | R | R | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   |

- Bits 7:1 - Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 - EW: Early Warning**  
This flag is cleared by writing a one to it.  
This flag is set when an Early Warning interrupt occurs, as defined by the EWOFFSET bit group in ["EWCTRL"](#) .  
Writing a zero to this bit has no effect.  
Writing a one to this bit clears the Early Warning interrupt flag.

### 23.8.7 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x08

**Reset:** 0x00000000

**Property:** -

|        |    |    |    |       |          |     |        |    |
|--------|----|----|----|-------|----------|-----|--------|----|
| Bit    | 31 | 30 | 29 | 28    | 27       | 26  | 25     | 24 |
|        |    |    |    |       |          |     |        |    |
| Access | R  | R  | R  | R     | R        | R   | R      | R  |
| Reset  | 0  | 0  | 0  | 0     | 0        | 0   | 0      | 0  |
| Bit    | 23 | 22 | 21 | 20    | 19       | 18  | 17     | 16 |
|        |    |    |    |       |          |     |        |    |
| Access | R  | R  | R  | R     | R        | R   | R      | R  |
| Reset  | 0  | 0  | 0  | 0     | 0        | 0   | 0      | 0  |
| Bit    | 15 | 14 | 13 | 12    | 11       | 10  | 9      | 8  |
|        |    |    |    |       |          |     |        |    |
| Access | R  | R  | R  | R     | R        | R   | R      | R  |
| Reset  | 0  | 0  | 0  | 0     | 0        | 0   | 0      | 0  |
| Bit    | 7  | 6  | 5  | 4     | 3        | 2   | 1      | 0  |
|        |    |    |    | CLEAR | ALWAYSON | WEN | ENABLE |    |
| Access | R  | R  | R  | R/W   | R/W      | R/W | R/W    | R  |
| Reset  | 0  | 0  | 0  | 0     | 0        | 0   | 0      | 0  |

- **Bits 31:5 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 - CLEAR: Clear Synchronization Busy**

0: Write synchronization of the CLEAR register is complete.

1: Write synchronization of the CLEAR register is ongoing.

- **Bit 3 - ALWAYSON: Always-On Synchronization Busy**

0: Write synchronization of the CTRLA.ALWAYSON bit is complete.

1: Write synchronization of the CTRLA.ALWAYSON bit is ongoing.

- **Bit 2 - WEN: Window Enable Synchronization Busy**

0: Write synchronization of the CTRLA.WEN bit is complete.

1: Write synchronization of the CTRLA.WEN bit is ongoing.

- **Bit 1 - ENABLE: Enable Synchronization Busy**

0: Write synchronization of the CTRLA.ENABLE bit is complete.

1: Write synchronization of the CTRLA.ENABLE bit is ongoing.

- **Bit 0 - Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

23.8.8 Clear

**Name:** CLEAR  
**Offset:** 0x0C  
**Reset:** 0x00  
**Property:** Write-Synchronized

|        |            |     |     |     |     |     |     |     |
|--------|------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 7          | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | CLEAR[7:0] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- Bits 7:0 - CLEAR: Watchdog Clear**  
Writing 0xA5 to this register will clear the Watchdog Timer and the watchdog time-out period is restarted. Writing any other value will issue an immediate system reset.

## 24. RTC – Real-Time Counter

### 24.1 Overview

The Real-Time Counter (RTC) is a 32-bit counter with a 10-bit programmable prescaler that typically runs continuously to keep track of time. The RTC can wake up the device from sleep modes using the alarm/compare wake up, periodic wake up or overflow wake up mechanisms.

The RTC can generate periodic peripheral events from outputs of the prescaler, as well as alarm/compare interrupts and peripheral events, which can trigger at any counter value. Additionally, the timer can trigger an overflow interrupt and peripheral event, and be reset on the occurrence of an alarm/compare match. This allows periodic interrupts and peripheral events at very long and accurate intervals.

The 10-bit programmable prescaler can scale down the clock source, and so a wide range of resolutions and time-out periods can be configured. With a 32.768kHz clock source, the minimum counter tick interval is 30.5μs, and time-out periods can range up to 36 hours. With the counter tick interval configured to 1s, the maximum time-out period is more than 136 years.

### 24.2 Features

- 32-bit counter with 10-bit prescaler
- Multiple clock sources
- 32-bit or 16-bit Counter mode
  - One 32-bit or two 16-bit compare values
- Clock/Calendar mode
  - Time in seconds, minutes and hours (12/24)
  - Date in day of month, month and year
  - Leap year correction
- Digital prescaler correction/tuning for increased accuracy
- Overflow, alarm/compare match and prescaler interrupts and events
  - Optional clear on alarm/compare match

### 24.3 Block Diagram

Figure 24-1. RTC Block Diagram (Mode 0 - 32-Bit Counter)

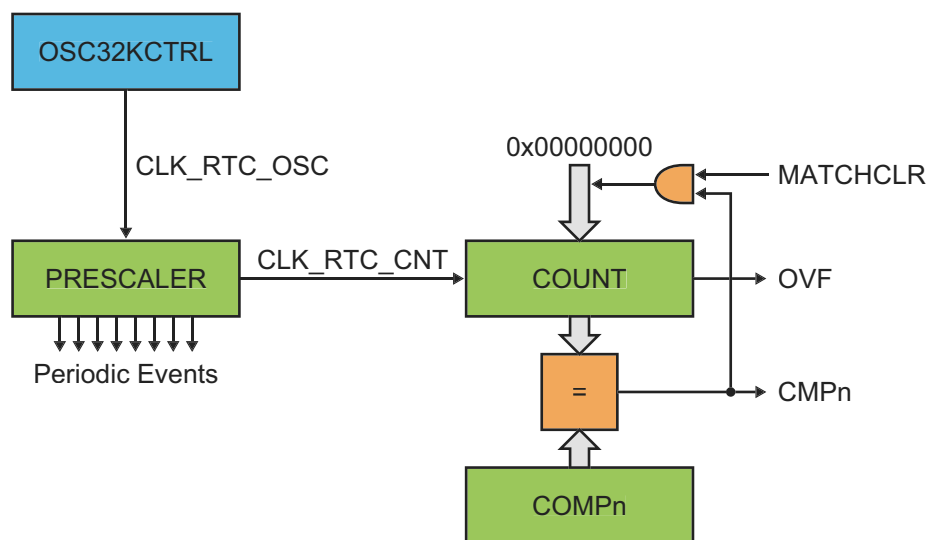

Figure 24-2. RTC Block Diagram (Mode 1 - 16-Bit Counter)

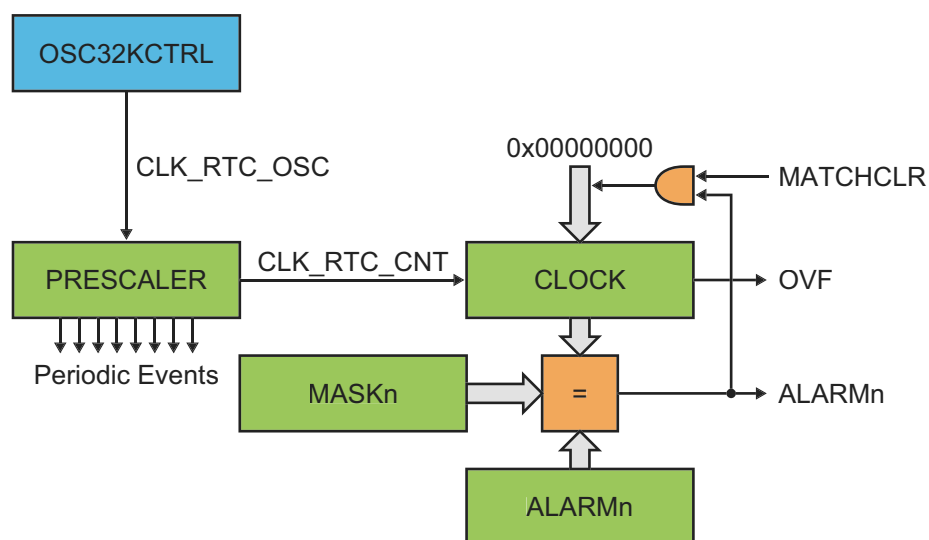

Figure 24-3. RTC Block Diagram (Mode 2 - Clock/Calendar)

## 24.4 Signal Description

Not applicable.

## 24.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 24.5.1 I/O Lines

Not applicable.

## 24.5.2 Power Management

The RTC can continue to operate in any sleep mode. The RTC interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

The RTC will continue to operate in any sleep mode where the selected source clock is running. The RTC’s interrupts can be used to wake up the device from sleep modes. Events connected to the event system can trigger other operations in the system without exiting sleep modes. Refer to the Power Manager chapter for details on the different sleep modes.

The RTC will be reset only at power-on (POR) or by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST).

## 24.5.3 Clocks

The RTC bus clock (CLK\_RTC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_RTC\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

A 32kHz or 1kHz oscillator clock (CLK\_RTC\_OSC) is required to clock the RTC. This clock must be configured and enabled in the 32kHz oscillator controller (OSC32CTRL) before using the RTC. Refer to the 32kHz Oscillator Controller chapter for details.

This oscillator clock is asynchronous to the bus clock (CLK\_RTC\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 274](#) for further details.

## 24.5.4 DMA

Not applicable.

## 24.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the RTC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

## 24.5.6 Events

The events are connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

## 24.5.7 Debug Operation

When the CPU is halted in debug mode the RTC will halt normal operation. The RTC can be forced to continue operation during debugging. Refer to [DBGCTRL](#) for details.

## 24.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag Status and Clear (INTFLAG) register

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

## 24.5.9 Analog Connections

A 32.768kHz crystal can be connected to the XIN32 and XOUT32 pins, along with any required load capacitors. For details on recommended crystal characteristics and load capacitors, refer to [“Electrical Characteristics” on page 903](#) for details.

## 24.6 Functional Description

### 24.6.1 Principle of Operation

The RTC keeps track of time in the system and enables periodic events, as well as interrupts and events at a specified time. The RTC consists of a 10-bit prescaler that feeds a 32-bit counter. The actual format of the 32-bit counter depends on the RTC operating mode.

### 24.6.2 Basic Operation

#### 24.6.2.1 Initialization

The following bits are enable-protected, meaning that they can only be written when the RTC is disabled (CTRLA.ENABLE is zero):

- Operating Mode bits in the Control A register (CTRLA.MODE)
- Prescaler bits in the Control A register (CTRLA.PRESCALER)
- Clear on Match bit in the Control A register (CTRLA.MATCHCLR)
- Clock Representation bit in the Control A register (CTRLA.CLKREP)

The following register is enable-protected:

- Event Control register (EVCTRL)

Enable-protected bits in the CTRLA register can be written at the same time as CTRLA.ENABLE is written to one, but not at the same time as CTRLA.ENABLE is written to zero.

Enable-protection is denoted by the Enable-Protected property in the register description.

The RTC prescaler divides down the source clock for the RTC counter. The frequency of the RTC clock (CLK\_RTC\_CNT) is given by the following formula:

$$f_{\text{CLK\_RTC\_CNT}} = \frac{f_{\text{CLK\_RTC\_OSC}}}{2^{\text{PRESCALER}}}$$

The frequency of the oscillator clock, CLK\_RTC\_OSC, is given by  $f_{\text{CLK\_RTC\_OSC}}$ , and  $f_{\text{CLK\_RTC\_CNT}}$  is the frequency of the internal prescaled RTC clock, CLK\_RTC\_CNT.

Note that in the Clock/Calendar mode, the prescaler must be configured to provide a 1Hz clock to the counter for correct operation.

#### 24.6.2.2 Enabling, Disabling and Resetting

The RTC is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The RTC is disabled by writing a zero to CTRLA.ENABLE.

The RTC is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the RTC, except DEBUG, will be reset to their initial state, and the RTC will be disabled. Refer to [CTRLA](#) for details. The RTC must be disabled before resetting it.

#### 24.6.2.3 32-Bit Counter (Mode 0)

When the RTC Operating Mode bits in the Control A register (CTRLA.MODE) are zero, the counter operates in 32-bit Counter mode. The block diagram of this mode is shown in [Figure 24-1](#). When the RTC is enabled, the counter will increment on every 0-to-1 transition of CLK\_RTC\_CNT. The counter will increment until it reaches the top value of

0xFFFFFFFF, and then wrap to 0x00000000. This sets the Overflow Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.OVF).

The RTC counter value can be read from or written to the Counter Value register (COUNT) in 32-bit format.

The counter value is continuously compared with the 32-bit Compare register (COMP0). When a compare match occurs, the Compare 0 Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.CMP0) is set on the next 0-to-1 transition of CLK\_RTC\_CNT.

If the Clear on Match bit in the Control A register (CTRLA.MATCHCLR) is one, the counter is cleared on the next counter cycle when a compare match with COMP0 occurs. This allows the RTC to generate periodic interrupts or events with longer periods than are possible with the prescaler events. Note that when CTRLA.MATCHCLR is one, INTFLAG.CMP0 and INTFLAG.OVF will both be set simultaneously on a compare match with COMP0.

#### 24.6.2.4 16-Bit Counter (Mode 1)

When CTRLA.MODE is one, the counter operates in 16-bit Counter mode as shown in Figure 24-2. When the RTC is enabled, the counter will increment on every 0-to-1 transition of CLK\_RTC\_CNT. In 16-bit Counter mode, the 16-bit Period register (PER) holds the maximum value of the counter. The counter will increment until it reaches the PER value, and then wrap to 0x0000. This sets the Overflow Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.OVF).

The RTC counter value can be read from or written to the Counter Value register (COUNT) in 16-bit format.

The counter value is continuously compared with the 16-bit Compare registers (COMPn, n=0-1). When a compare match occurs, the Compare n Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.CMPn, n=0-1) is set on the next 0-to-1 transition of CLK\_RTC\_CNT.

#### 24.6.2.5 Clock/Calendar (Mode 2)

When CTRLA.MODE is two, the counter operates in Clock/Calendar mode, as shown in Figure 24-3. When the RTC is enabled, the counter will increment on every 0-to-1 transition of CLK\_RTC\_CNT. The selected clock source and RTC prescaler must be configured to provide a 1Hz clock to the counter for correct operation in this mode.

The time and date can be read from or written to the Clock Value register (CLOCK) in a 32-bit time/date format. Time is represented as:

- Seconds
- Minutes
- Hours

Hours can be represented in either 12- or 24-hour format, selected by the Clock Representation bit in the Control A register (CTRLA.CLKREP). This bit can be changed only while the RTC is disabled.

Date is represented as:

- Day as the numeric day of the month (starting at 1)
- Month as the numeric month of the year (1 = January, 2 = February, etc.)
- Year as a value counting the offset from a reference value that must be defined in software

The date is automatically adjusted for leap years, assuming every year divisible by 4 is a leap year. Therefore, the reference value must be a leap year, e.g. 2000. The RTC will increment until it reaches the top value of 23:59:59 December 31 of year 63, and then wrap to 00:00:00 January 1 of year 0. This will set the Overflow Interrupt flag in the Interrupt Flag Status and Clear registers (INTFLAG.OVF).

The clock value is continuously compared with the 32-bit Alarm register (ALARM0). When an alarm match occurs, the Alarm 0 Interrupt flag in the Interrupt Flag Status and Clear registers (INTFLAG.ALARM0) is set on the next 0-to-1 transition of CLK\_RTC\_CNT.

A valid alarm match depends on the setting of the Alarm Mask Selection bits in the Alarm 0 Mask register (MASK0.SEL). These bits determine which time/date fields of the clock and alarm values are valid for comparison and which are ignored.

If the Clear on Match bit in the Control A register (CTRLA.MATCHCLR) is one, the counter is cleared on the next counter cycle when an alarm match with ALARM0 occurs. This allows the RTC to generate periodic interrupts or events with longer periods than are possible with the prescaler events (see [Periodic Intervals on page 274](#)). Note that when CTRLA.MATCHCLR is one, INTFLAG.ALARM0 and INTFLAG.OVF will both be set simultaneously on an alarm match with ALARM0.

### 24.6.3 DMA Operation

Not applicable.

### 24.6.4 Interrupts

The RTC has the following interrupt sources:

- Overflow (OVF): Indicates that the counter has reached its top value and wraps to zero.
- Compare (CMP): Indicates a match between the counter value and the compare register.
- Alarm (ALARM): Indicates a match between the clock value and the alarm register.
- Period n (PERn): The corresponding bit in the prescaler has toggled. Refer to [Periodic Intervals on page 274](#) for details.

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the RTC is reset. See [INTFLAG](#) for details on how to clear interrupt flags. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 for details.

### 24.6.5 Events

The RTC can generate the following output events:

- Overflow (OVF): Generated when the counter reaches its top value and wraps to zero.
- Compare (CMPn): Indicates a match between the counter value and the compare register.
- Alarm (ALARM0): Indicates a match between the clock value and the alarm register.
- Period n (PERn): The corresponding bit in the prescaler has toggled. Refer to [Periodic Intervals on page 274](#) for details.

Writing a one to an Event Output bit in the Event Control Register (EVCTRL.xxEO) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to the Event System chapter for details on configuring the event system.

### 24.6.6 Sleep Mode Operation

The RTC will continue to operate in any sleep mode where the source clock is active. The RTC interrupts can be used to wake up the device from a sleep mode, or the RTC events can trigger other operations in the system without exiting the sleep mode.

An interrupt request will be generated after the wake-up if the Interrupt Controller is configured accordingly. Otherwise the CPU will wake up directly, without triggering an interrupt. In this case, the CPU will continue executing from the instruction following the entry into sleep.

The periodic events can also wake up the CPU through the interrupt function of the Event System. In this case, the event must be enabled and connected to an event channel with its interrupt enabled. See “EVSYS – Event System” on page 467 for more information.

## 24.6.7 Synchronization

Due to the asynchronicity between CLK\_RTC\_APB and CLK\_RTC\_OSC some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding status bit in the Synchronization Busy register (SYNCBUSY.X) will be set immediately, and cleared when synchronization is complete.

If an operation that requires synchronization is executed while SYNCBUSY.X is one, the operation is discarded and an error is generated. The following bits need synchronization when written:

- Software Reset bit in Control A register (CTRLA.SWRST)
- Enable bit in Control A register (CTRLA.ENABLE)
- Count/Clock Read Sync bit in Control A register (CTRLA.COUNTSYNC/CTRLA.CLOCKSYNC)

The following registers need synchronization when written:

- The Counter Value register (COUNT)
- The Clock Value register (CLOCK)
- The Counter Period register (PER)
- The Compare n Value registers (COMPn)
- The Alarm 0 Value registers (ALARM0)
- The Frequency Correction register (FREQCORR)
- The Alarm 0 Mask register (MASK0)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

The following registers need synchronization when read:

- The Counter Value register (COUNT)
- The Clock Value register (CLOCK)

Read-synchronization is denoted by the Read-Synchronized property in the register description.

## 24.6.8 Additional Features

### 24.6.8.1 Periodic Intervals

The RTC prescaler can generate interrupts and events at periodic intervals, allowing flexible system tick creation. Any of the upper eight bits of the prescaler (bits 2 to 9) can be the source of an interrupt/event. When one of the Periodic Event Output bits in the Event Control register (EVCTRL.PERnEO) is one, an event is generated on the 0-to-1 transition of the related bit in the prescaler, resulting in a periodic event frequency of:

$$f_{\text{PERIODIC}(n)} = \frac{f_{\text{CLK\_RTC\_OSC}}}{2^{n+3}}$$

$f_{\text{CLK\_RTC\_OSC}}$  is the frequency of the internal prescaler clock, CLK\_RTC\_OSC, and  $n$  is the position of the EVCTRL.PERnEO bit. For example, PER0 will generate an event every 8 CLK\_RTC\_OSC cycles, PER1 every 16 cycles, etc. This is shown in Figure 24-4. Periodic events are independent of the prescaler setting used by the RTC counter, except if CTRLA.PRESCALER is zero. Then, no periodic events will be generated.

**Figure 24-4. Example Periodic Events**

#### 24.6.8.2 Frequency Correction

The RTC Frequency Correction module employs periodic counter corrections to compensate for a too-slow or too-fast oscillator. Frequency correction requires that CTRLA.PRESCALER is greater than 1.

The digital correction circuit adds or subtracts cycles from the RTC prescaler to adjust the frequency in approximately 1PPM steps. Digital correction is achieved by adding or skipping a single count in the prescaler once every 1024 CLK\_RTC\_OSC cycles. The Value bit group in the Frequency Correction register (FREQCORR.VALUE) determines the number of times the adjustment is applied over 976 of these periods. The resulting correction is as follows:

$$\text{Correction in PPM} = \frac{\text{FREQCORR.VALUE}}{1024 \cdot 960} \cdot 10^6 \text{ PPM}$$

This results in a resolution of 1.0172PPM.

The Sign bit in the Frequency Correction register (FREQCORR.SIGN) determines the direction of the correction. A positive value will speed up the frequency, and a negative value will slow down the frequency.

Digital correction also affects the generation of the periodic events from the prescaler. When the correction is applied at the end of the correction cycle period, the interval between the previous periodic event and the next occurrence may also be shortened or lengthened depending on the correction value.

## 24.7 Register Summary

The register mapping depends on the Operating Mode bits in the Control register (CTRLA.MODE). The register summary is presented for each of the three modes.

## 24.7.1 Register Summary - COUNT 32

**Table 24-1. Register Summary - Mode 0 Registers**

| Offset      | Name     | Bit Pos. |              |            |        |        |                |          |        |        |
|-------------|----------|----------|--------------|------------|--------|--------|----------------|----------|--------|--------|
| 0x00        | CTRLA    | 7:0      | MATCHCLR     |            |        |        | MODE[1:0]      |          | ENABLE | SWRST  |

## 24.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 270](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 274](#) for details.

Some registers are enable-protected, meaning they can only be written when the RTC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

## 24.8.1 Register Description - COUNT32

### 24.8.1.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x0000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

|        |           |    |    |    |                |     |        |       |
|--------|-----------|----|----|----|----------------|-----|--------|-------|
| Bit    | 15        | 14 | 13 | 12 | 11             | 10  | 9      | 8     |
|        | COUNTSYNC |    |    |    | PRESCALER[3:0] |     |        |       |
| Access | R/W       | R  | R  | R  | R/W            | R/W | R/W    | R/W   |
| Reset  | 0         | 0  | 0  | 0  | 0              | 0   | 0      | 0     |
| Bit    | 7         | 6  | 5  | 4  | 3              | 2   | 1      | 0     |
|        | MATCHCLR  |    |    |    | MODE[1:0]      |     | ENABLE | SWRST |
| Access | R/W       | R  | R  | R  | R/W            | R/W | R/W    | R/W   |
| Reset  | 0         | 0  | 0  | 0  | 0              | 0   | 0      | 0     |

- **Bit 15 - COUNTSYNC: Count Read Synchronization Enable**

The COUNT register requires synchronization when reading. Disabling the synchronization will prevent reading valid values from the COUNT register.

0: Count read synchronization is disabled.

1: Count read synchronization is enabled.

Due to synchronization there is delay from writing CTRLA.COUNTSYNC until this feature is enabled/disabled. The value written to CTRLA.COUNTSYNC will read back immediately and the Countsync Busy bit in the Synchronization Busy register (SYNCBUSY.COUNTSYNC) will be set. SYNCBUSY.COUNTSYNC will be cleared when the operation is complete.

- **Bits 14:12 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 - PRESCALER[3:0]: Prescaler**

These bits define the prescaling factor for the RTC clock source (CLK\_RTC) to generate the counter clock (CLK\_RTC\_CNT). Periodic events and interrupts are not available when the prescaler is off.

These bits are not synchronized.

**Table 24-4. Prescaler**

| Value | Name  | Description                                   |
|-------|-------|---|
| 0x0   | OFF   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1$  |
| 0x1   | DIV1  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1$  |
| 0x2   | DIV2  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 2$  |
| 0x3   | DIV4  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 4$  |
| 0x4   | DIV8  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 8$  |
| 0x5   | DIV16 | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 16$ |

| Value     | Name    | Description                                     |
|-----------|---------|---|
| 0x6       | DIV32   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 32$   |
| 0x7       | DIV64   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 64$   |
| 0x8       | DIV128  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 128$  |
| 0x9       | DIV256  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 256$  |
| 0xA       | DIV512  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 512$  |
| 0xB       | DIV1024 | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1024$ |
| 0xC - 0xF | -       | Reserved  |

- **Bit 7 - MATCHCLR: Clear on Match**

This bit is valid only in Mode 0 and Mode 2. This bit can be written only when the peripheral is disabled.

0: The counter is not cleared on a Compare match.

1: The counter is cleared on a Compare match.

This bit is not synchronized.

- **Bits 6:4 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 3:2 - MODE: Operating Mode**

This field defines the operating mode of the RTC.

These bits are not synchronized.

**Table 24-5. Operating Mode**

| Value | Name    | Description            |
|-------|---------|------------------------|
| 0x0   | COUNT32 | Mode 0: 32-bit Counter |
| 0x1   | COUNT16 | Mode 1: 16-bit Counter |
| 0x2   | CLOCK   | Mode 2: Clock/Calendar |
| 0x3   | -       | Reserved               |

- **Bit 1 - ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Enable Busy bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

- **Bit 0 - SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the RTC, except DBGCTRL, to their initial state, and the RTC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 24.8.1.2 Event Control

**Name:** EVCTRL

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Bit    | 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     |
|        |        |        |        |        |        |        |        |        |
| Access | R      | R      | R      | R      | R      | R      | R      | R      |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| Bit    | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |
|        |        |        |        |        |        |        |        |        |
| Access | R      | R      | R      | R      | R      | R      | R      | R      |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| Bit    | 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |
|        | OVF    |        |        |        |        |        |        | CMPEO0 |
| Access | R/W    | R      | R      | R      | R      | R      | R      | R/W    |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| Bit    | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
|        | PEREO7 | PEREO6 | PEREO5 | PEREO4 | PEREO3 | PEREO2 | PEREO1 | PEREO0 |
| Access | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |

- Bits 31:16 - Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 15 - OVFE0: Overflow Event Output Enable**  
 0: Overflow event is disabled and will not be generated.  
 1: Overflow event is enabled and will be generated for every overflow.
- Bits 14:9 - Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 8 - CMPEO0: Compare 0 Event Output Enable**  
 0: Compare 0 event is disabled and will not be generated.  
 1: Compare 0 event is enabled and will be generated for every compare match.
- Bits 7:0 - PEREO[n=7..0]: Periodic Interval n Event Output Enable**  
 0: Periodic Interval n event is disabled and will not be generated.  
 1: Periodic Interval n event is enabled and will be generated.

### 24.8.1.3 Interrupt Enable Clear

**Name:** INTENCLR

**Offset:** 0x08

**Reset:** 0x0000

**Property:** Write-Protected

|        |     |    |    |    |    |    |   |      |
|--------|-----|----|----|----|----|----|---|------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8    |
|        | OVF |    |    |    |    |    |   | CMP0 |
| Access | R/W | R  | R  | R  | R  | R  | R | R/W  |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0 | 0    |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bit 15 - OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Overflow Interrupt Enable bit, which disables the Overflow interrupt.

- **Bits 14:9 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 - CMP0: Compare 0 Interrupt Enable**

0: The Compare 0 interrupt is disabled.

1: The Compare 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Compare 0 Interrupt Enable bit, which disables the Compare 0 interrupt.

- **Bits 7:0 - PERn [n=7..0]: Periodic Interval n Interrupt Enable**

0: Periodic Interval n interrupt is disabled.

1: Periodic Interval n interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Periodic Interval n Interrupt Enable bit, which disables the Periodic Interval n interrupt.

#### 24.8.1.4 Interrupt Enable Set

**Name:** INTENSET

**Offset:** 0x0A

**Reset:** 0x0000

**Property:** Write-Protected

|        |     |    |    |    |    |    |   |      |
|--------|-----|----|----|----|----|----|---|------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8    |
|        | OVF |    |    |    |    |    |   | CMP0 |
| Access | R/W | R  | R  | R  | R  | R  | R | R/W  |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0 | 0    |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bit 15 - OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Overflow Interrupt Enable bit, which enables the Overflow interrupt.

- **Bits 14:9 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 - CMP0: Compare 0 Interrupt Enable**

0: The Compare 0 interrupt is disabled.

1: The Compare 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Compare 0 Interrupt Enable bit, which enables the Compare 0 interrupt.

- **Bits 7:0 - PERn [n=7..0]: Periodic Interval n Interrupt Enable**

0: Periodic Interval n interrupt is disabled.

1: Periodic Interval n interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Periodic Interval n Interrupt Enable bit, which enables the Periodic Interval n interrupt.

### 24.8.1.5 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x0C

**Reset:** 0x0000

**Property:** -

|        |     |    |    |    |    |    |   |      |
|--------|-----|----|----|----|----|----|---|------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8    |
|        | OVF |    |    |    |    |    |   | CMP0 |
| Access | R/W | R  | R  | R  | R  | R  | R | R/W  |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0 | 0    |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bit 15 - OVF: Overflow**

This flag is set on the next CLK\_RTC\_CNT cycle after an overflow condition occurs, and an interrupt request will be generated if INTENCLR.OVF/INTENSET.OVF is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Overflow interrupt flag.

- **Bits 14:9 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 - CMP0: Compare 0**

This flag is set on the next CLK\_RTC\_CNT cycle after a match with the compare condition, and an interrupt request will be generated if INTENCLR.CMP0/INTENSET.CMP0 is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Compare 0 interrupt flag.

- **Bits 7:0 - PERn [n=7..0]: Periodic Interval n**

This flag is set on the 0-to-1 transition of prescaler bit[n+2], and an interrupt request will be generated if INTENCLR.PERn/INTENSET.PERn is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Periodic Interval n interrupt flag.

#### 24.8.1.6 Debug Control

**Name:** DBGCTRL

**Offset:** 0x0E

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
|--------|---|---|---|---|---|---|---|--------|
|        |   |   |   |   |   |   |   | DBGRUN |
| Access | R | R | R | R | R | R | R | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |

- **Bits 7:1 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 - DBGRUN: Debug Run**

This bit is not reset by a software reset.

This bit controls the functionality when the CPU is halted by an external debugger.

0: The RTC is halted when the CPU is halted by an external debugger.

1: The RTC continues normal operation when the CPU is halted by an external debugger.

### 24.8.1.7 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x10

**Reset:** 0x00000000

**Property:** Read-Only

|        |           |    |       |    |       |          |        |       |
|--------|-----------|----|-------|----|-------|----------|--------|-------|
| Bit    | 31        | 30 | 29    | 28 | 27    | 26       | 25     | 24    |
|        |           |    |       |    |       |          |        |       |
| Access | R         | R  | R     | R  | R     | R        | R      | R     |
| Reset  | 0         | 0  | 0     | 0  | 0     | 0        | 0      | 0     |
| Bit    | 23        | 22 | 21    | 20 | 19    | 18       | 17     | 16    |
|        |           |    |       |    |       |          |        |       |
| Access | R         | R  | R     | R  | R     | R        | R      | R     |
| Reset  | 0         | 0  | 0     | 0  | 0     | 0        | 0      | 0     |
| Bit    | 15        | 14 | 13    | 12 | 11    | 10       | 9      | 8     |
|        | COUNTSYNC |    |       |    |       |          |        |       |

- Bits 31:16 - Reserved**  
 These bits are unused and reserved for future use. These bits will always return zero when read.
- Bit 15 - COUNTSYNC - Count Read Sync Enable Synchronization Busy Status**  
 0: Write synchronization for CTRLA.COUNTSYNC bit is complete.  
 1: Write synchronization for CTRLA.COUNTSYNC bit is ongoing.
- Bits 14:6 - Reserved**  
 These bits are unused and reserved for future use. These bits will always return zero when read.
- Bit 5 - COMP0: Compare 0 Synchronization Busy Status**  
 0: Write synchronization for COMP0 register is complete.  
 1: Write synchronization for COMP0 register is ongoing.
- Bit 4 - Reserved**  
 This bit is unused and reserved for future use. This bit will always return zero when read.
- Bit 3 - COUNT: Count Value Synchronization Busy Status**  
 0: Read/write synchronization for COUNT register is complete.  
 1: Read/write synchronization for COUNT register is ongoing.

- **Bit 2 - FREQCORR: Frequency Correction Synchronization Busy Status**  
0: Write synchronization for FREQCORR register is complete.  
1: Write synchronization for FREQCORR register is ongoing.
- **Bit 1 - ENABLE: Enable Synchronization Busy Status**  
0: Write synchronization for CTRLA.ENABLE bit is complete.  
1: Write synchronization for CTRLA.ENABLE bit is ongoing.
- **Bit 0 - SWRST: Software Reset Synchronization Busy Status**  
0: Write synchronization for CTRLA.SWRST bit is complete.  
1: Write synchronization for CTRLA.SWRST bit is ongoing.

24.8.1.8 Frequency Correction

**Name:**       FREQCORR  
**Offset:**     0x14  
**Reset:**      0x00  
**Property:**   Write-Protected, Write-Synchronized

|        |      |     |            |     |     |     |     |     |
|--------|------|-----|------------|-----|-----|-----|-----|-----|
| Bit    | 7    | 6   | 5          | 4   | 3   | 2   | 1   | 0   |
|        | SIGN |     | VALUE[6:0] |     |     |     |     |     |
| Access | R/W  | R/W | R/W        | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0    | 0   | 0          | 0   | 0   | 0   | 0   | 0   |

- **Bits 7 - SIGN: Correction Sign**  
0: The correction value is positive, i.e. frequency will be increased.  
1: The correction value is negative, i.e. frequency will be decreased.
- **Bits 6:0 - VALUE[6:0]: Correction Value**  
These bits define the amount of correction applied to the RTC prescaler.  
0: Correction is disabled and the RTC frequency is unchanged.  
1-127: The RTC frequency is adjusted according to the value.

### 24.8.1.9 Counter Value

**Name:** COUNT

**Offset:** 0x18

**Reset:** 0x00000000

**Property:** Write-Protected, Write-Synchronized, Read-Synchronized

|        |              |     |     |     |     |     |     |     |
|--------|--------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31           | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | COUNT[31:24] |     |     |     |     |     |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23           | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | COUNT[23:16] |     |     |     |     |     |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15           | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | COUNT[15:8]  |     |     |     |     |     |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7            | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | COUNT[7:0]   |     |     |     |     |     |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 - COUNT[31:0]: Counter Value**

These bits define the value of the 32-bit RTC counter in mode 0.

### 24.8.1.10 Compare 0 Value

**Name:** COMP0

**Offset:** 0x20

**Reset:** 0x00000000

**Property:** Write-Protected, Write-Synchronized

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | COMP[31:24] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23          | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | COMP[23:16] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | COMP[15:8]  |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | COMP[7:0]   |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 - COMP[31:0]: Compare Value**

The 32-bit value of COMP0 is continuously compared with the 32-bit COUNT value. When a match occurs, the Compare n interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.CMP0) is set on the next counter cycle, and the counter value is cleared if CTRLA.MATCHCLR is one.

## 24.8.2 Register Description - COUNT16

### 24.8.2.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x0000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

|        |           |    |    |    |                |     |        |       |
|--------|-----------|----|----|----|----------------|-----|--------|-------|
| Bit    | 15        | 14 | 13 | 12 | 11             | 10  | 9      | 8     |
|        | COUNTSYNC |    |    |    | PRESCALER[3:0] |     |        |       |
| Access | R/W       | R  | R  | R  | R/W            | R/W | R/W    | R/W   |
| Reset  | 0         | 0  | 0  | 0  | 0              | 0   | 0      | 0     |
| Bit    | 7         | 6  | 5  | 4  | 3              | 2   | 1      | 0     |
|        |           |    |    |    | MODE[1:0]      |     | ENABLE | SWRST |
| Access | R         | R  | R  | R  | R/W            | R/W | R/W    | R/W   |
| Reset  | 0         | 0  | 0  | 0  | 0              | 0   | 0      | 0     |

- **Bit 15 - COUNTSYNC: Count Read Synchronization Enable**

The COUNT register requires synchronization when reading. Disabling the synchronization will prevent reading valid values from the COUNT register.

0: Count read synchronization is disabled.

1: Count read synchronization is enabled.

Due to synchronization there is delay from writing CTRLA.COUNTSYNC until this feature is enabled/disabled. The value written to CTRLA.COUNTSYNC will read back immediately and the Countsync Busy bit in the Synchronization Busy register (SYNCBUSY.COUNTSYNC) will be set. SYNCBUSY.COUNTSYNC will be cleared when the operation is complete.

- **Bits 14:12 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 - PRESCALER[3:0]: Prescaler**

These bits define the prescaling factor for the RTC clock source (CLK\_RTC) to generate the counter clock (CLK\_RTC\_CNT). Periodic events and interrupts are not available when the prescaler is off.

These bits are not synchronized.

**Table 24-6. Prescaler**

| Value | Name  | Description                                   |
|-------|-------|---|
| 0x0   | OFF   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1$  |
| 0x1   | DIV1  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1$  |
| 0x2   | DIV2  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 2$  |
| 0x3   | DIV4  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 4$  |
| 0x4   | DIV8  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 8$  |
| 0x5   | DIV16 | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 16$ |

| Value     | Name    | Description                                     |
|-----------|---------|---|
| 0x6       | DIV32   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 32$   |
| 0x7       | DIV64   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 64$   |
| 0x8       | DIV128  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 128$  |
| 0x9       | DIV256  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 256$  |
| 0xA       | DIV512  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 512$  |
| 0xB       | DIV1024 | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1024$ |
| 0xC - 0xF | -       | Reserved  |

- **Bits 7:4 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 3:2 - MODE: Operating Mode**

This field defines the operating mode of the RTC.

These bits are not synchronized.

**Table 24-7. Operating Mode**

| Value | Name    | Description            |
|-------|---------|------------------------|
| 0x0   | COUNT32 | Mode 0: 32-bit Counter |
| 0x1   | COUNT16 | Mode 1: 16-bit Counter |
| 0x2   | CLOCK   | Mode 2: Clock/Calendar |
| 0x3   | -       | Reserved               |

- **Bit 1 - ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Enable Busy bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

- **Bit 0 - SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the RTC, except DBGCTRL, to their initial state, and the RTC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 24.8.2.2 Event Control

**Name:** EVCTRL

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Bit    | 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     |
|        |        |        |        |        |        |        |        |        |
| Access | R      | R      | R      | R      | R      | R      | R      | R      |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| Bit    | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |
|        |        |        |        |        |        |        |        |        |
| Access | R      | R      | R      | R      | R      | R      | R      | R      |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| Bit    | 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |
|        | OVF    |        |        |        |        |        | CMPEO1 | CMPEO0 |
| Access | R/W    | R      | R      | R      | R      | R      | R/W    | R/W    |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| Bit    | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
|        | PEREO7 | PEREO6 | PEREO5 | PEREO4 | PEREO3 | PEREO2 | PEREO1 | PEREO0 |
| Access | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    |
| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |

- **Bits 31:16 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 15 - OVFE0: Overflow Event Output Enable**

0: Overflow event is disabled and will not be generated.

1: Overflow event is enabled and will be generated for every overflow.

- **Bits 14:10 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 9:8 - CMPEOn [n=1..0]: Compare n Event Output Enable**

0: Compare n event is disabled and will not be generated.

1: Compare n event is enabled and will be generated for every compare match.

- **Bits 7:0 - PEREO n [n=7..0]: Periodic Interval n Event Output Enable**

0: Periodic Interval n event is disabled and will not be generated.

1: Periodic Interval n event is enabled and will be generated.

### 24.8.2.3 Interrupt Enable Clear

**Name:** INTENCLR

**Offset:** 0x08

**Reset:** 0x0000

**Property:** Write-Protected

| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9    | 8    |
|--------|-----|----|----|----|----|----|------|------|
|        | OVF |    |    |    |    |    | CMP1 | CMP0 |
| Access | R/W | R  | R  | R  | R  | R  | R/W  | R/W  |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0    | 0    |

| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|--------|------|------|------|------|------|------|------|------|
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- Bit 15 - OVF: Overflow Interrupt Enable**  
 0: The Overflow interrupt is disabled.  
 1: The Overflow interrupt is enabled.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Overflow Interrupt Enable bit, which disables the Overflow interrupt.
- Bits 14:10 - Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 9:8 - CMPn [n=1..0]: Compare n Interrupt Enable**  
 0: The Compare n interrupt is disabled.  
 1: The Compare n interrupt is enabled.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Compare n Interrupt Enable bit, which disables the Compare n interrupt.
- Bits 7:0 - PERn [n=7..0]: Periodic Interval n Interrupt Enable**  
 0: Periodic Interval n interrupt is disabled.  
 1: Periodic Interval n interrupt is enabled.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Periodic Interval n Interrupt Enable bit, which disables the Periodic Interval n interrupt.

#### 24.8.2.4 Interrupt Enable Set

**Name:** INTENSET

**Offset:** 0x0A

**Reset:** 0x0000

**Property:** Write-Protected

|        |     |    |    |    |    |    |      |      |
|--------|-----|----|----|----|----|----|------|------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9    | 8    |
|        | OVF |    |    |    |    |    | CMP1 | CMP0 |
| Access | R/W | R  | R  | R  | R  | R  | R/W  | R/W  |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0    | 0    |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bit 15 - OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Overflow Interrupt Enable bit, which enables the Overflow interrupt.

- **Bits 14:10 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 9:8 - CMPn [n=1..0]: Compare n Interrupt Enable**

0: The Compare n interrupt is disabled.

1: The Compare n interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Compare n Interrupt Enable bit, which enables the Compare n interrupt.

- **Bits 7:0 - PERn [n=7..0]: Periodic Interval n Interrupt Enable**

0: Periodic Interval n interrupt is disabled.

1: Periodic Interval n interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Periodic Interval n Interrupt Enable bit, which enables the Periodic Interval n interrupt.

### 24.8.2.5 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x0C

**Reset:** 0x0000

**Property:** -

|        |     |    |    |    |    |    |      |      |
|--------|-----|----|----|----|----|----|------|------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9    | 8    |
|        | OVF |    |    |    |    |    | CMP1 | CMP0 |
| Access | R/W | R  | R  | R  | R  | R  | R/W  | R/W  |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0    | 0    |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- Bit 15 - OVF: Overflow**  
 This flag is set on the next CLK\_RTC\_CNT cycle after an overflow condition occurs, and an interrupt request will be generated if INTENCLR.OVF/INTENSET.OVF is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Overflow interrupt flag.
- Bits 14:10 - Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 9:8 - CMPn [n=1..0]: Compare n**  
 This flag is set on the next CLK\_RTC\_CNT cycle after a match with the compare condition, and an interrupt request will be generated if INTENCLR.CMPn/INTENSET.CMPn is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Compare n interrupt flag.
- Bits 7:0 - PERn [n=7..0]: Periodic Interval n**  
 This flag is set on the 0-to-1 transition of prescaler bit[n+2], and an interrupt request will be generated if INTENCLR.PERn/INTENSET.PERn is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Periodic Interval n interrupt flag.

#### 24.8.2.6 Debug Control

**Name:** DBGCTRL

**Offset:** 0x0E

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
|--------|---|---|---|---|---|---|---|--------|
|        |   |   |   |   |   |   |   | DBGRUN |
| Access | R | R | R | R | R | R | R | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |

- **Bits 7:1 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 - DBGRUN: Debug Run**

This bit is not reset by a software reset.

This bit controls the functionality when the CPU is halted by an external debugger.

0: The RTC is halted when the CPU is halted by an external debugger.

1: The RTC continues normal operation when the CPU is halted by an external debugger.

### 24.8.2.7 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x10

**Reset:** 0x00000000

**Property:** Read-Only

|        |           |       |       |     |       |          |        |       |
|--------|-----------|-------|-------|-----|-------|----------|--------|-------|
| Bit    | 31        | 30    | 29    | 28  | 27    | 26       | 25     | 24    |
|        |           |       |       |     |       |          |        |       |
| Access | R         | R     | R     | R   | R     | R        | R      | R     |
| Reset  | 0         | 0     | 0     | 0   | 0     | 0        | 0      | 0     |
| Bit    | 23        | 22    | 21    | 20  | 19    | 18       | 17     | 16    |
|        |           |       |       |     |       |          |        |       |
| Access | R         | R     | R     | R   | R     | R        | R      | R     |
| Reset  | 0         | 0     | 0     | 0   | 0     | 0        | 0      | 0     |
| Bit    | 15        | 14    | 13    | 12  | 11    | 10       | 9      | 8     |
|        | COUNTSYNC |       |       |     |       |          |        |       |
| Access | R         | R     | R     | R   | R     | R        | R      | R     |
| Reset  | 0         | 0     | 0     | 0   | 0     | 0        | 0      | 0     |
| Bit    | 7         | 6     | 5     | 4   | 3     | 2        | 1      | 0     |
|        |           | COMP1 | COMP0 | PER | COUNT | FRECCORR | ENABLE | SWRST |
| Access | R         | R     | R     | R   | R     | R        | R      | R     |
| Reset  | 0         | 0     | 0     | 0   | 0     | 0        | 0      | 0     |

- Bits 31:16 - Reserved**  
 These bits are unused and reserved for future use. These bits will always return zero when read.
- Bit 15 - COUNTSYNC - Count Read Sync Enable Synchronization Busy Status**  
 0: Write synchronization for CTRLA.COUNTSYNC bit is complete.  
 1: Write synchronization for CTRLA.COUNTSYNC bit is ongoing.
- Bits 14:7 - Reserved**  
 These bits are unused and reserved for future use. These bits will always return zero when read.
- Bits 6:5 - COMPn [n=1..0]: Compare n Synchronization Busy Status**  
 0: Write synchronization for COMPn register is complete.  
 1: Write synchronization for COMPn register is ongoing.
- Bit 4 - PER: Period Synchronization Busy Status**  
 0: Write synchronization for PER register is complete.  
 1: Write synchronization for PER register is ongoing.

- **Bit 3 - COUNT: Count Value Synchronization Busy Status**  
0: Read/write synchronization for COUNT register is complete.  
1: Read/write synchronization for COUNT register is ongoing.
- **Bit 2 - FREQCORR: Frequency Correction Synchronization Busy Status**  
0: Write synchronization for FREQCORR register is complete.  
1: Write synchronization for FREQCORR register is ongoing.
- **Bit 1 - ENABLE: Enable Synchronization Busy Status**  
0: Write synchronization for CTRLA.ENABLE bit is complete.  
1: Write synchronization for CTRLA.ENABLE bit is ongoing.
- **Bit 0 - SWRST: Software Reset Synchronization Busy Status**  
0: Write synchronization for CTRLA.SWRST bit is complete.  
1: Write synchronization for CTRLA.SWRST bit is ongoing.

24.8.2.8 Frequency Correction

**Name:**       FREQCORR  
**Offset:**     0x14  
**Reset:**      0x00  
**Property:**   Write-Protected, Write-Synchronized

|        |      |            |     |     |     |     |     |     |
|--------|------|------------|-----|-----|-----|-----|-----|-----|
| Bit    | 7    | 6          | 5   | 4   | 3   | 2   | 1   | 0   |
|        | SIGN | VALUE[6:0] |     |     |     |     |     |     |
| Access | R/W  | R/W        | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0    | 0          | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 7 - SIGN: Correction Sign**  
0: The correction value is positive, i.e. frequency will be increased.  
1: The correction value is negative, i.e. frequency will be decreased.
- **Bits 6:0 - VALUE[6:0]: Correction Value**  
These bits define the amount of correction applied to the RTC prescaler.  
0: Correction is disabled and the RTC frequency is unchanged.  
1-127: The RTC frequency is adjusted according to the value.

24.8.2.9 Counter Value

**Name:** COUNT  
**Offset:** 0x18  
**Reset:** 0x0000  
**Property:** Write-Protected, Write-Synchronized, Read-Synchronized

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | COUNT[15:8] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | COUNT[7:0]  |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:0 - COUNT[15:0]: Counter Value**  
These bits define the value of the 16-bit RTC counter in Mode 1.

24.8.2.10 Counter Period

**Name:** PER  
**Offset:** 0x1C  
**Reset:** 0x0000  
**Property:** Write-Protected, Write-Synchronized

|        |           |     |     |     |     |     |     |     |
|--------|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | PER[15:8] |     |     |     |     |     |     |     |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | PER[7:0]  |     |     |     |     |     |     |     |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:0 - PER[15:0]: Counter Period**  
These bits define the value of the 16-bit RTC period in Mode 1.

### 24.8.2.11 Compare n Value

**Name:** COMPn

**Offset:** 0x20 + n\*0x2 [n=0..1]

**Reset:** 0x0000

**Property:** Write-Protected, Write-Synchronized

|        |            |     |     |     |     |     |     |     |
|--------|------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | COMP[15:8] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7          | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | COMP[7:0]  |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:0 - COMP[15:0]: Compare Value**

The 16-bit value of COMPn is continuously compared with the 16-bit COUNT value. When a match occurs, the Compare n interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.CMPn) is set on the next counter cycle.

## 24.8.3 Register Description - CLOCK

### 24.8.3.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x0000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

|        |           |        |    |    |                |     |        |       |
|--------|-----------|--------|----|----|----------------|-----|--------|-------|
| Bit    | 15        | 14     | 13 | 12 | 11             | 10  | 9      | 8     |
|        | CLOCKSYNC |        |    |    | PRESCALER[3:0] |     |        |       |
| Access | R/W       | R      | R  | R  | R/W            | R/W | R/W    | R/W   |
| Reset  | 0         | 0      | 0  | 0  | 0              | 0   | 0      | 0     |
| Bit    | 7         | 6      | 5  | 4  | 3              | 2   | 1      | 0     |
|        | MATCHCLR  | CLKREP |    |    | MODE[1:0]      |     | ENABLE | SWRST |
| Access | R/W       | R/W    | R  | R  | R/W            | R/W | R/W    | R/W   |
| Reset  | 0         | 0      | 0  | 0  | 0              | 0   | 0      | 0     |

- **Bit 15 - CLOCKSINC: Clock Read Synchronization Enable**

The CLOCK register requires synchronization when reading. Disabling the synchronization will prevent reading valid values from the CLOCK register.

0: Clock read synchronization is disabled.

1: Clock read synchronization is enabled.

Due to synchronization there is delay from writing CTRLA.CLOCKSINC until this feature is enabled/disabled. The value written to CTRLA.CLOCKSINC will read back immediately and the Clocksync Busy bit in the Synchronization Busy register (SYNCBUSY.CLOCKSINC) will be set. SYNCBUSY.CLOCKSINC will be cleared when the operation is complete.

- **Bits 14:12 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 - PRESCALER[3:0]: Prescaler**

These bits define the prescaling factor for the RTC clock source (CLK\_RTC) to generate the counter clock (CLK\_RTC\_CNT). Periodic events and interrupts are not available when the prescaler is off.

These bits are not synchronized.

**Table 24-8. Prescaler**

| Value | Name  | Description                     |
|-------|-------|---------------------------------|
| 0x0   | OFF   | $CLK\_RTC\_CNT = CLK\_RTC / 1$  |
| 0x1   | DIV1  | $CLK\_RTC\_CNT = CLK\_RTC / 1$  |
| 0x2   | DIV2  | $CLK\_RTC\_CNT = CLK\_RTC / 2$  |
| 0x3   | DIV4  | $CLK\_RTC\_CNT = CLK\_RTC / 4$  |
| 0x4   | DIV8  | $CLK\_RTC\_CNT = CLK\_RTC / 8$  |
| 0x5   | DIV16 | $CLK\_RTC\_CNT = CLK\_RTC / 16$ |

| Value     | Name    | Description                                     |
|-----------|---------|---|
| 0x6       | DIV32   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 32$   |
| 0x7       | DIV64   | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 64$   |
| 0x8       | DIV128  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 128$  |
| 0x9       | DIV256  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 256$  |
| 0xA       | DIV512  | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 512$  |
| 0xB       | DIV1024 | $\text{CLK\_RTC\_CNT} = \text{CLK\_RTC} / 1024$ |
| 0xC - 0xF | -       | Reserved  |

- Bit 7 - MATCHCLR: Clear on Match**  
 This bit is valid only in Mode 0 and Mode 2. This bit can be written only when the peripheral is disabled.  
 0: The counter is not cleared on an Alarm match.  
 1: The counter is cleared on an Alarm match.  
 This bit is not synchronized.
- Bit 6 - CLKREP: Clock Representation**  
 This bit is valid only in Mode 2 and determines how the hours are represented in the Clock Value (CLOCK) register. This bit can be written only when the peripheral is disabled.  
 0: 24 Hour  
 1: 12 Hour (AM/PM)  
 This bit is not synchronized.
- Bits 5:4 - Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 3:2 - MODE: Operating Mode**  
 This field defines the operating mode of the RTC.  
 These bits are not synchronized.

**Table 24-9. Operating Mode**

| Value | Name    | Description            |
|-------|---------|------------------------|
| 0x0   | COUNT32 | Mode 0: 32-bit Counter |
| 0x1   | COUNT16 | Mode 1: 16-bit Counter |
| 0x2   | CLOCK   | Mode 2: Clock/Calendar |
| 0x3   | -       | Reserved               |

- Bit 1 - ENABLE: Enable**  
 0: The peripheral is disabled.  
 1: The peripheral is enabled.  
 Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Enable Busy bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.
- Bit 0 - SWRST: Software Reset**  
 0: There is no reset operation ongoing.  
 1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the RTC, except DBGCTRL, to their initial state, and the RTC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 24.8.3.2 Event Control

**Name:** EVCTRL

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |        |        |        |        |        |        |        |          |
|--------|--------|--------|--------|--------|--------|--------|--------|----------|

- **Bits 31:16 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 15 - OVFE0: Overflow Event Output Enable**

0: Overflow event is disabled and will not be generated.

1: Overflow event is enabled and will be generated for every overflow.

- **Bits 14:9 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 - ALARMEO0: Alarm 0 Event Output Enable**

0: Alarm 0 event is disabled and will not be generated.

1: Alarm 0 event is enabled and will be generated for every alarm.

- **Bits 7:0 - PEREO[n=7..0]: Periodic Interval n Event Output Enable**

0: Periodic Interval n event is disabled and will not be generated.

1: Periodic Interval n event is enabled and will be generated.

### 24.8.3.3 Interrupt Enable Clear

**Name:** INTENCLR

**Offset:** 0x08

**Reset:** 0x0000

**Property:** Write-Protected

| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8      |
|--------|-----|----|----|----|----|----|---|--------|
|        | OVF |    |    |    |    |    |   | ALARM0 |
| Access | R/W | R  | R  | R  | R  | R  | R | R/W    |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0 | 0      |

| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|--------|------|------|------|------|------|------|------|------|
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bit 15 - OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Overflow Interrupt Enable bit, which disables the Overflow interrupt.

- **Bits 14:9 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 - ALARM0: Alarm 0 Interrupt Enable**

0: The Alarm 0 interrupt is disabled.

1: The Alarm 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Alarm 0 Interrupt Enable bit, which disables the Alarm 0 interrupt.

- **Bits 7:0 - PERn [n=7..0]: Periodic Interval n Interrupt Enable**

0: Periodic Interval n interrupt is disabled.

1: Periodic Interval n interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Periodic Interval n Interrupt Enable bit, which disables the Periodic Interval n interrupt.

#### 24.8.3.4 Interrupt Enable Set

**Name:** INTENSET

**Offset:** 0x0A

**Reset:** 0x0000

**Property:** Write-Protected

|        |     |    |    |    |    |    |   |        |
|--------|-----|----|----|----|----|----|---|--------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8      |
|        | OVF |    |    |    |    |    |   | ALARM0 |
| Access | R/W | R  | R  | R  | R  | R  | R | R/W    |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0 | 0      |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bit 15 - OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Overflow Interrupt Enable bit, which enables the Overflow interrupt.

- **Bits 14:9 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 - ALARM0: Alarm 0 Interrupt Enable**

0: The Alarm 0 interrupt is disabled.

1: The Alarm 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Alarm 0 Interrupt Enable bit, which enables the Alarm 0 interrupt.

- **Bits 7:0 - PERn [n=7..0]: Periodic Interval n Interrupt Enable**

0: Periodic Interval n interrupt is disabled.

1: Periodic Interval n interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Periodic Interval n Interrupt Enable bit, which enables the Periodic Interval n interrupt.

### 24.8.3.5 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x0C

**Reset:** 0x0000

**Property:** -

|        |     |    |    |    |    |    |   |        |
|--------|-----|----|----|----|----|----|---|--------|
| Bit    | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8      |
|        | OVF |    |    |    |    |    |   | ALARM0 |
| Access | R/W | R  | R  | R  | R  | R  | R | R/W    |
| Reset  | 0   | 0  | 0  | 0  | 0  | 0  | 0 | 0      |

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
| Bit    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|        | PER7 | PER6 | PER5 | PER4 | PER3 | PER2 | PER1 | PER0 |
| Access | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- Bit 15 - OVF: Overflow**  
 This flag is set on the next CLK\_RTC\_CNT cycle after an overflow condition occurs, and an interrupt request will be generated if INTENCLR.OVF/INTENSET.OVF is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Overflow interrupt flag.
- Bits 14:9 - Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 8 - ALARM0: Alarm 0**  
 This flag is set on the next CLK\_RTC\_CNT cycle after a match with the alarm condition, and an interrupt request will be generated if INTENCLR.ALARM0/INTENSET.ALARM0 is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Alarm 0 interrupt flag.
- Bits 7:0 - PERn [n=7..0]: Periodic Interval n**  
 This flag is set on the 0-to-1 transition of prescaler bit[n+2], and an interrupt request will be generated if INTENCLR.PERn/INTENSET.PERn is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Periodic Interval n interrupt flag.

### 24.8.3.6 Debug Control

**Name:** DBGCTRL

**Offset:** 0x0E

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
|--------|---|---|---|---|---|---|---|--------|
|        |   |   |   |   |   |   |   | DBGRUN |
| Access | R | R | R | R | R | R | R | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |

- **Bits 7:1 - Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 - DBGRUN: Debug Run**

This bit is not reset by a software reset.

This bit controls the functionality when the CPU is halted by an external debugger.

0: The RTC is halted when the CPU is halted by an external debugger.

1: The RTC continues normal operation when the CPU is halted by an external debugger.

### 24.8.3.7 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x10

**Reset:** 0x00000000

**Property:** Read-Only

|        |           |    |        |    |       |          |        |       |
|--------|-----------|----|--------|----|-------|----------|--------|-------|
| Bit    | 31        | 30 | 29     | 28 | 27    | 26       | 25     | 24    |
|        |           |    |        |    |       |          |        |       |
| Access | R         | R  | R      | R  | R     | R        | R      | R     |
| Reset  | 0         | 0  | 0      | 0  | 0     | 0        | 0      | 0     |
| Bit    | 23        | 22 | 21     | 20 | 19    | 18       | 17     | 16    |
|        |           |    |        |    |       |          |        |       |
| Access | R         | R  | R      | R  | R     | R        | R      | R     |
| Reset  | 0         | 0  | 0      | 0  | 0     | 0        | 0      | 0     |
| Bit    | 15        | 14 | 13     | 12 | 11    | 10       | 9      | 8     |
|        | CLOCKSYNC |    |        |    | MASK0 |          |        |       |
| Access | R         | R  | R      | R  | R     | R        | R      | R     |
| Reset  | 0         | 0  | 0      | 0  | 0     | 0        | 0      | 0     |
| Bit    | 7         | 6  | 5      | 4  | 3     | 2        | 1      | 0     |
|        |           |    | ALARM0 |    | COUNT | FRECCORR | ENABLE | SWRST |
| Access | R         | R  | R      | R  | R     | R        | R      | R     |
| Reset  | 0         | 0  | 0      | 0  | 0     | 0        | 0      | 0     |

- **Bits 31:16 - Reserved**  
These bits are unused and reserved for future use. These bits will always return zero when read.
- **Bit 15 - CLOCKSYNC - Clock Read Sync Enable Synchronization Busy Status**  
0: Write synchronization for CTRLA.CLOCKSYNC bit is complete.  
1: Write synchronization for CTRLA.CLOCKSYNC bit is ongoing.
- **Bits 14:12 - Reserved**  
These bits are unused and reserved for future use. These bits will always return zero when read.
- **Bit 11 - MASK0: Mask 0 Synchronization Busy Status**  
0: Write synchronization for MASK 0 register is complete.  
1: Write synchronization for MASK 0 register is ongoing.
- **Bits 10:6 - Reserved**  
These bits are unused and reserved for future use. These bits will always return zero when read.
- **Bit 5 - ALARM0: Alarm 0 Synchronization Busy Status**  
0: Write synchronization for ALARM 0 register is complete.  
1: Write synchronization for ALARM 0 register is ongoing.

- **Bit 4 - Reserved**  
This bit is unused and reserved for future use. This bit will always return zero when read.
- **Bit 3 - CLOCK: Clock Value Synchronization Busy Status**  
0: Read/write synchronization for CLOCK register is complete.  
1: Read/write synchronization for CLOCK register is ongoing.
- **Bit 2 - FREQCORR: Frequency Correction Synchronization Busy Status**  
0: Write synchronization for FREQCORR register is complete.  
1: Write synchronization for FREQCORR register is ongoing.
- **Bit 1 - ENABLE: Enable Synchronization Busy Status**  
0: Write synchronization for CTRLA.ENABLE bit is complete.  
1: Write synchronization for CTRLA.ENABLE bit is ongoing.
- **Bit 0 - SWRST: Software Reset Synchronization Busy Status**  
0: Write synchronization for CTRLA.SWRST bit is complete.  
1: Write synchronization for CTRLA.SWRST bit is ongoing.

24.8.3.8 Frequency CorrectionI

**Name:**       FREQCORR  
**Offset:**     0x14  
**Reset:**      0x00  
**Property:**   Write-Protected, Write-Synchronized

|        |      |     |            |     |     |     |     |     |
|--------|------|-----|------------|-----|-----|-----|-----|-----|
| Bit    | 7    | 6   | 5          | 4   | 3   | 2   | 1   | 0   |
|        | SIGN |     | VALUE[6:0] |     |     |     |     |     |
| Access | R/W  | R/W | R/W        | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0    | 0   | 0          | 0   | 0   | 0   | 0   | 0   |

- **Bits 7 - SIGN: Correction Sign**  
0: The correction value is positive, i.e. frequency will be increased.  
1: The correction value is negative, i.e. frequency will be decreased.
- **Bits 6:0 - VALUE[6:0]: Correction Value**  
These bits define the amount of correction applied to the RTC prescaler.  
0: Correction is disabled and the RTC frequency is unchanged.  
1-127: The RTC frequency is adjusted according to the value.

### 24.8.3.9 Clock Value

**Name:** CLOCK

**Offset:** 0x18

**Reset:** 0x00000000

**Property:** Write-Protected, Write-Synchronized, Read-Synchronized

|        |             |     |             |     |     |             |            |         |
|--------|-------------|-----|-------------|-----|-----|-------------|------------|---------|
| Bit    | 31          | 30  | 29          | 28  | 27  | 26          | 25         | 24      |
|        | YEAR[5:0]   |     |             |     |     |             | MONTH[3:2] |         |
| Access | R/W         | R/W | R/W         | R/W | R/W | R/W         | R/W        | R/W     |
| Reset  | 0           | 0   | 0           | 0   | 0   | 0           | 0          | 0       |
| Bit    | 23          | 22  | 21          | 20  | 19  | 18          | 17         | 16      |
|        | MONTH[1:0]  |     | DAY[4:0]    |     |     |             |            | hour[4] |
| Access | R/W         | R/W | R/W         | R/W | R/W | R/W         | R/W        | R/W     |
| Reset  | 0           | 0   | 0           | 0   | 0   | 0           | 0          | 0       |
| Bit    | 15          | 14  | 13          | 12  | 11  | 10          | 9          | 8       |
|        | HOUR[3:0]   |     |             |     |     | MINUTE[5:2] |            |         |
| Access | R/W         | R/W | R/W         | R/W | R/W | R/W         | R/W        | R/W     |
| Reset  | 0           | 0   | 0           | 0   | 0   | 0           | 0          | 0       |
| Bit    | 7           | 6   | 5           | 4   | 3   | 2           | 1          | 0       |
|        | MINUTE[1:0] |     | SECOND[5:0] |     |     |             |            |         |
| Access | R/W         | R/W | R/W         | R/W | R/W | R/W         | R/W        | R/W     |
| Reset  | 0           | 0   | 0           | 0   | 0   | 0           | 0          | 0       |

- **Bits 31:26 - YEAR[5:0]: Year**  
The year offset with respect to the reference year (defined in software).  
The year is considered a leap year if YEAR[1:0] is zero.
- **Bits 25:22 - MONTH[3:0]: Month**  
1 = January, 2 = February ... 11 = November, 12 = December
- **Bits 21:17 - DAY[4:0]: Day**  
Day starts at 1 and ends at 28, 29, 30 or 31, depending on the month and year.
- **Bits 16:12 - HOUR[4:0]: Hour**  
When CTRLA.CLKREP is zero, the Hour bit group is in 24-hour format, with values 0-23. When CTRLA.CLKREP is one, HOUR[3:0] has values 1-12 and HOUR[4] represents AM (0) or PM (1).
- **Bits 11:6 - MINUTE[5:0]: Minute**  
0 – 59.
- **Bits 5:0 - SECOND[5:0]: Second**  
0 – 59.

### 24.8.3.10 Alarm 0 Value

**Name:** ALARM0

**Offset:** 0x20

**Reset:** 0x00000000

**Property:** Write-Protected, Write-Synchronized

The 32-bit value of ALARM0 is continuously compared with the 32-bit CLOCK value, based on the masking set by MASK0.SEL. When a match occurs, the Alarm 0 interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.ALARM0) is set on the next counter cycle, and the counter is cleared if CTRLA.MATCHCLR is one.

- **Bits 31:26 – YEAR[5:0]: Year**  
The alarm year. Years are only matched if MASK0.SEL is 6.
- **Bits 25:22 – MONTH[3:0]: Month**  
The alarm month. Months are matched only if MASK0.SEL is greater than 4.
- **Bits 21:17 – DAY[4:0]: Day**  
The alarm day. Days are matched only if MASK0.SEL is greater than 3.
- **Bits 16:12 – HOUR[4:0]: Hour**  
The alarm hour. Hours are matched only if MASK0.SEL is greater than 2.
- **Bits 11:6 – MINUTE[5:0]: Minute**  
The alarm minute. Minutes are matched only if MASK0.SEL is greater than 1.
- **Bits 5:0 – SECOND[5:0]: Second**  
The alarm second. Seconds are matched only if MASK0.SEL is greater than 0.

### 24.8.3.11 Alarm 0 Mask

## 25. DMAC – Direct Memory Access Controller

### 25.1 Overview

The Direct Memory Access Controller (DMAC) contains both a Direct Memory Access engine and a Cyclic Redundancy Check (CRC) engine. The DMAC can transfer data between memories and peripherals, and thus off-load these tasks from the CPU. It enables high data transfer rates with minimum CPU intervention, and frees up CPU time. With access to all peripherals, the DMAC can handle automatic transfer of data between communication modules.

The DMA part of the DMAC has several DMA channels which all can receive different types of transfer triggers, which will result in transfer requests from the DMA channels to the arbiter. Refer to [Figure 25-1](#). The arbiter will grant one DMA channel at a time to act as the active channel. When the active channel has been granted, the fetch engine of the DMAC will fetch a transfer descriptor from SRAM into the internal memory of the active channel, before the active channel starts its data transmission. A DMA channel's data transfer can be interrupted by a higher prioritized channel. The DMAC will write back the updated transfer descriptor from the internal memory of the active channel to SRAM, before the higher prioritized channel gets to start its transfer. Once a DMA channel is done with its transfer optionally interrupts and events can be generated.

As one can see from [Figure 25-1](#), the DMAC has four bus interfaces. The data transfer bus, which is used for performing the actual DMA transfer is an AHB master interface. The AHB/APB Bridge bus is an APB slave interface and is the bus used when writing and reading the I/O registers of the DMAC. The descriptor fetch bus is an AHB master interface and is used by the fetch engine, to fetch transfer descriptors from SRAM before a transfer can be started or continued. At last there is the write-back bus, which is an AHB master interface and it is used to write the transfer descriptor back to SRAM.

As mentioned, the DMAC also has a CRC module available. This can be used by software to detect an accidental error in the transferred data and to take corrective action, such as requesting the data to be sent again or simply not using the incorrect data.

### 25.2 Features

- Data transfer between
  - Peripheral to peripheral
  - Peripheral to memory
  - Memory to peripheral
  - Memory to memory
- Transfer trigger sources
  - Software
  - Events from Event System
  - Dedicated requests from peripherals
- SRAM based transfer descriptors
  - Single transfer using one descriptor
  - Multi-buffer or circular buffer modes by linking multiple descriptors
- 6 channels
  - Enable 6 independent transfers
  - Automatic descriptor fetch for each channel
  - Suspend/resume operation support for each channel
- Flexible arbitration scheme
  - 4 configurable priority levels for each channel
  - Fixed or round-robin priority scheme within each priority level
- From 1 to 256kB data transfer in a single block transfer
- Multiple addressing modes
  - Static
  - Configurable increment scheme

- Optional interrupt generation
  - On block transfer complete
  - On error detection
  - On channel suspend
- 4 event inputs
  - One event input for each of the 4 least significant DMA channels
  - Can be selected to trigger normal transfers, periodic transfers or conditional transfers
  - Can be selected to suspend or resume channel operation
- 4 event outputs
  - One output event for each of the 4 least significant DMA channels
  - Selectable generation on AHB, burst, block or transaction transfer complete
- Error management supported by write-back function
  - Dedicated Write-Back memory section for each channel to store ongoing descriptor transfer
- CRC polynomial software selectable to
  - CRC-16 (CRC-CCITT)
  - CRC-32 (IEEE 802.3)

## 25.3 Block Diagram

Figure 25-1. DMAC Block Diagram

## 25.4 Signal Description

Not applicable.

## 25.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 25.5.1 I/O Lines

Not applicable.

### 25.5.2 Power Management

The DMAC will continue to operate in any sleep mode where the selected source clock is running. The DMAC's interrupts can be used to wake up the device from sleep modes. Events connected to the event system can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes. On hardware or software reset, all registers are set to their reset value.

### 25.5.3 Clocks

The DMAC bus clock (CLK\_DMAC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_DMAC\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

An AHB clock (CLK\_DMAC\_AHB) is required to clock the DMAC. This clock must be configured and enabled in the Main Clock module before using the DMAC, and the default state of CLK\_DMAC\_AHB can be found in [Table 17-1](#).

This bus clock (CLK\_DMAC\_APB) is always synchronous to the module clock (CLK\_DMAC\_AHB), but can be divided by a prescaler and may run even when the module clock is turned off.

### 25.5.4 DMA

Not applicable.

### 25.5.5 Interrupts

The interrupt request line is connected to the interrupt controller. Using the DMAC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 25.5.6 Events

The events are connected to the event system. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

### 25.5.7 Debug Operation

When the CPU is halted in debug mode the DMAC will halt normal operation. The DMAC can be forced to continue operation during debugging. Refer to [DBGCTRL](#) for details.

### 25.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Pending ([INTPEND](#)) register
- Channel ID ([CHID](#)) register
- Channel Interrupt Flag Status and Clear ([CHINTFLAG](#)) register

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 25.5.9 Analog Connections

Not applicable.

## 25.6 Functional Description

### 25.6.1 Principle of Operation

The DMAC consists of a DMA module and a CRC module.

### 25.6.1.1 DMA

The DMAC can, without interaction from the CPU, transfer data between peripherals and memories. The data transferred by the DMAC are called transactions, and these transactions can be split into smaller data transfers. Figure 25-2 shows the relationship between the different transfer sizes.

**Figure 25-2. DMA Transfer Sizes**

- Beat transfer: Defined as the size of one data transfer bus access, and the size is selected by writing the Beat Size bit group in the Block Transfer Control register (**BTCTRL.BEATSIZE**)
- Burst transfer: Defined as n beat transfers, where n will differ from one device family to another. For this device family, n is 1. A burst transfer is atomic, and cannot be interrupted.
- Block transfer: The amount of data one transfer descriptor can transfer, and the amount can range from 1 to 64k beats. In contrast to the burst transfer, a block transfer can be interrupted.
- Transaction: The DMAC can link several transfer descriptors by having the first descriptor pointing to the second and so forth, as shown in Figure 25-2. A DMA transaction is defined as all block transfers within a linked list, being completed.

A transfer descriptor describes how a block transfer should be carried out by the DMAC, and it must remain in SRAM. For further details on the transfer descriptor refer to “[Transfer Descriptors](#)” on page 326.

Figure 25-2 shows several block transfers linked together, which are called linked descriptors. For further information about linked descriptors, refer to “[Linked Descriptors](#)” on page 333.

A DMA transfer is initiated by an incoming transfer trigger on one of the DMA channels. This trigger can be configured to be either a software trigger, an event trigger or one of the dedicated peripheral triggers. The transfer trigger will result in a DMA transfer request from the specific channel to the arbiter, and if there are several DMA channels with pending transfer requests, the arbiter has to choose which channel to grant access to become the active channel. The DMA channel granted access as the active channel will carry out the transaction as configured in the transfer descriptor. The DMA channel can be interrupted by a higher prioritized channel after each burst transfer, but will resume its block transfer when it is granted access as the active channel again.

For each beat transfer an optional output event can be generated, and for each block transfer optional interrupts and an optional output event can be generated. When a transaction is completed, dependent of the configuration, the DMA channel will either be suspended or disabled.

### 25.6.1.2 CRC

The internal CRC supports two commonly used CRC polynomials; CRC-16 (CRC-CCITT) and CRC-32 (IEEE 802.3). It can be used with selectable DMA channel or independently, with I/O interface.

## 25.6.2 Basic Operation

### 25.6.2.1 Initialization

The following DMAC registers are enable-protected, meaning that they can only be written when the DMAC is disabled (**CTRL.DMAENABLE** is zero):

- Descriptor Base Memory Address ([BASEADDR](#)) register
- Write-Back Memory Base Address ([WRBADDR](#)) register

The following DMAC bit is enable-protected, meaning that it can only be written when both the DMAC and CRC are disabled ([CTRL.DMAENABLE](#) and [CTRL.CRCENABLE](#) is zero):

- Software Reset bit in Control register ([CTRL.SWRST](#))

The following DMA channel register is enable-protected, meaning that it can only be written when the corresponding DMA channel is disabled ([CHCTRLA.ENABLE](#) is zero):

- Channel Control B ([CHCTRLB](#)) register, except the Command ([CHCTRLB.CMD](#)) and Channel Arbitration Level ([CHCTRLB.LVL](#)) bits

The following DMA channel bit is enable-protected, meaning that it can only be written when the corresponding DMA channel is disabled:

- Channel Software Reset bit in Channel Control A register ([CHCTRLA.SWRST](#))

The following CRC registers are enable-protected, meaning that they can only be written when the CRC is disabled ([CTRL.CRCENABLE](#) is zero):

- CRC Control ([CRCCTRL](#)) register
- CRC Checksum ([CRCCHKSUM](#)) register

Enable-protection is denoted by the Enable-Protected property in the register description.

Before the DMAC is enabled, it must be configured, as outlined by the following steps:

- The SRAM address of where the descriptor memory section is located must be written to the Description Base Address ([BASEADDR](#)) register
- The SRAM address of where the write-back section should be located must be written to the Write-Back Memory Base Address ([WRBADDR](#)) register
- Priority level x of the arbiter can be enabled by writing a one to the Priority Level x Enable bit in the Control register([CTRL.LVLENx](#))

Before a DMA channel is enabled, the DMA channel and the corresponding first transfer descriptor must be configured, as outlined by the following steps:

- DMA channel configurations
  - The channel number of the DMA channel to configure must be written to the Channel ID ([CHID](#)) register
  - Trigger action must be selected by writing the Trigger Action bit group in the Channel Control B register ([CHCTRLB.TRIGACT](#))
  - Trigger source must be selected by writing the Trigger Source bit group in the Channel Control B register ([CHCTRLB.TRIGSRC](#))
- Transfer Descriptor
  - The size of each access of the data transfer bus must be selected by writing the Beat Size bit group in the Block Transfer Control register ([BTCTRL.BEATSIZE](#))
  - The transfer descriptor must be made valid by writing a one to the Valid bit in the Block Transfer Control register ([BTCTRL.VALID](#))
  - Number of beats in the block transfer must be selected by writing the Block Transfer Count ([BTCNT](#)) register
  - Source address for the block transfer must be selected by writing the Block Transfer Source Address ([SRCADDR](#)) register
  - Destination address for the block transfer must be selected by writing the Block Transfer Destination Address ([DSTADDR](#)) register

If CRC calculation is needed the CRC module must be configured before it is enabled, as outlined by the following steps:

- CRC input source must selected by writing the CRC Input Source bit group in the CRC Control register ([CRCCTRL.CRCSRC](#))

- Type of CRC calculation must be selected by writing the CRC Polynomial Type bit group in the CRC Control register ([CRCCTRL.CRCPOLY](#))
- If I/O is chosen as input source, the beat size must be selected by writing the CRC Beat Size bit group in the CRC Control register ([CRCCTRL.CRCBEATSIZE](#))

### 25.6.2.2 Enabling, Disabling and Resetting

The DMAC is enabled by writing a one to the DMA Enable bit in the Control register ([CTRL.DMAENABLE](#)). The DMAC is disabled by writing a zero to [CTRL.DMAENABLE](#).

A DMA channel is enabled by writing a one to Enable bit in the Channel Control A register ([CHCTRLA.ENABLE](#)), after writing the corresponding channel id to the Channel ID bit group in the Channel ID register ([CHID.ID](#)). A DMA channel is disabled by writing a zero to [CHCTRLA.ENABLE](#).

The CRC is enabled by writing a one to the CRC Enable bit in the Control register ([CTRL.CRCENABLE](#)). The CRC is disabled by writing a zero to [CTRL.CRCENABLE](#).

The DMAC is reset by writing a one to the Software Reset bit in the Control register ([CTRL.SWRST](#)), when the DMAC and CRC are disabled. All registers in the DMAC, except [DBGCTRL](#), will be reset to their initial state.

A DMA channel is reset by writing a one to the Software Reset bit in the Channel Control A register ([CHCTRLA.SWRST](#)), after writing the corresponding channel id to the Channel ID bit group in the Channel ID register ([CHID.ID](#)). The channel registers will be reset to their initial state. The corresponding DMA channel must be disabled in order for the reset to take effect.

### 25.6.2.3 Transfer Descriptors

Together with the channel configurations the transfer descriptors decides how a block transfer should be executed. Before a DMA channel is enabled ([CHCTRLA.ENABLE](#) is written to one), and receives a transfer trigger, its first transfer descriptor has to be initialized and valid ([BTCTRL.VALID](#)). The first transfer descriptor describes the first block transfer of a transaction. For further details on the content of a transfer descriptor, refer to [Table 25-2 on page 343](#).

All transfer descriptors must reside in SRAM and the addresses stored in the Descriptor Memory Section Base Address ([BASEADDR](#)) and Write-Back Memory Section Base Address ([WRBADDR](#)) registers tells the DMAC where to find the descriptor memory section and the write-back memory section.

The descriptor memory section is where the DMAC expects to find the first transfer descriptors for all DMA channels. As [BASEADDR](#) points only to the first transfer descriptor of channel 0, refer to [Figure 25-3](#), all first transfer descriptors must be stored in a contiguous memory section, where the transfer descriptors must be ordered according to their channel number. [Figure 25-3](#) shows an example of linked descriptors on DMA channel 0. For further details on linked descriptors, refer to “[Linked Descriptors](#)” on page 333.

The write-back memory section is the section where the DMAC stores the transfer descriptors for the ongoing block transfers. [WRBADDR](#) points to the ongoing transfer descriptor of channel 0. All ongoing transfer descriptors will be stored in a contiguous memory section where the transfer descriptors are ordered according to their channel number. [Figure 25-3](#) shows an example of linked descriptors on DMA channel 0. For further details on linked descriptors, refer to “[Linked Descriptors](#)” on page 333.

**Figure 25-3. Memory Sections**

The size of the descriptor and write-back memory sections is dependant on most significant enabled DMA channel, as shown below:

$$Size = 128bits \cdot (MostSignificantEnabledChannelNumber + 1)$$

For memory optimization, it is recommended to always use the less significant DMA channels if not all channels are required.

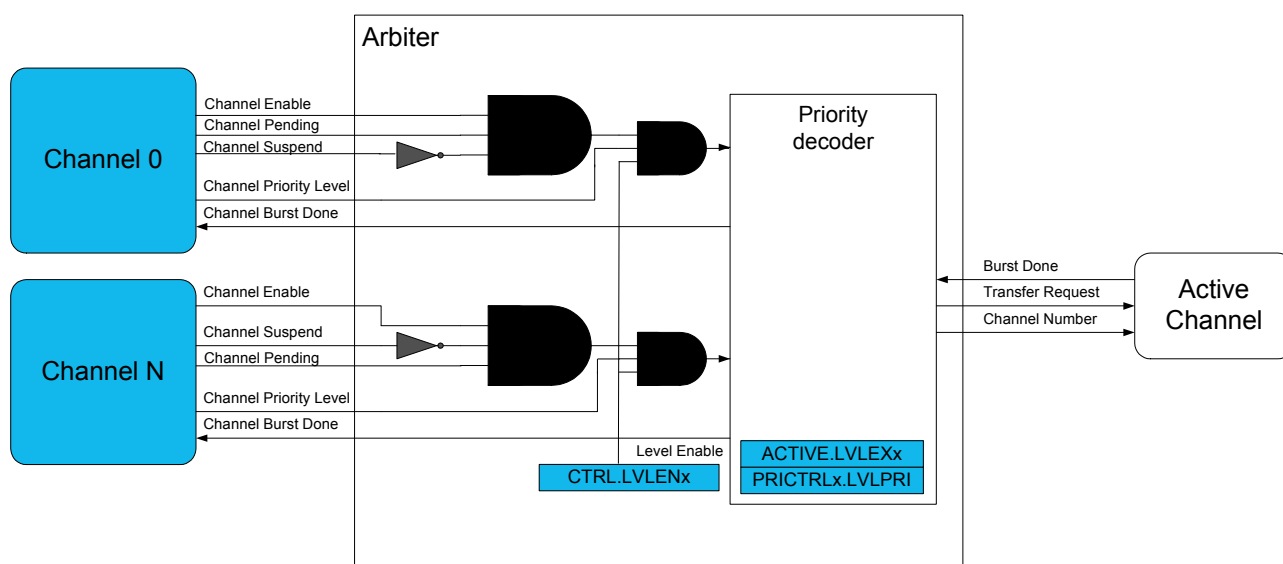

The descriptor and write-back memory sections can either be two separate memory sections, or they can share memory section (**BASEADDR=WRBADDR**). The benefit of having them in two separate sections, is that the same transaction for a channel can be repeated without having to modify the first transfer descriptor. The benefit of having descriptor memory and write-back memory in the same section is that it requires less SRAM. In addition, the latency from fetching the first descriptor of a transaction to the first burst transfer is executed, is reduced.

## 25.6.2.4 Arbitration

If a DMA channel is enabled and not suspended when it receives a transfer trigger, it will send a transfer request to the arbiter. When the arbiter receives the transfer request it will include the DMA channel in the queue of channels having pending transfers, and the corresponding Pending Channel x bit in the Pending Channels registers (**PENDCH.PENDCHx**) will be set. Dependent of the arbitration scheme, the arbiter will choose which DMA channel will be the next active channel. Refer to Figure 25-4. The active channel is the DMA channel being granted access to perform its next burst transfer. When the arbiter has granted a DMA channel access to the DMAC, the corresponding **PENDCH.PENDCHx** will be cleared. Depending on if the upcoming burst transfer is the first for the transfer request or not, the corresponding Busy Channel x bit in the Busy Channels register (**BUSYCH.BUSYCHx**) will either be set or remain one. When the channel has performed its granted burst transfer(s) it will either be fed into the queue of channels with pending transfers, set to be waiting for a new transfer trigger, it will be suspended or it will be disabled. This depends on the channel and block transfer configuration. If the DMA channel is fed into the queue of channels with pending transfers, the corresponding **BUSYCH.BUSYCHx** will remain one. If the DMA channel is set to wait for a new transfer trigger, suspended or disabled, the corresponding **BUSYCH.BUSYCHx** will be cleared.

If a DMA channel is suspended while it has a pending transfer, it will be removed from the queue of pending channels, but the corresponding **PENDCH.PENDCHx** will remain set. When the same DMA channel is resumed, it will be added to the queue of pending channels again. If a DMA channel gets disabled (**CHCTRLA.ENABLE** is zero) while it has a pending transfer, it will be removed from the queue of pending channels, and the corresponding **PENDCH.PENDCHx** will be cleared.

Figure 25-4. Arbiter overview

When a channel level is pending or the channel is transferring data, the corresponding Level Executing bit is set in the Active Channel and Levels register (**ACTIVE.LVLEXx**).

Each DMA channel supports a 4-level priority scheme. The priority level for a channel is configured by writing to the Channel Arbitration Level bit group in the Channel Control B register (**CHCTRLB.LVL**). As long as all priority levels are enabled, a channel with lower priority level number will have priority over a channel with higher priority level number. A priority level is enabled by writing the Priority Level x Enable bit in the Control register (**CTRL.LVLENx**) to one, for the corresponding level.

Within each priority level the DMAC's arbiter can be configured to prioritize statically or dynamically. For the arbiter to perform static arbitration within a priority level, the Level x Round-Robin Scheduling Enable bit in the Priority Control 0 register (**PRICTRL0.RRLVLENx**) has to be written to zero. When static arbitration is enabled (**PRICTRL0.RRLVLENx** is zero), the arbiter will prioritize a low channel number over a high channel number as shown in Figure 25-5. When using

the static scheme there is a risk of high channel numbers never being granted access as the active channel. This can be avoided using a dynamic arbitration scheme.

Figure 25-5. Static priority

The dynamic arbitration scheme available in the DMAC is round-robin. Round-robin arbitration is enabled by writing `PRICTRL0.RRLVLENx` to one, for a given priority level  $x$ . With the round-robin scheme, the channel number of the last channel being granted access will have the lowest priority the next time the arbiter has to grant access to a channel within the same priority level, as shown in Figure 25-6. The channel number of the last channel being granted access as the active channel, will be stored in the Level  $x$  Channel Priority Number bit group in the Priority Control 0 register (`PRICTRL0.LVLPRIx`), for the corresponding priority level.

Figure 25-6. Round-robin scheduling

25.6.2.5 Data Transmission

Before the DMAC can perform a data transmission, a DMA channel has to be configured and enabled, its corresponding transfer descriptor has to be initialized and the arbiter has to grant the DMA channel access as the active channel.

Once the arbiter has granted a DMA channel access as the active channel (refer to Figure 25-1) the transfer descriptor for the DMA channel will be fetched from SRAM using the fetch bus, and stored in the internal memory for the active channel. Depending on if it is a new or ongoing block transfer, the transfer descriptor will either be fetched from the descriptor memory section (`BASEADDR`) or the write-back memory section (`WRBADDR`). By using the data transfer bus, the DMAC will read the data from the current source address and write it to the current destination address. For further details on how the current source and destination addresses are calculated, refer to “Addressing” on page 331.

The arbitration procedure is performed after each burst transfer. If the current DMA channel is granted access again, the block transfer counter (**BTCNT**) of the internal transfer descriptor will be decremented with the number of beats in a burst, and the active channel will perform a new burst transfer. If a different DMA channel than the current active channel is granted access, the **BTCNT** of the internal transfer descriptor will be decremented with the number of beats in a burst. The block transfer counter value will be written to the write-back section before the transfer descriptor of the newly granted DMA channel is fetched into the internal memory of the active channel. The optional output event, Beat, will be generated if configured and enabled.

When a block transfer has come to its end, **BTCNT** has reached zero, the Valid bit in the Block Transfer Control register will be written to zero in the internal transfer descriptor for the active channel before the entire transfer descriptor is written to the write-back memory. The optional interrupts, Channel Transfer Complete and Channel Suspend, and the optional output event, Block, will be generated if configured and enabled. If it was the last block transfer in a transaction, Next Address (**DESCADDR**) register will hold the value 0x00000000, and the DMA channel will either be suspended or disabled, depending on the configuration in the Block Action bit group in the Block Transfer Control register(**BTCTRL.BLOCKACT**). If the transaction has further block transfers pending, **DESCADDR** will hold the SRAM address to the next transfer descriptor to be fetched. The DMAC will fetch the next descriptor into the internal memory of the active channel and write its content to the write-back section for the channel, before the arbiter gets to choose the next active channel.

### 25.6.2.6 Transfer Triggers and Actions

A DMA transfer can be started only when a DMA transfer request is detected. A transfer request can be triggered from software, from peripheral, or from an event. There are dedicated Trigger Source selections for each DMA Channel Control B (**CHCTRLB.TRIGSRC**).

The trigger actions are available in the Trigger Action bit group in the Channel Control B register (**CHCTRLB.TRIGACT**). By default, a trigger starts a block transfer operation. If a single descriptor is defined for a channel, the channel is automatically disabled when a block transfer is complete. If a list of linked descriptors is defined for a channel, the channel is automatically disabled if the last descriptor in the list is executed or the channel will be waiting for the next block transfer trigger if the list still has descriptors to execute. When enabled again, the channel will wait for the next block transfer trigger. It is also possible to select the trigger to start beat or transaction transfers instead of a block transfer.

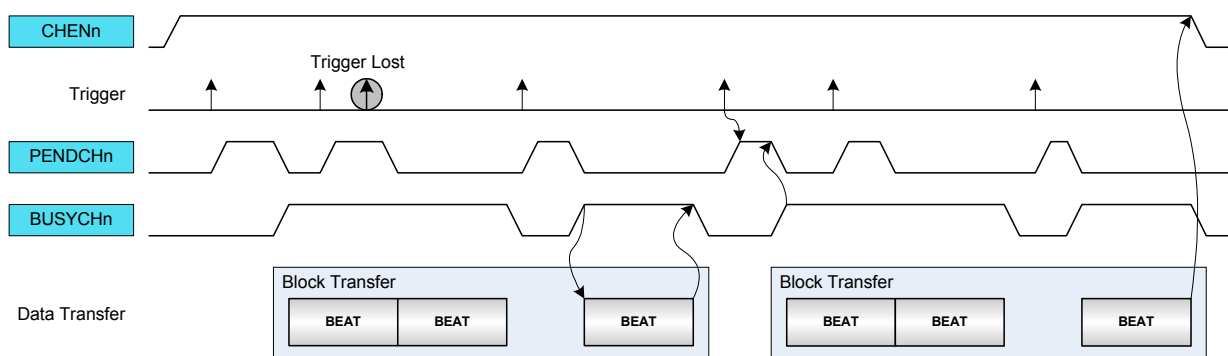

If the trigger source generates a transfer request during an ongoing transfer, this will be kept pending (**CHSTATUS.PEND** is one), and the transfer can start when the ongoing one is done. Only one pending transfer can be kept, and so if the trigger source generates more transfer requests when one is already pending, these will be lost. All channels pending status flags are also available in the Pending Channels register (**PENDCH**).

When the transfer starts, the corresponding Channel Busy status flag is set in Channel Status register (**CHSTATUS.BUSY**). When the trigger action is complete, the Channel Busy status flag is cleared. All channels busy status flags are also available in the Busy Channels register (**BUSYCH**) in DMAC.

Figure 25-7 on page 331 shows an example where triggers are used with two linked block descriptors.

Figure 25-7. Trigger action and transfers

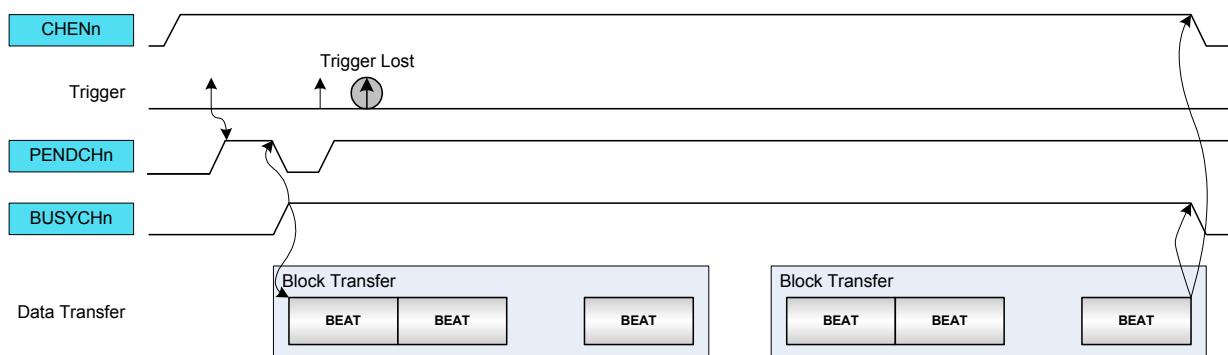

### Beat Trigger Action

### Block Trigger Action

### Transaction Trigger Action

#### 25.6.2.7 Addressing

For the DMAC to know from where to where it should transfer the data, each block transfer needs to have a source and destination address defined. The source address can be set by writing the Transfer Source Address ([SRCADDR](#)) register, and the destination address can be set by writing the Transfer Destination Address ([SRCADDR](#)) register.

The addressing of this DMAC module can be static or incremental, for either source or destination of a block transfer, or both.

Incrementation for the source address of a block transfer is enabled by writing the Source Address Incrementation Enable bit in the Block Transfer Control register ([BTCTRL.SRCINC](#)) to one. The step size of the incrementation is configurable and can be chosen by writing the Step Selection bit in the Block Transfer Control

register(**BTCTRL**.STEPSEL) to one, and the Address Increment Step Size bit group in the Block Transfer Control register (**BTCTRL**.STEPSIZE), to the desired step size. If **BTCTRL**.STEPSEL is zero, the step size for the source incrementation will be the size of one beat.

When source address incrementation is configured (**BTCTRL**.SRCINC is one), **SRCADDR** must be set and calculated as follows:

$$SRCADDR = SRCADDR_{START} + BTCNT \cdot (BEATSIZE + 1) \cdot 2^{STEPSIZE} \quad , \text{ where } \mathbf{BTCTRL.STEPSEL} \text{ is one}$$

$$SRCADDR = SRCADDR_{START} + BTCNT \cdot (BEATSIZE + 1) \quad , \text{ where } \mathbf{BTCTRL.STEPSEL} \text{ is zero}$$

- SRCADDRSTART is the source address of the first beat transfer in the block transfer
- BTCNT is the initial number of beats remaining in the block transfer
- BEATSIZE is the configured number of bytes in a beat
- STEPSIZE is the configured number of beats for each incrementation

Figure 25-8 shows an example where DMA channel 0 is configured to increment the source address by one beat (**BTCTRL**.SRCINC is one) after each beat transfer, and DMA channel 1 is configured to increment source address by two beats (**BTCTRL**.SRCINC is one, **BTCTRL**.STEPSEL is one, and **BTCTRL**.STEPSIZE is 0x1). As the destination address for both channels are peripherals, destination incrementation is disabled(**BTCTRL**.DSTINC is zero).

**Figure 25-8. Source address increment**

Incrementation for the destination address of a block transfer is enabled by writing the Destination Address Incrementation Enable bit in the Block Transfer Control register (**BTCTRL**.DSTINC) to one. The step size of the incrementation is configurable and can be chosen by writing **BTCTRL**.STEPSEL to zero, and **BTCTRL**.STEPSIZE to the desired step size. If **BTCTRL**.STEPSEL is one, the step size for the destination incrementation will be the size of one beat.

When destination address incrementation is configured (**BTCTRL**.DSTINC is one), **SRCADDR** must be set and calculated as follows:

$$DSTADDR = DSTADDR_{START} + BTCNT \cdot (BEATSIZE + 1) \cdot 2^{STEPSIZE} \quad , \text{ where } \mathbf{BTCTRL.STEPSEL} \text{ is zero}$$

$$DSTADDR = DSTADDR_{START} + BTCNT \cdot (BEATSIZE + 1) \quad , \text{ where } \mathbf{BTCTRL.STEPSEL} \text{ is one}$$

- DSTADDRSTART is the destination address of the first beat transfer in the block transfer
- BTCNT is the initial number of beats remaining in the block transfer
- BEATSIZE is the configured number of bytes in a beat
- STEPSIZE is the configured number of beats for each incrementation

Figure 25-9 shows an example where DMA channel 0 is configured to increment destination address by one beat (**BTCTRL**.DSTINC is one) and DMA channel 1 is configured to increment destination address by two beats (**BTCTRL**.DSTINC is one, **BTCTRL**.STEPSEL is zero, and **BTCTRL**.STEPSIZE is 0x1). As the source address for both channels are peripherals, source incrementation is disabled(**BTCTRL**.SRCINC is zero).

**Figure 25-9. Destination address increment**

### 25.6.2.8 Error Handling

If a bus error is received from AHB slave during a DMA data transfer, the corresponding active channel is disabled and the corresponding Channel Transfer Error Interrupt flag in the Channel Interrupt Status and Clear register ([CHINTFLAG.TERR](#)) is set. If transfer error interrupt is enabled, optional error interrupt is generated. The transfer counter will not be decremented and its current value is written-back in the write-back memory section before the channel is disabled.

When the DMAC fetches an invalid descriptor ([BTCTRL.VALID](#) is zero) or when the channel is resumed and the DMA fetches the next descriptor with null address ([DESCADDR](#) is 0x00000000), the corresponding channel operation is suspended, the Channel Suspend Interrupt Flag in the Channel Interrupt Flag Status and Clear register ([CHINTFLAG.SUSP](#)) is set and the Channel Fetch Error bit in the Channel Status register ([CHSTATUS.FERR](#)) is set. If enabled, optional suspend interrupt is generated.

## 25.6.3 Additional Features

### 25.6.3.1 Linked Descriptors

A transaction can either consist of a single block transfer, or it can consist of several block transfers. When a transaction consist of several block transfers it is called linked descriptors.

[Figure 25-3](#) shows how linked descriptors work. When the first block transfer is completed on DMA channel 0, the DMAC fetches the next transfer descriptor which is pointed to by the value stored in the Next Descriptor Address ([DESCADDR](#)) register, in the first transfer descriptor. Fetching the next transfer descriptor ([DESCADDR](#)) is continued until the last transfer descriptor. When the block transfer for the last transfer descriptor is executed and [DESCADDR](#)=0x00000000, the transaction is terminated. For further details on how the next descriptor is fetched from SRAM, refer to “[Data Transmission](#)” on page 329.

#### Adding Descriptor to the End of a List

To add a new descriptor at the end of the descriptor list, create the descriptor in SRAM, with [DESCADDR](#)=0x00000000 indicating it is the new last descriptor in the list, and modify the [DESCADDR](#) value of the current last descriptor to the address of the newly created descriptor.

#### Modifying a Descriptor in a List

In order to add descriptors to a list, the following actions must be performed:

1. Before enabling a channel, the Suspend interrupt must be enabled
2. Reserve memory space addresses to configure a new descriptor
3. Configure the new descriptor
  - Set the next descriptor address ([DESCADDR](#))
  - Set the destination address ([DSTADDR](#))
  - Set the source address ([SRCADDR](#))
  - Configure the block transfer control ([BTCTRL](#)) including
    - Optionally enable the Suspend block action
    - Set the descriptor [VALID](#) bit
4. In the existing list and for the descriptor which has to be updated, set the [VALID](#) bit to zero
5. Read [DESCADDR](#) from the Write-Back memory

- If the DMA has not already fetched the descriptor which requires changes:
  - Update the DESCADDR location of the descriptor from the List
  - Optionally clear the Suspend block action
  - Set the descriptor VALID bit to one
  - Optionally enable the Resume software command
- If the DMA is executing the same descriptor as the one which requires changes:
  - Set the Channel Suspend software command and wait for the Suspend interrupt
  - Update the Write-Back next descriptor address (DESCRADDR)
  - Clear the interrupt sources and set the Resume software command
  - Update the DESCADDR location of the descriptor from the List
  - Optionally clear the Suspend block action
  - Set the descriptor VALID bit to one

6. Go to step 3 if needed

### Adding a Descriptor Between Existing Descriptors

To insert a descriptor C between 2 existing descriptors (A & B), the descriptor currently executed by the DMA must be identified.

1. If DMA is executing descriptor B, descriptor C cannot be inserted.
2. If DMA has not started to execute descriptor A, follow the steps:
  - a. Set the descriptor A VALID bit to 0
  - b. Set the DESCADDR value of descriptor A to point descriptor C instead of descriptor B
  - c. Set the DESCADDR value of descriptor C to point descriptor B
  - d. Set the descriptor A VALID bit to 1.
3. If DMA is executing descriptor A,
  - a. Apply the software suspend command to the channel and
  - b. Perform steps 2a through 2d

Apply the software resume command to the channel.

#### 25.6.3.2 Channel Suspend

The channel operation can be suspended at anytime by software, by setting the Suspend command in Command bit field of Channel Control B register ([CHCTRLB.CMD](#)). When the ongoing burst transfer is completed, the channel operation is suspended and the suspend command is automatically cleared.

It is also possible to suspend a channel operation after a block transfer completes. The software must set the Suspend Block Action in the corresponding Block Transfer Control location ([BTCTRL.BLOCKACT](#)). When the block transfer is completed, the channel operation is suspended. The channel is kept enabled, can receive transfer triggers, but it will be removed from the arbitration scheme. The channel will automatically suspend the operation if an invalid transfer control descriptor is fetched from system memory ([BTCTRL.VALID=0](#)). The Channel Fetch Error bit in the Channel Status register ([CHSTATUS.FERR](#)) is set when an invalid descriptor is fetched. Only an enabled channel can be suspended. If the channel is disabled when suspended, the internal suspend command is cleared. When suspended, the Channel Suspend Interrupt flag in the Channel Interrupt Status and Clear register ([CHINTFLAG.SUSP](#)) is set and optional suspend interrupt is generated.

For more details on transfer descriptors, refer to “Transfer Descriptors” on page 326.

#### 25.6.3.3 Channel Resume and Next Suspend Skip

A channel operation can be resumed by software by setting the Resume command in Command bitfield of Channel Control B register ([CHCTRLB.CMD](#)). If the channel is already suspended, the channel operation resumes from where it previously stopped when the Resume command is detected. When the Resume command is issued before the channel is suspended, the next suspend action is skipped and the channel continues the normal operation.

**Figure 25-10. Channel suspend/resume operation**

### 25.6.3.4 Event Input Actions

The event input actions are available only for channels supporting event inputs. For details on channels with event input support, refer to [Table 29-6](#) and [Table 29-4](#).

The Event Actions bits in the Channel Control B register ([CHCTRLB.EVACT](#)) specify the actions the DMA will take on an input event. Before using event actions, the event controller must be configured first and the corresponding Channel Event Input Enable bit ([CHCTRLB.EVIE](#)) must be set. The DMA supports only resynchronized events. For details on how to configure the resynchronized event path, refer to the Event System.

**Normal transfer:** When this event action is selected for a channel, the event input is used to trigger a beat or burst transfer on peripherals.

The transfer trigger is selected by setting the Trigger Source bits in Channel Control B register to zero ([CHCTRLB.TRIGSRC](#)). The event is acknowledged as soon as the event is received. When received, the Channel Pending status bit is set ([CHSTATUS.PEND](#)). If the event is received while the channel is pending, the event trigger is lost. [Figure 25-11](#) shows an example where beat transfers are enabled by internal events.

**Figure 25-11. Beat event trigger action**

**Periodic transfers:** When this event action is selected for a channel, the event input is used to trigger a transfer on peripherals with pending transfer requests. This type of event is intended to be used with peripheral triggers for example, for timed communication protocols or periodic transfers between peripherals, as examples. The peripheral trigger is selected by the Trigger Source bits in the Channel Control B register ([CHCTRLB.TRIGSRC](#)).

The event is acknowledged as soon as the event is received. The peripheral trigger request is stored internally when the previous trigger action is completed (i.e. channel is not pending) and when an active event is received. If the peripheral trigger is active, the DMA will wait for an event before the peripheral trigger is internally registered. When both event and peripheral transfer trigger are active, the Channel Pending status bit is set ([CHSTATUS.PEND](#)). A software trigger will now trigger a transfer.

[Figure 25-12](#) shows an example where the peripheral beat transfers are enabled by periodic events.

**Figure 25-12. Periodic event with beat peripheral triggers**

**Conditional transfer:** When the conditional transfer event action is selected, the event input is used to trigger a conditional transfer on peripherals with pending transfer requests. As example, this type of event can be used for peripheral to peripheral transfers, where one peripheral is source of event and the second peripheral is source of DMA trigger.

The peripheral Trigger Source must be set in Channel Control B register ([CHCTRLB.TRIGSRC](#)). Each peripheral trigger is stored internally when the event is received. When the peripheral trigger is stored internally, the Channel Pending status bit is set ([CHSTATUS.PEND](#)) and the event is acknowledged. A software trigger will now trigger a transfer.

[Figure 25-13](#) shows an example where conditional event is enabled with peripheral beat trigger requests.

**Figure 25-13. Conditional event with beat peripheral triggers**

**Conditional block transfer:** When the conditional block event action is selected, the event input is used to trigger a conditional block transfer on peripherals. The peripheral Trigger Source must be set in Channel Control B register ([CHCTRLB.TRIGSRC](#)).

Before starting transfers within a block, an event must be received. When received, the event is acknowledged when the block transfer is completed. A software trigger will trigger a transfer.

[Figure 25-14](#) shows an example where conditional event block transfer is enabled with peripheral beat trigger requests.

**Figure 25-14. Conditional block transfer with beat peripheral triggers**

**Channel suspend:** When the channel suspend event action is selected, the event input is used to suspend an ongoing channel operation. The event is acknowledged when the current AHB access is completed. For further details on channel suspend, refer to [“Channel Suspend” on page 334](#).

**Channel resume:** When the channel resume event action is selected, the event input is used to resume a suspended channel operation. The event is acknowledged as soon as the event is received and the Channel Suspend Interrupt Flag (`CHINTFLAG.SUSP`) is cleared. For further details on channel suspend, refer to [“Channel Suspend” on page 334](#).

**Skip next block suspend:** This event can be used to skip the next block suspend action. If the channel is suspended before the event rises, the channel operation is resumed and the event is acknowledged. If the event rises before a suspend block action is detected, the event is kept until the next block suspend detection. When the block transfer is completed, the channel continues the operation (not suspended) and the event is acknowledged.

### 25.6.3.5 Event Output Selections

The event output selections are available only for channels supporting event outputs. The pulse width of an event output from a channel is one AHB clock cycle.

The Channel Event Output Enable can be set in Control B register ([CHCTRLB.EVOE](#)). The Event Output Selection is available in each Descriptor Block Control location ([BTCTRL.EVOSEL](#)). It is possible to generate events after each beat, burst or block transfer. To enable an event when the transaction is complete, the block event selection must be set in the last transfer descriptor only. [Figure 25-15](#) shows an example where the event output generation is enabled in the first block transfer, and disabled in the second block.

**Figure 25-15.**Event output generation

#### Beat Event Output

#### Block Event Output

### 25.6.3.6 Aborting Transfers

Transfers on any channel can be gracefully aborted by software, by disabling the corresponding DMA channel. It is also possible to abort all ongoing or pending transfers, by disabling the DMAC.

When DMAC disable request is detected:

- Active channel with ongoing transfers will be disabled when the ongoing beat access is completed and the Write-Back memory section is updated. This prevents transfer corruption before the channel is disabled.
- All other enabled channels will be disabled in the next clock cycle.

The corresponding Channel Enable bit in the Channel Control A register ([CHCTRLA.ENABLE](#)) is read as zero when the channel is disabled.

The corresponding DMAC Enable bit in the Control register ([CTRL.DMAENABLE](#)) is read as zero when the entire DMAC module is disabled.

### 25.6.3.7 CRC Operation

A cyclic redundancy check (CRC) is an error detection technique used to find accidental errors in data. It is commonly used to determine whether the data during a transmission, or data present in data and programme memories has been corrupted or not. A CRC takes a data stream or a block of data as input and generates a 16- or 32-bit output that can be appended to the data and used as a checksum. When the same data are later received or read, the device or application repeats the calculation. If the new CRC result does not match the one calculated earlier, the block contains a data error. The application will then detect this and may take a corrective action, such as requesting the data to be sent again or simply not using the incorrect data.

Typically, a CRC-n applied to a data block of arbitrary length will detect any single error burst not longer than n bits (any single alteration that spans no more than n bits of the data), and will detect the fraction  $1-2^{-n}$  of all longer error bursts. The

CRC module in DMAC supports two commonly used CRC polynomials: CRC-16 (CRC-CCITT) and CRC-32 (IEEE 802.3).

- CRC-16:
  - Polynomial:  $x^{16} + x^{12} + x^5 + 1$
  - Hex value: 0x1021
- CRC-32:
  - Polynomial:  $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$
  - Hex value: 0x04C11DB7

The data source for the CRC module must be selected in software as either the DMA channels or the APB bus interface. The CRC module then takes data input from the selected source and generates a checksum based on these data. The checksum is available in the CRC Checksum register (CRCCHKSUM). When CRC-32 polynomial is used, the final checksum read is bit reversed and complemented, as shown in Figure 25-16 on page 339.

The CRC polynomial to be used is configurable, and the default setting is CRC-16. The CRC module operates on byte only. When the DMA is used as data source for the CRC module, the DMA channel beat size setting will be used. When used with APB bus interface, the application must set the CRC Beat Size bit field of CRC Control register (CRCCTRL.CRCBEATSIZE). 8-, 16- or 32-bit bus transfer access type is supported. The corresponding number of bytes will be written in the CRCDATAIN register and the CRC module will operate on the input data in a byte by byte manner.

**Figure 25-16.CRC generator block diagram**

**CRC on DMA data:** CRC-16 or CRC-32 calculations can be performed on data passing through any DMA channel. Once a DMA channel is selected as the source, the CRC module will continuously generate the CRC on the data passing through the DMA channel. The checksum is available for readout once the DMA transaction is completed or aborted. A CRC can also be generated on SRAM, Flash or I/O memory by passing these data through a DMA channel. If the latter is done, the destination register for the DMA data can be the data input (CRCDATAIN) register in the CRC module.

**CRC using the I/O interface:** Before using the CRC module with the I/O interface, the application must set the CRC Beat Size bits in the CRC Control register (CRCCTRL.CRCBEATSIZE). 8/16/32-bit bus transfer type can be selected.

CRC can be performed on any data by loading them into the CRC module using the CPU and writing the data to the [CRCDATAIN](#) register. Using this method, an arbitrary number of bytes can be written to the register by the CPU, and CRC is done continuously for each byte. This means if a 32-bit data is written to the CRCDATAIN register the CRC module takes 4 cycles to calculate the CRC. The CRC complete is signaled by the CRCBUSY bit in the [CRCSTATUS](#) register. New data can be written only when CRCBUSY flag is not set.

#### 25.6.4 DMA Operation

Not applicable.

#### 25.6.5 Interrupts

The DMAC has the following interrupt sources:

- Transfer Complete (TCMPL): Indicates that a block transfer is completed on the corresponding channel. Refer to [“Data Transmission” on page 329](#) for details.
- Transfer Error (TERR): Indicates that a bus error has occurred during a burst transfer, or that an invalid descriptor has been fetched. Refer to [“Error Handling” on page 333](#) for details.
- Channel Suspend (SUSP): Indicates that the corresponding channel has been suspended. Refer to [“Channel Suspend” on page 334](#) and [“Data Transmission” on page 329](#) for details.

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Channel Interrupt Flag Status and Clear ([CHINTFLAG](#)) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Channel Interrupt Enable Set ([CHINTENSET](#)) register, and disabled by writing a one to the corresponding bit in the Channel Interrupt Enable Clear ([CHINTENCLR](#)) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, the DMAC is reset or the corresponding DMA channel is reset. See [CHINTFLAG](#) for details on how to clear interrupt flags. All interrupt requests are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

The user must read the Channel Interrupt Status ([INTSTATUS](#)) register to identify the channels with pending interrupts and must read the Channel Interrupt Flag Status and Clear ([CHINTFLAG](#)) register to determine which interrupt condition is present for the corresponding channel. It is also possible to read the Interrupt Pending register ([INTPEND](#)), which provides the lowest channel number with pending interrupt and the respective interrupt flags.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

#### 25.6.6 Events

The DMAC can generate the following output events:

- Channel (CH): Generated when a block transfer for a given channel has been completed, or when a beat transfer within a block transfer for a given channel has been completed. Refer to [“Event Output Selections” on page 338](#) for details.

Writing a one to the Channel Control B Event Output Enable bit ([CHCTRLB.EVOE](#)) enables the corresponding output event configured in the Event Output Selection bit group in the Block Transfer Control register ([BTCTRL.EVOSEL](#)). Writing a zero to [CHCTRLB.EVOE](#) disables the corresponding output event. Refer to [“EVSYS – Event System” on page 467](#) for details on configuring the event system.

The DMAC can take the following actions on an input event:

- Transfer and Periodic Transfer Trigger (TRIG): normal transfer or periodic transfers on peripherals are enabled
- Conditional Transfer Trigger (CTRIG): conditional transfers on peripherals are enabled
- Conditional Block Transfer Trigger (CBLOCK): conditional block transfers on peripherals are enabled
- Channel Suspend Operation (SUSPEND): suspend a channel operation
- Channel Resume Operation (RESUME): resume a suspended channel operation

- Skip Next Block Suspend Action (SSKIP): skip the next block suspend transfer condition

Writing a one to the Channel Control B Event Input Enable bit ([CHCTRLB.EVIE](#)) enables the corresponding action on input event. Writing a zero to this bit disables the corresponding action on input event. Note that several actions can be enabled for incoming events. If several events are connected to the peripheral, any enabled action will be taken for any of the incoming events. For further details on event input actions, refer to [“Event Input Actions” on page 335](#). Refer to the Event System chapter for details on configuring the event system.

### 25.6.7 Sleep Mode Operation

Each DMA channel can be configured to operate in any sleep mode. To be able to run in standby, the RUNSTDBY bit in Channel Control A register ([CHCTRLA.RUNSTDBY](#)) must be written to one. The DMAC can wake up the device using interrupts from any sleep mode or perform actions through the Event System.

### 25.6.8 Synchronization

Not applicable.

## 25.7 Register Summary

Table 25-1. DMAC Register Summary

| Offset              | Name       | Bit Pos. |                  |      |             |         |              |              |                  |         |
|---------------------|------------|----------|------------------|------|-------------|---------|--------------|--------------|------------------|---------|
| 0x00                | CTRL       | 7:0      |                  |      |             |         |              | CRCENABLE    | DMAENABLE        | SWRST   |
| 0x01                |            | 15:8     |                  |      |             |         | LVLEN3       | LVLEN2       | LVLEN1           | LVLEN0  |
| 0x02                | CRCCTRL    | 7:0      |                  |      |             |         | CRCPOLY[1:0] |              | CRCBEATSIZE[1:0] |         |
| 0x03                |            | 15:8     |                  |      | CRCSRC[5:0] |         |              |              |                  |         |
| 0x04                | CRCDATAIN  | 7:0      | CRCDATAIN[7:0]   |      |             |         |              |              |                  |         |
| 0x05                |            | 15:8     | CRCDATAIN[15:8]  |      |             |         |              |              |                  |         |
| 0x06                |            | 23:16    | CRCDATAIN[23:16] |      |             |         |              |              |                  |         |
| 0x07                |            | 31:24    | CRCDATAIN[31:24] |      |             |         |              |              |                  |         |
| 0x08                | CRCCHKSUM  | 7:0      | CRCCHKSUM[7:0]   |      |             |         |              |              |                  |         |

## 25.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 323](#) for details.

Some registers are enable-protected, meaning they can only be written when the DMAC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

## 25.8.1 DMAC Registers

### 25.8.1.1 Control

**Name:** CTRL

**Offset:** 0x00

**Reset:** 0x00X0

**Property:** Write-Protected

| Bit    | 15 | 14 | 13 | 12 | 11     | 10     | 9      | 8      |
|--------|----|----|----|----|--------|--------|--------|--------|
|        |    |    |    |    | LVLEN3 | LVLEN2 | LVLEN1 | LVLEN0 |
| Access | R  | R  | R  | R  | R/W    | R/W    | R/W    | R/W    |
| Reset  | 0  | 0  | 0  | 0  | 0      | 0      | 0      | 0      |

| Bit    | 7 | 6 | 5 | 4 | 3 | 2         | 1         | 0     |
|--------|---|---|---|---|---|-----------|-----------|-------|
|        |   |   |   |   |   | CRCENABLE | DMAENABLE | SWRST |
| Access | R | R | R | R | R | R/W       | R/W       | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0         | 0         | 0     |

- **Bits 15:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 – LVLENx [x=3..0]: Priority Level x Enable**

0: Transfer requests for Priority level x will not be handled.

1: Transfer requests for Priority level x will be handled.

When this bit is set, all requests with the corresponding level will be fed into the arbiter block. When cleared, all requests with the corresponding level will be ignored.

For details on arbitration schemes, refer to [“Arbitration” on page 328](#) section.

These bits are not enable-protected.

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – CRCENABLE: CRC Enable**

0: The CRC module is disabled.

1: The CRC module is enabled.

Writing a zero to this bit will disable the CRC module if the CRC Status Busy bit in the CRC Status register ([CRC-STATUS.CRCBUSY](#)) is zero. If the [CRCSTATUS.CRCBUSY](#) is one, the write will be ignored and the CRC module will not be disabled.

Writing a one to this bit will enable the CRC module.

This bit is not enable-protected.

- **Bit 1 – DMAENABLE: DMA Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Writing a zero to this bit during an ongoing transfer, the bit will not be cleared until the internal data transfer buffer is empty and the DMA transfer is aborted. The internal data transfer buffer will be empty once the ongoing burst transfer is completed.

Writing a one to this bit will enable the DMA module.

This bit is not enable-protected.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit when both the DMAC and the CRC module are disabled (DMAENABLE and CRCENABLE is zero), resets all registers in the DMAC, except DBGCTRL, to their initial state. If either the DMAC or CRC module is enabled, the reset request will be ignored and the DMAC will return an access error.

### 25.8.1.2 CRC Control

**Name:** CRCCTRL

**Offset:** 0x02

**Reset:** 0x0000

**Property:** Write-Protected

|        |    |    |             |     |     |     |     |     |
|--------|----|----|-------------|-----|-----|-----|-----|-----|
| Bit    | 15 | 14 | 13          | 12  | 11  | 10  | 9   | 8   |
|        |    |    | CRCSRC[5:0] |     |     |     |     |     |
| Access | R  | R  | R/W         | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0  | 0  | 0           | 0   | 0   | 0   | 0   | 0   |

|        |   |   |   |   |              |     |                  |     |
|--------|---|---|---|---|--------------|-----|------------------|-----|
| Bit    | 7 | 6 | 5 | 4 | 3            | 2   | 1                | 0   |
|        |   |   |   |   | CRCPOLY[1:0] |     | CRCBEATSIZE[1:0] |     |
| Access | R | R | R | R | R/W          | R/W | R/W              | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0            | 0   | 0                | 0   |

- **Bits 15:14 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 13:8 – CRCSRC[5:0]: CRC Input Source**

These bits select the input source for generating the CRC, as shown in [Table 25-3](#). The selected source is locked until either the CRC generation is completed or the CRC module is disabled. This means the CRCSRC cannot be modified when the CRC operation is ongoing. The lock is signaled by the CRCBUSY status bit. CRC generation complete is generated and signaled from the selected source when used with the DMA channel.

**Table 25-3. CRC Input Source**

| CRCSRC[5:0] | Name  | Description   |
|-------------|-------|---------------|
| 0x0         | NOACT | No action     |
| 0x1         | IO    | I/O interface |
| 0x2-0x1F    |       | Reserved      |
| 0x20-0x3F   | CHN   | DMA channel n |

- **Bits 7:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 3:2 – CRCPOLY[1:0]: CRC Polynomial Type**

These bits select the CRC polynomial type, as shown in [Table 25-4](#).

**Table 25-4. CRC Polynomial Type**

| CRCPOLY[1:0] | Name  | Description        |
|--------------|-------|--------------------|
| 0x0          | CRC16 | CRC-16 (CRC-CCITT) |
| 0x1          | CRC32 | CRC32 (IEEE 802.3) |
| 0x2-0x3      |       | Reserved           |

- **Bits 1:0 – CRCBEATSIZE[1:0]: CRC Beat Size**

These bits define the size of the data transfer for each bus access when the CRC is used with I/O interface, as shown in [Table 25-5](#).

**Table 25-5. CRC Beat Size**

| CRCBEATSIZE[1:0] | Name  | Description         |
|------------------|-------|---------------------|
| 0x0              | BYTE  | 8-bit bus transfer  |
| 0x1              | HWORD | 16-bit bus transfer |
| 0x2              | WORD  | 32-bit bus transfer |
| 0x3              |       | Reserved            |

### 25.8.1.3 CRC Data Input

**Name:** CRCDATAIN  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Write-Protected

|        |                  |     |     |     |     |     |     |     |
|--------|------------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31               | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | CRCDATAIN[31:24] |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23               | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | CRCDATAIN[23:16] |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15               | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | CRCDATAIN[15:8]  |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7                | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | CRCDATAIN[7:0]   |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – CRCDATAIN[31:0]: CRC Data Input**

These bits store the data for which the CRC checksum is computed. After the CRCDATAIN register has been written, the number of cycles for the new CRC checksum to be ready is dependent of the configuration of the CRC Beat Size bit group in the CRC Control register([CRCCTRL.CRCBEATSIZE](#)). Each byte needs one clock cycle to be calculated.

#### 25.8.1.4 CRC Checksum

The CRCCHKSUM represents the 16- or 32-bit checksum value and the generated CRC.

**Name:** CRCCHKSUM

**Offset:** 0x08

**Reset:** 0x00000000

**Property:** Write-Protected

|        |                  |     |     |     |     |     |     |     |
|--------|------------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31               | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | CRCCHKSUM[31:24] |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23               | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | CRCCHKSUM[23:16] |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15               | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | CRCCHKSUM[15:8]  |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7                | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | CRCCHKSUM[7:0]   |     |     |     |     |     |     |     |
| Access | R/W              | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0                | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – CRCCHKSUM[31:0]: CRC Checksum**

These bits store the generated CRC result. The 16 MSB bits are always read zero when CRC-16 is enabled.

These bits should only be read when CRC Module Busy bit in the CRC Status register (CRCSTATUS.BUSY) is zero.

If CRC-16 is selected and CRCSTATUS.BUSY is zero (CRC generation is completed), this bit group will contain a valid checksum.

If CRC-32 is selected and CRCSTATUS.BUSY is zero (CRC generation is completed), this bit group will contain a valid reversed checksum. Bit 31 is swapped with bit 0, bit 30 with bit 1, etc.

### 25.8.1.5 CRC Status

**Name:** CRCSTATUS

**Offset:** 0x0C

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1       | 0       |
|--------|---|---|---|---|---|---|---------|---------|
|        |   |   |   |   |   |   | CRCZERO | CRCBUSY |
| Access | R | R | R | R | R | R | R       | R/W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0       | 0       |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – CRCZERO: CRC Zero**

This bit is cleared when a new CRC source is selected.

This bit is set when the CRC generation is complete and the CRC Checksum is zero.

- **Bit 0 – CRCBUSY: CRC Module Busy**

When used with an I/O interface ([CRCCTRL.CRCSRC](#) is 0x1), this bit is cleared by writing a one to it.

When used with an I/O interface ([CRCCTRL.CRCSRC](#) is 0x1), this bit is set when the CRC Data Input ([CRC-DATAIN](#)) register is written.

When used with a DMA channel ([CRCCTRL.CRCSRC](#) is 0x20 to 0x3F), this bit is cleared when the corresponding DMA channel is disabled.

When used with a DMA channel ([CRCCTRL.CRCSRC](#) is 0x20 to 0x3F), this bit is set when the corresponding DMA channel is enabled.

Writing a zero to this bit has no effect.

When used with an I/O interface([CRCCTRL.CRCSRC](#) is 0x1), writing a one to this bit will clear the CRC Module Busy bit.

When used with a DMA channel, writing a one to this bit has no effect.

### 25.8.1.6 Debug Control

**Name:** DBGCTRL

**Offset:** 0x0D

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
|--------|---|---|---|---|---|---|---|--------|
|        |   |   |   |   |   |   |   | DBGRUN |
| Access | R | R | R | R | R | R | R | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGRUN: Debug Run**

This bit is not reset by a software reset.

This bit controls the functionality when the CPU is halted by an external debugger.

0: The DMAC is halted when the CPU is halted by an external debugger.

1: The DMAC continues normal operation when the CPU is halted by an external debugger.

### 25.8.1.7 QOS Control

**Name:** QOSCTRL

**Offset:** 0x0E

**Reset:** 0x2A

**Property:** Write-Protected

| Bit    | 7 | 6 | 5         | 4   | 3         | 2   | 1           | 0   |
|--------|---|---|-----------|-----|-----------|-----|-------------|-----|
|        |   |   | DQOS[1:0] |     | FQOS[1:0] |     | WRBQOS[1:0] |     |
| Access | R | R | R/W       | R/W | R/W       | R/W | R/W         | R/W |
| Reset  | 0 | 0 | 1         | 0   | 1         | 0   | 1           | 0   |

- Bits 7:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- Bits 5:4 – DQOS[1:0]: Data Transfer Quality of Service**

These bits define the memory priority access during the data transfer operation, as shown in [Table 25-6 on page 354](#)

**Table 25-6. Data Transfer Quality of Service**

| DQOS[1:0] | Name    | Description                         |
|-----------|---------|-------------------------------------|
| 0x0       | DISABLE | Background (no sensitive operation) |
| 0x1       | LOW     | Sensitive Bandwidth                 |
| 0x2       | MEDIUM  | Sensitive Latency                   |
| 0x3       | HIGH    | Critical Latency                    |

- Bits 3:2 – FQOS[1:0]: Fetch Quality of Service**

These bits define the memory priority access during the fetch operation, as shown in [Table 25-7 on page 354](#)

**Table 25-7. Fetch Quality of Service**

| FQOS[1:0] | Name    | Description                         |
|-----------|---------|-------------------------------------|
| 0x0       | DISABLE | Background (no sensitive operation) |
| 0x1       | LOW     | Sensitive Bandwidth                 |
| 0x2       | MEDIUM  | Sensitive Latency                   |
| 0x3       | HIGH    | Critical Latency                    |

- Bits 1:0 – WRBQOS[1:0]: Write-Back Quality of Service**

These bits define the memory priority access during the write-back operation, as shown in [Table 25-8 on page 355](#)

**Table 25-8. Write-Back Quality of Service**

| WRBQOS[1:0] | Name    | Description                         |
|-------------|---------|-------------------------------------|
| 0x0         | DISABLE | Background (no sensitive operation) |
| 0x1         | LOW     | Sensitive Bandwidth                 |
| 0x2         | MEDIUM  | Sensitive Latency                   |
| 0x3         | HIGH    | Critical Latency                    |

### 25.8.1.8 Software Trigger Control

**Name:** SWTRIGCTRL

**Offset:** 0x10

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|

- **Bits 31:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – SWTRIGx [x=5..0]: Channel x Software Trigger**

This bit is cleared when the Channel Pending bit in the Channel Status register ([CHSTATUS.PEND](#)) for the corresponding channel is set, or by writing a one to it.

This bit is set if [CHSTATUS.PEND](#) is already one, when writing a one to this bit.

Writing a zero to this bit will clear the bit.

Writing a one to this bit will generate a DMA software trigger on channel x, if [CHSTATUS.PEND](#) is zero for channel x.

### 25.8.1.9 Priority Control 0

**Name:** PRICTRL0

**Offset:** 0x14

**Reset:** 0x00000000

- Bit 31 – RRLVLEN3: Level 3 Round-Robin Scheduling Enable**  
 0: Static scheduling scheme for channels with level 3 priority.  
 1: Round-robin scheduling scheme for channels with level 3 priority.  
 For details on scheduling schemes, refer to [“Arbitration” on page 328](#).
- Bits 30:27 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 26:24 – LVLPR13[2:0]: Level 3 Channel Priority Number**  
 When round-robin arbitration is enabled (PRICTRL0.RRLVLEN3 is one) for priority level 3, this register holds the channel number of the last DMA channel being granted access as the active channel with priority level 3.  
 When static arbitration is enabled (PRICTRL0.RRLVLEN3 is zero) for priority level 3, and the value of this bit group is non-zero, it will affect the static priority scheme. If the value of this bit group is x, channel x will have the highest priority. The priority will decrease as the channel number increases from x to n, where n is the maximum number of channels. Channel n has higher priority than channel 0, and the priority will continue to decrease from channel 0 to channel (x-1).  
 This bit group is not reset when round-robin scheduling gets disabled (PRICTRL0.RRLVLEN3 written to zero).

- Bit 23 – RRLVLEN2: Level 2 Round-Robin Scheduling Enable**  
 0: Static scheduling scheme for channels with level 2 priority.  
 1: Round-robin scheduling scheme for channels with level 2 priority.  
 For details on scheduling schemes, refer to [“Arbitration” on page 328](#).
- Bits 22:19 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 18:16 – LVLPR12[2:0]: Level 2 Channel Priority Number**  
 When round-robin arbitration is enabled (PRICTRL0.RRLVLEN2 is one) for priority level 2, this register holds the channel number of the last DMA channel being granted access as the active channel with priority level 2.  
 When static arbitration is enabled (PRICTRL0.RRLVLEN2 is zero) for priority level 2, and the value of this bit group is non-zero, it will affect the static priority scheme. If the value of this bit group is x, channel x will have the highest priority. The priority will decrease as the channel number increases from x to n, where n is the maximum number of channels. Channel n has higher priority than channel 0, and the priority will continue to decrease from channel 0 to channel (x-1).  
 This bit group is not reset when round-robin scheduling gets disabled (PRICTRL0.RRLVLEN2 written to zero).
- Bit 15 – RRLVLEN1: Level 1 Round-Robin Scheduling Enable**  
 0: Static scheduling scheme for channels with level 1 priority.  
 1: Round-robin scheduling scheme for channels with level 1 priority.  
 For details on scheduling schemes, refer to [“Arbitration” on page 328](#).
- Bits 14:11 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 10:8 – LVLPR11[2:0]: Level 1 Channel Priority Number**  
 When round-robin arbitration is enabled (PRICTRL0.RRLVLEN1 is one) for priority level 1, this register holds the channel number of the last DMA channel being granted access as the active channel with priority level 1.  
 When static arbitration is enabled (PRICTRL0.RRLVLEN1 is zero) for priority level 1, and the value of this bit group is non-zero, it will affect the static priority scheme. If the value of this bit group is x, channel x will have the highest priority. The priority will decrease as the channel number increases from x to n, where n is the maximum number of channels. Channel n has higher priority than channel 0, and the priority will continue to decrease from channel 0 to channel (x-1).  
 This bit group is not reset when round-robin scheduling gets disabled (PRICTRL0.RRLVLEN1 written to zero).
- Bit 7 – RRLVLEN0: Level 0 Round-Robin Scheduling Enable**  
 0: Static scheduling scheme for channels with level 0 priority.  
 1: Round-robin scheduling scheme for channels with level 0 priority.  
 For details on scheduling schemes, refer to [“Arbitration” on page 328](#).
- Bits 6:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 2:0 – LVLPR10[2:0]: Level 0 Channel Priority Number**  
 When round-robin arbitration is enabled (PRICTRL0.RRLVLEN0 is one) for priority level 0, this register holds the channel number of the last DMA channel being granted access as the active channel with priority level 0.  
 When static arbitration is enabled (PRICTRL0.RRLVLEN0 is zero) for priority level 0, and the value of this bit group is non-zero, it will affect the static priority scheme. If the value of this bit group is x, channel x will have the highest priority. The priority will decrease as the channel number increases from x to n, where n is the maximum

number of channels. Channel  $n$  has higher priority than channel 0, and the priority will continue to decrease from channel 0 to channel  $(x-1)$ .

This bit group is not reset when round-robin scheduling gets disabled (PRICTRL0.RRLVLEN0 written to zero).

### 25.8.1.10 Interrupt Pending

This register allows the user to identify the lowest DMA channel with pending interrupt.

**Name:** INTPEND

**Offset:** 0x20

**Reset:** 0x0000

**Property:** -

|        |      |      |      |    |    |      |       |      |

| Reset  | 0    | 0    | 0    | 0  | 0  | 0    | 0     | 0    |

|        |   |   |   |   |   |         |     |     |
|--------|---|---|---|---|---|---------|-----|-----|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2       | 1   | 0   |
|        |   |   |   |   |   | ID[2:0] |     |     |
| Access | R | R | R | R | R | R/W     | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0       | 0   | 0   |

- Bit 15 – PEND: Pending**  
 This bit is read one when the channel selected by Channel ID field (ID) is pending.
- Bit 14 – BUSY: Busy**  
 This bit is read one when the channel selected by Channel ID field (ID) is busy.
- Bit 13 – FERR: Fetch Error**  
 This bit is read one when the channel selected by Channel ID field (ID) fetched an invalid descriptor.
- Bits 12:11 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 10 – SUSP: Channel Suspend**  
 This bit is read one when the channel selected by Channel ID field (ID) has pending Suspend interrupt.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Channel ID (ID) Suspend interrupt flag.
- Bit 9 – TCMPL: Transfer Complete**  
 This bit is read one when the channel selected by Channel ID field (ID) has pending Transfer Complete interrupt.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Channel ID (ID) Transfer Complete interrupt flag.
- Bit 8 – TERR: Transfer Error**  
 This bit is read one when the channel selected by Channel ID field (ID) has pending Transfer Error interrupt.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Channel ID (ID) Transfer Error interrupt flag.
- Bits 7:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:0 – ID[2:0]: Channel ID**

These bits store the lowest channel number with pending interrupts. The number is valid if Suspend (SUSP), Transfer Complete (TCMPL) or Transfer Error (TERR) bits are set. The Channel ID field is refreshed when a new channel (with channel number less than the current one) with pending interrupts is detected, or when the application clears the corresponding channel interrupt sources. When no pending channels interrupts are available, these bits will always return zero value when read.

When the bits are written, indirect access to the corresponding Channel Interrupt Flag register is enabled.

### 25.8.1.11 Interrupt Status

**Name:** INTSTATUS

- **Bits 31:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – PENDCHx [x=5..0]: Pending Channel x**

This bit is cleared when trigger execution defined by channel trigger action settings for DMA channel x is started, when a bus error for DMA channel x is detected or when DMA channel x is disabled. For details on trigger action settings, refer to [Table 25-10](#).

This bit is set when a transfer is pending on DMA channel x.

### 25.8.1.14 Active Channel and Levels

**Name:** ACTIVE  
**Offset:** 0x30  
**Reset:** 0x00000000  
**Property:** -

- Bits 31:16 – BTCNT[15:0]: Active Channel Block Transfer Count**  
 These bits hold the 16-bit block transfer count of the ongoing transfer. This value is stored in the active channel and written back in the corresponding Write-Back channel memory location when the arbiter grants a new channel access. The value is valid only when the active channel active busy flag (ABUSY) is set.
- Bit 15 – ABUSY: Active Channel Busy**  
 This bit is cleared when the active transfer count is written back in the Write-Back memory section.  
 This flag is set when the next descriptor transfer count is read from the Write-Back memory section.
- Bits 14:12 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 11:8 – ID[3:0]: Active Channel ID**  
 These bits hold the channel index currently stored in the active channel registers. The value is updated each time the arbiter grants a new channel transfer access request.
- Bits 7:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 3:0 – LVLEXx [x=3..0]: Level x Channel Trigger Request Executing**  
This bit is set when a level-x channel trigger request is executing or pending.

### 25.8.1.15 Descriptor Memory Section Base Address

**Name:** BASEADDR

**Offset:** 0x34

**Reset:** 0x00000000

**Property:** Write-Protected

|        |                 |     |     |     |     |     |     |     |
|--------|-----------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31              | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | BASEADDR[31:24] |     |     |     |     |     |     |     |

| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15             | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | WRBADDR[15:8]  |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7              | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | WRBADDR[7:0]   |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- Bits 31:0 – WRBADDR[31:0]: Write-Back Memory Base Address**

These bits store the Write-Back memory base address. The value must be 128-bit aligned.

### 25.8.1.17 Channel ID

**Name:** CHID

**Offset:** 0x3F

**Reset:** 0x00

**Property:** -

| Bit    | 7 | 6 | 5 | 4 | 3 | 2       | 1   | 0   |
|--------|---|---|---|---|---|---------|-----|-----|
|        |   |   |   |   |   | ID[2:0] |     |     |
| Access | R | R | R | R | R | R/W     | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0       | 0   | 0   |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:0 – ID[2:0]: Channel ID**

These bits define the channel number that will be accessed. Before reading or writing a channel register, the channel ID bit group must be written first.

### 25.8.1.18 Channel Control A

**Name:** CHCTRLA

**Offset:** 0x40

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6        | 5 | 4 | 3 | 2 | 1      | 0     |
|--------|---|----------|---|---|---|---|--------|-------|
|        |   | RUNSTDBY |   |   |   |   | ENABLE | SWRST |
| Access | R | R/W      | R | R | R | R | R/W    | R/W   |
| Reset  | 0 | 0        | 0 | 0 | 0 | 0 | 0      | 0     |

- **Bit 7 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 6 – RUNSTDBY: Channel run in standby**

This bit is used to keep the DMAC channel running in standby mode.

0: The DMAC channel is halted in standby.

1: The DMAC channel continues to run in standby.

- **Bits 5:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Channel Enable**

0: DMA channel is disabled.

1: DMA channel is enabled.

Writing a zero to this bit during an ongoing transfer, the bit will not be cleared until the internal data transfer buffer is empty and the DMA transfer is aborted. The internal data transfer buffer will be empty once the ongoing burst transfer is completed.

Writing a one to this bit will enable the DMA channel.

This bit is not enable-protected.

- **Bit 0 – SWRST: Channel Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets the channel registers to their initial state. The bit can be set when the channel is disabled (ENABLE = 0). Writing a one to this bit will be ignored as long as the channel is enabled (ENABLE = 1). This bit is automatically cleared when the reset is completed.

Writing a one to this bit when the corresponding DMA channel is disabled (ENABLE is zero), resets all registers for the corresponding DMA channel to their initial state. If the corresponding DMA channel is enabled, the reset request will be ignored.

### 25.8.1.19 Channel Control B

**Name:** CHCTRLB

**Offset:** 0x44

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |    |    |    |    |          |     |

|        |   |          |     |      |      |            |     |     |
|--------|---|----------|-----|------|------|------------|-----|-----|
| Bit    | 7 | 6        | 5   | 4    | 3    | 2          | 1   | 0   |
|        |   | LVL[1:0] |     | EVOE | EVIE | EVACT[2:0] |     |     |
| Access | R | R/W      | R/W | R/W  | R/W  | R/W        | R/W | R/W |
| Reset  | 0 | 0        | 0   | 0    | 0    | 0          | 0   | 0   |

- **Bits 31:26 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 25:24 – CMD[1:0]: Software Command**

These bits define the software commands, as shown in [Table 25-9](#).

These bits are not enable-protected.

**Table 25-9. Software Command**

| CMD[1:0] | Name    | Description               |
|----------|---------|---------------------------|
| 0x0      | NOACT   | No action                 |
| 0x1      | SUSPEND | Channel suspend operation |
| 0x2      | RESUME  | Channel resume operation  |
| 0x3      |         | Reserved                  |

- **Bits 23:22 – TRIGACT[1:0]: Trigger Action**

These bits define the trigger action used for a transfer, as shown in [Table 25-10](#).

**Table 25-10. Trigger Action**

| TRIGACT[1:0] | Name        | Description                                  |
|--------------|-------------|--|
| 0x0          | BLOCK       | One trigger required for each block transfer |
| 0x1          |             | Reserved                                     |
| 0x2          | BEAT        | One trigger required for each beat transfer  |
| 0x3          | TRANSACTION | One trigger required for each transaction    |

- **Bits 21:14 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 13:8 – TRIGSRC[5:0]: Trigger Source**

These bits define the peripheral trigger which is source of the transfer. For details on trigger selection and trigger modes, refer to “[Transfer Triggers and Actions](#)” on [page 330](#) and [Table 25-10](#).

**Table 25-11. Peripheral Trigger Source**

| Value     | Name       | Description                  |
|-----------|------------|------------------------------|
| 0x00      | DISABLE    | Only software/event triggers |
| 0x01      | Reserved   |                              |
| 0x02      | SERCOM0 RX | SERCOM0 RX Trigger           |
| 0x03      | SERCOM0 TX | SERCOM0 TX Trigger           |
| 0x04      | SERCOM1 RX | SERCOM1 RX Trigger           |
| 0x05      | SERCOM1 TX | SERCOM1 TX Trigger           |
| 0x06      | SERCOM2 RX | SERCOM2 RX Trigger           |
| 0x07      | SERCOM2 TX | SERCOM2 TX Trigger           |
| 0x08      | SERCOM3 RX | SERCOM3 RX Trigger           |
| 0x09      | SERCOM3 TX | SERCOM3 TX Trigger           |
| 0x0A–0x0F | Reserved   |                              |
| 0x10      | TCC0 OVF   | TCC0 Overflow Trigger        |
| 0x11      | TCC0 MC0   | TCC0 Match/Compare 0 Trigger |
| 0x12      | TCC0 MC1   | TCC0 Match/Compare 1 Trigger |
| 0x13      | TCC0 MC2   | TCC0 Match/Compare 2 Trigger |
| 0x14      | TCC0 MC3   | TCC0 Match/Compare 3 Trigger |
| 0x15–0x1A | Reserved   |                              |
| 0x1B      | TC0 OVF    | TC0 Overflow Trigger         |
| 0x1C      | TC0 MC0    | TC0 Match/Compare 0 Trigger  |

**Table 25-11. Peripheral Trigger Source (Continued)**

| Value | Name        | Description                   |
|-------|-------------|-------------------------------|
| 0x1D  | TC0 MC1     | TC0 Match/Compare 1 Trigger   |
| 0x1E  | TC1 OVF     | TC1 Overflow Trigger          |
| 0x1F  | TC1 MC0     | TC1 Match/Compare 0 Trigger   |
| 0x20  | TC1 MC1     | TC1 Match/Compare 1 Trigger   |
| 0x21  | TC2 OVF     | TC2 Overflow Trigger          |
| 0x22  | TC2 MC0     | TC2 Match/Compare 0 Trigger   |
| 0x23  | TC2 MC1     | TC2 Match/Compare 1 Trigger   |

| 0x30  | PTC SEQ     | PTC Sequence Trigger          |

- **Bit 7 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 6:5 – LVL[1:0]: Channel Arbitration Level**

These bits define the arbitration level used for the DMA channel. The available levels are shown in [Table 25-12](#), where a high level has priority over a low level. For further details on arbitration schemes, refer to [“Arbitration” on page 328](#).

These bits are not enable-protected.

**Table 25-12. Channel Arbitration level**

| TRIGACT[1:0] | Name | Description              |
|--------------|------|--------------------------|
| 0x0          | LVL0 | Channel Priority Level 0 |
| 0x1          | LVL1 | Channel Priority Level 1 |
| 0x2          | LVL2 | Channel Priority Level 2 |
| 0x3          | LVL3 | Channel Priority Level 3 |

- **Bit 4 – EVOE: Channel Event Output Enable**

This bit indicates if the Channel event generation is enabled. The event will be generated for every condition defined in the descriptor Event Output Selection ([BTCTRL.EVOSEL](#)).

0: Channel event generation is disabled.

1: Channel event generation is enabled.

This bit is available only on channels with event output support. Refer to [Table 29-6](#) and [Table 29-4](#) for details.

- **Bit 3 – EVIE: Channel Event Input Enable**

0: Channel event action will not be executed on any incoming event.

1: Channel event action will be executed on any incoming event.

This bit is available only on channels with event input support. Refer to [Table 29-6](#) and [Table 29-4](#) for details.

- **Bits 2:0 – EVACT[2:0]: Event Input Action**

These bits define the event input action, as shown in [Table 25-13](#). The action is executed only if the corresponding EVIE bit in CHCTRLB register of the channel is set. For details on event actions, refer to “[Event Input Actions](#)” on [page 335](#).

These bits are available only for channels with event input support. Refer to [Table 29-6](#) and [Table 29-4](#) for details.

**Table 25-13. Event Input Action**

| EVACT[2:0] | Name    | Description                            |
|------------|---------|--|
| 0x0        | NOACT   | No action                              |
| 0x1        | TRIG    | Transfer and periodic transfer trigger |
| 0x2        | CTRIG   | Conditional transfer trigger           |
| 0x3        | CBLOCK  | Conditional block transfer             |
| 0x4        | SUSPEND | Channel suspend operation              |
| 0x5        | RESUME  | Channel resume operation               |
| 0x6        | SSKIP   | Skip next block suspend action         |
| 0x7        |         | Reserved                               |

### 25.8.1.20 Channel Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Channel Interrupt Enable Set ([CHINTENSET](#)) register.

**Name:** CHINTENCLR

**Offset:** 0x4C

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2    | 1     | 0    |
|--------|---|---|---|---|---|------|-------|------|
|        |   |   |   |   |   | SUSP | TCMPL | TERR |
| Access | R | R | R | R | R | R/W  | R/W   | R/W  |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0    | 0     | 0    |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – SUSP: Channel Suspend Interrupt Enable**

0: The Channel Suspend interrupt is disabled.

1: The Channel Suspend interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Channel Suspend Interrupt Enable bit, which disables the Channel Suspend interrupt.

- **Bit 1 – TCMPL: Channel Transfer Complete Interrupt Enable**

0: The Channel Transfer Complete interrupt is disabled. When block action is set to none, the TCMPL flag will not be set when a block transfer is completed.

1: The Channel Transfer Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Channel Transfer Complete Interrupt Enable bit, which disables the Channel Transfer Complete interrupt.

- **Bit 0 – TERR: Channel Transfer Error Interrupt Enable**

0: The Channel Transfer Error interrupt is disabled.

1: The Channel Transfer Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Channel Transfer Error Interrupt Enable bit, which disables the Channel Transfer Error interrupt.

### 25.8.1.21 Channel Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Channel Interrupt Enable Clear ([CHINTENCLR](#)) register.

**Name:** CHINTENSET

**Offset:** 0x4D

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2    | 1     | 0    |
|--------|---|---|---|---|---|------|-------|------|
|        |   |   |   |   |   | SUSP | TCMPL | TERR |
| Access | R | R | R | R | R | R/W  | R/W   | R/W  |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0    | 0     | 0    |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – SUSP: Channel Suspend Interrupt Enable**

0: The Channel Suspend interrupt is disabled.

1: The Channel Suspend interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Channel Suspend Interrupt Enable bit, which enables the Channel Suspend interrupt.

- **Bit 1 – TCMPL: Channel Transfer Complete Interrupt Enable**

0: The Channel Transfer Complete interrupt is disabled.

1: The Channel Transfer Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Channel Transfer Complete Interrupt Enable bit, which enables the Channel Transfer Complete interrupt.

- **Bit 0 – TERR: Channel Transfer Error Interrupt Enable**

0: The Channel Transfer Error interrupt is disabled.

1: The Channel Transfer Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Channel Transfer Error Interrupt Enable bit, which enables the Channel Transfer Error interrupt.

### 25.8.1.22 Channel Interrupt Flag Status and Clear

**Name:** CHINTFLAG

**Offset:** 0x4E

**Reset:** 0x00

**Property:** -

| Bit    | 7 | 6 | 5 | 4 | 3 | 2    | 1     | 0    |
|--------|---|---|---|---|---|------|-------|------|
|        |   |   |   |   |   | SUSP | TCMPL | TERR |
| Access | R | R | R | R | R | R/W  | R/W   | R/W  |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0    | 0     | 0    |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – SUSP: Channel Suspend**

This flag is cleared by writing a one to it.

This bit is set when a block transfer with suspend block action is completed, when a software suspend command is executed, when a suspend event is received or when an invalid descriptor is fetched by the DMA.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Channel Suspend interrupt flag for the corresponding channel.

For details on available software commands, refer to [Table 25-9](#).

For details on available event input actions, refer to [Table 25-13](#).

For details on available block actions, refer to [Table 25-17](#).

- **Bit 1 – TCMPL: Channel Transfer Complete**

This flag is cleared by writing a one to it.

This flag is set when a block transfer is completed and the corresponding interrupt block action is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Transfer Complete interrupt flag for the corresponding channel.

- **Bit 0 – TERR: Channel Transfer Error**

This flag is cleared by writing a one to it.

This flag is set when a bus error is detected during a beat transfer or when the DMAC fetches an invalid descriptor.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Transfer Error interrupt flag for the corresponding channel.

### 25.8.1.23 Channel Status

**Name:** CHSTATUS

**Offset:** 0x4F

**Reset:** 0x00

**Property:** -

| Bit    | 7 | 6 | 5 | 4 | 3 | 2    | 1    | 0    |
|--------|---|---|---|---|---|------|------|------|
|        |   |   |   |   |   | FERR | BUSY | PEND |
| Access | R | R | R | R | R | R    | R    | R    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0    | 0    | 0    |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – FERR: Channel Fetch Error**

This bit is cleared when the software resume command is executed.

This bit is set when an invalid descriptor is fetched.

- **Bit 1 – BUSY: Channel Busy**

This bit is cleared when the channel trigger action is complete, when a bus error is detected or when the channel is disabled.

This bit is set when the DMA channel starts a DMA transfer.

- **Bit 0 – PEND: Channel Pending**

This bit is cleared when trigger execution defined by channel trigger action settings is started, when a bus error is detected or when the channel is disabled. For details on trigger action settings, refer to [Table 25-10](#).

This bit is set when a transfer is pending on the DMA channel.

## 25.8.2 DMAC SRAM Registers

### 25.8.2.1 Block Transfer Control

The BTCTRL register offset is relative to (BASEADDR or WRBADDR) + Channel Number \* 0x10

**Name:** BTCTRL

**Offset:** 0x00

|     |               |    |    |               |        |             |               |       |
|-----|---------------|----|----|---------------|--------|-------------|---------------|-------|
| Bit | 15            | 14 | 13 | 12            | 11     | 10          | 9             | 8     |
|     | STEPSIZE[2:0] |    |    | STEPSEL       | DSTINC | SRCINC      | BEATSIZE[1:0] |       |
| Bit | 7             | 6  | 5  | 4             | 3      | 2           | 1             | 0     |
|     |               |    |    | BLOCKACT[1:0] |        | EVOSEL[1:0] |               | VALID |

- Bits 15:13 – STEPSIZE[2:0]: Address Increment Step Size**

These bits select the address increment step size, as shown in [Table 25-14](#). The setting apply to source or destination address, depending on STEPSEL setting.

**Table 25-14. Address Increment Step Size**

| STEPSIZE[2:0] | Name | Description                           |
|---------------|------|---------------------------------------|
| 0x0           | X1   | Next ADDR = ADDR + (BEATSIZE+1) * 1   |
| 0x1           | X2   | Next ADDR = ADDR + (BEATSIZE+1) * 2   |
| 0x2           | X4   | Next ADDR = ADDR + (BEATSIZE+1) * 4   |
| 0x3           | X8   | Next ADDR = ADDR + (BEATSIZE+1) * 8   |
| 0x4           | X16  | Next ADDR = ADDR + (BEATSIZE+1) * 16  |
| 0x5           | X32  | Next ADDR = ADDR + (BEATSIZE+1) * 32  |
| 0x6           | X64  | Next ADDR = ADDR + (BEATSIZE+1) * 64  |
| 0x7           | X128 | Next ADDR = ADDR + (BEATSIZE+1) * 128 |

- Bit 12 – STEPSEL: Step Selection**

This bit selects if source or destination addresses are using the step size settings, according to [Table 25-15](#).

**Table 25-15. Step Selection**

| STEPSEL | Name | Description   |
|---------|------|---|
| 0x0     | DST  | Step size settings apply to the destination address |
| 0x1     | SRC  | Step size settings apply to the source address      |

- Bit 11 – DSTINC: Destination Address Increment Enable**

0: The Destination Address Increment is disabled.

1: The Destination Address Increment is enabled.

Writing a zero to this bit will disable the destination address incrementation. The address will be kept fixed during the data transfer.

Writing a one to this bit will enable the destination address incrementation. By default, the destination address is incremented by 1. If the STEPSEL bit is cleared, flexible step-size settings are available in the STEPSIZE register, as shown in [Table 25-14](#).

- **Bit 10 – SRCINC: Source Address Increment Enable**

0: The Source Address Increment is disabled.

1: The Source Address Increment is enabled.

Writing a zero to this bit will disable the source address incrementation. The address will be kept fixed during the data transfer.

Writing a one to this bit will enable the source address incrementation. By default, the source address is incremented by 1. If the STEPSEL bit is set, flexible step-size settings are available in the STEPSIZE register, as shown in [Table 25-14](#).

- **Bits 9:8 – BEATSIZE[1:0]: Beat Size**

These bits define the size of one beat, as shown in [Table 25-16](#). A beat is the size of one data transfer bus access, and the setting apply to both read and write accesses.

**Table 25-16. Beat Size**

| BEATSIZE[1:0] | Name | Description         |
|---------------|------|---------------------|
| 0x0           | BYTE | 8-bit bus transfer  |
| 0x1           | WORD | 16-bit bus transfer |
| 0x2           | WORD | 32-bit bus transfer |
| 0x3           |      | Reserved            |

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 4:3 – BLOCKACT[1:0]: Block Action**

These bits define what actions the DMAC should take after a block transfer has completed. The available actions are listed in [Table 25-17](#).

**Table 25-17. Block Action**

| BLOCKACT[1:0] | Name    | Description  |
|---------------|---------|--|
| 0x0           | NOACT   | Channel will be disabled if it is the last block transfer in the transaction                     |
| 0x1           | INT     | Channel will be disabled if it is the last block transfer in the transaction and block interrupt |
| 0x2           | SUSPEND | Channel suspend operation is completed   |
| 0x3           | BOTH    | Both channel suspend operation and block interrupt   |

- **Bits 2:1 – EVOSEL[1:0]: Event Output Selection**

These bits define the event output selection, as shown in [Table 25-18](#).

**Table 25-18. Event Output Selection**

| EVOSEL[1:0] | Name    | Description                               |
|-------------|---------|---|
| 0x0         | DISABLE | Event generation disabled                 |
| 0x1         | BLOCK   | Event strobe when block transfer complete |
| 0x2         |         | Reserved                                  |
| 0x3         | BEAT    | Event strobe when beat transfer complete  |

- **Bit 0 – VALID: Descriptor Valid**

0: The descriptor is not valid.

1: The descriptor is valid.

Writing a zero to this bit in the Descriptor or Write-Back memory will suspend the DMA channel operation when fetching the corresponding descriptor.

The bit is automatically cleared in the Write-Back memory section when channel is aborted, when an error is detected during the block transfer, or when the block transfer is completed.

25.8.2.2 Block Transfer Count

The BTCNT register offset is relative to (BASEADDR or WRBADDR) + Channel Number \* 0x10

**Name:** BTCNT

**Offset:** 0x02

- **Bits 15:0 – BTCNT[15:0]: Block Transfer Count**

This bit group holds the 16-bit block transfer count.

During a transfer, the internal counter value is decremented by one after each beat transfer. The internal counter is written to the corresponding write-back memory section for the DMA channel when the DMA channel loses priority, is suspended or gets disabled. The DMA channel can be disabled by a complete transfer, a transfer error or by software.

25.8.2.3 Block Transfer Source Address

The SRCADDR register offset is relative to (BASEADDR or WRBADDR) + Channel Number \* 0x10

**Name:** SRCADDR

**Offset:** 0x04

- **Bits 31:0 – SRCADDR[31:0]: Transfer Source Address**  
This bit group holds the source address corresponding to the last beat transfer address in the block transfer.

25.8.2.4 Block Transfer Destination Address

The DSTADDR register offset is relative to (BASEADDR or WRBADDR) + Channel Number \* 0x10

**Name:** DSTADDR

**Offset:** 0x08

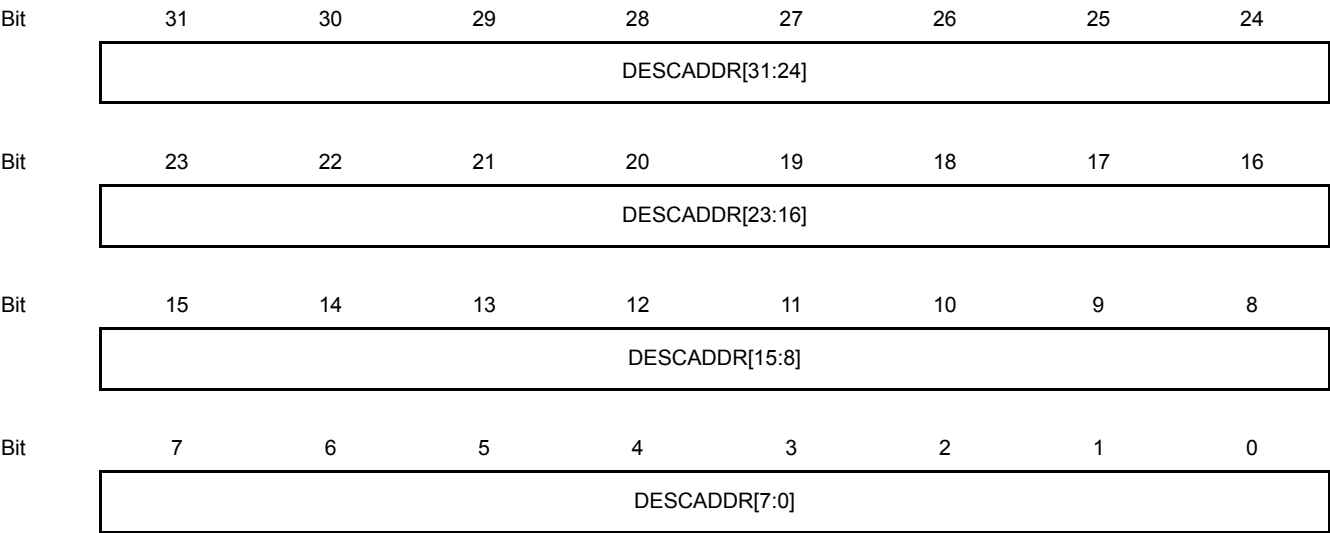

- **Bits 31:0 – DSTADDR[31:0]: Transfer Destination Address**  
This bit group holds the destination address corresponding to the last beat transfer address in the block transfer.

25.8.2.5 Next Descriptor Address

The DESCADDR register offset is relative to (BASEADDR or WRBADDR) + Channel Number \* 0x10

**Name:** DESCADDR

**Offset:** 0x0C

- **Bits 31:0 – DESCADDR[31:0]: Next Descriptor Address**  
This bit group holds the SRAM address of the next descriptor. The value must be 128-bit aligned. If the value of this SRAM register is 0x00000000, the transaction will be terminated when the DMAC tries to load the next transfer descriptor.

## 26. EIC – External Interrupt Controller

### 26.1 Overview

The External Interrupt Controller (EIC) allows external pins to be configured as interrupt lines. Each interrupt line can be individually masked and can generate an interrupt on rising, falling or both edges, or on high or low levels. Each external pin has a configurable filter to remove spikes. Each external pin can also be configured to be asynchronous in order to wake up the device from sleep modes where all clocks have been disabled. External pins can also generate an event.

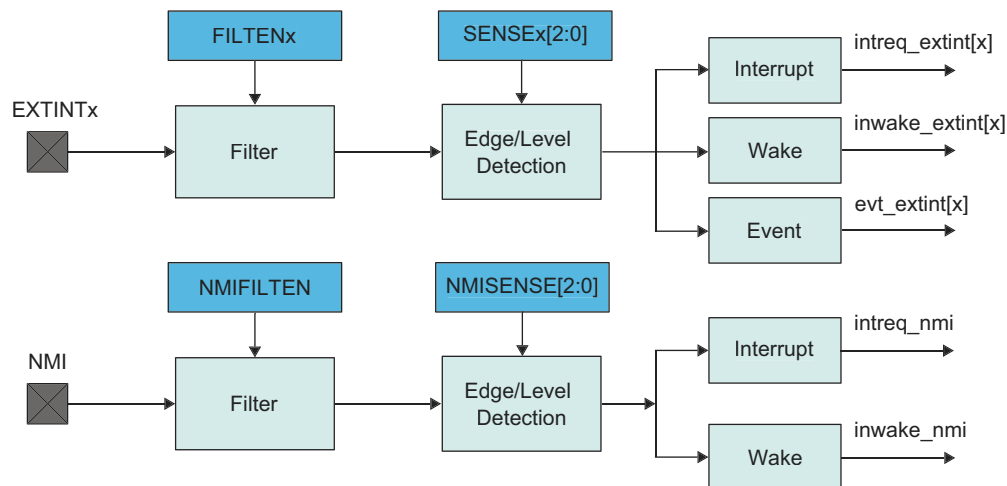

A separate non-maskable interrupt (NMI) is also supported. It has properties similar to the other external interrupts, but is connected to the NMI request of the CPU, enabling it to interrupt any other interrupt mode.

### 26.2 Features

- Up to 32 external pins, plus 1 non-maskable pin
- Dedicated interrupt line for each pin
- Individually maskable interrupt lines
- Interrupt on rising, falling or both edges
- synchronous or asynchronous edge detection mode
- Interrupt on high or low levels
- Asynchronous interrupts for sleep modes without clock
- Filtering of external pins
- Event generation

### 26.3 Block Diagram

Figure 26-1. EIC Block Diagram

### 26.4 Signal Description

| Signal Name  | Type          | Description                |
|--------------|---------------|----------------------------|
| EXTINT[x..0] | Digital Input | External interrupt pin     |
| NMI          | Digital Input | Non-maskable interrupt pin |

Please refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 26.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 26.5.1 I/O Lines

Using the EIC's I/O lines requires the I/O pins to be configured. Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

### 26.5.2 Power Management

All interrupts are available in all sleep modes, but the EIC can be configured to automatically mask some interrupts in order to prevent device wake-up.

The EIC will continue to operate in any sleep mode where the selected source clock is running. The EIC's interrupts can be used to wake up the device from sleep modes. Events connected to the Event System can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 26.5.3 Clocks

The EIC bus clock (CLK\_EIC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_EIC\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

A generic clock (GCLK\_EIC) is optional to clock the peripheral. If needed, this clock must be configured and enabled in the Generic Clock Controller before using the peripheral. Please refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

A Ultra Low Power 32KHz clock (CLK\_ULP32K) is optional to clock the peripheral. This clock is provided by the internal ultra-low-power (ULPOSC32K) oscillator. Please refer to [“OSC32CTRL – 32k Oscillators Controller” on page 201](#) for details.

Both clocks are asynchronous to the user interface clock (CLK\_EIC\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Please refer to [“Synchronization” on page 392](#) for further details.

### 26.5.4 DMA

Not applicable.

### 26.5.5 Interrupts

There are two interrupt request lines, one for the external interrupts (EXTINT) and one for non-maskable interrupt (NMI).

The EXTINT interrupt request line is connected to the interrupt controller. Using the EIC interrupt requires the interrupt controller to be configured first. Please refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

The NMI interrupt request line is also connected to the interrupt controller, but does not require the interrupt to be configured.

### 26.5.6 Events

The events are connected to the Event System. Using the events requires the Event System to be configured first. Please refer to [“EVSYS – Event System” on page 467](#) for details.

### 26.5.7 Debug Operation

When the CPU is halted in debug mode, the EIC continues normal operation. If the EIC is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

## 26.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag Status and Clear register (INTFLAG)
- Non-Maskable Interrupt Flag Status and Clear register (NMIFLAG)

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

## 26.5.9 Analog Connections

Not applicable.

# 26.6 Functional Description

## 26.6.1 Principle of Operation

The EIC detects edge or level condition to generate interrupts to the CPU Interrupt Controller or events to the Event System. Each external interrupt pin (EXTINT) can be filtered using majority vote filtering, clocked by GCLK\_EIC or by CLK\_ULP32K.

## 26.6.2 Basic Operation

### 26.6.2.1 Initialization

The EIC must be initialized in the following order:

1. Enable CLK\_EIC\_APB
2. If edge detection or filtering is required, GCLK\_EIC or CLK\_ULP32K must be enabled
3. If the 32K ULP clock is required, Clock Selection bit in CTRLA register must be written to one (CTRLA.CKSEL)
4. Write the EIC configuration registers (NMICTRL, EVCTRL, CONFIGy)
5. Enable the EIC

When NMI is used, GCLK\_EIC or CLK\_ULP32K must be enabled after EIC configuration.

The following bit is enable-protected, meaning that it can only be written when the EIC is disabled (CTRLA.ENABLE is zero):

- Clock Selection bit in Control A register (CTRLA.CKSEL)
- Asynchronous edge detection bit in EIC\_ASYNC register (EIC\_ASYNC.ASYNCH) or NMICTRL register (NMICTRL.ASYNCH)
- Prescaler bit in Control A register (CTRLA.PRESCALER)

The following registers are enable-protected:

- Event Control register (EVCTRL)
- Configuration n register (CONFIG0, CONFIG1...)

Enable-protected bits in the CTRLA register can be written at the same time as CTRLA.ENABLE is written to one, but not at the same time as CTRLA.ENABLE is written to zero.

Enable-protection is denoted by the Enable-Protected property in the register description.

### 26.6.2.2 Enabling, Disabling and Resetting

The EIC is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The EIC is disabled by writing a zero to CTRLA.ENABLE.

The EIC is reset by writing a one to the Software Reset bit in the Control register (CTRLA.SWRST). All registers in the EIC will be reset to their initial state, and the EIC will be disabled.

Refer to [CTRLA](#) register for details.

### 26.6.3 External Pin Processing

Each external pin can be configured to generate an interrupt/event on edge detection (rising, falling or both edges) or level detection (high or low). The sense of external pins is configured by writing the Interrupt Sense x bits in the Config y register (CONFIGy.SENSEx). The corresponding interrupt flag (INTFLAG.EXTINT[x]) in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition is met (CONFIGy.SENSEx must be different from zero).

When the interrupt has been cleared in edge-sensitive mode, INTFLAG.EXTINT[x] will only be set if a new interrupt condition is met. In level-sensitive mode, when interrupt has been cleared, INTFLAG.EXTINT[x] will be set immediately if the EXTINTx pin still matches the interrupt condition.

Each external pin can be filtered by a majority vote filtering, clocked by GCLK\_EIC or CLK\_ULP32K. Filtering is enabled if bit Filter Enable x in the Configuration y register (CONFIGy.FILTENx) is written to one. The majority vote filter samples the external pin three times with GCLK\_EIC or CLK\_ULP32K and outputs the value when two or more samples are equal.

**Table 26-1. Majority Vote Filter**

| Samples [0, 1, 2] | Filter Output |
|-------------------|---------------|
| [0,0,0]           | 0             |
| [0,0,1]           | 0             |
| [0,1,0]           | 0             |
| [0,1,1]           | 1             |
| [1,0,0]           | 0             |
| [1,0,1]           | 1             |
| [1,1,0]           | 1             |
| [1,1,1]           | 1             |

When an external interrupt is configured for level detection, or if filtering is disabled, detection is made asynchronously, GCLK\_EIC is not required and CLK\_ULP32K is not used.

If filtering or edge detection is enabled, the EIC automatically requests the GCLK\_EIC or CLK\_ULP32K to operate. The selection between these two clocks is configured by writing the Clock Selection bits in the Control A register (CTRLA.CKSEL). (GCLK\_EIC must be enabled in the GCLK module, see [“GCLK – Generic Clock Controller”](#) on page 109 for details). If level detection is enabled, CLK\_ULP32K and GCLK\_EIC clocks are not required, but interrupt and events can still be generated.

**Figure 26-2. Interrupt detections**

The detection delay depends on the detection mode.

**Table 26-2. Interrupt Latency**

| Detection Mode       | Latency (Worst Case)                                  |
|----------------------|---|
| Level without filter | 5 CLK_EIC_APB periods                                 |
| Level with filter    | 4 GCLK_EIC/CLK_ULP32K periods + 5 CLK_EIC_APB periods |
| Edge without filter  | 4 GCLK_EIC/CLK_ULP32K periods + 5 CLK_EIC_APB periods |
| Edge with filter     | 6 GCLK_EIC/CLK_ULP32K periods + 5 CLK_EIC_APB periods |

## 26.6.4 Additional Features

The non-maskable interrupt pin can also generate an interrupt on edge or level detection, but it is configured with the dedicated NMI Control register (NMICTRL). To select the sense for NMI, write to the NMISENSE bit group in the NMI Control register (NMICTRL.NMISENSE). NMI filtering is enabled by writing a one to the NMI Filter Enable bit (NMICTRL.NMIFILTEN).

NMI detection is enabled only by the NMICTRL.NMISENSE value, and the EIC is not required to be enabled.

After reset, NMI is configured to no detection mode.

When an NMI is detected, the non-maskable interrupt flag in the NMI Flag Status and Clear register is set (NMIFLAG.NMI). NMI interrupt generation is always enabled, and NMIFLAG.NMI generates an interrupt request when set.

## 26.6.5 DMA Operation

Not applicable.

## 26.6.6 Interrupts

The EIC has the following interrupt sources:

- External interrupt pins (EXTINTx). See [“Basic Operation” on page 389](#)
- Non-maskable interrupt pin (NMI). See [“Additional Features” on page 391](#)

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when an interrupt condition occurs (NMIFLAG for NMI). Each interrupt, except NMI, can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request

is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the EIC is reset. See the [INTFLAG](#) register for details on how to clear interrupt flags. The EIC has one common interrupt request line for all the interrupt sources (except the NMI interrupt request line). Refer to [“Processor And Architecture” on page 26](#) for details. The user must read the INTFLAG (or NMIFLAG) register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Processor And Architecture” on page 26](#) for details.

### 26.6.7 Events

The EIC can generate the following output events:

- External event from pin (EXTINTx).

Writing a one to an Event Output Control register (EVCTRLEXTINTEO) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to [“EVSYS – Event System” on page 467](#) for details on configuring the Event System.

When the condition on pin EXTINTx matches the configuration in the CONFIGy register, the corresponding event is generated, if enabled.

### 26.6.8 Sleep Mode Operation

In sleep modes, an EXTINTx pin can wake up the device if the corresponding condition matches the configuration in CONFIGy register. Writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET) enables the wake-up from this pin. Writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR) disables the wake-up from this pin. Note that, as soon as EIC module is enable and SENSEx is configured with different settings than “no detection”, the INTFLAGx bit records the activity on the EXTINTx pin whatever if the Interrupt Enable is set or not.

**Figure 26-3. Wake-Up Operation Example (High-Level Detection, No Filter, Interrupt Enable Set)**

### 26.6.9 Synchronization

Due to the asynchronicity between CLK\_EIC\_APB and GCLK\_EIC/CLK32\_ULP, some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding status bit in the Synchronization Busy register (SYNCBUSY.X) will be set immediately, and cleared when synchronization is complete.

If an operation that requires synchronization is executed while SYNCBUSY.X is one, the operation is discarded and a bus error is raised.

The following bits need synchronization when written:

- Software Reset bit in control register (CTRLA.SWRST)
- Enable bit in control register (CTRLA.ENABLE)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

#### 26.6.10 Asynchronous edge detection mode

The EIC external interrupt edge detection is synchronously or asynchronously operated depending on the control bit EIC\_ASYNC.ASYNCH[x] for external pin x. The EIC non-maskable interrupt edge detection is synchronously or asynchronously operated depending on the control bit NMICTRL.ASYNCH. The EIC edge detection is operated synchronously when the asynchronous control bit mode is written to zero (default value), or it is operated asynchronously when the asynchronous control bit mode is written to one.

In the synchronous edge detection mode, the external interrupt (EXTINT) or the non-maskable interrupt (NMI) pins are sampled using the EIC clock as defined by the bit CTRLA.CKSEL. The external interrupt flag (EXTINT[x] or NMIFLAG) is set when the pin and the pin sampler have a different value. In this mode, the EIC clock is required. The synchronous edge detection mode can be used in all sleep modes, except STANDBY.

In the asynchronous edge detection mode, the external interrupt (EXTINT) or the non-maskable interrupt (NMI) pins directly drives the set of the external interrupt flag (EXTINT[x] or NMIFLAG). In this mode, the EIC clock is not requested. The asynchronous edge detection mode can be used in all sleep modes.

## 26.7 Register Summary

Table 26-3. Register Summary

| Offset | Name     | Bit Pos. |                 |              |  |        |           |               |        |       |
|--------|----------|----------|-----------------|--------------|--|--------|-----------|---------------|--------|-------|
| 0x00   | CTRLA    | 7:0      |                 |              |  | CKSEL  |           |               | ENABLE | SWRST |
| 0x01   | NMICTRL  | 7:0      |                 |              |  | ASYNCH | NMIFILTEN | NMISENSE[2:0] |        |       |
| 0x02   | NMIFLAG  | 7:0      |                 |              |  |        |           |               |        | NMI   |
| 0x03   |          | 15:8     |                 |              |  |        |           |               |        |       |
| 0x04   | SYNCBUSY | 7:0      |                 |              |  |        |           |               | ENABLE | SWRST |
| 0x05   |          | 15:8     |                 |              |  |        |           |               |        |       |
| 0x06   |          | 23:16    |                 |              |  |        |           |               |        |       |
| 0x07   |          | 31:24    |                 |              |  |        |           |               |        |       |
| 0x08   | EVCTRL   | 7:0      | EXTINTEO[7:0]   |              |  |        |           |               |        |       |
| 0x09   |          | 15:8     | EXTINTEO[15:8]  |              |  |        |           |               |        |       |
| 0x0A   |          | 23:16    | EXTINTEO[23:16] |              |  |        |           |               |        |       |
| 0x0B   |          | 31:24    | EXTINTEO[31:24] |              |  |        |           |               |        |       |

## 26.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-protected property in each individual register description. Please refer to [“Register Access Protection” on page 389](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Synchronized property in each individual register description. Please refer to [“Synchronization” on page 392](#) for details.

Some registers are enable-protected, meaning they can be written only when the EIC is disabled. Enable-protection is denoted by the Enabled-Protected property in each individual register description.

## 26.8.1 Control

**Name:** CTRLA

**Offset:** 0x00

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized, Enable-Protected (CKSEL bit)

| Bit    | 7 | 6 | 5 | 4     | 3 | 2 | 1      | 0     |
|--------|---|---|---|-------|---|---|--------|-------|
|        |   |   |   | CKSEL |   |   | ENABLE | SWRST |
| Access | R | R | R | R/W   | R | R | R/W    | R/W   |
| Reset  | 0 | 0 | 0 | 0     | 0 | 0 | 0      | 0     |

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 – CKSEL: Clock Selection**

0: The EIC is clocked by GCLK\_EIC.

1: The EIC is clocked by CLK\_ULP32K.

The EIC can be clocked either by GCLK\_EIC when higher frequency than 32KHz is required for filtering or either by CLK\_ULP32K when power consumption is the priority.

CKSEL is not Write-Synchronized but is Enable-Protected, meaning that EIC must be disabled before modifying its value.

- **Bits 3:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

0: The EIC is disabled.

1: The EIC is enabled.

Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Enable bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

This bit is not enable-protected.

- **Bit 0 – SWRST: Software Reset**

0: There is no ongoing reset operation.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the EIC to their initial state, and the EIC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

This bit is not enable-protected.

## 26.8.2 Non-Maskable Interrupt Control

**Name:** NMICTRL  
**Offset:** 0x01  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4      | 3         | 2             | 1   | 0   |
|--------|---|---|---|--------|-----------|---------------|-----|-----|
|        |   |   |   | ASYNCH | NMIFILTEN | NMISENSE[2:0] |     |     |
| Access | R | R | R | R/W    | R/W       | R/W           | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0      | 0         | 0             | 0   | 0   |

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 – ASYNCH: Asynchronous Edge Detection Mode**

0: The NMI edge detection is synchronously operated.

1: The NMI edge detection is asynchronously operated.

The NMI edge detection can be operated synchronously or asynchronously.

In the synchronous edge detection mode, the non-maskable interrupt (NMI) pin is sampled using the EIC clock as defined by the bit CTRLA.CKSEL. The non-maskable interrupt flag (NMIFLAG) is set when the pin and the pin sampler have a different value. In this mode, the EIC clock is required. The synchronous edge detection mode can be used in all sleep modes, except STANDBY.

In the asynchronous edge detection mode, the non-maskable interrupt (NMI) pins directly drives the set of the non-maskable interrupt flag (NMIFLAG). In this mode, the EIC clock is not requested. The asynchronous edge detection mode can be used in all sleep modes.

- **Bit 3 – NMIFILTEN: Non-Maskable Interrupt Filter Enable**

0: NMI filter is disabled.

1: NMI filter is enabled.

- **Bits 2:0 – NMISENSE: Non-Maskable Interrupt Sense**

These bits define on which edge or level the NMI triggers.

**Table 26-4. NMI Sense Configuration**

| NMISENSE | Name | Description            |
|----------|------|------------------------|
| 0x0      | NONE | No detection           |
| 0x1      | RISE | Rising-edge detection  |
| 0x2      | FALL | Falling-edge detection |
| 0x3      | BOTH | Both-edges detection   |
| 0x4      | HIGH | High-level detection   |
| 0x5      | LOW  | Low-level detection    |
| 0x6-0x7  | -    | Reserved               |

### 26.8.3 Non-Maskable Interrupt Flag Status and Clear

**Name:** NMIFLAG

**Offset:** 0x02

**Access:** Read/Write

**Reset:** 0x0000

**Property:** -

|        |    |    |    |    |    |    |   |     |
|--------|----|----|----|----|----|----|---|-----|
| Bit    | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8   |
|        |    |    |    |    |    |    |   |     |
| Access | R  | R  | R  | R  | R  | R  | R | R   |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0   |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2  | 1 | 0   |
|        |    |    |    |    |    |    |   | NMI |
| Access | R  | R  | R  | R  | R  | R  | R | R/W |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0   |

- **Bits 15:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – NMI: Non-Maskable Interrupt**

This flag is cleared by writing a one to it.

This flag is set when the NMI pin matches the NMI sense configuration, and will generate an interrupt request.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the non-maskable interrupt flag.

## 26.8.4 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x04

**Access:** Read-Only

**Reset:** 0x00000000

**Property:** –

|        |    |    |    |    |    |    |        |       |
|--------|----|----|----|----|----|----|--------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25     | 24    |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18 | 17     | 16    |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10 | 9      | 8     |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2  | 1      | 0     |
|        |    |    |    |    |    |    | ENABLE | SWRST |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |

- **Bits 32:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable Synchronization Busy Status**

0: Read/write synchronization for CTRLA.ENABLE bit is complete.

1: Read/write synchronization for CTRLA.ENABLE bit is ongoing.

- **Bit 0 – SWRST: Software Reset Synchronization Busy Status**

0: Read/write synchronization for CTRLA.SWRST bit is complete.

1: Read/write synchronization for CTRLA.SWRST bit is ongoing.

## 26.8.5 Event Control

**Name:** EVCTRL

**Offset:** 0x08

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |                 |     |     |     |     |     |     |     |
|--------|-----------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31              | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | EXTINTEO[31:24] |     |     |     |     |     |     |     |

| Bit    | 7               | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | EXTINTEO[7:0]   |     |     |     |     |     |     |     |
| Access | R/W             | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – EXTINTEO: External Interrupt x Event Output**

These bits indicate whether the event associated with the EXTINTx pin is enabled or not to generated for every detection.

0: Event from pin EXTINTx is disabled.

1: Event from pin EXTINTx is enabled.

## 26.8.6 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x0C

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | EXTINT[31:24] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | EXTINT[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | EXTINT[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | EXTINT[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – EXTINT: External Interrupt x Enable**

0: The external interrupt x is disabled.

1: The external interrupt x is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the External Interrupt x Enable bit, which enables the external interrupt.

## 26.8.7 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear (INTENCLR) register.

**Name:** INTENSET

**Offset:** 0x10

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | EXTINT[31:24] |     |     |     |     |     |     |     |

| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | EXTINT[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | EXTINT[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – EXTINT: External Interrupt x Enable**

0: The external interrupt x is disabled.

1: The external interrupt x is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the External Interrupt x Enable bit, which enables the external interrupt.

## 26.8.8 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x14  
**Access:** Read/Write  
**Reset:** 0x00000000  
**Property:** -

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | EXTINT[31:24] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | EXTINT[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | EXTINT[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | EXTINT[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – EXTINT: External Interrupt x**

This flag is cleared by writing a one to it.

This flag is set when EXTINTx pin matches the external interrupt sense configuration and will generate an interrupt request if INTENCLR/SET.EXTINT[x] is one.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the External Interrupt x flag.

## 26.8.9 External Interrupt Asynchronous Mode

**Name:** ASYNCH  
**Offset:** 0x18  
**Access:** Read/Write  
**Reset:** 0x00000000  
**Property:** -

|        |              |     |     |     |     |     |     |     |

| Bit    | 15           | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | ASYNC[15:8]  |     |     |     |     |     |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7            | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | ASYNC[7:0]   |     |     |     |     |     |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:16 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 15:0 – ASYNCH: Asynchronous Edge Detection Mode**

0: The EXTINT edge detection is synchronously operated.

1: The EXTINT edge detection is asynchronously operated.

The EXTINT edge detection can be operated synchronously or asynchronously.

In the synchronous edge detection mode, the external interrupt (EXTINT) pins are sampled using the EIC clock as defined by the bit CTRLA.CKSEL. The external interrupt flag (EXTINT[x]) is set when the pin and the pin sampler have a different value. In this mode, the EIC clock is required. The synchronous edge detection mode can be used in all sleep modes, except STANDBY.

In the asynchronous edge detection mode, the external interrupt (EXTINT) pins directly drives the set of the external interrupt flag (EXTINT[x]). In this mode, the EIC clock is not requested. The asynchronous edge detection mode can be used in all sleep modes.

## 26.8.10 Configuration n

**Name:** CONFIGn

**Offset:** 0x1C+n\*0x4 [n=range(NUMBER\_OF\_CONFIG\_REGS) max(4)]

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |                |                    |     |     |                |                    |     |     |
|--------|----------------|--------------------|-----|-----|----------------|--------------------|-----|-----|

## 27. NVMCTRL – Non-Volatile Memory Controller

### 27.1 Overview

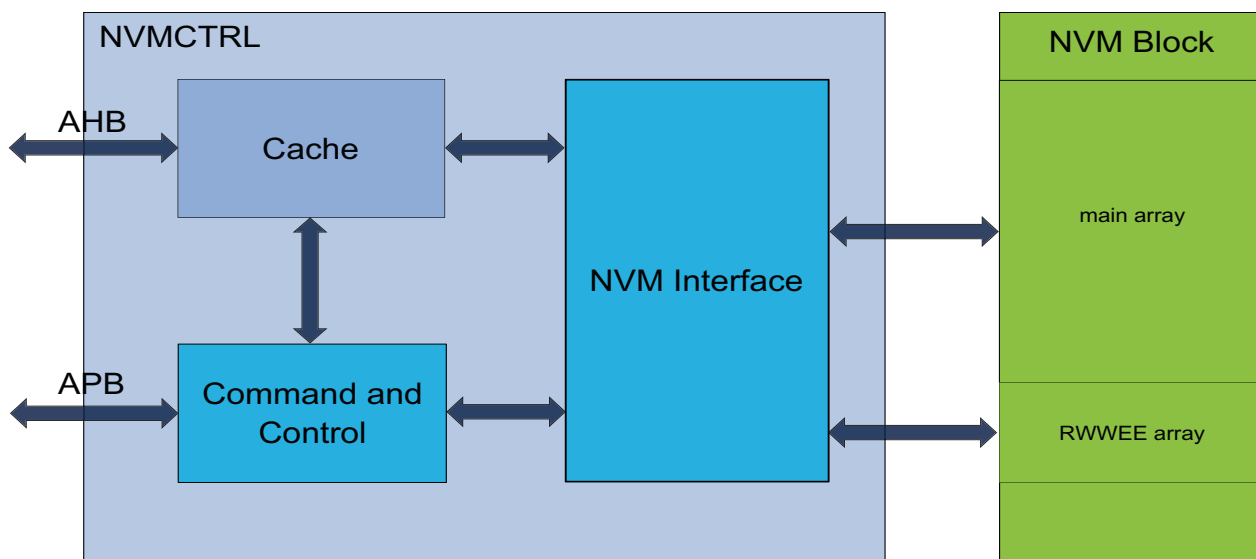

Non-volatile memory (NVM) is a re-programmable flash memory that retains program and data storage even with power off. It embeds a main array and a separate smaller Read While Write array intended for EEPROM emulation (RWWEE) that can be programmed while reading the main array. The NVM Controller (NVMCTRL) connects to the AHB and APB bus interfaces for system access to the NVM block. The AHB interface is used for reads and writes to the NVM block, while the APB interface is used for commands and configuration.

### 27.2 Features

- 32-bit AHB interface for reads and writes
- Read While Write EEPROM (RWWEE) emulation area
- All NVM sections are memory mapped to the AHB, including calibration and system configuration
- 32-bit APB interface for commands and control
- Programmable wait states for read optimization
- 16 regions can be individually protected or unprotected
- Additional protection for boot loader
- Supports device protection through a security bit
- Interface to Power Manager for power-down of flash blocks in sleep modes
- Can optionally wake up on exit from sleep or on first access
- Direct-mapped cache

### 27.3 Block Diagram

Figure 27-1. Block Diagram

### 27.4 Signal Description

Not applicable

## 27.5 Product Dependencies

In order to use this module, other parts of the system must be configured correctly, as described below.

### 27.5.1 Power Management

The NVMCTRL will continue to operate in any sleep mode where the selected source clock is running. The NVMCTRL's interrupts can be used to wake up the device from sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

The Power Manager will automatically put the NVM block into a low-power state when entering sleep mode. This is based on the Control B register (CTRLB) SLEEPFRM bit setting. Read the [CTRLB](#) register description for more details.

### 27.5.2 Clocks

Two synchronous clocks are used by the NVMCTRL. One is provided by the AHB bus (CLK\_NVMCTRL\_AHB) and the other is provided by the APB bus (CLK\_NVMCTRL\_APB). For higher system frequencies, a programmable number of wait states can be used to optimize performance. When changing the AHB bus frequency, the user must ensure that the NVM Controller is configured with the proper number of wait states. Refer to the [“Electrical Characteristics” on page 903](#) for the exact number of wait states to be used for a particular frequency range. Alternately, automatic wait-state generation can be used by setting the AUTOWS bit.

### 27.5.3 Interrupts

The NVM Controller interrupt request line is connected to the interrupt controller. Using the NVMCTRL interrupt requires the interrupt controller to be programmed first.

### 27.5.4 Debug Operation

When an external debugger forces the CPU into debug mode, the peripheral continues normal operation.

Access to the NVM block can be protected by the security bit. In this case, the NVM block will not be accessible. See [“Security Bit” on page 417](#) for details.

### 27.5.5 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag Status and Clear register (INTFLAG)
- Status register (STATUS)

Write-protection is denoted by the Write-Protected property in the register description. Write-protection does not apply for accesses through an external debugger.

When the CPU is halted in debug mode, all write-protection is automatically disabled. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 27.5.6 Analog Connections

Not applicable.

## 27.6 Functional Description

### 27.6.1 Principle of Operation

The NVM Controller is a slave on the AHB and APB buses. It responds to commands, read requests and write requests, based on user configuration.

27.6.1.1 Initialization

After power up, the NVM Controller goes through a power-up sequence. During this time, access to the NVM Controller from the AHB bus is halted. Upon power-up completion, the NVM Controller is operational without any need for user configuration.

27.6.2 Memory Organization

Refer to “Physical Memory Map” on page 23 for memory sizes and addresses for each device.

The NVM is organized into rows, where each row contains four pages, as shown in Figure 27-2. The NVM has a row-erase granularity, while the write granularity is by page. In other words, a single row erase will erase all four pages in the row, while four write operations are used to write the complete row.

Figure 27-2. Row Organization

The NVM block contains a calibration and auxiliary space plus a dedicated EEPROM emulation space that are memory mapped. Refer to Figure 27-3 for details.

The calibration and auxiliary space contains factory calibration and system configuration information. These spaces can be read from the AHB bus in the same way as the main NVM main address space.

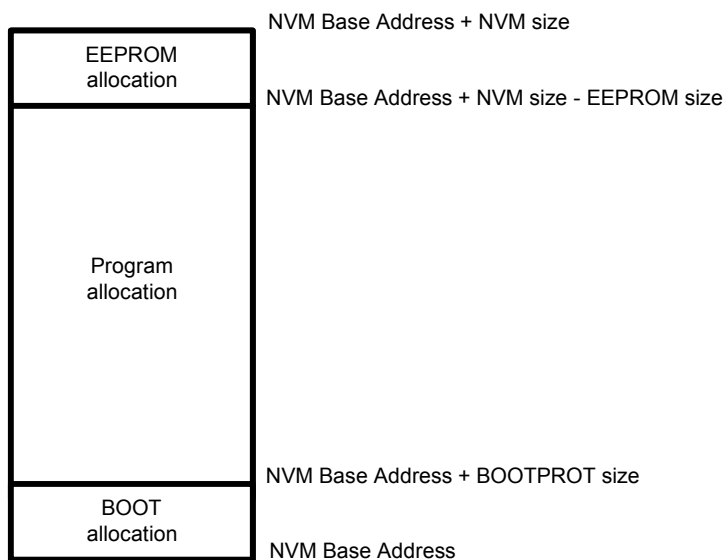

In addition, a boot loader section can be allocated at the beginning of the main array., and an EEPROM section can be allocated at the end of the NVM main address space.

Figure 27-3. NVM Memory Organization

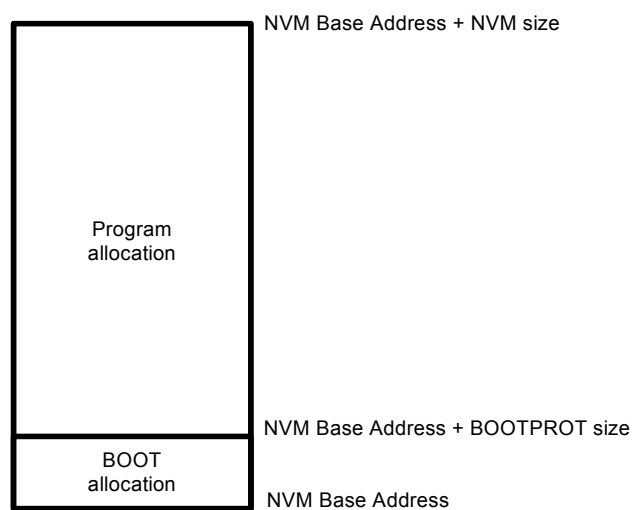

The lower rows in the NVM main address space can be allocated as a boot loader section by using the BOOTPROT fuses, and the upper rows can be allocated to EEPROM, as shown in Figure 27-4. The boot loader section is protected by the lock bit(s) corresponding to this address space and by the BOOTPROT[2:0] fuse. The EEPROM rows can be written regardless of the region lock status. The number of rows protected by BOOTPROT and the number of rows allocated to the EEPROM are given in Table 27-2 and Table , respectively. The number of rows protected by BOOTPROT is given in Table 27-2.

**Figure 27-4. EEPROM and Boot LoaderAllocation**

**Figure 27-5. Boot LoaderAllocation**

### 27.6.3 Region Lock Bits

The NVM block is grouped into 16 equally sized regions. The region size is dependent on the flash memory size, and is given in the table below. Each region has a dedicated lock bit preventing writing and erasing pages in the region. After production, all regions will be unlocked.

**Table 27-1. Region Size**

| Memory Size [KB] | Region Size [KB] |
|------------------|------------------|
| 256              | 16               |
| 128              | 8                |
| 64               | 4                |
| 32               | 2                |

To lock or unlock a region, the Lock Region and Unlock Region commands are provided. Writing one of these commands will temporarily lock/unlock the region containing the address loaded in the ADDR register. ADDR can be written by software, or the automatically loaded value from a write operation can be used. The new setting will stay in effect until the next reset, or the setting can be changed again using the lock and unlock commands. The current status of the lock can be determined by reading the LOCK register.

To change the default lock/unlock setting for a region, the user configuration section of the auxiliary space must be written using the Write Auxiliary Page command. Writing to the auxiliary space will take effect after the next reset. Therefore, a boot of the device is needed for changes in the lock/unlock setting to take effect. See [“Physical Memory Map” on page 23](#) for calibration and auxiliary space address mapping.

### 27.6.4 Command and Data Interface

The NVM Controller is addressable from the APB bus, while the NVM main address space is addressable from the AHB bus. Read and automatic page write operations are performed by addressing the NVM main address space or the RWWEE address space directly, while other operations such as manual page writes and row erase must be performed by issuing commands through the NVM Controller.

To issue a command, the CTRLA.CMD bits must be written along with the CTRLA.CMDEX value. When a command is issued, INTFLAG.READY will be cleared until the command has completed. Any commands written while INTFLAG.READY is low will be ignored. Read the [CTRLA](#) register description for more details.

The CTRLB register must be used to control the power reduction mode, read wait states and the write mode.

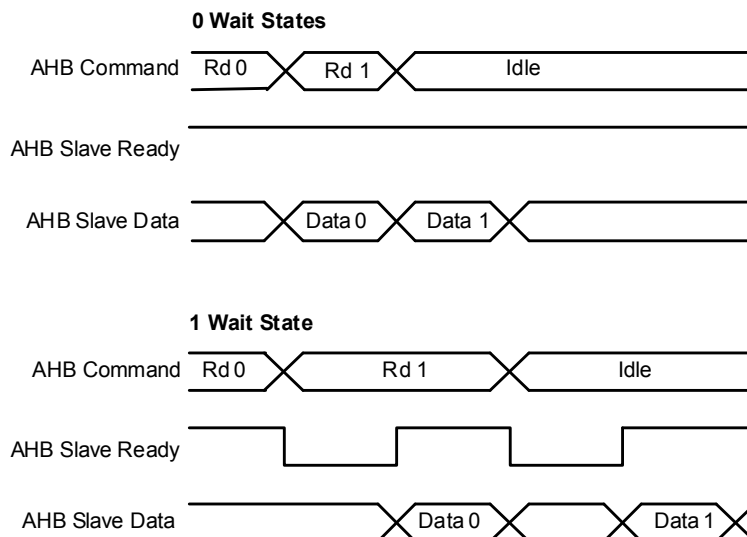

#### 27.6.4.1 NVM Read

Reading from the NVM main address space is performed via the AHB bus by addressing the NVM main address space or auxiliary address space directly. Read data is available after the configured number of read wait states (CTRLB.RWS) set in the NVM Controller.

The number of cycles data are delayed to the AHB bus is determined by the read wait states. Examples of using zero and one wait states are shown in [Figure 27-6](#).

Reading the NVM main address space while a programming or erase operation is ongoing on the NVM main array results in an AHB bus stall until the end of the operation. Reading the NVM main array does not stall the bus when the RWWEE array is being programmed or erased.

**Figure 27-6. Read Wait State Examples**

#### 27.6.4.2 RWWEE Read

Reading from the RWW EEPROM address space is performed via the AHB bus by addressing the RWWEE address space directly. Refer to [Figure 27-3](#) for details. Read timing is similar to regular NVM read timing. It is not possible reading the RWWEE area while the NVM main array is being programmed or erased whereas the contrary is possible. The RWWEE address space is cached when the cache disable field in CTRLB (CTRLB.CACHEDIS) is set accordingly.

#### 27.6.4.3 NVM Write

The NVM Controller requires that an erase must be done before programming. The entire NVM main address space and the RWWEE address space can be erased by a debugger Chip Erase command. Alternatively, rows can be individually erased by the Erase Row command or the RWWEE Erase Row command to erase respectively the NVM main address space and the RWWEE address space.

After programming the NVM main array, the region that the page resides in can be locked to prevent spurious write or erase sequences. Locking is performed on a per-region basis, and so locking a region locks all pages inside the region.

Data to be written to the NVM block are first written and stored in an internal buffer called the page buffer. The page buffer contains the same number of bytes as an NVM page. Writes to the page buffer must be 16 or 32 bits. 8-bit writes to the page buffer are not allowed, and will cause a system exception. Internally, writes to the page buffer are on a 64-bit basis through the page buffer load data register (PBLDATA1 and PBLDATA0). THE PBLDATA register is a holding register for writes to the same 64-bit page buffer section. Data within a 64-bit section can be written in any order. Crossing a 64-bit boundary will reset the PBLDATA register to all ones. The following example assumes startup from reset where the current address is 0 and PBLDATA is all ones. Only 64 bits of the page buffer are written at a time, but 128 bits are shown for reference.

##### Sequential 32-bit write example:

- 32-bit 0x1 written to address 0
  - Page buffer[127:0] = {0xFFFFFFFF\_FFFFFFFF, PBLDATA[63:32], 0x00000001}
  - PBLDATA[63:0] = {PBLDATA[63:32], 0x00000001}
- 32-bit 0x2 written to address 1
  - Page buffer[127:0] = {0xFFFFFFFF\_FFFFFFFF, 0x00000002, PBLDATA[31:0]}
  - PBLDATA[63:0] = 0x00000002, PBLDATA[31:0]}
- 32-bit 0x3 written to address 2 (crosses 64-bit boundary)
  - Page buffer[127:0] = 0xFFFFFFFF\_00000003\_00000002\_00000001
  - PBLDATA[63:0] = 0xFFFFFFFF\_00000003

Random access writes to 32-bit words within the page buffer will overwrite the opposite word within the same 64-bit section with ones. In the following example, notice that 0x00000001 is overwritten with 0xFFFFFFFF from the third write due to the 64-bit boundary crossing. Only 64 bits of the page buffer are written at a time, but 128 bits are shown for reference.

**Random access 32-bit write example:**

- 32-bit 0x1 written to address 2
  - Page buffer[127:0] = 0xFFFFFFFF\_00000001\_FFFFFFFF\_FFFFFFFF
  - PBLDATA[63:0] = 0xFFFFFFFF\_00000001
- 32-bit 0x2 written to address 1
  - Page buffer[127:0] = 0xFFFFFFFF\_00000001\_00000002\_FFFFFFFF
  - PBLDATA[63:0] = 0x00000002\_FFFFFFFF
- 32-bit 0x3 written to address 3
  - Page buffer[127:0] = 0x00000003\_FFFFFFFF\_00000002\_FFFFFFFF
  - PBLDATA[63:0] = 0x00000003\_0xFFFFFFFF

Both the NVM main array and the RWWEE array share the same page buffer. Writing to the NVM block via the AHB bus is performed by a load operation to the page buffer. For each AHB bus write, the address is stored in the ADDR register. After the page buffer has been loaded with the required number of bytes, the page can be written to the addressed location by setting CMD to Write Page or RWWEE Write Page to write respectively the NVM main array or the RWWEE array and setting the key value to CMDEX. The LOAD bit in the STATUS register indicates whether the page buffer has been loaded or not. Before writing the page to memory, the accessed row must be erased.

By default, automatic page writes are enabled (MANW=0). This will trigger a write operation to the page addressed by ADDR when the last location of the page is written.

Because the address is automatically stored in ADDR during the I/O bus write operation, the last given address will be present in the ADDR register. There is no need to load the ADDR register manually, unless a different page in memory is to be written.

**Procedure for Manual Page Writes (MANW=1)**

The row to be written must be erased before the write command is given.

- Write to the page buffer by addressing the NVM main address space directly
- Write the page buffer to memory: CMD=Write Page and CMDEX
- The READY bit in the INTFLAG register will be low while programming is in progress, and access through the AHB will be stalled

**Procedure for Automatic Page Writes (MANW=0)**

The row to be written must be erased before the last write to the page buffer is performed.

Note that partially written pages must be written with a manual write.

- Write to the page buffer by addressing the NVM main address space directly.
  - When the last location in the page buffer is written, the page is automatically written to NVM main address space.
- INTFLAG.READY will be zero while programming is in progress and access through the AHB will be stalled.

**27.6.4.4 Page Buffer Clear**

The page buffer is automatically cleared to all ones after a page write is performed. If a partial page has been written and it is desired to clear the contents of the page buffer, the Page Buffer Clear command can be used.

**27.6.4.5 Erase Row**

Before a page can be written, the row that contains the page must be erased. The Erase Row command can be used to erase the desired row in the NVM main address space. The RWWEE Erase Row can be used to erase the desired row in

the RWWEE array. Erasing the row sets all bits to one. If the row resides in a region that is locked, the erase will not be performed and the Lock Error bit in the Status register (STATUS.LOCKE) will be set.

#### Procedure for Erase Row

- Write the address of the row to erase ADDR. Any address within the row can be used.
- Issue an Erase Row command.

#### 27.6.4.6 Lock and Unlock Region

These commands are used to lock and unlock regions as detailed in section “[Region Lock Bits](#)” on page 413.

#### 27.6.4.7 Set and Clear Power Reduction Mode

The NVM Controller and block can be taken in and out of power reduction mode through the set and clear power reduction mode commands. When the NVM Controller and block are in power reduction mode, the Power Reduction Mode bit in the Status register (STATUS.PRM) is set.

### 27.6.5 NVM User Configuration

The NVM user configuration resides in the auxiliary space. See “[Physical Memory Map](#)” on page 23 for calibration and auxiliary space address mapping.

The bootloader resides in the main array starting at offset zero. The allocated boot loader section is protected against write.

**Table 27-2. Boot Loader Size**

| BOOTPROT [2:0] | Rows Protected by BOOTPROT | Boot Loader Size in Bytes |
|----------------|----------------------------|---------------------------|
| 7              | None                       | 0                         |
| 6              | 2                          | 512                       |
| 5              | 4                          | 1024                      |
| 4              | 8                          | 2048                      |
| 3              | 16                         | 4096                      |
| 2              | 32                         | 8192                      |
| 1              | 64                         | 16384                     |
| 0              | 128                        | 32768                     |

The EEPROM bits indicates the EEPROM size according to the [Table](#) . EEPROM resides in the upper rows of the NVM main address space and are writable, regardless of the region lock status.

**Table 27-3. EEPROM Size**

| EEPROM[2:0] | Rows Allocated to EEPROM | EEPROM Size in Bytes |
|-------------|--------------------------|----------------------|
| 7           | None                     | 0                    |
| 6           | 1                        | 256                  |
| 5           | 2                        | 512                  |
| 4           | 4                        | 1024                 |
| 3           | 8                        | 2048                 |

**Table 27-3. EEPROM Size (Continued)**

| EEPROM[2:0] | Rows Allocated to EEPROM | EEPROM Size in Bytes |
|-------------|--------------------------|----------------------|
| 2           | 16                       | 4096                 |
| 1           | 32                       | 8192                 |
| 0           | 64                       | 16384                |

## 27.6.6 Security Bit

The security bit allows the entire chip to be locked from external access for code security. The security bit can be written by a dedicated command, Set Security Bit (SSB). Once set, the only way to clear the security bit is through a debugger Chip Erase command. After issuing the SSB command, the PROGE error bit can be checked. Refer to [“DSU – Device Service Unit” on page 55](#) for details.

## 27.6.7 Cache

The NVM Controller cache reduces the device power consumption and improves system performance when wait states are required. Both the NVM main array and RWW EEPROM address spaces are cached. It is a direct-mapped cache that implements 8 lines of 64 bits (i.e., 64 bytes). The CACHEDIS[1:0] field in the CTRLB register (CTRLB.CACHEDIS[1:0]) can be used to independently enable caching of the NVM and RWW EEPROM sections. Cache can be configured to three different modes using the READMODE bit group in the CTRLB register. Refer to [CTRLB](#) register description for more details. The INVALL command can be issued through the CTRLA register to invalidate all cache lines. Commands affecting NVM content automatically invalidate cache lines.

## 27.7 Register Summary

Table 27-4. Register Summary

| Offset | Name     | Bit Pos. |              |          |  |          |             |          |               |       |  |
|--------|----------|----------|--------------|----------|--|----------|-------------|----------|---------------|-------|--|
| 0x00   | CTRLA    | 7:0      |              | CMD[6:0] |  |          |             |          |               |       |  |
| 0x01   |          | 15:8     | CMDEX[7:0]   |          |  |          |             |          |               |       |  |

## 27.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to the Register Access Protection section and the PAC chapter for details.

## 27.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x0000

**Property:** Write-Protected

|        |            |          |     |     |     |     |     |     |
|--------|------------|----------|-----|-----|-----|-----|-----|-----|
| Bit    | 15         | 14       | 13  | 12  | 11  | 10  | 9   | 8   |
|        | CMDEX[7:0] |          |     |     |     |     |     |     |
| Access | R/W        | R/W      | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0        | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7          | 6        | 5   | 4   | 3   | 2   | 1   | 0   |
|        |            | CMD[6:0] |     |     |     |     |     |     |
| Access | R          | R/W      | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0        | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:8 – CMDEX: Command Execution**

This bit group should be written with the key value 0xA5 to enable the command written to CMD to be executed. If the bit group is written with a different key value, the write is not performed and the PROGE status bit is set. PROGE is also set if the a previously written command is not complete.

The key value must be written at the same time as CMD. If a command is issued through the APB bus on the same cycle as an AHB bus access, the AHB bus access will be given priority. The command will then be executed when the NVM block and the AHB bus are idle.

The READY status must be one when the command is issued.

Bit 0 of the CMDEX bit group will read back as one until the command is issued.

- **Bit 7 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 6:0 – CMD: Command**

These bits define the command to be executed when the CMDEX key is written, as shown in [Table 27-5](#).

**Table 27-5. Command Bit Description**

| CMD[4:0]  | Group Configuration | Description  |
|-----------|---------------------|--|
| 0x00-0x01 | -                   | Reserved   |
| 0x02      | ER                  | Erase Row - Erases the row addressed by the ADDR register in the NVM main array.   |
| 0x03      | -                   | Reserved   |
| 0x04      | WP                  | Write Page - Writes the contents of the page buffer to the page addressed by the ADDR register.  |
| 0x05      | EAR                 | Erase Auxiliary Row - Erases the auxiliary row addressed by the ADDR register. This command can be given only when the security bit is not set and only to the user configuration row. |

**Table 27-5. Command Bit Description (Continued)**

| CMD[4:0]  | Group Configuration | Description   |
|-----------|---------------------|---|
| 0x06      | WAP                 | Write Auxiliary Page - Writes the contents of the page buffer to the page addressed by the ADDR register. This command can be given only when the security bit is not set and only to the user configuration row. |
| 0x07-0x19 | -                   | Reserved  |
| 0x1A      | RWWEEER             | RWWEER Erase Row - Erases the row addressed by the ADDR register in the RWWEER array.   |
| 0x1B      | -                   | Reserved  |
| 0x1C      | RWWEERP             | RWWEER Write Page - Writes the contents of the page buffer to the page addressed by the ADDR register in the RWWEER array.  |
| 0x1D-0x3F | -                   | Reserved  |
| 0x40      | LR                  | Lock Region - Locks the region containing the address location in the ADDR register.  |
| 0x41      | UR                  | Unlock Region - Unlocks the region containing the address location in the ADDR register.  |
| 0x42      | SPRM                | Sets the power reduction mode.  |
| 0x43      | CPRM                | Clears the power reduction mode.  |
| 0x44      | PBC                 | Page Buffer Clear - Clears the page buffer.   |
| 0x45      | SSB                 | Set Security Bit - Sets the security bit by writing 0x00 to the first byte in the lockbit row.  |
| 0x46      | INVAL               | Invalidates all cache lines.  |
| 0x46-0x7F | -                   | Reserved  |

## 27.8.2 Control B

**Name:** CTRLB

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected

|        |      |    |    |     |               |     |               |     |
|--------|------|----|----|-----|---------------|-----|---------------|-----|
| Bit    | 31   | 30 | 29 | 28  | 27            | 26  | 25            | 24  |
|        |      |    |    |     |               |     |               |     |
| Access | R    | R  | R  | R   | R             | R   | R             | R   |
| Reset  | 0    | 0  | 0  | 0   | 0             | 0   | 0             | 0   |
| Bit    | 23   | 22 | 21 | 20  | 19            | 18  | 17            | 16  |
|        |      |    |    |     | CACHEDIS[1:0] |     | READMODE[1:0] |     |
| Access | R    | R  | R  | R   | R/W           | R/W | R/W           | R/W |
| Reset  | 0    | 0  | 0  | 0   | 0             | 0   | 0             | 0   |
| Bit    | 15   | 14 | 13 | 12  | 11            | 10  | 9             | 8   |
|        |      |    |    |     |               |     | SLEEPFRM[1:0] |     |
| Access | R    | R  | R  | R   | R             | R   | R/W           | R/W |
| Reset  | 0    | 0  | 0  | 0   | 0             | 0   | 0             | 0   |
| Bit    | 7    | 6  | 5  | 4   | 3             | 2   | 1             | 0   |
|        | MANW |    |    |     | RWS[3:0]      |     |               |     |
| Access | R/W  | R  | R  | R/W | R/W           | R/W | R/W           | R/W |
| Reset  | 1    | 0  | 0  | 0   | 0             | 0   | 0             | 0   |

- **Bits 31:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 19:18 – CACHEDIS[1:0]: Cache Disable**

These bits are used to enable/disable caching of the NVM and RWW EEPROM sections. The same cache is used for both sections.

- **Bits 17:16 – READMODE: NVMCTRL Read Mode**  
Table 27-6. Cache Disable

| CACHEDIS[1:0] | RWW EEPROM Cache | NVM Cache |
|---------------|------------------|-----------|
| 0x0           | disabled         | enabled   |
| 0x1           | disabled         | disabled  |
| 0x2           | enabled          | enabled   |
| 0x3           | Reserved         |           |

| READMODE | Name            | Description  |
|----------|-----------------|--|
| 0x0      | NO_MISS_PENALTY | The NVM Controller (cache system) does not insert wait states on a cache miss. Gives the best system performance.  |
| 0x1      | LOW_POWER       | Reduces power consumption of the cache system, but inserts a wait state each time there is a cache miss. This mode may not be relevant if CPU performance is required, as the application will be stalled and may lead to increase run time. |
| 0x2      | DETERMINISTIC   | The cache system ensures that a cache hit or miss takes the same amount of time, determined by the number of programmed flash wait states. This mode can be used for real-time applications that require deterministic execution timings.    |
| 0x3      | Reserved        |  |

- **Bits 15:10 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 9:8 – SLEEPFRM: Power Reduction Mode during Sleep**  
Indicates the power reduction mode during sleep.

**Table 27-7. Power Reduction Mode during Sleep**

| SLEEPFRM[1:0] | Name          | Description   |
|---------------|---------------|---|
| 0x0           | WAKEONACCESS  | NVM block enters low-power mode when entering sleep. NVM block exits low-power mode upon first access.  |
| 0x1           | WAKEUPINSTANT | NVM block enters low-power mode when entering sleep. NVM block exits low-power mode when exiting sleep. |
| 0x2           | Reserved      |   |
| 0x3           | DISABLED      | Auto power reduction disabled.  |

- **Bit 7 – MANW: Manual Write**  
0: Writing to the last word in the page buffer will initiate a write operation to the page addressed by the last write operation. This includes writes to memory and auxiliary rows.  
1: Write commands must be issued through the CMD register.
- **Bits 6:5 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 4:1 – RWS: NVM Read Wait States**

These bits give the number of wait states for a read operation. Zero indicates zero wait states, one indicates one wait state, etc., up to 15 wait states.

This register is initialized to 0 wait states. Software can change this value based on the NVM access time and system frequency.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 27.8.3 NVM Parameter

**Name:** PARAM  
**Offset:** 0x08  
**Reset:** 0x000XXXXX  
**Property:** –

|        |              |    |    |    |    |          |    |    |
|--------|--------------|----|----|----|----|----------|----|----|
| Bit    | 31           | 30 | 29 | 28 | 27 | 26       | 25 | 24 |
|        | RWWEED[12:4] |    |    |    |    |          |    |    |
| Access | R            | R  | R  | R  | R  | R        | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0  | 0        | 0  | 0  |
| Bit    | 23           | 22 | 21 | 20 | 19 | 18       | 17 | 16 |
|        | RWWEED[3:0]  |    |    |    |    | PSZ[2:0] |    |    |
| Access | R            | R  | R  | R  | R  | R        | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0  | X        | X  | X  |
| Bit    | 15           | 14 | 13 | 12 | 11 | 10       | 9  | 8  |
|        | NVMP[15:8]   |    |    |    |    |          |    |    |
| Access | R            | R  | R  | R  | R  | R        | R  | R  |
| Reset  | X            | X  | X  | X  | X  | X        | X  | X  |
| Bit    | 7            | 6  | 5  | 4  | 3  | 2        | 1  | 0  |
|        | NVMP[7:0]    |    |    |    |    |          |    |    |
| Access | R            | R  | R  | R  | R  |          | R  | R  |
| Reset  | X            | X  | X  | X  | X  | X        | X  | X  |

- **Bits 31:19 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 18:16 – PSZ: Page Size**  
Indicates the page size. Not all device families will provide all the page sizes indicated in the table.

**Table 27-8. Page Size**

| PSZ[2:0] | Name | Description |
|----------|------|-------------|
| 0x0      | 8    | 8 bytes     |
| 0x1      | 16   | 16 bytes    |
| 0x2      | 32   | 32 bytes    |
| 0x3      | 64   | 64 bytes    |
| 0x4      | 128  | 128 bytes   |
| 0x5      | 256  | 256 bytes   |
| 0x6      | 512  | 512 bytes   |
| 0x7      | 1024 | 1024 bytes  |

- Bits 15:0 – NVMP: NVM Pages**  
 Indicates the number of pages in the NVM main address space.
- Bits 12:0 – RWEEP: Read While Write EEPROM emulation area Pages**  
 Indicates the number of pages in the RWW EEPROM emulation address space.

## 27.8.4 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x0C

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1            | 0            |
|--------|---|---|---|---|---|---|--------------|--------------|
|        |   |   |   |   |   |   | <b>ERROR</b> | <b>READY</b> |
| Access | R | R | R | R | R | R | R/W          | R/W          |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0            | 0            |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ERROR: Error Interrupt Enable**

Writing a zero to this bit has no effect.

Writing a one to this bit clears the ERROR interrupt enable.

This bit will read as the current value of the ERROR interrupt enable.

- **Bit 0 – READY: NVM Ready Interrupt Enable**

Writing a zero to this bit has no effect.

Writing a one to this bit clears the READY interrupt enable.

This bit will read as the current value of the READY interrupt enable.

### 27.8.5 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x10

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1            | 0            |
|--------|---|---|---|---|---|---|--------------|--------------|
|        |   |   |   |   |   |   | <b>ERROR</b> | <b>READY</b> |
| Access | R | R | R | R | R | R | R/W          | R/W          |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0            | 0            |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ERROR: Error Interrupt Enable**

Writing a zero to this bit has no effect.

Writing a one to this bit sets the ERROR interrupt enable.

This bit will read as the current value of the ERROR interrupt enable.

- **Bit 0 – READY: NVM Ready Interrupt Enable**

Writing a zero to this bit has no effect.

Writing a one to this bit sets the READY interrupt enable.

This bit will read as the current value of the READY interrupt enable.

## 27.8.6 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x14

**Reset:** 0x00

**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1            | 0            |
|--------|---|---|---|---|---|---|--------------|--------------|
|        |   |   |   |   |   |   | <b>ERROR</b> | <b>READY</b> |
| Access | R | R | R | R | R | R | R/W          | R            |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0            | 0            |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ERROR: Error**

This flag is set on the occurrence of an NVME, LOCKE or PROGE error.

0: No errors have been received since the last clear.

1: At least one error has occurred since the last clear.

This bit can be cleared by writing a one to its bit location.

- **Bit 0 – READY: NVM Ready**

0: The NVM controller is busy programming or erasing.

1: The NVM controller is ready to accept a new command.

## 27.8.7 Status

**Name:** STATUS

**Offset:** 0x18

**Reset:** 0x0X00

**Property:** –

|        |    |    |    |             |              |              |             |            |
|--------|----|----|----|-------------|--------------|--------------|-------------|------------|
| Bit    | 15 | 14 | 13 | 12          | 11           | 10           | 9           | 8          |
|        |    |    |    |             |              |              |             | <b>SB</b>  |
| Access | R  | R  | R  | R           | R            | R            | R           | R          |
| Reset  | 0  | 0  | 0  | 0           | 0            | 0            | 0           | X          |
| Bit    | 7  | 6  | 5  | 4           | 3            | 2            | 1           | 0          |
|        |    |    |    | <b>NVME</b> | <b>LOCKE</b> | <b>PROGE</b> | <b>LOAD</b> | <b>PRM</b> |
| Access | R  | R  | R  | R/W         | R/W          | R/W          | R/W         | R          |
| Reset  | 0  | 0  | 0  | 0           | 0            | 0            | 0           | 0          |

- Bits 15:9 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 8 – SB: Security Bit Status**  
 0: The Security bit is inactive.  
 1: The Security bit is active.
- Bits 7:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 4 – NVME: NVM Error**  
 0: No programming or erase errors have been received from the NVM controller since this bit was last cleared.  
 1: At least one error has been registered from the NVM Controller since this bit was last cleared.  
 This bit can be cleared by writing a one to its bit location.
- Bit 3 – LOCKE: Lock Error Status**  
 0: No programming of any locked lock region has happened since this bit was last cleared.  
 1: Programming of at least one locked lock region has happened since this bit was last cleared.  
 This bit can be cleared by writing a one to its bit location.
- Bit 2 – PROGE: Programming Error Status**  
 0: No invalid commands or bad keywords were written in the NVM Command register since this bit was last cleared.  
 1: An invalid command and/or a bad keyword was/were written in the NVM Command register since this bit was last cleared.  
 This bit can be cleared by writing a one to its bit location.
- Bit 1 – LOAD: NVM Page Buffer Active Loading**  
 This bit indicates that the NVM page buffer has been loaded with one or more words. Immediately after an NVM load has been performed, this flag is set, and it remains set until a page write or a page buffer clear (PBCLR) command is given.

This bit can be cleared by writing a one to its bit location.

- **Bit 0 – PRM: Power Reduction Mode**

This bit indicates the current NVM power reduction state. The NVM block can be set in power reduction mode in two ways: through the command interface or automatically when entering sleep with SLEEPPRM set accordingly. PRM can be cleared in three ways: through AHB access to the NVM block, through the command interface (SPRM and CPRM) or when exiting sleep with SLEEPPRM set accordingly.

0: NVM is not in power reduction mode.

1: NVM is in power reduction mode.

## 27.8.8 Address

**Name:** ADDR

**Offset:** 0x1C

**Reset:** 0x00000000

**Property:** Write-Protected

|        |            |     |     |             |     |     |     |     |
|--------|------------|-----|-----|-------------|-----|-----|-----|-----|
| Bit    | 31         | 30  | 29  | 28          | 27  | 26  | 25  | 24  |
|        |            |     |     |             |     |     |     |     |

|        |            |     |     | ADDR[21:16] |     |     |     |     |
| Access | R          | R   | R/W | R/W         | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0           | 0   | 0   | 0   | 0   |
| Bit    | 15         | 14  | 13  | 12          | 11  | 10  | 9   | 8   |
|        | ADDR[15:8] |     |     |             |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W         | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0           | 0   | 0   | 0   | 0   |
| Bit    | 7          | 6   | 5   | 4           | 3   | 2   | 1   | 0   |
|        | ADDR[7:0]  |     |     |             |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W         | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0           | 0   | 0   | 0   | 0   |

- **Bits 31:22 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 20:0 – ADDR: NVM Address**

ADDR drives the hardware (16-bit) address to the NVM when a command is executed using CMDEX. This register is also automatically updated when writing to the page buffer.

## 27.8.9 Lock Section

**Name:** LOCK  
**Offset:** 0x20  
**Reset:** 0xFFFF  
**Property:** –

|        |            |    |    |    |    |    |   |   |
|--------|------------|----|----|----|----|----|---|---|
| Bit    | 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|        | LOCK[15:8] |    |    |    |    |    |   |   |
| Access | R          | R  | R  | R  | R  | R  | R | R |
| Reset  | X          | X  | X  | X  | X  | X  | X | X |
| Bit    | 7          | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
|        | LOCK[7:0]  |    |    |    |    |    |   |   |
| Access | R          | R  | R  | R  | R  | R  | R | R |
| Reset  | X          | X  | X  | X  | X  | X  | X | X |

- **Bits 15:0 – LOCK: Region Lock Bits**  
 In order to set or clear these bits, the CMD register must be used.  
 0: The corresponding lock region is locked.  
 1: The corresponding lock region is not locked.

### 27.8.10 Page Buffer Load Data 0

**Name:** PBLDATA0  
**Offset:** 0x28  
**Reset:** 0x00000000

- **Bits 31:0 – PBLDATA[31:0]: Page Buffer Load Data**

THE PBLDATA register is a holding register for partial AHB writes to the same 64-bit page buffer section. Page buffer loads are performed on a 64-bit basis.

This is a read only register.

### 27.8.11 Page Buffer Load Data 1

**Name:** PBLDATA1  
**Offset:** 0x2C

| Bit    | 7              | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | PBLDATA[39:32] |    |    |    |    |    |    |    |
| Access | R              | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 1              | 1  | 1  | 1  | 1  | 1  | 1  | 1  |

- Bits 31:0 – PBLDATA[63:31]: Page Buffer Load Data**

THE PBLDATA register is a holding register for partial AHB writes to the same 64-bit page buffer section. Page buffer loads are performed on a 64-bit basis.

This is a read only register.

## 28. PORT – IO Pin Controller

### 28.1 Overview

The Port (PORT) controls the I/O pins of the microcontroller. The I/O pins are organized in a series of groups, collectively referred to as a line bundle, and each group can have up to 32 pins that can be configured and controlled individually or as a group. Each pin may either be used for general-purpose I/O under direct application control or assigned to an embedded device peripheral. When used for general-purpose I/O, each pin can be configured as input or output, with highly configurable driver and pull settings.

All I/O pins have true read-modify-write (RMW) functionality when used for general-purpose I/O; the direction or the output value of one or more pins may be changed (set, reset or toggled) without unintentionally changing the state of any other pins in the same line bundle via a single, atomic 8-, 16- or 32-bit write.

The PORT is connected to the high-speed bus matrix through an AHB/APB bridge. The Pin Direction, Data Output Value and Data Input Value registers may also be accessed using the low-latency CPU local bus (IOBUS; ARM® single-cycle I/O port).

### 28.2 Features

- Selectable input and output configuration individually for each pin
- Software-controlled multiplexing of peripheral functions on I/O pins
- Flexible pin configuration through a dedicated Pin Configuration register
- Configurable output driver and pull settings:
  - Totem-pole (push-pull)
  - Pull configuration
  - Driver strength
- Configurable input buffer and pull settings:
  - Internal pull-up or pull-down
  - Input sampling criteria
  - Input buffer can be disabled if not needed for lower power consumption
- Read-modify-write (RMW) support for pin configuration, output value and pin direction
- Input event:
  - Up to four input events for each PORT group
  - SET/CLEAR/TOGGLE event actions for each event input on output value of a pin
  - Can be output to pin
- Power saving using STANDBY mode
  - No access to configuration registers
  - Possible access to data registers

## 28.3 Block Diagram

Figure 28-1. PORT Block Diagram

## 28.4 Signal Description

| Signal name | Type        | Description               |
|-------------|-------------|---------------------------|
| Pxy         | Digital I/O | General-purpose I/O pin y |

Refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 28.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 28.5.1 I/O Lines

The I/O lines of the PORT are mapped to pins of the physical device package according to a simple naming scheme. Each line bundle of up to 32 pins is assigned a letter identifier, starting with A, that monotonically increases through the alphabet for each subsequent line bundle. Within each line bundle, each pin is assigned a numerical identifier according to its bit position.

The resulting PORT pins are mapped as Pxy, where x=A, B, C,... and y=00, 01, ..., 31 to uniquely identify each pin in the device, e.g., PA24, PC03, etc.

Each pin may have one or more peripheral multiplexer settings, which allow the pad to be routed internally to a dedicated peripheral function. When enabled, the selected peripheral is given control over the output state of the pad, as well as the ability to read the current physical pad state. Refer to [“I/O Multiplexing and Considerations” on page 13](#) for details.

Device-specific configurations may result in some pins (and the corresponding Pxy pin) not being implemented.

## 28.5.2 Power Management

During reset, all PORT lines are configured as inputs with input buffers, output buffers and pull disabled.

If the PORT peripheral is shut down, the latches contained in the pad will retain their current configuration, such as the output value and pull settings. However, the PORT configuration registers and input synchronizers will lose their contents, and these will not be restored when PORT is powered up again. The user must, therefore, reconfigure the PORT peripheral at power up to ensure it is in a well-defined state before use.

The PORT will continue to operate in any sleep mode where the selected module source clock is running.

## 28.5.3 Clocks

The PORT bus clock (CLK\_PORT\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_PORT\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

The PORT is fed by two different clocks: a CPU main clock, which allows the CPU to access the PORT through the low-latency CPU local bus (IOBUS), and an APB clock, which is a divided clock of the CPU main clock and allows the CPU to access the PORT registers through the high-speed matrix and the AHB/APB bridge.

IOBUS accesses have priority over event accesses and APB accesses. The EVSYS and APB must insert wait states in the event of concurrent PORT accesses.

The PORT input synchronizers use the CPU main clock so that the resynchronization delay is minimized with respect to the APB clock.

## 28.5.4 DMA

Not applicable.

## 28.5.5 Interrupts

Not applicable.

## 28.5.6 Events

The events are connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

## 28.5.7 Debug Operation

When the CPU is halted in debug mode, the PORT continues normal operation. If the PORT is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

## 28.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC).

Write-protection is denoted by the Write-Protected property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

## 28.5.9 Analog Connections

Analog functions are connected directly between the analog blocks and the I/O pads using analog buses. However, selecting an analog peripheral function for a given pin will disable the corresponding digital features of the pad.

When the direction is set as output, the corresponding bit in the OUT register is used to set the level of the pin. If bit y of OUT is written to one, pin y is driven high. If bit y of OUT is written to zero, pin y is driven low.

Additional pin configuration can be set by writing to the Pin Configuration (PINCFGy) registers.

The Data Input Value bit (IN) is used to read the port pin with resynchronization to the PORT clock. By default, these input synchronizers are clocked only when an input value read is requested in order to reduce power consumption. Input value can always be read, whether the pin is configured as input or output, except if digital input is disabled by writing a zero to the INEN bit in the Pin Configuration registers (PINCFGy).

The PORT also allows peripheral functions to be connected to individual I/O pins by writing a one to the corresponding PMUXEN bit in the PINCFGy registers and by writing the chosen selection to the Peripheral Multiplexing registers (PMUXn) for that pin. This will override the connection between the PORT and that I/O pin, and connect the selected peripheral line bundle to the pad instead of the PORT line bundle.

Each group of up to 32 pins is controlled by a set of registers, as described in [Figure 28-3](#). This set of registers is duplicated for each group of pins, with increasing base addresses.

**Figure 28-3. Overview of the peripheral functions multiplexing**

## 28.6.2 Basic Operation

### 28.6.2.1 Initialization

After reset, all standard function device I/O pads are connected to the PORT with outputs tri-stated and input buffers disabled, even if no clocks are running. Specific pins such as the ones used for connection to a debugger may be configured differently, as required by their special function.

### 28.6.2.2 Basic Operation

Each I/O pin y can be configured and accessed by reading or writing PORT registers. Because PORT registers are grouped into sets of registers for each group of up to 32 pins, the base address of the register set for pin y is at byte address  $\text{PORT} + (y / 32) * 0x80$ .  $(y \% 32)$  will be used as the index within that register set.

To use pin y as an output, configure it as output by writing the  $(y \% 32)$  bit in the DIR register to one. To avoid disturbing the configuration of other pins in that group, this can also be done by writing the  $(y \% 32)$  bit in the DIRSET register to one. The desired output value can be set by writing the  $(y \% 32)$  bit to that value in register OUT.

Similarly, writing an OUTSET bit to one will set the corresponding bit in the OUT register to one, while writing an OUTCLR bit to one will set it to zero, and writing an OUTTGL bit to one will toggle that bit in OUT.

To use pin  $y$  as an input, configure it as input by writing the  $(y \% 32)$  bit in the DIR register to zero. To avoid disturbing the configuration of other pins in that group, this can also be done by writing the  $(y \% 32)$  bit in DIRCLR register to one. The desired input value can be read from the  $(y \% 32)$  bit in register IN as soon as the INEN bit in the Pin Configuration register (PINCFGy) is written to one. Refer to “[I/O Multiplexing and Considerations](#)” on page 13 for details on pin configuration.

By default, the input synchronizer is clocked only when an input read is requested, which will delay the read operation by two CLK\_PORT cycles. To remove that delay, the input synchronizers for each group of eight pins can be configured to be always active, but this comes at the expense of higher power consumption. This is controlled by writing a one to the corresponding SAMPLINGn bit group of the CTRL register, where  $n = (y \% 32) / 8$ .

To use pin  $y$  as one of the available peripheral functions for that pin, configure it by writing a one to the corresponding PMUXEN bit of the PINCFGy register. The PINCFGy register for pin  $y$  is at byte offset  $(\text{PINCFG0} + (y \% 32))$ .

The peripheral function can be selected by writing to the PMUXO or PMUXE bit group in the PMUXn register. The PMUXO/PMUXE bit group is at byte offset  $(\text{PMUX0} + (y \% 32) / 2)$ , in bits 3:0 if  $y$  is even and in bits 7:4 if  $y$  is odd.

The chosen peripheral must also be configured and enabled.

### 28.6.3 I/O Pin Configuration

The Pin Configuration register (PINCFGy) is used for additional I/O pin configuration. A pin can be set in a totem-pole, open-drain or pull configuration.

Because pull configuration is done through the Pin Configuration register, all intermediate PORT states during switching of pin direction and pin values are avoided.

The I/O pin configurations are described further in this chapter, and summarized in [Table 28-1](#).

#### 28.6.3.1 Pin Configurations Summary

**Table 28-1. Pin Configurations Summary**

| DIR | INEN | PULLEN | OUT | Configuration                             |
|-----|------|--------|-----|---|
| 0   | 0    | 0      | X   | Reset or analog I/O: all digital disabled |
| 0   | 0    | 1      | 0   | Pull-down; input disabled                 |
| 0   | 0    | 1      | 1   | Pull-up; input disabled                   |
| 0   | 1    | 0      | X   | Input                                     |
| 0   | 1    | 1      | 0   | Input with pull-down                      |
| 0   | 1    | 1      | 1   | Input with pull-up                        |
| 1   | 0    | X      | X   | Output; input disabled                    |
| 1   | 1    | X      | X   | Output; input enabled                     |

### 28.6.3.2 Input Configuration

**Figure 28-4. I/O configuration - Standard Input**

**Figure 28-5. I/O Configuration - Input with Pull**

Note that when pull is enabled, the pull value is defined by the OUT value.

### 28.6.3.3 Totem-Pole Output

When configured for totem-pole (push-pull) output, the pin is driven low or high according to the corresponding bit setting in the OUT register. In this configuration there is no current limitation for sink or source other than what the pin is capable of. If the pin is configured for input, the pin will float if no external pull is connected. Note, that enabling output driver, automatically disables pull.

**Figure 28-6. I/O Configuration - Totem-Pole Output with Disabled Input**

**Figure 28-7. I/O Configuration - Totem-Pole Output with Enabled Input**

**Figure 28-8. I/O Configuration - Output with Pull**

#### 28.6.3.4 Digital Functionality Disabled

**Figure 28-9. I/O Configuration - Reset or Analog I/O: Digital Output, Input and Pull Disabled**

#### 28.6.4 Events

The PORT allows input events to control individual I/O pins. These input events are generated by the EVSYS module and could be of different clock domain to the PORT.

The PORT can take the following actions on an input event:

- Output (OUT): I/O pin will be set when the incoming event has a high level (one) and cleared when the incoming event has a low-level (zero).
- Set (SET): I/O pin will be set when an incoming event is detected.
- Clear (CLR): I/O pin will be cleared when an incoming event is detected.
- Toggle (TGL): I/O pin will toggle when an incoming event is detected.

The event is output to pin without any internal latency. When SET, CLEAR or TOGGLE event actions are used, the action will be executed up to three clock cycles after an rising edge is detected.

The event actions are available in the Event Action x bits group into the Event Control register (EVCTRL.EVACTx). Writing a one to an Port Event Enable Input x bit into the Event Control register (EVCTRL.PORTEIx) enables the corresponding action on input event. Writing a zero to this bit disables the corresponding action on input event. Note that several actions can be enabled for incoming events. If several events are connected to the peripheral, any enabled action will be taken for any of the incoming events. Refer to the Event System chapter for details on configuring the event system.

Each event input can address one and only one I/O pin at a time. The selection of the pin is done by configuring the pin identifier in the Event Input Control register (EVCTR.PIDn). On the other hand, a same I/O pin can be addressed by up to four input events. To avoid action conflict on the output value of the register (OUT) of this particular I/O pin, one action is performed according to [Table 28-2](#).

Note that this truth table can be applied to any SET/CLR/TGL configuration from two to four active input events.

**Table 28-2. Priority on Simultaneous SET/CLR/TGL Event Actions**

| EVACT0                 | EVACT1 | EVACT2 | EVACT3 | Executed Event Action |
|------------------------|--------|--------|--------|-----------------------|
| SET                    | SET    | SET    | SET    | SET                   |
| CLR                    | CLR    | CLR    | CLR    | CLR                   |
| All Other Combinations |        |        |        | TGL                   |

Special care must be taken when the event is output to pin. Due to the fact the events are asynchronously received, the I/O pin may have unpredictable levels, depending on time where the events are received. When several events are set to be output to the same pin, the lowest event line will get the access. All other events will be ignored.

### 28.6.5 PORT Access Priority

The PORT is accessed by different systems which need arbitration:

- The ARM® CPU through the ARM® single-cycle I/O port (IOBUS)
- 
- The ARM® CPU through the high-speed matrix and the AHB/APB bridge (APB)
- The EVSYS through four asynchronous input events

The following priority is adopted:

- ARM® CPU IOBUS (No wait tolerated)
- APB
- EVSYS input events

For input events when different actions are needed on the same I/O pin, refer to [“Events” on page 444](#).

## 28.7 Register Summary

The I/O pins are organized in groups with up to 32 pins. Group 0 consists of the PA pins, group 1 the PB pins, etc. Each group has its own set of registers. For example, the register address offset for the Data Direction (DIR) register for group 0 (PA00 to PA31) is 0x00, while the register address offset for the DIR register for group 1 (PB00 to PB31) is 0x80.

| Offset | Name   | Bit Pos. |                 |  |  |  |  |  |  |
|--------|--------|----------|-----------------|--|--|--|--|--|--|
| 0x00   | DIR    | 7:0      | DIR[7:0]        |  |  |  |  |  |  |
| 0x01   |        | 15:8     | DIR[15:8]       |  |  |  |  |  |  |
| 0x02   |        | 23:16    | DIR[23:16]      |  |  |  |  |  |  |
| 0x03   |        | 31:24    | DIR[31:24]      |  |  |  |  |  |  |
| 0x04   | DIRCLR | 7:0      | DIRCLR[7:0]     |  |  |  |  |  |  |
| 0x05   |        | 15:8     | DIRCLR[15:8]    |  |  |  |  |  |  |
| 0x06   |        | 23:16    | DIRCLR[23:16]   |  |  |  |  |  |  |
| 0x07   |        | 31:24    | DIRCLR[31:24]   |  |  |  |  |  |  |
| 0x08   | DIRSET | 7:0      | DIRSET[7:0]     |  |  |  |  |  |  |
| 0x09   |        | 15:8     | DIRSET[15:8]    |  |  |  |  |  |  |
| 0x0A   |        | 23:16    | DIRSET[23:16]   |  |  |  |  |  |  |
| 0x0B   |        | 31:24    | DIRSET[31:24]   |  |  |  |  |  |  |
| 0x0C   | DIRTGL | 7:0      | DIRTGL[7:0]     |  |  |  |  |  |  |
| 0x0D   |        | 15:8     | DIRTGL[15:8]    |  |  |  |  |  |  |
| 0x0E   |        | 23:16    | DIRTGL[23:16]   |  |  |  |  |  |  |
| 0x0F   |        | 31:24    | DIRTGL[31:24]   |  |  |  |  |  |  |
| 0x10   | OUT    | 7:0      | OUT[7:0]        |  |  |  |  |  |  |
| 0x11   |        | 15:8     | OUT[15:8]       |  |  |  |  |  |  |

## 28.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 439](#) for details.

### 28.8.1 Data Direction

**Name:** DIR

**Offset:** 0x00+x\*0x80 [x=range(GROUPS) max(4)]

**Reset:** 0x00000000

**Property:** Write-Protected

|        |            |     |     |     |     |     |     |     |
|--------|------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31         | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIR[31:24] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23         | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | DIR[23:16] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | DIR[15:8]  |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7          | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | DIR[7:0]   |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – DIR[31:0]: Port Data Direction**

These bits set the data direction for the individual I/O pins in the PORT group.

0: The corresponding I/O pin in the group is configured as an input.

1: The corresponding I/O pin in the group is configured as an output.

## 28.8.2 Data Direction Clear

This register allows the user to set one or more I/O pins as an input, without doing a read-modify-write operation. Changes in this register will also be reflected in the Data Direction (DIR), Data Direction Toggle (DIRTGL) and Data Direction Set (DIRSET) registers.

**Name:** DIRCLR

**Offset:** 0x04 +x\*0x80 [x=range(GROUPS) max(4)]

**Reset:** 0x00000000

**Property:** Write-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIRCLR[31:24] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | DIRCLR[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | DIRCLR[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | DIRCLR[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – DIRCLR[31:0]: Port Data Direction Clear**

0: The I/O pin direction is cleared.

1: The I/O pin direction is set.

Writing a zero to a bit has no effect.

Writing a one to a bit will clear the corresponding bit in the DIR register, which configures the I/O pin as an input.

### 28.8.3 Data Direction Set

This register allows the user to set one or more I/O pins as an output, without doing a read-modify-write operation. Changes in this register will also be reflected in the Data Direction (DIR), Data Direction Toggle (DIRTGL) and Data Direction Clear (DIRCLR) registers.

**Name:** DIRSET

**Offset:**  $0x08 + x \times 0x80$  [ $x = \text{range}(\text{GROUPS}) \text{ max}(4)$ ]

**Reset:** 0x00000000

**Property:** Write-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIRSET[31:24] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | DIRSET[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | DIRSET[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | DIRSET[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – DIRSET[31:0]: Port Data Direction Set**

0: The I/O pin direction is cleared.

1: The I/O pin direction is set.

Writing a zero to a bit has no effect.

Writing a one to a bit will set the corresponding bit in the DIR register, which configures the I/O pin as an output.

## 28.8.4 Data Direction Toggle

This register allows the user to toggle the direction of one or more I/O pins, without doing a read-modify-write operation. Changes in this register will also be reflected in the Data Direction (DIR), Data Direction Set (DIRSET) and Data Direction Clear (DIRCLR) registers.

**Name:** DIRTGL

**Offset:**  $0x0C + x \times 0x80$  [ $x = \text{range}(\text{GROUPS}) \text{ max}(4)$ ]

**Reset:** 0x00000000

**Property:** Write-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | DIRTGL[31:24] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | DIRTGL[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | DIRTGL[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | DIRTGL[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – DIRTGL[31:0]: Port Data Direction Toggle**

0: The I/O pin direction is cleared.

1: The I/O pin direction is set.

Writing a zero to a bit has no effect.

Writing a one to a bit will toggle the corresponding bit in the DIR register, which reverses the direction of the I/O pin.

## 28.8.5 Data Output Value

This register sets the data output drive value for the individual I/O pins in the PORT.

**Name:** OUT

**Offset:**  $0x10 + x \times 0x80$  [ $x = \text{range}(\text{GROUPS}) \text{ max}(4)$ ]

**Reset:** 0x00000000

**Property:** Write-Protected

|        |            |     |     |     |     |     |     |     |
|--------|------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31         | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | OUT[31:24] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23         | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | OUT[23:16] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | OUT[15:8]  |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7          | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | OUT[7:0]   |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- Bits 31:0 – OUT[31:0]: Port Data Output Value**

These bits set the logical output drive level of I/O pins configured as outputs via the Data Direction register (DIR). For pins configured as inputs via the Data Direction register (DIR) with pull enabled via the Pull Enable register (PULLEN), these bits will set the input pull direction.

0: The I/O pin output is driven low, or the input is connected to an internal pull-down.

1: The I/O pin output is driven high, or the input is connected to an internal pull-up.

## 28.8.6 Data Output Value Clear

This register allows the user to set one or more output I/O pin drive levels low, without doing a read-modify-write operation. Changes in this register will also be reflected in the Data Output Value (OUT), Data Output Value Toggle (OUTTGL) and Data Output Value Set (OUTSET) registers.

**Name:** OUTCLR

**Offset:**  $0x14 + x \times 0x80$  [ $x = \text{range}(\text{GROUPS}) \text{ max}(4)$ ]

**Reset:** 0x00000000

**Property:** Write-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | OUTCLR[31:24] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | OUTCLR[23:16] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | OUTCLR[15:8]  |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | OUTCLR[7:0]   |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – OUTCLR[31:0]: PORT Data Output Value Clear**

0: The I/O pin output is driven low.

1: The I/O pin output is driven high.

Writing a zero to a bit has no effect.

Writing a one to a bit will clear the corresponding bit in the OUT register, which sets the output drive level low for I/O pins configured as outputs via the Data Direction register (DIR). For pins configured as inputs via Data Direction register (DIR) with pull enabled via the Pull Enable register (PULLEN), these bits will set the input pull direction to an internal pull-down.

## 28.8.7 Data Output Value Set

This register allows the user to set one or more output I/O pin drive levels high, without doing a read-modify-write operation. Changes in this register will also be reflected in the Data Output Value (OUT), Data Output Value Toggle (OUTTGL) and Data Output Value Clear (OUTCLR) registers.

**Name:** OUTSET

- **Bits 31:0 – OUTSET[31:0]: PORT Data Output Value Set**

0: The I/O pin output is driven low.

1: The I/O pin output is driven high.

Writing a zero to a bit has no effect.

Writing a one to a bit will set the corresponding bit in the OUT register, which sets the output drive level high for I/O pins configured as outputs via the Data Direction register (DIR). For pins configured as inputs via Data Direction register (DIR) with pull enabled via the Pull Enable register (PULLEN), these bits will set the input pull direction to an internal pull-up.

## 28.8.8 Data Output Value Toggle

This register allows the user to toggle the drive level of one or more output I/O pins, without doing a read-modify-write operation. Changes in this register will also be reflected in the Data Output Value (OUT), Data Output Value Set (OUTSET) and Data Output Value Clear (OUTCLR) registers.

**Name:** OUTTGL

| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – OUTTGL[31:0]: PORT Data Output Value Toggle**

0: The I/O pin output is driven low.

1: The I/O pin output is driven high.

Writing a zero to a bit has no effect.

Writing a one to a bit will toggle the corresponding bit in the OUT register, which inverts the output drive level for I/O pins configured as outputs via the Data Direction register (DIR). For pins configured as inputs via Data Direction register (DIR) with pull enabled via the Pull Enable register (PULLEN), these bits will toggle the input pull direction.

## 28.8.9 Data Input Value

| Reset  | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:0 – SAMPLING[31:0]: Input Sampling Mode**

Configures the input sampling functionality of the I/O pin input samplers, for pins configured as inputs via the Data Direction register (DIR).

0: The I/O pin input synchronizer is disabled.

1: The I/O pin input synchronizer is enabled.

The input samplers are enabled and disabled in sub-groups of eight. Thus if any pins within a byte request continuous sampling, all pins in that eight pin sub-group will be continuously sampled.

## 28.8.11 Write Configuration

This write-only register is used to configure several pins simultaneously with the same configuration and/or peripheral multiplexing.

In order to avoid side effect of non-atomic access, **8-bit or 16-bit writes to this register will have no effect**. Reading this register always returns zero.

**Name:** WRCONFIG

**Offset:** 0x28 + x\*0x80 [x=range(GROUPS) max(4)]

**Reset:** 0x00000000

- **Bit 31 – HWSEL: Half-Word Select**

This bit selects the half-word field of a 32-pin group to be reconfigured in the atomic write operation.

0: The lower 16 pins of the PORTgroup will be configured.

1: The upper 16 pins of the PORTgroup will be configured.

This bit will always read as zero.

- **Bit 30 – WRPINCFG: Write PINCFG**

This bit determines whether the atomic write operation will update the Pin Configuration register (PINCFGy) or not for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits.

0: The PINCFGy registers of the selected pins will not be updated.

1: The PINCFGy registers of the selected pins will be updated.

Writing a zero to this bit has no effect.

Writing a one to this bit updates the configuration of the selected pins with the written WRCONFIG.DRVSTR, WRCONFIG.PULLEN, WRCONFIG.INEN, WRCONFIG.PMUXEN and WRCONFIG.PINMASK values.

This bit will always read as zero.

- **Bit 29 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 28 – WRPMUX: Write PMUX**

This bit determines whether the atomic write operation will update the Peripheral Multiplexing register (PMUXn) or not for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits.

0: The PMUXn registers of the selected pins will not be updated.

1: The PMUXn registers of the selected pins will be updated.

Writing a zero to this bit has no effect.

Writing a one to this bit updates the pin multiplexer configuration of the selected pins with the written WRCONFIG.PMUX value.

This bit will always read as zero.

- **Bits 27:24 – PMUX[3:0]: Peripheral Multiplexing**

These bits determine the new value written to the Peripheral Multiplexing register (PMUXn) for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits, when the WRCONFIG.WRPMUX bit is set.

These bits will always read as zero.

- **Bit 23 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 22 – DRVSTR: Output Driver Strength Selection**

This bit determines the new value written to PINCFGy.DRVSTR for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits, when the WRCONFIG.WRPINCFG bit is set.

This bit will always read as zero.

- **Bits 21:19 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 18 – PULLEN: Pull Enable**

This bit determines the new value written to PINCFGy.PULLEN for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits, when the WRCONFIG.WRPINCFG bit is set.

This bit will always read as zero.

- **Bit 17 – INEN: Input Enable**

This bit determines the new value written to PINCFGy.DRVSTR for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits, when the WRCONFIG.WRPINCFG bit is set.

This bit will always read as zero.

- **Bit 16 – PMUXEN: Peripheral Multiplexer Enable**

This bit determines the new value written to PINCFGy.PMUXEN for all pins selected by the WRCONFIG.PINMASK and WRCONFIG.HWSEL bits, when the WRCONFIG.WRPINCFG bit is set.

This bit will always read as zero.

- **Bits 15:0 – PINMASK[15:0]: Pin Mask for Multiple Pin Configuration**

These bits select the pins to be configured within the half-word group selected by the WRCONFIG.HWSEL bit.

0: The configuration of the corresponding I/O pin in the half-word group will be left unchanged.

1: The configuration of the corresponding I/O pin in the half-word pin group will be updated. These bits will always read as zero.

## 28.8.12 Event Input Control

There is one 32-bit Event Input Control register for each PORT group. Each byte of this register addresses a group of 32-bit I/O lines. The x denotes the number of the PORT group.

**Name:** EVCTRL

**Offset:** 0x2C + x\*0x80 [x=range(GROUPS) max(4)]

**Reset:** 0x00000000

**Property:** Write-Protected

| Reset  | 0              | 0   | 0                  | 0   | 0                | 0   | 0   | 0   |

- Bit 31 – PORTEI3: PORT Event Input 3 Enable**  
 0: The event action 3 (EVACT3) will not be triggered on any incoming event.  
 1: The event action 3 (EVACT3) will be triggered on any incoming event.
- Bit 30:29 – EVACT3[1:0]: PORT Event Action 3**  
 These bits define, according to [Table 28-3](#), the event action the PORT will perform on the output register.
- Bit 28:24 – PID3[4:0]: PORT Event Pin Identifier 3**  
 These bits define the I/O pin on which the event action will be performed, according to [Table 28-4](#).
- Bit 23 – PORTEI2: PORT Event Input 2 Enable**  
 0: The event action 2 (EVACT2) will not be triggered on any incoming event.  
 1: The event action 2 (EVACT2) will be triggered on any incoming event.
- Bit 22:21 – EVACT2[1:0]: PORT Event Action 2**  
 These bits define, according to [Table 28-3](#), the event action the PORT will perform on the output register.

- **Bit 20:16 – PID2[4:0]: PORT Event Pin Identifier 2**  
These bits define the I/O pin on which the event action will be performed, according to [Table 28-4](#).
- **Bit 15 – PORTEI1: PORT Event Input 1 Enable**  
0: The event action 1 (EVACT1) will not be triggered on any incoming event.  
1: The event action 1 (EVACT1) will be triggered on any incoming event.
- **Bit 14:13 – EVACT1[1:0]: PORT Event Action 1**  
These bits define, according to [Table 28-3](#), the event action the PORT will perform on the output register.
- **Bit 12:8 – PID1[4:0]: PORT Event Pin Identifier 1**  
These bits define the I/O pin on which the event action will be performed, according to [Table 28-4](#).
- **Bit 7– PORTEI0: PORT Event Input 0 Enable**  
0: The event action 0 (EVACT0) will not be triggered on any incoming event.  
1: The event action 0 (EVACT0) will be triggered on any incoming event.
- **Bit 6:5 – EVACT0[1:0]: PORT Event Action 0**  
These bits define, according to [Table 28-3](#), the event action the PORT will perform on the output register.
- **Bit 4:0 – PID0[4:0]: PORT Event Pin Identifier 0**  
These bits define the I/O pin on which the event action will be performed, according to [Table 28-4](#).

**Table 28-3. PORT Event n Action (n=[0..3])**

| Value | Name | Description                         |
|-------|------|-------------------------------------|
| 0x0   | OUT  | Event output to pin                 |
| 0x1   | SET  | Set output register of pin on event |
| 0x2   | CLR  | Clear output register pin on event  |
| 0x3   | TGL  | Toggle output register pin on event |

**Table 28-4. PORT Event n Pin Identifier(n=[0..3])**

| Value | Name  | Description                           |
|-------|-------|---------------------------------------|
| 0x0   | PIN0  | Event action to be executed on PIN 0  |
| 0x1   | PIN1  | Event action to be executed on PIN 1  |
| ...   | ...   | ...                                   |
| 0x31  | PIN31 | Event action to be executed on PIN 31 |

### 28.8.13 Peripheral Multiplexing n

There are up to 16 Peripheral Multiplexing registers in each group, one for every set of two subsequent I/O lines. The n denotes the number of the set of I/O lines, while the x denotes the number of the group.

**Name:** PMUXn

**Offset:**  $0x30 + n[n=0..15] + m*0x80 [m=0..1]$

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7          | 6   | 5   | 4   | 3          | 2   | 1   | 0   |
|--------|------------|-----|-----|-----|------------|-----|-----|-----|
|        | PMUXO[3:0] |     |     |     | PMUXE[3:0] |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W        | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0          | 0   | 0   | 0   |

- **Bits 7:4 – PMUXO[3:0]: Peripheral Multiplexing Odd**

These bits select the peripheral function for odd-numbered pins ( $2*n + 1$ ) of a PORT group, if the corresponding PINCFGy.PMUXEN bit is one. See [Table 28-5](#) below.

Not all possible values for this selection may be valid. For more details, refer to “[I/O Multiplexing and Considerations](#)” on page 13.

- **Bits 3:0 – PMUXE[3:0]: Peripheral Multiplexing Even**

These bits select the peripheral function for even-numbered pins ( $2*n$ ) of a PORT group, if the corresponding PINCFGy.PMUXEN bit is one. See [Table 28-5](#) below

Not all possible values for this selection may be valid. For more details, refer to “[I/O Multiplexing and Considerations](#)” on page 13.

**Table 28-5. Peripheral Multiplexing Selection**

| Value   | Name     | Description                    |
|---------|----------|--------------------------------|
| 0x0     | A        | Peripheral function A selected |
| 0x1     | B        | Peripheral function B selected |
| 0x2     | C        | Peripheral function C selected |
| 0x3     | D        | Peripheral function D selected |
| 0x4     | E        | Peripheral function E selected |
| 0x5     | F        | Peripheral function F selected |
| 0x6     | G        | Peripheral function G selected |
| 0x7     | H        | Peripheral function H selected |
| 0x8     | I        | Peripheral function I selected |
| 0x9-0xF | Reserved |                                |

## 28.8.14 Pin Configuration y

There are up to 32 Pin Configuration registers in each group, one for each I/O line. The n denotes the number of the I/O line, while the m denotes the number of the group.

**Name:** PINCFGy

**Offset:** 0x40+n [n=0..31] + m\*0x80 [m=0..1]

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6             | 5 | 4 | 3 | 2             | 1           | 0             |
|--------|---|---------------|---|---|---|---------------|-------------|---------------|
|        |   | <b>DRVSTR</b> |   |   |   | <b>PULLEN</b> | <b>INEN</b> | <b>PMUXEN</b> |
| Access | R | R/W           | R | R | R | R/W           | R/W         | R/W           |
| Reset  | 0 | 0             | 0 | 0 | 0 | 0             | 0           | 0             |

- Bit 7 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 6 – DRVSTR: Output Driver Strength Selection**  
 This bit controls the output driver strength of an I/O pin configured as an output.  
 0: Pin drive strength is set to normal drive strength.  
 1: Pin drive strength is set to stronger drive strength.
- Bits 5:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 2 – PULLEN: Pull Enable**  
 This bit enables the internal pull-up or pull-down resistor of an I/O pin configured as an input.  
 0: Internal pull resistor is disabled, and the input is in a high-impedance configuration.  
 1: Internal pull resistor is enabled, and the input is driven to a defined logic level in the absence of external input.
- Bit 1 – INEN: Input Enable**  
 This bit controls the input buffer of an I/O pin configured as either an input or output.  
 0: Input buffer for the I/O pin is disabled, and the input value will not be sampled.  
 1: Input buffer for the I/O pin is enabled, and the input value will be sampled when required.  
 Writing a zero to this bit disables the input buffer completely, preventing read-back of the physical pin state when the pin is configured as either an input or output.
- Bit 0 – PMUXEN: Peripheral Multiplexer Enable**  
 This bit enables or disables the peripheral multiplexer selection set in the Peripheral Multiplexing register (PMUXn) to enable or disable alternative peripheral control over an I/O pin direction and output drive value.  
 0: The peripheral multiplexer selection is disabled, and the PORT registers control the direction and output drive value.  
 1: The peripheral multiplexer selection is enabled, and the selected peripheral controls the direction and output drive value.  
 Writing a zero to this bit allows the PORT to control the pad direction via the Data Direction register (DIR) and output drive value via the Data Output Value register (OUT). The peripheral multiplexer value in PMUXn is ignored.  
 Writing a one to this bit enables the peripheral selection in PMUXn to control the pad. In this configuration, the physical pin state may still be read from the Data Input Value register (IN) if PINCFGy.INEN is set.

## 29. EVSYS – Event System

### 29.1 Overview

The Event System (EVSYS) allows autonomous, low-latency and configurable communication between peripherals.

Several peripherals can be configured to emit and/or respond to signals known as events. The exact condition to generate an event, or the action taken upon receiving an event, is specific to each peripheral. Peripherals that respond to events are called event users. Peripherals that emit events are called event generators. A peripheral can have one or more event generators and can have one or more event users.

Communication is made without CPU intervention and without consuming system resources such as bus or RAM bandwidth. This reduces the load on the CPU and other system resources, compared to a traditional interrupt-based system.

### 29.2 Features

- System for direct peripheral-to-peripheral communication and signaling
- 6 configurable event channels, where each channel can:
  - Be connected to any event generator
  - Provide a pure asynchronous, resynchronized or synchronous path
- 68 event generators
- 31 event users
- Configurable edge detector
- Peripherals can be event generators, event users or both
- SleepWalking and interrupt for operation in sleep modes
- Software event generation
- Each event user can choose which channel to listen to

### 29.3 Block Diagram

Figure 29-1. Event System Block Diagram

### 29.4 Signal Description

Not applicable.

## 29.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 29.5.1 I/O Lines

Not applicable.

### 29.5.2 Power Management

The EVSYS can be used to wake up the CPU from all sleep modes, even if the clock used by the EVSYS channel and the EVSYS bus clock are disabled. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

In all sleep modes where the clock for the EVSYS is stopped, the device can wake up the EVSYS clock.

Some event generators can generate an event when their clocks are stopped. The generic clock (GCLK) for this channel will be restarted if the channel uses a synchronized path or a resynchronized path, without waking the system from sleep. The clock remains active only as long as necessary to handle the event. After the event has been handled, the clock will be turned off and the system will remain in the original sleep mode. This is known as SleepWalking. When an asynchronous path is used, there is no need for the clock to be activated for the event to be propagated to the user.

On a software reset, all registers are set to their reset values and any ongoing events are canceled.

### 29.5.3 Clocks

The EVSYS bus clock (CLK\_EVSYS\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_EVSYS\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

Each EVSYS channel has a dedicated generic clock (GCLK\_EVSYS\_x). These are used for event detection and propagation for each channel. These clocks must be configured and enabled in the generic clock controller before using the EVSYS. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

### 29.5.4 DMA

Not applicable.

### 29.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the EVSYS interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 29.5.6 Events

Not applicable.

### 29.5.7 Debug Operation

When the CPU is halted in debug mode, the EVSYS continues normal operation. If the EVSYS is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

### 29.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following register:

- Channel Status (CHSTATUS)
- Interrupt Flag Status and Clear register (INTFLAG)

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

## 29.5.9 Analog Connections

Not applicable.

## 29.6 Functional Description

### 29.6.1 Principle of Operation

The Event System consists of several channels which route the internal events from peripherals (generators) to other internal peripherals or IO pins (users). Each event generator can be selected as source for multiple channels, but a channel cannot be set to use multiple event generators at the same time.

A channel path can be configured in asynchronous, synchronous or re-synchronized mode of operation. The mode of operation must be selection depending on application needs.

When using synchronous or resynchronized path, the Event System includes options to transfer events to users when rising, falling or both edges are detected on event generator.

For further details, refer to [“Channel Path” on page 470](#).

### 29.6.2 Basic Operation

#### 29.6.2.1 Initialization

Before enabling events routing within the system, the Event Users Multiplexer and Event Channels must be configured.

For further details on users multiplexer configuration, refer to [“User Multiplexer Setup” on page 469](#).

For further details on event channels configuration, refer to [“Event System Channel” on page 469](#).

Note that for a proper operation, the event users multiplexer must be configured first.

#### 29.6.2.2 Enabling, Disabling and Resetting

The EVSYS is always enabled.

The EVSYS is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the EVSYS will be reset to their initial state. Refer to the [CTRLA](#) register for details.

#### 29.6.2.3 User Multiplexer Setup

The user multiplexer defines the channel to be connected to an event user. Each user multiplexer is dedicated to one event user. A user multiplexer receives all event channels output and must be configured to select one of these channels, as shown in [Figure 29-1](#). The selection is done thru the CHANNEL bits group in the USER register (USERn.CHANNEL).

The user multiplexer must always be configured before the channel is configured. A full list of selectable users can be found in the User Multiplexer register (USERn) description. Refer to [Table 29-6](#) for details.

#### 29.6.2.4 Event System Channel

An event channel will select one event from a list of event generators. Depending on configuration, the selected event can be synchronized, resynchronized or asynchronously sent to the users. When synchronization or resynchronization is required, the channel includes an internal edge detector, allowing the Event System to generate internal events when rising, falling or both edges are detected on the selected event generator.

An event channel has also the capability to generate internal events when specific software commands are written. A channel block diagram is shown in [Figure 29-1](#).

### 29.6.2.5 Event Generators

Each event channel receives all event generators. For details on available list event generators, refer to [Table 29-4](#). For details on event generation, refer to the corresponding module chapter.

The channel event generator is selected by the Event Generator bit group in the Channel register (CHANNELm.EVGEN). By default, the channels are not connected to any event generators (ie CHANNELM.EVGEN = 0).

### 29.6.2.6 Channel Path

There are three different ways to propagate the event provided by an event generator:

- Asynchronous path
- Synchronous path
- Resynchronized path

The path is selected by writing to the Path Selection bit group in the Channel register (CHANNELm.PATH).

#### Asynchronous Path

When using the asynchronous path, the events are propagated from the event generator to the event user with no intervention from the Event System. The GCLK for this channel (GCLK\_EVSYS\_CHANNEL\_x) is not mandatory, meaning that an event will be propagated to the user without any clock latency.

When the asynchronous path is selected, the channel cannot generate any interrupts and the Channel Status register (CHSTATUS) is always read zero. In the same way, the edge detection is not required and must be disabled by software when this path is selected. Each peripheral event user has the responsibility to select which event edge must trigger internal actions. For further details, refer to each peripheral chapter description.

#### Synchronous Path

The synchronous path should be used when the event generator and the event channel share the same generator for the generic clock. If they do not share the same clock, a logic change from the event generator to the event channel might not be detected in the channel, which means that the event will not be propagated to the event user. For details on generic clock generators, refer to [“GCLK – Generic Clock Controller” on page 109](#).

When using the synchronous path, the channel is able to generate interrupts. The Channel Status bits in the Channel Status register (CHSTATUS) are also updated and available for use.

#### Resynchronized Path

The resynchronized path should be used when the event generator and the event channel do not share the same generator for the generic clock. When the resynchronized path is used, resynchronization of the event from the event generator is done in the channel. For details on generic clock generators, refer to [“GCLK – Generic Clock Controller” on page 109](#).

When the resynchronized path is used, the channel is able to generate interrupts. The Channel Status bits in the Channel Status register (CHSTATUS) are also updated and available for use.

### 29.6.2.7 Edge Detection

When synchronous or resynchronized paths are used, edge detection must be enabled. The event system can perform edge detection in three different ways:

- Generate an event only on the rising edge
- Generate an event only on the falling edge
- Generate an event on rising and falling edges.

Edge detection is selected by writing to the Edge Selection bit group in the Channel register (CHANNELm.EDGSEL).

### 29.6.2.8 Event Latency

An event generator is propagated to an event user with a different latency, depending on event channel configuration.

- Asynchronous Path: The maximum routing latency of an external event is related to the internal signal routing and it is device dependent.
- Synchronous Path: The maximum routing latency of an external event is one GCLK\_EVSYS\_CHANNEL\_x clock cycle.
- Resynchronized Path: The maximum routing latency of an external event is three GCLK\_EVSYS\_CHANNEL\_x clock cycles.

The maximum routing latency of an user event to the peripheral clock core domain is three peripheral clock cycles.

The event generators, event channel and event users clocks ratio must be selected in relationship with the internal event latency constraints. Events propagation or event actions in peripherals may be lost for clock setup violating the internal latencies.

#### 29.6.2.9 The Overrun Channel x Interrupt

The Overrun Channel x interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.OVRx) is set and the optional interrupt is generated in the following cases:

- At least one of the event users on channel x is not ready when a new event occurs
- An event occurs when the previous event on channel x has not yet been handled by all event users

The flag can be set only when using synchronous or resynchronized paths. In the case of asynchronous path, the INTFLAG.OVRx is always read zero.

#### 29.6.2.10 The Event Detected Channel x Interrupt

The Event Detected Channel x interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.EVDx) is set when an event coming from the event generator configured on channel x is detected.

The flag can be set only when using a synchronous or resynchronized paths. , In the case of asynchronous path, the INTFLAG.EVDx is always read zero.

#### 29.6.2.11 Channel Status

The Channel Status register (CHSTATUS) shows the status of the channels when a synchronous or resynchronized path is in use. There are two different status bits in CHSTATUS for each of the available channels:

- The CHSTATUS.CHBUSYx bit is set if an event on the corresponding channel x has not been handled by all event users connected to that channel.
- The CHSTATUS.USRDYx bit is set if all event users connected to the corresponding channel x are ready to handle incoming events on that channel.

#### 29.6.2.12 Software Event

A software event can be initiated on a channel by writing a one to the Software Event bit in the Channel register (CHANNELm.SWEVT). The software event can be used as any event generator, ie when the bit is written, an event will be generated on the respective channel

### 29.6.3 Interrupts

The EVSYS has the following interrupt sources:

- Overrun Channel x interrupt (OVRx): for details, refer to [“The Overrun Channel x Interrupt” on page 471](#).
- Event Detected Channel x interrupt (EVDx): for details, refer to [“The Event Detected Channel x Interrupt” on page 471](#).

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the Event System is reset. See [INTFLAG](#) for details on how to clear interrupt flags. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request

to the NVIC. Refer to <“[Nested Vector Interrupt Controller](#)” on page 27> for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to <“[Nested Vector Interrupt Controller](#)” on page 27> for details.

#### 29.6.4 Sleep Mode Operation

The EVSYS can generate interrupts to wake up the device from any sleep mode.

An event channel configured with asynchronous path works in any sleep mode. To be able to run in standby, the RUNSTDBY bit in CHANNEL register must be set to one (CHANNELx.RUNSTDBY). When the ONDEMAND bit in CHANNEL register (CHANNELx.ONDEMAND) is set to one, the event channel will request its clock (GCLK\_EVSYS\_x) only when an event generator is detected. The event latency for a resynchronized channel path will increase by two GCLK\_EVSYS\_CHANNEL\_x clock (ie up to five GCLK\_EVSYS\_CHANNEL\_x clock cycles).

A channel will behave differently in different sleep modes based on the settings of CHANNELx.RUNSTDBY, CHANNELx.ONDEMAND and CHANNELx.PATH, as shown in [Table 29-1](#):

**Table 29-1. Event Channel Sleep Behavior**

| CHANNELx.PATH | CHANNELx.ONDEMAND | CHANNELx.RUNSTDBY | Sleep Behavior   |
|---------------|-------------------|-------------------|--|
| ASYNCH        | -                 | -                 | Always run in IDLE and STANDBY sleep modes.  |
| SYNCH/RESYNCH | 0                 | 0                 | Only run in IDLE sleep modes if an event must be propagated. Disabled in STANDBY sleep mode.   |
| SYNCH/RESYNCH | 0                 | 1                 | Always run in IDLE and STANDBY sleep modes.  |
| SYNCH/RESYNCH | 1                 | 0                 | Only run in IDLE sleep modes if an event must be propagated. Disabled in STANDBY sleep mode. Two GCLK_EVSYS_x latency added in RESYNCH path before the event is propagated internally. |
| SYNCH/RESYNCH | 1                 | 1                 | Always run in IDLE and STANDBY sleep modes. Two GCLK_EVSYS_x latency added in RESYNCH path before the event is propagated internally.  |

## 29.7 Register Summary

### 29.7.1 Common Registers

| Offset    | Name     | Bit Pos. |  |  |          |          |          |          |          |          |
|-----------|----------|----------|--|--|----------|----------|----------|----------|----------|----------|
| 0x00      | CTRLA    | 7:0      |  |  |          |          |          |          |          | SWRST    |
| 0x01-0x0B | Reserved |          |  |  |          |          |          |          |          |          |

### 29.7.2 Channel Registers

| Offset       | Name    | Bit Pos. |            |          |  |  |             |  |           |  |
|--------------|---------|----------|------------|----------|--|--|-------------|--|-----------|--|
| 0x20 + 0x4*n | CHANNEL | 7:0      | EVGEN[7:0] |          |  |  |             |  |           |  |
| 0x21 + 0x4*n |         | 15:8     | ONDEMAND   | RUNSTDBY |  |  | EDGSEL[1:0] |  | PATH[1:0] |  |
| 0x22 + 0x4*n |         | 23:16    |            |          |  |  |             |  |           |  |
| 0x23 + 0x4*n |         | 31:24    |            |          |  |  |             |  |           |  |

### 29.7.3 User Registers

| Offset | Name | Bit Pos. |
|--------|------|----------|
|--------|------|----------|

|              |      |       |              |  |  |  |  |  |  |  |
|--------------|------|-------|--------------|--|--|--|--|--|--|--|
| 0x80 + 0x4*n | USER | 7:0   | CHANNEL[7:0] |  |  |  |  |  |  |  |
| 0x81 + 0x4*n |      | 15:8  |              |  |  |  |  |  |  |  |
| 0x82 + 0x4*n |      | 23:16 |              |  |  |  |  |  |  |  |
| 0x83 + 0x4*n |      | 31:24 |              |  |  |  |  |  |  |  |

## 29.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Refer to [“Register Access Protection” on page 468](#) and [“PAC – Peripheral Access Control” on page 33](#) for details.

### 29.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|--------|---|---|---|---|---|---|---|-------|
|        |   |   |   |   |   |   |   | SWRST |
| Access | R | R | R | R | R | R | R | W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0     |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – SWRST: Software Reset**

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the EVSYS to their initial state.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

## 29.8.2 Channel Status

**Name:** CHSTATUS

**Offset:** 0x0C

**Reset:** 0x00000FFF

**Property:** –

|        |    |    |         |         |         |         |         |         |
|--------|----|----|---------|---------|---------|---------|---------|---------|
| Bit    | 31 | 30 | 29      | 28      | 27      | 26      | 25      | 24      |
|        |    |    |         |         |         |         |         |         |
| Access | R  | R  | R       | R       | R       | R       | R       | R       |
| Reset  | 0  | 0  | 0       | 0       | 0       | 0       | 0       | 0       |
| Bit    | 23 | 22 | 21      | 20      | 19      | 18      | 17      | 16      |
|        |    |    | CHBUSY5 | CHBUSY4 | CHBUSY3 | CHBUSY2 | CHBUSY1 | CHBUSY0 |
| Access | R  | R  | R       | R       | R       | R       | R       | R       |
| Reset  | 0  | 0  | 0       | 0       | 0       | 0       | 0       | 0       |
| Bit    | 15 | 14 | 13      | 12      | 11      | 10      | 9       | 8       |
|        |    |    |         |         |         |         |         |         |
| Access | R  | R  | R       | R       | R       | R       | R       | R       |
| Reset  | 0  | 0  | 0       | 0       | 1       | 1       | 1       | 1       |
| Bit    | 7  | 6  | 5       | 4       | 3       | 2       | 1       | 0       |
|        |    |    | USRRDY5 | USRRDY4 | USRRDY3 | USRRDY2 | USRRDY1 | USRRDY0 |
| Access | R  | R  | R       | R       | R       | R       | R       | R       |
| Reset  | 1  | 1  | 1       | 1       | 1       | 1       | 1       | 1       |

- Bits 31:22 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 21:16 – CHBUSYx: Channel Busy x**  
 This bit is cleared when channel x is idle  
 This bit is set if an event on channel x has not been handled by all event users connected to channel x.
- Bits 15:6 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 5:0 – USRRDYx: User Ready for Channel x**  
 This bit is cleared when at least one of the event users connected to the channel is not ready.  
 This bit is set when all event users connected to channel x are ready to handle incoming events on channel x.

### 29.8.3 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x10

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |      |      |      |      |      |      |
|--------|----|----|------|------|------|------|------|------|
| Bit    | 31 | 30 | 29   | 28   | 27   | 26   | 25   | 24   |
|        |    |    |      |      |      |      |      |      |
| Access | R  | R  | R    | R    | R    | R    | R    | R    |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |
| Bit    | 23 | 22 | 21   | 20   | 19   | 18   | 17   | 16   |
|        |    |    | EVD5 | EVD4 | EVD3 | EVD  | EVD1 | EVD0 |
| Access | R  | R  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |
| Bit    | 15 | 14 | 13   | 12   | 11   | 10   | 9    | 8    |
|        |    |    |      |      |      |      |      |      |
| Access | R  | R  | R    | R    | R    | R    | R    | R    |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |
| Bit    | 7  | 6  | 5    | 4    | 3    | 2    | 1    | 0    |
|        |    |    | OVR5 | OVR4 | OVR3 | OVR2 | OVR1 | OVR0 |
| Access | R  | R  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bits 31:22 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 21:16 – EVDx: Event Detected Channel x Interrupt Enable**

0: The Event Detected Channel x interrupt is disabled.

1: The Event Detected Channel x interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Event Detected Channel x Interrupt Enable bit, which disables the Event Detected Channel x interrupt.

- **Bits 15:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – OVRx: Overrun Channel x Interrupt Enable**

0: The Overrun Channel x interrupt is disabled.

1: The Overrun Channel x interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Overrun Channel x Interrupt Enable bit, which disables the Overrun Channel x interrupt.

## 29.8.4 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x14

**Reset:** 0x00000000

**Property:** Write-Protected

|        |    |    |      |      |      |      |      |      |
|--------|----|----|------|------|------|------|------|------|
| Bit    | 31 | 30 | 29   | 28   | 27   | 26   | 25   | 24   |
|        |    |    |      |      |      |      |      |      |
| Access | R  | R  | R    | R    | R    | R    | R    | R    |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |
| Bit    | 23 | 22 | 21   | 20   | 19   | 18   | 17   | 16   |
|        |    |    | EVD5 | EVD4 | EVD3 | EVD  | EVD1 | EVD0 |
| Access | R  | R  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |
| Bit    | 15 | 14 | 13   | 12   | 11   | 10   | 9    | 8    |
|        |    |    |      |      |      |      |      |      |
| Access | R  | R  | R    | R    | R    | R    | R    | R    |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |
| Bit    | 7  | 6  | 5    | 4    | 3    | 2    | 1    | 0    |
|        |    |    | OVR5 | OVR4 | OVR3 | OVR2 | OVR1 | OVR0 |
| Access | R  | R  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |
| Reset  | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    |

- **Bits 31:22 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 21:16 – EVDx: Event Detected Channel x Interrupt Enable**

0: The Event Detected Channel x interrupt is disabled.

1: The Event Detected Channel x interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Event Detected Channel x Interrupt Enable bit, which enables the Event Detected Channel x interrupt.

- **Bits 15:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – OVRx: Overrun Channel x Interrupt Enable**

0: The Overrun Channel x interrupt is disabled.

1: The Overrun Channel x interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Overrun Channel x Interrupt Enable bit, which enables the Overrun Channel x interrupt.

## 29.8.5 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x18  
**Reset:** 0x00000000  
**Property:** –

- Bits 31:22 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 21:16 – EVDx: Event Detected Channel x**  
 This flag is set on the next CLK\_EVSYS\_APB cycle when an event is being propagated through the channel, and an interrupt request will be generated if INTENCLR/SET.EVDx is one.  
 When the event channel path is asynchronous, the EVDx interrupt flag will not be set.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Event Detected Channel n interrupt flag.
- Bits 15:6 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 5:0 – OVRx: Overrun Channel x**  
 This flag is set on the next CLK\_EVSYS cycle after an overrun channel condition occurs, and an interrupt request will be generated if INTENCLR/SET.OVRx is one.  
 There are two possible overrun channel conditions:

- One or more of the event users on channel x are not ready when a new event occurs
- An event happens when the previous event on channel x has not yet been handled by all event users

When the event channel path is asynchronous, the OVRx interrupt flag will not be set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Overrun Channel x interrupt flag.

- Bits 5:0 - CHANNELn: Channel n Software Selections**

Writing '0' to this bit has no effect.

Writing '1' to this bit will trigger a software event for the channel n.

These bits will always return zero when read.

## 29.8.7 Channel

This register allows the user to configure channel n. To write to this register, do a single, 32-bit write of all the configuration data.

**Name:** CHANNEL

**Offset:**  $0x20+n*0x4$  [ $n=0..11$ ]

**Reset:** 0x00008000

**Property:** Write-Protected

- **Bits 31:16 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 15 – ONDEMAND: Generic Clock On Demand**

0: Generic clock for a channel is always on, if the channel is configured and generic clock source is enabled.

1: Generic clock is requested on demand while an event is handled.

- **Bit 14 – RUNSTDBY: Run in Standby**

This bit is used to define the behavior during standby sleep mode.

0: The channel is disabled in standby sleep mode.

1: The channel is not stopped in standby sleep mode and depends on the CHANNEL.ONDEMAND.

- **Bits 13:12 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 11:20 – EDGSEL[1:0]: Edge Detection Selection**  
These bits set the type of edge detection to be used on the channel.  
These bits must be written to zero when using the asynchronous path.

**Table 29-2. Edge Detection Selection**

| Value | Name          | Description  |
|-------|---------------|--|
| 0x0   | NO_EVT_OUTPUT | No event output when using the resynchronized or synchronous path                  |
| 0x1   | RISING_EDGE   | Event detection only on the rising edge of the signal from the event generator     |
| 0x2   | FALLING_EDGE  | Event detection only on the falling edge of the signal from the event generator    |
| 0x3   | BOTH_EDGES    | Event detection on rising and falling edges of the signal from the event generator |

- **Bits 9:8 – PATH[1:0]: Path Selection**  
These bits are used to chose which path will be used by the selected channel.  
The path choice can be limited by the channel source, see [Table 29-6](#).

**Table 29-3. Path Selection**

| Value | Name           | Description         |
|-------|----------------|---------------------|
| 0x0   | SYNCHRONOUS    | Synchronous path    |
| 0x1   | RESYNCHRONIZED | Resynchronized path |
| 0x2   | ASYNCHRONOUS   | Asynchronous path   |
| 0x3   | -              | Reserved            |

- **Bits 7:0 – EVGEN[7:0]: Event Generator**  
These bits are used to choose the event generator to connect to the selected channel.

**Table 29-4. Event Generator Selection**

| Value | Event Generator | Description                                  |
|-------|-----------------|--|
| 0x00  | NONE            | No event generator selected                  |
| 0x01  | OSCCTRL FAIL    | XOSC Clock Failure                           |
| 0x02  | OSC32KCTRL FAIL | XOSC32K Clock Failure                        |

## 29.8.8 User

This register is used to configure a specified event user. To write to this register, do a single, 16-bit write of all the configuration and event user selection data.

To read from this register, first do an 8-bit write to the USER.USER bit group specifying the event user configuration to be read, and then read USER.

**Name:** USER

**Offset:**  $0x80+m*0x4$  [ $m=0..46$ ]

**Reset:** 0x0000

**Property:** Write-protected

- Bits 15:8 – CHANNEL: Channel Event Selection**

These bits are used to select the channel to connect to the event user.

Note that to select channel  $n$ , the value  $(m+1)$  must be written to the USER.CHANNEL bit group.

**Table 29-5. Channel Event Selection**

| Value     | Channel Number             |
|-----------|----------------------------|
| 0x00      | No channel output selected |
| 0x01      | 0                          |

## 30. SERCOM – Serial Communication Interface

### 30.1 Overview

The serial communication interface (SERCOM) can be configured to support a number of modes; I<sup>2</sup>C, SPI, and USART. Once configured and enabled, all SERCOM resources are dedicated to the selected mode.

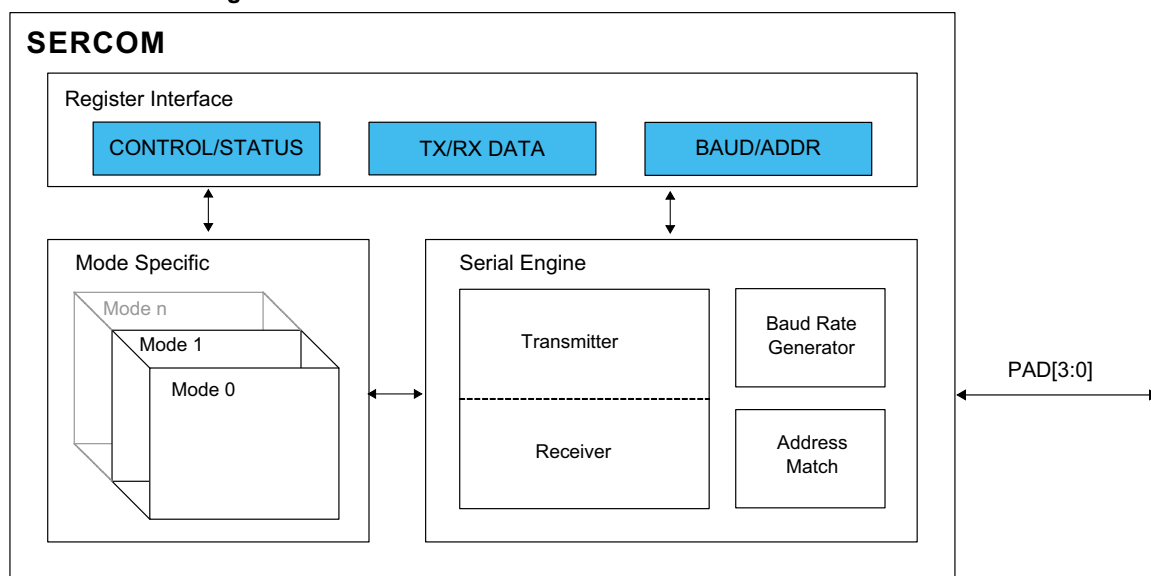

The SERCOM serial engine consists of a transmitter and receiver, baud-rate generator and address matching functionality. It can be configured to use the internal generic clock or an external clock, making operation in all sleep modes possible.

### 30.2 Features

- Combined interface configurable as one of the following:
  - I<sup>2</sup>C – Two-wire serial interface
    - SMBus™ compatible.
  - SPI – Serial peripheral interface
  - USART – Universal synchronous and asynchronous serial receiver and transmitter
- Single transmit buffer and double receive buffer
- Baud-rate generator
- Address match/mask logic
- Operational in all sleep modes
- Can be used with DMA

### 30.3 Block Diagram

Figure 30-1. SERCOM Block Diagram

### 30.4 Signal Description

See the respective SERCOM mode chapters for details:

- [“SERCOM USART – SERCOM Universal Synchronous and Asynchronous Receiver and Transmitter” on page 500](#)
- [“SERCOM SPI – SERCOM Serial Peripheral Interface” on page 542](#)
- [“SERCOM I2C – SERCOM Inter-Integrated Circuit” on page 575](#)

## 30.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 30.5.1 I/O Lines

Using the SERCOM I/O lines requires the I/O pins to be configured using port configuration (PORT). Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

From [Figure 30-1](#) one can see that the SERCOM has four internal pads, PAD[3:0]. The signals from I<sup>2</sup>C, SPI and USART are routed through these SERCOM pads via a multiplexer. The configuration of the multiplexer is available from the different SERCOM modes. Refer to the mode specific chapters for details:

- [“SERCOM USART – SERCOM Universal Synchronous and Asynchronous Receiver and Transmitter” on page 500](#)
- [“SERCOM SPI – SERCOM Serial Peripheral Interface” on page 542](#)
- [“SERCOM I2C – SERCOM Inter-Integrated Circuit” on page 575](#)

### 30.5.2 Power Management

The SERCOM can operate in any sleep mode. SERCOM interrupts can be used to wake up the device from sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 30.5.3 Clocks

The SERCOM bus clock (CLK\_SERCOMx\_APB, where x represents the specific SERCOM instance number) can be enabled and disabled in the Main Clock module, and the default state of CLK\_SERCOMx\_APB can be found in the Peripheral Clock Masking section in [Table 17-1](#).

Two generic clocks are used by the SERCOM: GCLK\_SERCOMx\_CORE and GCLK\_SERCOMx\_SLOW. The core clock (GCLK\_SERCOMx\_CORE) is required to clock the SERCOM while operating as a master, while the slow clock (GCLK\_SERCOMx\_SLOW) is only required for certain functions. See specific mode chapters for details.

These clocks must be configured and enabled in the Generic Clock Controller (GCLK) before using the SERCOM. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

These generic clocks are asynchronous to the user interface clock (CLK\_SERCOMx\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 499](#) for further details.

### 30.5.4 DMA

The DMA request lines are connected to the DMA controller (DMAC). Using the SERCOM DMA requests, requires the DMA controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details.

### 30.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the SERCOM interrupts requires the Interrupt Controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 30.5.6 Events

Not applicable.

### 30.5.7 Debug Operation

When the CPU is halted in debug mode, the SERCOM continues normal operation. If the SERCOM is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging. The SERCOM can be forced to halt operation during debugging.

### 30.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag Status and Clear register (INTFLAG)
- Address register (ADDR)
- Data register (DATA)

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled. Refer to “PAC – Peripheral Access Control” on page 33 for details.

### 30.5.9 Analog Connections

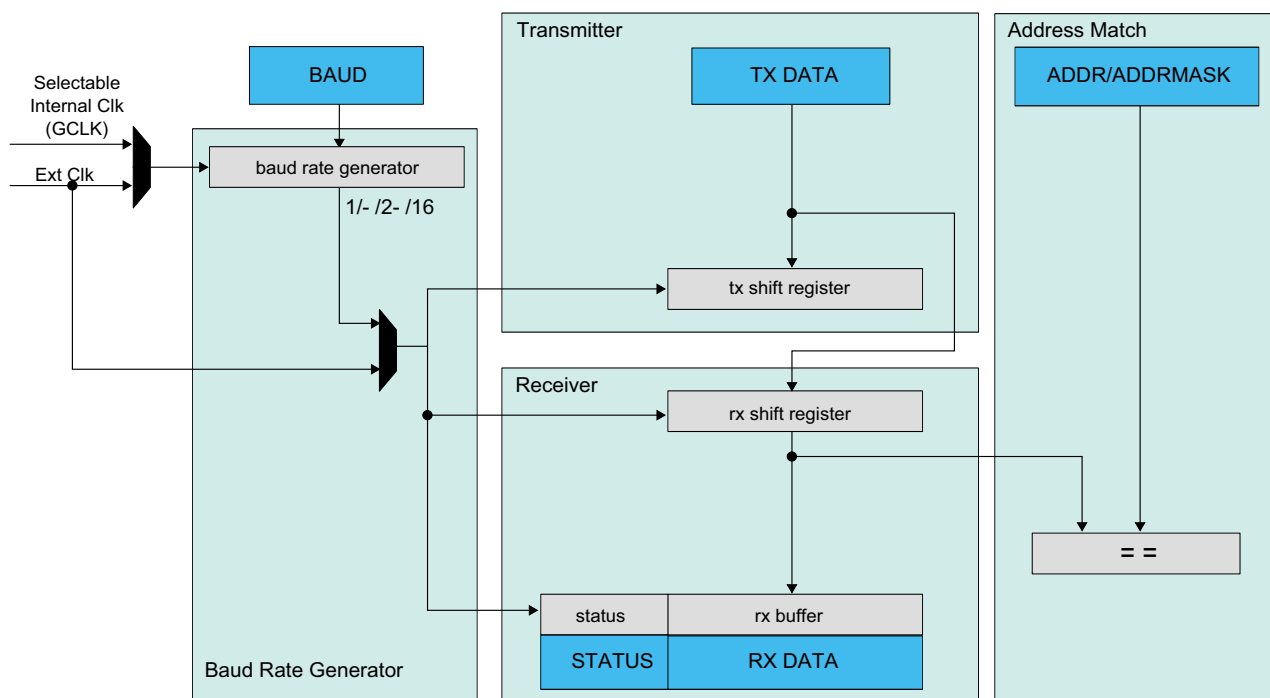

Not applicable.

## 30.6 Functional Description

### 30.6.1 Principle of Operation

The basic structure of the SERCOM serial engine is shown in Figure 30-2. Fields shown in capital letters are synchronous to the system clock and accessible by the CPU, while fields with lowercase letters can be configured to run on the GCLK\_SERCOMx\_CORE clock or an external clock.

Figure 30-2. SERCOM Serial Engine

The transmitter consists of a single write buffer and a shift register. The receiver consists of a two-level receive buffer and a shift register. The baud-rate generator is capable of running on the GCLK\_SERCOMx\_CORE clock or an external clock. Address matching logic is included for SPI and I<sup>2</sup>C operation.

## 30.6.2 Basic Operation

### 30.6.2.1 Initialization

The SERCOM must be configured to the desired mode by writing to the Operating Mode bits in the Control A register (CTRLA.MODE). Refer to [Figure 30-1](#) for details.

**Table 30-1. SERCOM Modes**

| CTRLA.MODE | Description                       |
|------------|-----------------------------------|
| 0x0        | USART with external clock         |
| 0x1        | USART with internal clock         |
| 0x2        | SPI in slave operation            |
| 0x3        | SPI in master operation           |
| 0x4        | I <sup>2</sup> C slave operation  |
| 0x5        | I <sup>2</sup> C master operation |
| 0x6-0x7    | Reserved                          |

For further initialization information, see the respective SERCOM mode chapters.

### 30.6.2.2 Enabling, Disabling and Resetting

The SERCOM is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The SERCOM is disabled by writing a zero to CTRLA.ENABLE.

The SERCOM is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the SERCOM, except DBGCTRL, will be reset to their initial state, and the SERCOM will be disabled. Refer to the CTRLA register descriptions for details.

### 30.6.2.3 Clock Generation – Baud-Rate Generator

The baud-rate generator, as shown in [Figure 30-3](#), is used for internal clock generation for asynchronous and synchronous communication. The generated output frequency ( $f_{\text{BAUD}}$ ) is determined by the Baud register (BAUD) setting and the baud reference frequency ( $f_{\text{REF}}$ ). The baud reference clock is the serial engine clock, and it can be internal or external.

For asynchronous operation, the /16 (divide-by-16) output is used when transmitting and the /1 (divide-by-1) output is used when receiving. For synchronous operation the /2 (divide-by-2) output is used. This functionality is automatically configured, depending on the selected operating mode.

**Figure 30-3. Baud Rate Generator**

Table 30-2 contains equations for calculating the baud rate (in bits per second) and for calculating the BAUD register value for each mode of operation.

For asynchronous operation there are two different modes. Using the arithmetic mode, the BAUD register value is 16 bits (0 to 65,535). Using the fractional mode, the BAUD register is 13 bits, while the fractional adjustment is 3 bits. In this mode the BAUD setting must be greater than or equal to 1.

For synchronous mode, the BAUD register value is 8 bits (0 to 255).

**Table 30-2. Baud Rate Equations**

| Operating Mode          | Condition                         | Baud Rate (Bits Per Second)                        | BAUD Register Value Calculation                               |
|-------------------------|-----------------------------------|--|---|
| Asynchronous Arithmetic | $f_{BAUD} \leq \frac{f_{REF}}{S}$ | $f_{BAUD} = \frac{f_{REF}}{S} (1 - BAUD / 65,536)$ | $BAUD = 65,536 \left( 1 - S \frac{f_{BAUD}}{f_{REF}} \right)$ |
| Asynchronous Fractional | $f_{BAUD} \leq \frac{f_{REF}}{S}$ | $f_{BAUD} = \frac{f_{REF}}{S(BAUD + (FP/8))}$      | $BAUD = \frac{f_{REF}}{S \times f_{BAUD}} - \frac{FP}{8}$     |
| Synchronous             | $f_{BAUD} \leq \frac{f_{REF}}{2}$ | $f_{BAUD} = \frac{f_{REF}}{2(BAUD + 1)}$           | $BAUD = \frac{f_{REF}}{2 f_{BAUD}} - 1$                       |

S – Number of samples per bit. Can be 16, 8, or 3.

The Asynchronous Fractional option is used for auto-baud detection.

The baud rate error is represented by the following formula:

$$Error = 1 - \left( \frac{ExpectedBaudRate}{ActualBaudRate} \right)$$

### Asynchronous Arithmetic Mode BAUD Value Selection

The formula given for  $f_{BAUD}$  calculates the average frequency over 65,536  $f_{REF}$  cycles. Although the BAUD register can be set to any value between 0 and 65,536, the values that will change the average frequency of  $f_{BAUD}$  over a single frame are more constrained. The BAUD register values that will affect the average frequency over a single frame lead to an integer increase in the cycles per frame (CPF)

$$CPF = \frac{f_{REF}}{f_{BAUD}} (D + S)$$

where

- D represent the data bits per frame
- S represent the sum of start and first stop bits, if present

Table 30-3 shows the BAUD register value versus baud frequency at a serial engine frequency of 48MHz. This assumes a D value of 8 bits and an S value of 2 bits (10 bits, including start and stop bits).

**Table 30-3. BAUD Register Value vs. Baud Frequency**

| BAUD Register Value | Serial Engine CPF | $f_{BAUD}$ at 48MHz Serial Engine Frequency ( $f_{REF}$ ) |
|---------------------|-------------------|---|
| 0 – 406             | 160               | 3MHz  |
| 407 – 808           | 161               | 2.981MHz  |
| 809 – 1205          | 162               | 2.963MHz  |
| ...                 |                   |   |
| 65206               | 31775             | 15.11kHz  |
| 65207               | 31871             | 15.06kHz  |
| 65208               | 31969             | 15.01kHz  |

30.6.3 Additional Features

30.6.3.1 Address Match and Mask

The SERCOM address match and mask feature is capable of matching one address with a mask, two unique addresses or a range of addresses, based on the mode selected. The match uses seven or eight bits, depending on the mode.

Address With Mask

An address written to the Address bits in the Address register (ADDR.ADDR) with a mask written to the Address Mask bits in the Address register (ADDR.ADDRMASK) will yield an address match. All bits that are masked are not included in the match. Note that setting the ADDR.ADDRMASK to all zeros will match a single unique address, while setting ADDR.ADDRMASK to all ones will result in all addresses being accepted.

Figure 30-4. Address With Mask

Two Unique Addresses

The two addresses written to ADDR and ADDRMask will cause a match.

Figure 30-5. Two Unique Addresses

Address Range

The range of addresses between and including ADDR.ADDR and ADDR.ADDRMASK will cause a match. ADDR.ADDR and ADDR.ADDRMASK can be set to any two addresses, with ADDR.ADDR acting as the upper limit and ADDR.ADDRMASK acting as the lower limit.

Figure 30-6. Address Range

30.6.4 DMA Operation

Not applicable.

### 30.6.5 Interrupts

Interrupt sources are mode-specific. See the respective SERCOM mode chapters for details.

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the SERCOM is reset. See the register description for details on how to clear interrupt flags.

The SERCOM has one common interrupt request line for all the interrupt sources. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 30.6.6 Events

Not applicable.

### 30.6.7 Sleep Mode Operation

The peripheral can operate in any sleep mode where the selected serial clock is running. This clock can be external or generated by the internal baud-rate generator.

The SERCOM interrupts can be used to wake up the device from sleep modes. Refer to the different SERCOM mode chapters for details.

### 30.6.8 Synchronization

Due to the asynchronicity between the main clock domain and the peripheral clock domains, some registers must be synchronized when written or read. See the Clock System [“Register Synchronization” on page 105](#) for details.

Required write-synchronization is denoted by the “Write-Synchronized” property in the register description.

Required read-synchronization is denoted by the “Read-Synchronized” property in the register description.

## 31. SERCOM USART – SERCOM Universal Synchronous and Asynchronous Receiver and Transmitter

### 31.1 Overview

The universal synchronous and asynchronous receiver and transmitter (USART) is one of the available modes in the Serial Communication Interface (SERCOM).

Refer to [“SERCOM – Serial Communication Interface” on page 492](#) for details.

The USART uses the SERCOM transmitter and receiver configured as shown in [Figure 31-1](#). Fields shown in capital letters are synchronous to the CLK\_SERCOMx\_APB and accessible by the CPU, while fields with lowercase letters can be configured to run on the internal generic clock or an external clock.

The transmitter consists of a single write buffer, a shift register and control logic for handling different frame formats. The write buffer allows continuous data transmission without any delay between frames.

The receiver consists of a two-level receive buffer and a shift register. Status information for the received data is available for error checking. Data and clock recovery units ensure robust synchronization and noise filtering during asynchronous data reception.

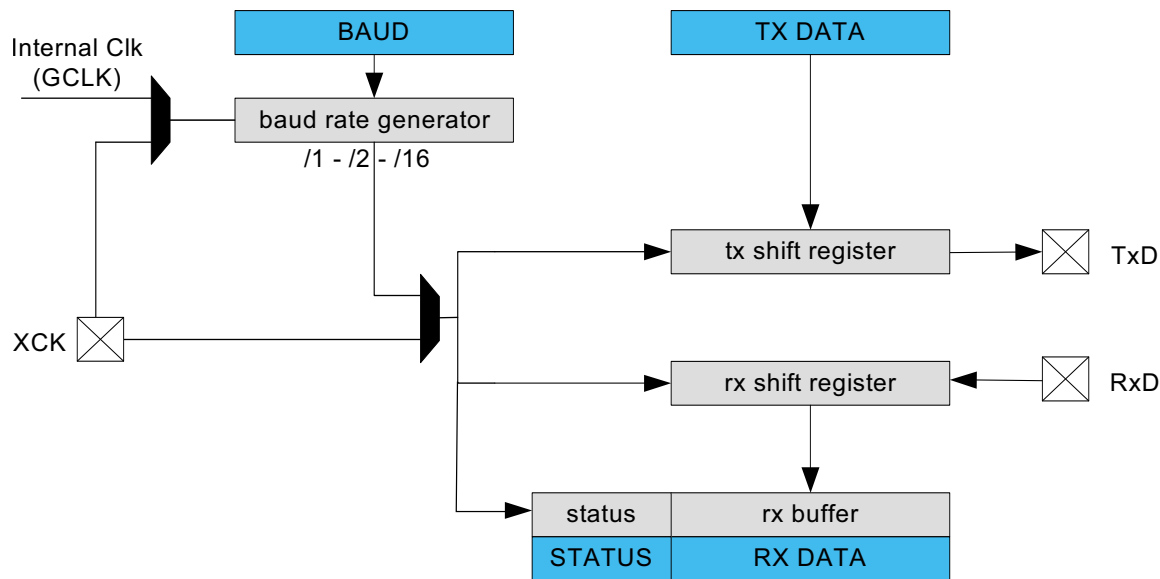

### 31.2 Features

- Full-duplex operation
- Asynchronous (with clock reconstruction) or synchronous operation
- Internal or external clock source for asynchronous and synchronous operation
- Baud-rate generator
- Supports serial frames with 5, 6, 7, 8 or 9 data bits and 1 or 2 stop bits
- Odd or even parity generation and parity check
- Selectable LSB- or MSB-first data transfer
- Buffer overflow and frame error detection
- Noise filtering, including false start-bit detection and digital low-pass filter
- Collision detection
- Can operate in all sleep modes
- Operation at speeds up to half the system clock for internally generated clocks
- Operation at speeds up to the system clock for externally generated clocks
- RTS and CTS flow control
- IrDA modulation and demodulation up to 115.2 kbps
- LIN slave support
  - Auto-baud and break character detection
- LIN master support
- RS485 driver control
- Start-of-frame detection
- Can be used with DMA

### 31.3 Block Diagram

Figure 31-1. USART Block Diagram

### 31.4 Signal Description

| Signal Name | Type        | Description         |
|-------------|-------------|---------------------|
| PAD[3:0]    | Digital I/O | General SERCOM pins |

Please refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

### 31.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

#### 31.5.1 I/O Lines

Using the USART’s I/O lines requires the I/O pins to be configured using port configuration (PORT).

Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

When the SERCOM is used in USART mode, the pins should be configured according to [Table 31-1](#). If the receiver or transmitter is disabled, these pins can be used for other purposes.

Table 31-1. USART Pin Configuration

| Pin | Pin Configuration |
|-----|-------------------|
| TxD | Output            |
| RxD | Input             |
| XCK | Output or input   |

The combined configuration of PORT and the Transmit Data Pinout and Receive Data Pinout bit groups (refer to the Control A register description) will define the physical position of the USART signals in [Table 31-1](#).

### 31.5.2 Power Management

The USART can continue to operate in any sleep mode where the selected source clock is running. The USART interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 31.5.3 Clocks

The SERCOM bus clock (CLK\_SERCOMx\_APB, where x represents the specific SERCOM instance number) can be enabled and disabled in the Main Clock module, and the default state of CLK\_SERCOMx\_APB can be found in the Peripheral Clock Masking section in [Table 17-1](#).

A generic clock (GCLK\_SERCOMx\_CORE) is required to clock the SERCOMx\_CORE. This clock must be configured and enabled in the Generic Clock Controller before using the SERCOMx\_CORE. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

This generic clock is asynchronous to the bus clock (CLK\_SERCOMx\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 514](#) for further details.

### 31.5.4 DMA

The DMA request lines are connected to the DMA controller (DMAC). Using the SERCOM DMA requests, requires the DMA controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details..

### 31.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the USART interrupts requires the Interrupt Controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 31.5.6 Events

Not applicable.

### 31.5.7 Debug Operation

When the CPU is halted in debug mode, the USART continues normal operation. If the USART is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging. The USART can be forced to halt operation during debugging.

Refer to [DBGCTRL](#) for details.

### 31.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag Status and Clear register (INTFLAG)
- Status register (STATUS)
- Data register (DATA)

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

## 31.5.9 Analog Connections

Not applicable.

## 31.6 Functional Description

### 31.6.1 Principle of Operation

The USART uses three communication lines for data transfer:

- RxD for receiving
- TxD for transmitting
- XCK for the transmission clock in synchronous operation

USART data transfer is frame based, where a serial frame consists of:

- 1 start bit
- 5, 6, 7, 8 or 9 data bits
- MSB or LSB first
- No, even or odd parity bit
- 1 or 2 stop bits

A frame starts with the start bit followed by one character of data bits. If enabled, the parity bit is inserted after the data bits and before the first stop bit. One frame can be directly followed by a new frame, or the communication line can return to the idle (high) state. [Figure 31-2](#) illustrates the possible frame formats. Bits inside brackets are optional.

**Figure 31-2. Frame Formats**

**St** Start bit; always low

**(n)** Data bits; 0 to 8

**P** Parity bit; odd or even

**Sp** Stop bit; always high

**IDLE** No transfers on the communication line; always high in this state

### 31.6.2 Basic Operation

#### 31.6.2.1 Initialization

The following registers are enable-protected, meaning they can only be written when the USART is disabled (CTRL.ENABLE is zero):

- Control A register (CTRLA), except the Enable (ENABLE) and Software Reset (SWRST) bits
- Control B register (CTRLB), except the Receiver Enable (RXEN) and Transmitter Enable (TXEN) bits
- Baud register (BAUD)

Any writes to these registers when the USART is enabled or is being enabled (CTRL.ENABLE is one) will be discarded. Writes to these registers while the peripheral is being disabled will be completed after the disabling is complete.

Before the USART is enabled, it must be configured, as outlined in the following steps:

- USART mode with external or internal clock must be selected first by writing 0x0 or 0x1 to the Operating Mode bit group in the Control A register (CTRLA.MODE)

- Communication mode (asynchronous or synchronous) must be selected by writing to the Communication Mode bit in the Control A register (CTRLA.CMODE)
- SERCOM pad to use for the receiver must be selected by writing to the Receive Data Pinout bit group in the Control A register (CTRLA.RXPO)
- SERCOM pads to use for the transmitter and external clock must be selected by writing to the Transmit Data Pinout bit in the Control A register (CTRLA.TXPO)
- Character size must be selected by writing to the Character Size bit group in the Control B register (CTRLB.CHSIZE)
- MSB- or LSB-first data transmission must be selected by writing to the Data Order bit in the Control A register (CTRLA.DORD)
- When parity mode is to be used, even or odd parity must be selected by writing to the Parity Mode bit in the Control B register (CTRLB.PMODE) and enabled by writing 0x1 to the Frame Format bit group in the Control A register (CTRLA.FORM)
- Number of stop bits must be selected by writing to the Stop Bit Mode bit in the Control B register (CTRLB.SBMODE)
- When using an internal clock, the Baud register (BAUD) must be written to generate the desired baud rate
- The transmitter and receiver can be enabled by writing ones to the Receiver Enable and Transmitter Enable bits in the Control B register (CTRLB.RXEN and CTRLB.TXEN)

#### 31.6.2.2 Enabling, Disabling and Resetting

The USART is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The USART is disabled by writing a zero to CTRLA.ENABLE.

The USART is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the USART, except DBGCTRL, will be reset to their initial state, and the USART will be disabled. Refer to the CTRLA register for details.

#### 31.6.2.3 Clock Generation and Selection

For both synchronous and asynchronous modes, the clock used for shifting and sampling data can be generated internally by the SERCOM baud-rate generator or supplied externally through the XCK line. Synchronous mode is selected by writing a one to the Communication Mode bit in the Control A register (CTRLA.CMODE) and asynchronous mode is selected by writing a zero to CTRLA.CMODE. The internal clock source is selected by writing 0x1 to the Operation Mode bit group in the Control A register (CTRLA.MODE) and the external clock source is selected by writing 0x0 to CTRLA.MODE.

The SERCOM baud-rate generator is configured as shown in [Figure 31-3](#). When CTRLA.CMODE is zero, the baud-rate generator is automatically set to asynchronous mode and the 16-bit Baud register value is used. When CTRLA.CMODE is one, the baud-rate generator is automatically set to synchronous mode and the eight LSBs of the Baud register are used. Refer to [“Clock Generation – Baud-Rate Generator” on page 495](#) for details on configuring the baud rate.

**Figure 31-3. Clock Generation**

### Synchronous Clock Operation

When synchronous mode is used, the **CTRLA.MODE** bit group controls whether the transmission clock (XCK line) is an input or output. The dependency between the clock edges and data sampling or data change is the same for internal and external clocks. Data input on the **RxD** pin is sampled at the opposite XCK clock edge as data is driven on the **TxD** pin.

The Clock Polarity bit in the Control A register (**CTRLA.CPOL**) selects which XCK clock edge is used for **RxD** sampling and which is used for **TxD** change. As shown in Figure 31-4, when **CTRLA.CPOL** is zero, the data will be changed on the rising XCK edge and sampled on the falling XCK edge. If **CTRLA.CPOL** is one, the data will be changed on the falling edge of XCK and sampled on the rising edge of XCK.

**Figure 31-4. Synchronous Mode XCK Timing**

When the clock is provided through XCK (**CTRLA.MODE** is 0x0), the shift registers operate directly on the XCK clock. This means that XCK is not synchronized with the system clock and, therefore, can operate at frequencies up to the system frequency.

#### 31.6.2.4 Data Register

The USART Transmit Data register (**TxDATA**) and USART Receive Data register (**RxDATA**) share the same I/O address, referred to as the Data register (**DATA**). Writing the **DATA** register will update the Transmit Data register. Reading the **DATA** register will return the contents of the Receive Data register.

### 31.6.2.5 Data Transmission

A data transmission is initiated by loading the DATA register with the data to be sent. The data in TxDATA is moved to the shift register when the shift register is empty and ready to send a new frame. When the shift register is loaded with data, one complete frame will be transmitted.

The Transmit Complete interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.TXC) is set, and the optional interrupt is generated, when the entire frame plus stop bit(s) have been shifted out and there is no new data written to the DATA register.

The DATA register should only be written when the Data Register Empty flag in the Interrupt Flag Status and Clear register (INTFLAG.DRE) is set, which indicates that the register is empty and ready for new data.

#### Disabling the Transmitter

Disabling the transmitter will not become effective until any ongoing and pending transmissions are completed, i.e., when the transmit shift register and TxDATA do not contain data to be transmitted. The transmitter is disabled by writing a zero to the Transmitter Enable bit in the Control B register (CTRLB.TXEN).

### 31.6.2.6 Data Reception

The receiver starts data reception when a valid start bit is detected. Each bit that follows the start bit will be sampled at the baud rate or XCK clock, and shifted into the receive shift register until the first stop bit of a frame is received. When the first stop bit is received and a complete serial frame is present in the receive shift register, the contents of the shift register will be moved into the two-level receive buffer. The Receive Complete interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.RXC) is set, and the optional interrupt is generated. A second stop bit will be ignored by the receiver.

The received data can be read by reading the DATA register. DATA should not be read unless the Receive Complete interrupt flag is set.

#### Disabling the Receiver

Disabling the receiver by writing a zero to the Receiver Enable bit in the Control B register (CTRLB.RXEN) will flush the two-level receive buffer, and data from ongoing receptions will be lost.

#### Error Bits

The USART receiver has three error bits. The Frame Error (FERR), Buffer Overflow (BUFOVF) and Parity Error (PERR) bits can be read from the Status (STATUS) register. Upon error detection, the corresponding bit will be set until it is cleared by writing a one to it. These bits are also automatically cleared when the receiver is disabled.

There are two methods for buffer overflow notification. When the immediate buffer overflow notification bit (CTRLA.IBON) is set, STATUS.BUFOVF is raised immediately upon buffer overflow. Software can then empty the receive FIFO by reading RxDATA until the receive complete interrupt flag (INTFLAG.RXC) goes low.

When CTRLA.IBON is zero, the buffer overflow condition travels with data through the receive FIFO. After the received data is read, STATUS.BUFOVF will be set along with INTFLAG.RXC.

#### Asynchronous Data Reception

The USART includes a clock recovery and data recovery unit for handling asynchronous data reception. The clock recovery logic is used to synchronize the incoming asynchronous serial frames at the RxD pin to the internally generated baud-rate clock. The data recovery logic samples and applies a low-pass filter to each incoming bit, thereby improving the noise immunity of the receiver. The asynchronous reception operational range depends on the accuracy of the internal baud-rate clock, the rate of the incoming frames and the frame size (in number of bits).

#### Asynchronous Operational Range

The operational range of the receiver depends on the difference between the received bit rate and the internally generated baud rate. If the baud rate of an external transmitter is too high or too low compared to the internally generated baud rate, the receiver will not be able to synchronize the frames to the start bit.

There are two possible sources for a mismatch in baud rate. The reference clock will always have some minor instability. In addition, the baud-rate generator can not always do an exact division of the reference clock frequency to get the baud

rate desired. In this case, the BAUD register value should be selected to give the lowest possible error. Refer to “Asynchronous Arithmetic Mode BAUD Value Selection” on page 497 for details.

Recommended maximum receiver baud-rate errors for various character sizes are shown in the table below.

**Table 31-2. Asynchronous Receiver Error for x16 Oversampling**

| D<br>(Data bits + Parity) | R <sub>SLOW</sub> (%) | R <sub>FAST</sub> (%) | Max Total Error (%) | Recommended Max Rx Error (%) |
|---------------------------|-----------------------|-----------------------|---------------------|------------------------------|
| 5                         | 94.12                 | 107.69                | +5.88/-7.69         | ±2.5                         |
| 6                         | 94.92                 | 106.67                | +5.08/-6.67         | ±2.0                         |
| 7                         | 95.52                 | 105.88                | +4.48/-5.88         | ±2.0                         |
| 8                         | 96.00                 | 105.26                | +4.00/-5.26         | ±2.0                         |
| 9                         | 96.39                 | 104.76                | +3.61/-4.76         | ±1.5                         |
| 10                        | 96.70                 | 104.35                | +3.30/-4.35         | ±1.5                         |

The recommended maximum receiver baud-rate error assumes that the receiver and transmitter equally divide the maximum total error.

The following equations can be used to calculate the ratio of the incoming data rate and internal receiver baud rate:

$$R_{SLOW} = \frac{(D+1)S}{S-1+D \cdot S+S_F}$$

$$R_{FAST} = \frac{(D+2)S}{(D+1)S+S_M}$$

where:

- S is the number of samples per bit (S = 16, 8 or 3)
- S<sub>F</sub> is the first sample number used for majority voting (S<sub>F</sub> = 7, 3, or 2) when CTRLA.SAMPA=0.
- S<sub>M</sub> is the middle sample number used for majority voting (S<sub>M</sub> = 8, 4, or 2) when CTRLA.SAMPA=0.
- D is the sum of character size and parity size (D = 5 to 10 bits)
- R<sub>SLOW</sub> is the ratio of the slowest incoming data rate that can be accepted in relation to the receiver baud rate
- R<sub>FAST</sub> is the ratio of the fastest incoming data rate that can be accepted in relation to the receiver baud rate

### 31.6.3 Additional Features

#### 31.6.3.1 Parity

Even or odd parity can be selected for error checking by writing 0x1 to the Frame Format bit group in the Control A register (CTRLA.FORM). If even parity is selected by writing a zero to the Parity Mode bit in the Control B register (CTRLB.PMODE), the parity bit of the outgoing frame is set to one if the number of data bits that are one is odd (making the total number of ones even). If odd parity is selected by writing a one to CTRLB.PMODE, the parity bit of the outgoing frame is set to one if the number of data bits that are one is even (making the total number of ones odd).

When parity checking is enabled, the parity checker calculates the parity of the data bits in incoming frames and compares the result with the parity bit of the corresponding frame. If a parity error is detected, the Parity Error bit in the Status register (STATUS.PERR) is set.

### 31.6.3.2 Hardware Handshaking

The USART features an out-of-band hardware handshaking flow control mechanism, implemented by connecting the RTS and CTS pins with the remote device, as shown in [Figure 31-5](#).

**Figure 31-5. Connection with a Remote Device for Hardware Handshaking**

Hardware handshaking is only available with the following configuration:

- USART with internal clock (CTRLA.MODE = 1).
- Asynchronous mode (CTRLA.CMODE = 0).
- Flow control pinout (CTRLA.TXPO = 2).

The receiver drives its RTS pin high when disabled, or when the receive FIFO is full. This indicates to the remote device that it must stop transmitting after the ongoing transmission is complete. Enabling and disabling the receiver by writing RXEN will set/clear the RTS pin after a synchronization delay. When the receive FIFO goes full, RTS is immediately set and the frame that is currently being received will be stored in the shift register until the receive FIFO is no longer full.

**Figure 31-6. Receiver Behavior when Operating with Hardware Handshaking**

The current CTS level is available in the STATUS register (STATUS.CTS). Character transmission will only start if CTS is low. When CTS goes high, the transmitter will stop transmitting after the ongoing transmission is complete.

**Figure 31-7. Transmitter Behavior when Operating with Hardware Handshaking**

### 31.6.3.3 IrDA Modulation and Demodulation

IrDA modulation and demodulation is available with the following configuration. When enabled, transmission and reception is IrDA compliant up to 115.2 kb/s.

- IrDA encoding enabled (CTRLB.ENC=1).
- Asynchronous mode (CTRLA.CMODE = 0).
- 16x sample rate (CTRLA.SAMPR[0] = 0).

During transmission, each low bit is transmitted as a high pulse with width as 3/16 of the baud rate period as illustrated in [Figure 31-8](#).

**Figure 31-8. IrDA Transmit Encoding**

The reception decoder has two main functions. The first is to synchronize the incoming data to the IrDA baud rate counter. Synchronization is performed at the start of each zero pulse. The second function is to decode incoming Rx data. If a pulse width meets the minimum length set by configuration (RXPL.RXPL), it is accepted. When the baud rate counter reaches its middle value (1/2 bit length), it is transferred to the receiver.

Figure 31-9 illustrates reception where RXPL.RXPL is set to 19. This indicates that the pulse width should be at least 20 SE clock cycles. When assuming BAUD = 0xE666 or 160 SE cycles per bit, this corresponds to 2/16 baud clock as minimum pulse width required. In this case the first bit is accepted as a zero, the second bit is a one, and the third bit is also a one. A low pulse is rejected since it does not meet the minimum requirement of 2/16 baud clock.

**Figure 31-9. IrDA Receive Decoding**

Note that the polarity of the transmitter and receiver are opposite. During transmission, a zero bit is transmitted as a one pulse. During reception, an accepted zero pulse is received as a zero bit.

#### 31.6.3.4 Break Character Detection and Auto-baud

Break character detection and auto-baud are available with the following configuration:

- Auto-baud frame format (CTRLA.FORM = 0x04 or 0x05)
- Asynchronous mode (CTRLA.CMODE = 0).
- 16x sample rate using fractional baud rate generation (CTRLA.SAMPR = 1).

The auto-baud follows the LIN format. All LIN Frames start with a Break Field followed by a Sync Field. The USART uses a break detection threshold of greater than 11 nominal bit times at the configured baud rate. At any time, if more than 11 consecutive dominant bits are detected on the bus, the USART detects a Break Field. When a Break Field has been detected, the Receive Break interrupt flag (INTFLAG.RXBRK) is set and the USART expects the Sync Field character to be 0x55. This field is used to update the actual baud rate in order to stay synchronized. If the received Sync character is not 0x55, then the Inconsistent Sync Field error flag (STATUS.ISF) is set along with the Error interrupt flag (INTFLAG.ERROR) and the baud rate is unchanged.

**Figure 31-10. LIN Break and Sync Fields**

After a break field is detected and the start bit of the Sync Field is detected, a counter is started. The counter is then incremented for the next 8 bit times of the Sync Field. At the end of these 8 bit times, the counter is stopped. At this moment, the 13 most significant bits of the counter (value divided by 8) gives the new clock divider (BAUD.BAUD) and the 3 least significant bits of this value (the remainder) gives the new Fractional Part (BAUD.FP). When the Sync Field has been received, the clock divider (BAUD.BAUD) and the Fractional Part (BAUD.FP) are updated in the Baud Rate Generator register (BAUD) after a synchronization delay.

After the Break and Sync Fields, n characters of data can be received.

### 31.6.3.5 LIN Master

LIN master is available with the following configuration:

- LIN master format (CTRLA.FORM = 0x02)
- Asynchronous mode (CTRLA.CMODE = 0).
- 16x sample rate using fractional baud rate generation (CTRLA.SAMPR = 1).

LIN frames start with a header transmitted by the master. The header consists of the break, sync, and identifier fields. After the master transmits the header, the addressed slave will respond with 1-8 bytes of data plus checksum.

**Figure 31-11.LIN Frame Format**

Using the LIN command field (CTRLB.LINCMD), the complete header can be automatically transmitted, or software can control transmission of the various header components.

When CTRLB.LINCMD=0x1, software controls transmission of the LIN header. In this case, software uses the following sequence.

- CTRLB.LINCMD is written with 0x1.
- DATA register written to 0x00 -- This triggers transmission of the break field by hardware. Note that writing the DATA register with any other value will also result in the transmission of the break field by hardware.
- DATA register written with 0x55 -- The 0x55 value (sync) is transmitted.
- DATA register written with the identifier -- The identifier is transmitted.

When CTRLB.LINCMD=0x2, hardware controls transmission of the LIN header. In this case, software uses the following sequence.

- CTRLB.LINCMD is written with 0x2.
- DATA register written with the identifier -- This triggers transmission of the complete header by hardware. First the break field is transmitted. Next, the sync field is transmitted, and finally the identifier is transmitted.

In LIN master mode, the length of the break field is programmable using the break length field (CTRLC.BRKLEN). When the LIN header command is used (CTRLB.LINCMD=0x2), the delay between the break and sync fields, in addition to the delay between the sync and ID fields are configurable using the header delay field (CTRLC.HDRDLY). When manual transmission is used (CTRLB.LINCMD=0x1), software controls the delay between break and sync.

**Figure 31-12.LIN Header Generation**

After header transmission is complete, the slave responds with 1-8 data bytes plus checksum.

### 31.6.3.6 RS485

RS485 is available with the following configuration:

- USART frame format (CTRLA.FORM = 0x00 or 0x01).
- RS485 pinout (CTRLA.TXPO=0x3).

The RS485 feature enables control of an external line driver as shown in [Figure 31-13](#). While operating in RS485 mode, the transmit enable pin (TE) is driven high when the transmitter is active.

**Figure 31-13.**RS485 Bus Connection

The TE pin will remain high for the complete frame including stop bit(s). If a guard time is programmed (CTRLC.GTIME), the line will remain driven after the last character completion. [Figure 31-14](#) shows a transfer with one stop bit and CTRLC.GTIME=3.

**Figure 31-14.**Example of TE Drive with Guard Time

The transmit complete interrupt flag (INTFLAG.TXC) will be raised after the guard time is complete and TE goes low.

### 31.6.3.7 Collision Detection

When the receiver and transmitter are connected either through pin configuration or externally, transmit collision can be detected by setting the Collision Detection Enable bit (CTRLB.COLDEN). For collision to be detected, the receiver and transmitter must be enabled (CTRLB.RXEN=1 and CTRLB.TXEN=1).

Collision detection is performed for each bit transmitted by checking the received value vs the transmit value as shown in [Figure 31-15](#). While the transmitter is idle (no transmission in progress), characters can be received on RxD without triggering a collision.

**Figure 31-15.**Collision Checking

Figure 31-16 shows the conditions for a collision detection. In this case, the start bit and the first data bit are received with the same value as transmitted. The second received data bit is found to be different than the transmitted bit at the detection point which indicates a collision.

**Figure 31-16. Collision Detected**

When a collision is detected, the USART automatically follows this sequence:

- The current transfer is aborted.
- The transmit buffer is flushed.
- The transmitter is disabled (CTRLB.TXEN=0).
  - This commences immediately and is complete after synchronization time. The CTRLB Synchronization Busy bit (SYNCBUSY.CTRLB) will be set until this is complete.
  - This results in the TxD pin being tri-stated.
- The Collision Detected bit (STATUS.COLL) is set along with the Error interrupt flag (INTFLAG.ERROR).
- Since the transmit buffer no longer contains data, the Transmit Complete interrupt flag (INTFLAG.TXC) is set.

After a collision, software must manually enable the transmitter before continuing. Software must ensure CTRLB Synchronization Busy bit (SYNCBUSY.CTRLB) is not asserted before re-enabling the transmitter.

### 31.6.3.8 Loop-back Mode

By configuring the Receive Data Pinout (CTRLA.RXPO) and Transmit Data Pinout (CTRLA.TXPO) to use the same data pins for transmit and receive, loop-back is achieved. The loop-back is through the pad, so the signal is also available externally.

### 31.6.3.9 Start-of-Frame Detection

The USART start-of-frame detector can wake up the CPU when it detects a start bit. In standby sleep mode, the internal fast startup oscillator must be selected as the GCLK\_SERCOMx\_CORE source.

When a 1-to-0 transition is detected on RxD, the fast startup internal oscillator is powered up and the USART clock is enabled. After startup, the rest of the data frame can be received, provided that the baud rate is slow enough in relation to the oscillator start-up time. Refer to “[Electrical Characteristics](#)” on page 903 for details. The start-up time of the oscillator varies with supply voltage and temperature.

The USART start-of-frame detection works both in asynchronous and synchronous modes. It is enabled by writing a one to the Start of Frame Detection Enable bit in the Control B register (CTRLB.SFDE). If the Receive Start Interrupt Enable bit in the Interrupt Enable Set register (INTENSET.RXS) is set, the Receive Start interrupt is generated immediately when a start is detected. When using start-of-frame detection without the Receive Start interrupt, start detection will force the 8MHz Internal Oscillator and USART clock active while the frame is being received, but the CPU will not wakeup until the Receive Complete interrupt is generated, if enabled.

### 31.6.3.10 Sample Adjustment

In asynchronous mode (CTRLA.CMODE=0), three samples in the middle are used to determine the value based on majority voting. The three samples used for voting can be selected using the Sample Adjustment bit field in Control A

register (CTRLA.SAMPA). When CTRLA.SAMPA is set to zero, samples 7-8-9 are used for 16x over sampling and samples 3-4-5 are used for 8x over sampling.

### 31.6.4 DMA, Interrupts and Events

**Table 31-3. Module Request for SERCOM USART**

| Condition                  | Interrupt request | Event output | Event input | DMA request | DMA request is cleared |
|----------------------------|-------------------|--------------|-------------|-------------|------------------------|
| Data Register Empty        | x                 |              |             | x           | When data is written   |
| Transmit Complete          | x                 |              |             |             |                        |
| Receive Complete           | x                 |              |             | x           | When data is read      |
| Receive Start              | x                 |              |             |             |                        |
| Clear to Send Input Change | x                 |              |             |             |                        |
| Receive Break              | x                 |              |             |             |                        |
| Error                      | x                 |              |             |             |                        |

#### 31.6.4.1 DMA Operation

The USART generates the following DMA requests.

- Data received (RX): The request is set when data is available in the receive FIFO. The request is cleared when DATA is read.
- Data transmit (TX): The request is set when the transmit buffer (TX DATA) is empty. The request is cleared when DATA is written.

#### 31.6.4.2 Interrupts

The USART has the following interrupt sources:

- Error
- Received Break
- Clear to Send Input Change
- Receive Start
- Receive Complete
- Transmit Complete
- Data Register Empty

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the USART is reset. See the register description for details on how to clear interrupt flags.

The USART has one common interrupt request line for all the interrupt sources. The user must read INTFLAG to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 31.6.4.3 Events

Not applicable.

### 31.6.5 Sleep Mode Operation

When using internal clocking, writing the Run In Standby bit in the Control A register (CTRLA.RUNSTDBY) to one will allow GCLK\_SERCOMx\_CORE to be enabled in all sleep modes. Any interrupt can wake up the device.

When using external clocking, writing a one to CTRLA.RUNSTDBY will allow the Receive Start or Receive Complete interrupt to wake up the device.

If CTRLA.RUNSTDBY is zero, the internal clock will be disabled when any ongoing transfer is finished. A Receive Start or Transfer Complete interrupt can wake up the device. When using external clocking, this will be disconnected when any ongoing transfer is finished, and all reception will be dropped.

### 31.6.6 Synchronization

Due to the asynchronicity between CLK\_SERCOMx\_APB and GCLK\_SERCOMx\_CORE, some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding Synchronization Busy bit in the Synchronization register (SYNCBUSY) will be set immediately, and cleared when synchronization is complete.

If an operation that requires synchronization is executed while the corresponding SYNCBUSY bit is one, a peripheral bus error is generated.

The following bits need synchronization when written:

- Software Reset bit in the Control A register (CTRLA.SWRST). SYNCBUSY.SWRST is set to one while synchronization is in progress.
- Enable bit in the Control A register (CTRLA.ENABLE). SYNCBUSY.ENABLE is set to one while synchronization is in progress.
- Receiver Enable bit in the Control B register (CTRLB.RXEN). SYNCBUSY.CTRLB is set to one while synchronization is in progress.
- Transmitter Enable bit in the Control B register (CTRLB.TXEN). SYNCBUSY.CTRLB is set to one while synchronization is in progress.

Synchronization is denoted by the Write-Synchronized property in the register description.

## 31.7 Register Summary

Table 31-4. Register Summary

| Offset | Name     | Bit Pos. |                     |        |           |            |             |             |             |        |
|--------|----------|----------|---------------------|--------|-----------|------------|-------------|-------------|-------------|--------|
| 0x00   | CTRLA    | 7:0      | RUNSTDBY            |        |           | MODE[2:0]  |             |             | ENABLE      | SWRST  |

## 31.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Refer to [“Register Access Protection” on page 502](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Synchronized property in each individual register description. Refer to [“Synchronization” on page 514](#) for details.

Some registers are enable-protected, meaning they can only be written when the USART is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

- Bit 31 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 30 – DORD: Data Order**  
 This bit indicates the data order when a character is shifted out from the Data register.  
 0: MSB is transmitted first.  
 1: LSB is transmitted first.  
 This bit is not synchronized.
- Bit 29 – CPOL: Clock Polarity**  
 This bit indicates the relationship between data output change and data input sampling in synchronous mode.  
 This bit is not synchronized.

**Table 31-5. Clock Polarity**

| CPOL | TxD Change       | RxD Sample       |
|------|------------------|------------------|
| 0x0  | Rising XCK edge  | Falling XCK edge |
| 0x1  | Falling XCK edge | Rising XCK edge  |

- Bit 28 – CMODE: Communication Mode**  
 This bit indicates asynchronous or synchronous communication.  
 0: Asynchronous communication.  
 1: Synchronous communication.  
 This bit is not synchronized.
- Bits 27:24 – FORM[3:0]: Frame Format**  
 These bits define the frame format.  
 These bits are not synchronized.

**Table 31-6. Frame Format**

| FORM[3:0] | Description  |
|-----------|--|
| 0x0       | USART frame  |
| 0x1       | USART frame with parity  |
| 0x2       | LIN Master -- Break and sync generation. See LIN Command (CTRLB.LINCMD). |
| 0x3       | Reserved   |
| 0x4       | Auto-baud(LIN slave) -- break detection and auto-baud.                   |
| 0x5       | Auto-baud -- break detection and auto-baud with parity                   |
| 0x6-0xF   | Reserved   |

- Bits 23:22 – SAMPA[1:0]: Sample Adjustment**  
 These bits define the sample adjustment.  
 These bits are not synchronized.

**Table 31-7. Sample Adjustment**

| SAMPA[1:0] | 16x Over-sampling<br>(CTRLA.SAMPR=0 or 1) | 8x Over-sampling<br>(CTRLA.SAMPR=2 or 3) |
|------------|---|--|
| 0x0        | 7-8-9                                     | 3-4-5                                    |
| 0x1        | 9-10-11                                   | 4-5-6                                    |
| 0x2        | 11-12-13                                  | 5-6-7                                    |
| 0x3        | 13-14-15                                  | 6-7-8                                    |

- Bits 21:20 – RXPO[1:0]: Receive Data Pinout**  
 These bits define the receive data (RxD) pin configuration.  
 These bits are not synchronized.

**Table 31-8. Receive Data Pinout**

| RXPO[1:0] | Name   | Description                              |
|-----------|--------|--|
| 0x0       | PAD[0] | SERCOM PAD[0] is used for data reception |
| 0x1       | PAD[1] | SERCOM PAD[1] is used for data reception |
| 0x2       | PAD[2] | SERCOM PAD[2] is used for data reception |
| 0x3       | PAD[3] | SERCOM PAD[3] is used for data reception |

- Bits 19:18 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 17:16 – TXPO[1:0]: Transmit Data Pinout**  
 These bits define the transmit data (TxD) and XCK pin configurations. Setting 0x2 is used for flow control, while setting 0x3 is used for RS485.  
 This bit is not synchronized.

**Table 31-9. Transmit Data Pinout**

| TXPO | TxD Pin Location | XCK Pin Location (When Applicable) | RTS/TE        | CTS           |
|------|------------------|------------------------------------|---------------|---------------|
| 0x0  | SERCOM PAD[0]    | SERCOM PAD[1]                      | N/A           | N/A           |
| 0x1  | SERCOM PAD[2]    | SERCOM PAD[3]                      | N/A           | N/A           |
| 0x2  | SERCOM PAD[0]    | N/A                                | SERCOM PAD[2] | SERCOM PAD[3] |
| 0x3  | SERCOM PAD[0]    | SERCOM[1]                          | SERCOM PAD[2] |               |

- Bits 15:13 – SAMPR[2:0]: Sample Rate**  
 These bits define the sample rate.  
 These bits are not synchronized.

**Table 31-10. Sample Rate**

| SAMPR[2:0] | Description  |
|------------|--|
| 0x0        | 16x over-sampling using arithmetic baud rate generation. |
| 0x1        | 16x over-sampling using fractional baud rate generation. |
| 0x2        | 8x over-sampling using arithmetic baud rate generation.  |
| 0x3        | 8x over-sampling using fractional baud rate generation.  |
| 0x4        | 3x over-sampling using arithmetic baud rate generation.  |
| 0x5-0x7    | Reserved   |

- Bits 12:9 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- Bit 8 – IBON: Immediate Buffer Overflow Notification**  
 This bit controls when the buffer overflow status bit (STATUS.BUFOVF) is asserted when a buffer overflow occurs.  
 0: STATUS.BUFOVF is asserted when it occurs in the data stream.  
 1: STATUS.BUFOVF is asserted immediately upon buffer overflow.
- Bit 7 – RUNSTDBY: Run In Standby**  
 This bit defines the functionality in standby sleep mode.  
 This bit is not synchronized.

**Table 31-11. Run In Standby**

| RUNSTDBY | External Clock  | Internal Clock   |
|----------|---|--|
| 0x0      | External clock is disconnected when ongoing transfer is finished. All reception is dropped. | Generic clock is disabled when ongoing transfer is finished. The device can wake up on Receive Start or Transfer Complete interrupt. |
| 0x1      | Wake on Receive Start or Receive Complete interrupt.  | Generic clock is enabled in all sleep modes. Any interrupt can wake up the device.   |

- Bits 6:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 4:2 – MODE: Operating Mode**  
 These bits must be written to 0x0 or 0x1 to select the USART serial communication interface of the SERCOM.  
 0x0: USART with external clock.  
 0x1: USART with internal clock.  
 These bits are not synchronized.
- Bit 1 – ENABLE: Enable**  
 0: The peripheral is disabled or being disabled.  
 1: The peripheral is enabled or being enabled.  
 Due to synchronization, there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Synchronization Enable Busy bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE is cleared when the operation is complete.  
 This bit is not enable-protected.
- Bit 0 – SWRST: Software Reset**  
 0: There is no reset operation ongoing.  
 1: The reset operation is ongoing.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit resets all registers in the SERCOM, except DBGCTRL, to their initial state, and the SERCOM will be disabled.  
 Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded. Any register write access during the ongoing reset will result in an APB error. Reading any register will return the reset value of the register.  
 Due to synchronization, there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.  
 This bit is not enable-protected.

### 31.8.2 Control B

**Name:** CTRLB

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Enable-Protected, Write-Protected, Write-Synchronized

|        |    |        |       |    |    |             |             |        |

|        |    |        | PMODE |    |    | ENC         | SFDE        | COLDEN |
| Access | R  | R      | R/W   | R  | R  | R/W         | R/W         | R/W    |
| Reset  | 0  | 0      | 0     | 0  | 0  | 0           | 0           | 0      |
| Bit    | 7  | 6      | 5     | 4  | 3  | 2           | 1           | 0      |
|        |    | SBMODE |       |    |    | CHSIZE[2:0] |             |        |
| Access | R  | R/W    | R     | R  | R  | R/W         | R/W         | R/W    |
| Reset  | 0  | 0      | 0     | 0  | 0  | 0           | 0           | 0      |

- **Bits 31:26 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 25:24 – LINCMD[1:0]: LIN Command**

These bits define the LIN header transmission control. This field is only valid in LIN master mode (CTRLA.FORM= LIN Master).

These are strobe bits and will always read back as zero.

These bits are not enable-protected.

**Table 31-12. LIN Command**

| LINCMD[2:0] | Description   |
|-------------|---|
| 0x0         | Normal USART transmission.  |
| 0x1         | Break field is transmitted when DATA is written.  |
| 0x2         | Break, sync, and identifier are automatically transmitted when DATA is written with the identifier. |
| 0x3         | Reserved  |

- **Bits 23:18 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 17 – RXEN: Receiver Enable**  
0: The receiver is disabled or being enabled.  
1: The receiver is enabled or will be enabled when the USART is enabled.  
Writing a zero to this bit will disable the USART receiver. Disabling the receiver will flush the receive buffer and clear the FERR, PERR and BUFOVF bits in the STATUS register.  
Writing a one to CTRLB.RXEN when the USART is disabled will set CTRLB.RXEN immediately. When the USART is enabled, CTRLB.RXEN will be cleared, and SYNCBUSY.CTRLB will be set and remain set until the receiver is enabled. When the receiver is enabled, CTRLB.RXEN will read back as one.  
Writing a one to CTRLB.RXEN when the USART is enabled will set SYNCBUSY.CTRLB, which will remain set until the receiver is enabled, and CTRLB.RXEN will read back as one.  
This bit is not enable-protected.
- **Bit 16 – TXEN: Transmitter Enable**  
0: The transmitter is disabled or being enabled.  
1: The transmitter is enabled or will be enabled when the USART is enabled.  
Writing a zero to this bit will disable the USART transmitter. Disabling the transmitter will not become effective until ongoing and pending transmissions are completed.  
Writing a one to CTRLB.TXEN when the USART is disabled will set CTRLB.TXEN immediately. When the USART is enabled, CTRLB.TXEN will be cleared, and SYNCBUSY.CTRLB will be set and remain set until the transmitter is enabled. When the transmitter is enabled, CTRLB.TXEN will read back as one.  
Writing a one to CTRLB.TXEN when the USART is enabled will set SYNCBUSY.CTRLB, which will remain set until the receiver is enabled, and CTRLB.TXEN will read back as one.  
This bit is not enable-protected.
- **Bits 15:14 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 13 – PMODE: Parity Mode**  
This bit selects the type of parity used when parity is enabled (CTRLA.FORM is one). The transmitter will automatically generate and send the parity of the transmitted data bits within each frame. The receiver will generate a parity value for the incoming data and parity bit, compare it to the parity mode and, if a mismatch is detected, STATUS.PERR will be set.  
0: Even parity.  
1: Odd parity.  
This bit is not synchronized.
- **Bits 12:11 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 10 – ENC: Encoding Format**  
This bit selects the data encoding format.  
0: Data is not encoded.  
1: Data is IrDA encoded.  
This bit is not synchronized.

- Bit 9 – SFDE: Start of Frame Detection Enable**  
 This bit controls whether the start-of-frame detector will wake up the device when a start bit is detected on the RxD line, according to the table below.  
 This bit is not synchronized.

**Table 31-13. Start of Frame Detection**

| SFDE | INTENSET.RXS | INTENSET.RXC | Description   |
|------|--------------|--------------|---|
| 0    | X            | X            | Start-of-frame detection disabled.  |
| 1    | 0            | 0            | Reserved  |
| 1    | 0            | 1            | Start-of-frame detection enabled. RXC wakes up the device from all sleep modes.             |
| 1    | 1            | 0            | Start-of-frame detection enabled. RXS wakes up the device from all sleep modes.             |
| 1    | 1            | 1            | Start-of-frame detection enabled. Both RXC and RXS wake up the device from all sleep modes. |

- Bit 8 -- COLDEN: Collision Detection Enable**  
 This bit enables collision detection.  
 0: Collision detection is not enabled.  
 1: Collision detection is enabled.  
 This bit is not synchronized.
- Bit 7 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 6 – SBMODE: Stop Bit Mode**  
 This bit selects the number of stop bits transmitted.  
 0: One stop bit.  
 1: Two stop bits.  
 This bit is not synchronized.
- Bits 5:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 2:0 – CHSIZE[2:0]: Character Size**  
 These bits select the number of bits in a character.  
 These bits are not synchronized.

**Table 31-14. Character Size**

| CHSIZE[2:0] | Description |
|-------------|-------------|
| 0x0         | 8 bits      |
| 0x1         | 9 bits      |
| 0x2-0x4     | Reserved    |
| 0x5         | 5 bits      |
| 0x6         | 6 bits      |
| 0x7         | 7 bits      |

### 31.8.3 Control C

|        |    |    |    |    | HDRDLY[1:0] |            | BRKLEN[1:0] |     |
| Access | R  | R  | R  | R  | R/W         | R/W        | R/W         | R/W |
| Reset  | 0  | 0  | 0  | 0  | 0           | 0          | 0           | 0   |
| Bit    | 7  | 6  | 5  | 4  | 3           | 2          | 1           | 0   |
|        |    |    |    |    |             | GTIME[2:0] |             |     |
| Access | R  | R  | R  | R  | R           | R/W        | R/W         | R/W |
| Reset  | 0  | 0  | 0  | 0  | 0           | 0          | 0           | 0   |

- **Bits 31:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:10– HDRDLY[1:0]: LIN Master Header Delay**

These bits define the delay between break and sync transmission in addition to the delay between the sync and identifier (ID) fields when in LIN master mode (CTRLA.FORM=0x2).

This field is only valid when using the LIN header command (CTRLB.LINCMD=0x2).

**Table 31-15. LIN Master Sync Delay**

| SYNCDLY[1:0] | Description  |
|--------------|--|
| 0x0          | Delay between break and sync transmission is 1 bit time.<br>Delay between sync and ID transmission is 1 bit time.    |
| 0x1          | Delay between break and sync transmission is 4 bit times.<br>Delay between sync and ID transmission is 4 bit times.  |
| 0x2          | Delay between break and sync transmission is 8 bit times.<br>Delay between sync and ID transmission is 4 bit times.  |
| 0x3          | Delay between break and sync transmission is 14 bit times.<br>Delay between sync and ID transmission is 4 bit times. |

- **Bits 9:8– BRKLEN[1:0]: LIN Master Break Length**

These bits define the length of the break field transmitted when in LIN master mode (CTRLA.FORM=0x2).

**Table 31-16. LIN Master Break Length**

| BRKLEN[1:0] | Description                               |
|-------------|---|
| 0x0         | Break field transmission is 13 bit times. |
| 0x1         | Break field transmission is 17 bit times. |
| 0x2         | Break field transmission is 21 bit times. |
| 0x3         | Break field transmission is 26 bit times. |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:0 – GTIME[2:0]: RS485 Guard Time**

These bits define the guard time when using RS485 mode (CTRLA.TXPO=0x3). The guard time is programmable from 0-7 bit times and defines the time that the transmit enable pin (TE) remains high after the last stop bit is transmitted.

### 31.8.4 Baud

**Name:** BAUD

**Offset:** 0x0C

**Reset:** 0x0000

**Property:** Enable-Protected, Write-Protected

|        |                     |     |     |            |     |     |     |     |
|--------|---------------------|-----|-----|------------|-----|-----|-----|-----|
| Bit    | 15                  | 14  | 13  | 12         | 11  | 10  | 9   | 8   |
|        | FP[2:0]/BAUD[15:13] |     |     | BAUD[12:8] |     |     |     |     |
| Access | R/W                 | R/W | R/W | R/W        | R/W | R/W | R/W | R/W |
| Reset  | 0                   | 0   | 0   | 0          | 0   | 0   | 0   | 0   |
| Bit    | 7                   | 6   | 5   | 4          | 3   | 2   | 1   | 0   |
|        | BAUD[7:0]           |     |     |            |     |     |     |     |
| Access | R/W                 | R/W | R/W | R/W        | R/W | R/W | R/W | R/W |
| Reset  | 0                   | 0   | 0   | 0          | 0   | 0   | 0   | 0   |

#### Arithmetic Baud Rate Generation (CTRLA.SAMPR[0]=0)

- **Bits 15:0 – BAUD[15:0]: Baud Value**  
These bits control the clock generation, as described in the SERCOM Baud Rate section.

#### Fractional Baud Rate Generation (CTRLA.SAMPR[0]=1)

- **Bits 15:13 – FP[2:0]: Fractional Part**  
These bits control the clock generation, as described in the SERCOM Baud Rate section.
- **Bits 15:0 – BAUD[12:0]: Baud Value**  
These bits control the clock generation, as described in the SERCOM Baud Rate section.

31.8.5 Receive Pulse Length Register

**Name:** RXPL  
**Offset:** 0x0E  
**Reset:** 0x00  
**Property:** Write-Protected

|        |           |     |     |     |     |     |     |     |
|--------|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | RXPL[7:0] |     |     |     |     |     |     |     |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- Bits 7:0 – RXPL[7:0]: Receive Pulse Length**  
When the encoding format is set to IrDA (CTRLB.ENC=1), these bits control the minimum pulse length that is required for a pulse to be accepted by the IrDA receiver with regards to the serial engine clock period.

$$PULSE \geq (RXPL + 1) \times SE_{per}$$

### 31.8.6 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x14

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5     | 4     | 3   | 2   | 1   | 0   |
|--------|-------|---|-------|-------|-----|-----|-----|-----|
|        | ERROR |   | RXBRK | CTSIC | RXS | RXC | TXC | DRE |
| Access | R/W   | R | R/W   | R/W   | R/W | R/W | R/W | R/W |
| Reset  | 0     | 0 | 0     | 0     | 0   | 0   | 0   | 0   |

- **Bit 7– ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Error Interrupt Enable bit, which disables the Error interrupt.

- **Bit 6 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 5 – RXBRK: Receive Break Interrupt Enable**

0: Receive Break interrupt is disabled.

1: Receive Break interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Receive Break Interrupt Enable bit, which disables the Receive Break interrupt.

- **Bit 4 – CTSIC: Clear to Send Input Change Interrupt Enable**

0: Clear To Send Input Change interrupt is disabled.

1: Clear To Send Input Change interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Clear To Send Input Change Interrupt Enable bit, which disables the Clear To Send Input Change interrupt.

- **Bit 3 – RXS: Receive Start Interrupt Enable**

0: Receive Start interrupt is disabled.

1: Receive Start interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Receive Start Interrupt Enable bit, which disables the Receive Start interrupt.

- **Bit 2 – RXC: Receive Complete Interrupt Enable**

0: Receive Complete interrupt is disabled.

1: Receive Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Receive Complete Interrupt Enable bit, which disables the Receive Complete interrupt.

- **Bit 1 – TXC: Transmit Complete Interrupt Enable**

0: Transmit Complete interrupt is disabled.

1: Transmit Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Transmit Complete Interrupt Enable bit, which disables the Receive Complete interrupt.

- **Bit 0 – DRE: Data Register Empty Interrupt Enable**

0: Data Register Empty interrupt is disabled.

1: Data Register Empty interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Data Register Empty Interrupt Enable bit, which disables the Data Register Empty interrupt.

### 31.8.7 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x16

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5     | 4     | 3   | 2   | 1   | 0   |
|--------|-------|---|-------|-------|-----|-----|-----|-----|
|        | ERROR |   | RXBRK | CTSIC | RXS | RXC | TXC | DRE |
| Access | R/W   | R | R/W   | R/W   | R/W | R/W | R/W | R/W |
| Reset  | 0     | 0 | 0     | 0     | 0   | 0   | 0   | 0   |

- **Bit 7 – ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Error Interrupt Enable bit, which enables the Error interrupt.

- **Bits 6 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 5– RXBRK: Receive Break Interrupt Enable**

0: Receive Break interrupt is disabled.

1: Receive Break interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Receive Break Interrupt Enable bit, which enables the Receive Break interrupt.

- **Bit 4 – CTSIC: Clear to Send Input Change Interrupt Enable**

0: Clear To Send Input Change interrupt is disabled.

1: Clear To Send Input Change interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Clear To Send Input Change Interrupt Enable bit, which enables the Clear To Send Input Change interrupt.

- **Bit 3 – RXS: Receive Start Interrupt Enable**

0: Receive Start interrupt is disabled.

1: Receive Start interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Receive Start Interrupt Enable bit, which enables the Receive Start interrupt.

- **Bit 2 – RXC: Receive Complete Interrupt Enable**

0: Receive Complete interrupt is disabled.

1: Receive Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Receive Complete Interrupt Enable bit, which enables the Receive Complete interrupt.

- **Bit 1– TXC: Transmit Complete Interrupt Enable**

0: Transmit Complete interrupt is disabled.

1: Transmit Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Transmit Complete Interrupt Enable bit, which enables the Transmit Complete interrupt.

- **Bit 0 – DRE: Data Register Empty Interrupt Enable**

0: Data Register Empty interrupt is disabled.

1: Data Register Empty interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Data Register Empty Interrupt Enable bit, which enables the Data Register Empty interrupt.

### 31.8.8 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x18

**Reset:** 0x00

**Property:**

| Bit    | 7     | 6 | 5     | 4     | 3   | 2   | 1   | 0   |
|--------|-------|---|-------|-------|-----|-----|-----|-----|
|        | ERROR |   | RXBRK | CTSIC | RXS | RXC | TXC | DRE |
| Access | R/W   | R | R/W   | R/W   | R/W | R   | R/W | R   |
| Reset  | 0     | 0 | 0     | 0     | 0   | 0   | 0   | 0   |

- **Bit 7– ERROR: Error**

This flag is cleared by writing a one to it.

This bit is set when any error is detected. Errors that will set this flag have corresponding status flags in the STATUS register. Errors that will set this flag are COLL, ISF, BUFOVF, FERR, and PERR. Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bits 6 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 5 – RXBRK: Receive Break**

This flag is cleared by writing a one to it.

This flag is set when auto-baud is enabled (CTRLA.FORM) and a break character is received.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bit 4 – CTSIC: Clear to Send Input Change**

This flag is cleared by writing a one to it.

This flag is set when a change is detected on the CTS pin.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bit 3 – RXS: Receive Start**

This flag is cleared by writing a one to it.

This flag is set when a start condition is detected on the RxD line and start-of-frame detection is enabled (CTRLB.SFDE is one).

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Receive Start interrupt flag.

- **Bit 2 – RXC: Receive Complete**

This flag is cleared by reading the Data register (DATA) or by disabling the receiver.

This flag is set when there are unread data in DATA.

Writing a zero to this bit has no effect.

Writing a one to this bit has no effect.

- **Bit 1 – TXC: Transmit Complete**

This flag is cleared by writing a one to it or by writing new data to DATA.

This flag is set when the entire frame in the transmit shift register has been shifted out and there are no new data in DATA.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bit 0 – DRE: Data Register Empty**

This flag is cleared by writing new data to DATA.

This flag is set when DATA is empty and ready to be written.

Writing a zero to this bit has no effect.

Writing a one to this bit has no effect.

### 31.8.9 Status

**Name:** STATUS

**Offset:** 0x1A

**Reset:** 0x0000

**Property:**

|        |    |     |      |     |     |        |      |      |
|--------|----|-----|------|-----|-----|--------|------|------|
| Bit    | 15 | 14  | 13   | 12  | 11  | 10     | 9    | 8    |
|        |    |     |      |     |     |        |      |      |
| Access | R  | R   | R    | R   | R   | R      | R    | R    |
| Reset  | 0  | 0   | 0    | 0   | 0   | 0      | 0    | 0    |
| Bit    | 7  | 6   | 5    | 4   | 3   | 2      | 1    | 0    |
|        |    | TXE | COLL | ISF | CTS | BUFOVF | FERR | PERR |
| Access | R  | R   | R/W  | R/W | R   | R/W    | R/W  | R/W  |
| Reset  | 0  | 0   | 0    | 0   | 0   | 0      | 0    | 0    |

- Bits 15:7 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 6– TXE: Transmitter Empty**  
 When CTRLA.FORM is set to LIN master mode, this bit is raised when any ongoing transmission is complete and TxDATA is empty.  
 When CTRLA.FORM is not set to LIN master mode, this bit will always read back as zero.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit has no effect.
- Bit 5 – COLL: Collision Detected**  
 This bit is cleared by writing a one to the bit or by disabling the receiver.  
 This bit is set when collision detection is enabled (CTRLB.COLDEN) and a collision is detected.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear it.
- Bit 4 – ISF: Inconsistent Sync Field**  
 This bit is cleared by writing a one to the bit or by disabling the receiver.  
 This bit is set when the frame format is set to auto-baud (CTRLA.FORM) and a sync field not equal to 0x55 is received.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear it.
- Bit 3 – CTS: Clear to Send**  
 This bit indicates the current level of the CTS pin when flow control is enabled (CTRLA.TXPO).  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit has no effect.
- Bit 2 – BUFOVF: Buffer Overflow**  
 Reading this bit before reading the Data register will indicate the error status of the next character to be read.  
 This bit is cleared by writing a one to the bit or by disabling the receiver.

This bit is set when a buffer overflow condition is detected. A buffer overflow occurs when the receive buffer is full, there is a new character waiting in the receive shift register and a new start bit is detected.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear it.

- **Bit 1 – FERR: Frame Error**

Reading this bit before reading the Data register will indicate the error status of the next character to be read.

This bit is cleared by writing a one to the bit or by disabling the receiver.

This bit is set if the received character had a frame error, i.e., when the first stop bit is zero.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear it.

- **Bit 0 – PERR: Parity Error**

Reading this bit before reading the Data register will indicate the error status of the next character to be read.

This bit is cleared by writing a one to the bit or by disabling the receiver.

This bit is set if parity checking is enabled (CTRLA.FORM is 0x1 or 0x5) and a parity error is detected.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear it.

### 31.8.10 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x1C

**Reset:** 0x00000000

**Property:** -

|        |    |    |    |    |    |       |        |       |
|--------|----|----|----|----|----|-------|--------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26    | 25     | 24    |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18    | 17     | 16    |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10    | 9      | 8     |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2     | 1      | 0     |
|        |    |    |    |    |    | CTRLB | ENABLE | SWRST |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2– CTRLB: CTRLB Synchronization Busy**

Writing CTRLB when the SERCOM is enabled requires synchronization. When written, the SYNCBUSY.CTRLB bit will be set until synchronization is complete. If CTRLB is written while SYNCBUSY.CTRLB is asserted, an APB error will be generated.

0: CTRLB synchronization is not busy.

1: CTRLB synchronization is busy.

- **Bit 1 – ENABLE: SERCOM Enable Synchronization Busy**

Enabling and disabling the SERCOM (CTRLA.ENABLE) requires synchronization. When written, the SYNCBUSY.ENABLE bit will be set until synchronization is complete.

Writes to any register (except for CTRLA.SWRST) while enable synchronization is on-going will be discarded and an APB error will be generated.

0: Enable synchronization is not busy.

1: Enable synchronization is busy.

- **Bit 0 – SWRST: Software Reset Synchronization Busy**

Resetting the SERCOM (CTRLA.SWRST) requires synchronization. When written, the SYNCBUSY.SWRST bit will be set until synchronization is complete.

Writes to any register while synchronization is on-going will be discarded and an APB error will be generated.

0: SWRST synchronization is not busy.

1: SWRST synchronization is busy.

### 31.8.11 Data

**Name:** DATA  
**Offset:** 0x28  
**Reset:** 0x0000  
**Property:** -

|        |           |     |     |     |     |     |     |         |
|--------|-----------|-----|-----|-----|-----|-----|-----|---------|
| Bit    | 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8       |
|        |           |     |     |     |     |     |     | DATA[8] |
| Access | R         | R   | R   | R   | R   | R   | R   | R/W     |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0       |
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0       |
|        | DATA[7:0] |     |     |     |     |     |     |         |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W     |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0       |

- **Bits 15:9 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 8:0 – DATA[8:0]: Data**

Reading these bits will return the contents of the Receive Data register. The register should be read only when the Receive Complete Interrupt Flag bit in the Interrupt Flag Status and Clear register (INTFLAG.RXC) is set. The status bits in STATUS should be read before reading the DATA value in order to get any corresponding error.

Writing these bits will write the Transmit Data register. This register should be written only when the Data Register Empty Interrupt Flag bit in the Interrupt Flag Status and Clear register (INTFLAG.DRE) is set.

### 31.8.12 Debug Control

**Name:** DBGCTRL

**Offset:** 0x30

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0       |
|--------|---|---|---|---|---|---|---|---------|
|        |   |   |   |   |   |   |   | DBGSTOP |
| Access | R | R | R | R | R | R | R | R/W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0       |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGSTOP: Debug Stop Mode**

This bit controls the baud-rate generator functionality when the CPU is halted by an external debugger.

0: The baud-rate generator continues normal operation when the CPU is halted by an external debugger.

1: The baud-rate generator is halted when the CPU is halted by an external debugger.

## 32. SERCOM SPI – SERCOM Serial Peripheral Interface

### 32.1 Overview

The serial peripheral interface (SPI) is one of the available modes in the Serial Communication Interface (SERCOM). Refer to “[SERCOM – Serial Communication Interface](#)” on page 492 for details.

The SPI uses the SERCOM transmitter and receiver configured as shown in “[Full-Duplex SPI Master Slave Interconnection](#)” on page 542. Each side, master and slave, depicts a separate SPI containing a shift register, a transmit buffer and two receive buffers. In addition, the SPI master uses the SERCOM baud-rate generator, while the SPI slave can use the SERCOM address match logic. Fields shown in capital letters are synchronous to CLK\_SERCOMx\_APB and accessible by the CPU, while fields with lowercase letters are synchronous to the SCK clock.

### 32.2 Features

- Full-duplex, four-wire interface (MISO, MOSI, SCK, \_SS)
- Single-buffered transmitter, double-buffered receiver
- Supports all four SPI modes of operation
- Single data direction operation allows alternate function on MISO or MOSI pin
- Selectable LSB- or MSB-first data transfer
- Can be used with DMA
- Master operation:
  - Serial clock speed up to half the system clock
  - 8-bit clock generator
  - Hardware controlled \_SS
- Slave operation:
  - Serial clock speed up to the system clock
  - Optional 8-bit address match operation
  - Operation in all sleep modes
  - Wake on \_SS transition

### 32.3 Block Diagram

Figure 32-1. Full-Duplex SPI Master Slave Interconnection

### 32.4 Signal Description

| Signal Name | Type        | Description         |
|-------------|-------------|---------------------|
| PAD[3:0]    | Digital I/O | General SERCOM pins |

Refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped to one of several pins.

## 32.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 32.5.1 I/O Lines

Using the SERCOM's I/O lines requires the I/O pins to be configured using port configuration (PORT). Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

When the SERCOM is configured for SPI operation, the pins should be configured according to [Table 32-1](#). If the receiver is disabled, the data input pin can be used for other purposes. In master mode the slave select line (\_SS) is hardware controlled when Master Slave Select Enable (CTRLB.MSSEN) is set to one.

**Table 32-1. SPI Pin Configuration**

| Pin  | Master SPI             | Slave SPI |
|------|------------------------|-----------|
| MOSI | Output                 | Input     |
| MISO | Input                  | Output    |
| SCK  | Output                 | Input     |
| _SS  | Output (CTRLB.MSSEN=1) | Input     |

The combined configuration of PORT and the Data In/Data Out and Data Out Pinout bit groups in Control A register will define the physical position of the SPI signals in [Table 32-1](#).

### 32.5.2 Power Management

The SPI can continue to operate in any sleep mode. The SPI interrupts can be used to wake up the device from sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 32.5.3 Clocks

The SERCOM bus clock (CLK\_SERCOMx\_APB, where x represents the specific SERCOM instance number) can be enabled and disabled in the Main Clock module, and the default state of CLK\_SERCOMx\_APB can be found in the Peripheral Clock Masking section in [Table 17-1](#).

A generic clock (GCLK\_SERCOMx\_CORE) is required to clock the SPI. This clock must be configured and enabled in the Generic Clock Controller before using the SPI. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

This generic clock is asynchronous to the bus clock (CLK\_SERCOMx\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 552](#) for further details.

### 32.5.4 DMA

The DMA request lines are connected to the DMA controller (DMAC). Using the SERCOM DMA requests, requires the DMA controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details.

### 32.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the SPI, interrupts requires the Interrupt Controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 32.5.6 Events

Not applicable.

### 32.5.7 Debug Operation

When the CPU is halted in debug mode, the SPI continues normal operation. If the SPI is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging. The SPI can be forced to halt operation during debugging. Refer to the Debug Control (DBGCTRL) register for details.

### 32.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag Clear and Status register (INTFLAG)
- Status register (STATUS)
- Data register (DATA)

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 32.5.9 Analog Connections

Not applicable.

## 32.6 Functional Description

### 32.6.1 Principle of Operation

The SPI is a high-speed synchronous data transfer interface. It allows fast communication between the device and peripheral devices.

The SPI can operate as master or slave. As master, the SPI initiates and controls all data transactions. The SPI is single buffered for transmitting and double buffered for receiving. When transmitting data, the Data register can be loaded with the next character to be transmitted while the current transmission is in progress. For receiving, this means that the data is transferred to the two-level receive buffer upon reception, and the receiver is ready for a new character.

The SPI transaction format is shown in [Figure 32-2](#), where each transaction can contain one or more characters. The character size is configurable, and can be either 8 or 9 bits.

**Figure 32-2. SPI Transaction Format**

The SPI master must initiate a transaction by pulling low the slave select line (\_SS) of the desired slave. The master and slave prepare data to be sent in their respective shift registers, and the master generates the serial clock on the SCK line.

Data are always shifted from master to slave on the master output, slave input line (MOSI), and from slave to master on the master input, slave output line (MISO). The master signals the end of the transaction by pulling the `_SS` line high.

As each character is shifted out from the master, another character is shifted in from the slave.

## 32.6.2 Basic Operation

### 32.6.2.1 Initialization

The following registers are enable-protected, meaning that they can only be written when the SPI is disabled (`CTRLA.ENABLE` is zero):

- Control A register (`CTRLA`), except Enable (`CTRLA.ENABLE`) and Software Reset (`CTRLA.SWRST`)
- Control B register (`CTRLB`), except Receiver Enable (`CTRLB.RXEN`)
- Baud register (`BAUD`)
- Address register (`ADDR`)

Any writes to these registers when the SPI is enabled or is being enabled (`CTRLA.ENABLE` is one) will be discarded. Writes to these registers while the SPI is being disabled will be completed after the disabling is complete.

Enable-protection is denoted by the Enable-Protection property in the register description.

Before the SPI is enabled, it must be configured, as outlined by the following steps:

- SPI mode in master or slave operation must be selected by writing 0x2 or 0x3 to the Operating Mode bit group in the Control A register (`CTRLA.MODE`)
- Transfer mode must be selected by writing the Clock Polarity bit and the Clock Phase bit in the Control A register (`CTRLA.CPOL` and `CTRLA.CPHA`)
- Transaction format must be selected by writing the Frame Format bit group in the Control A register (`CTRLA.FORM`)
- SERCOM pad to use for the receiver must be selected by writing the Data In Pinout bit group in the Control A register (`CTRLA.DIPO`)
- SERCOM pads to use for the transmitter, slave select and serial clock must be selected by writing the Data Out Pinout bit group in the Control A register (`CTRLA.DOPO`)
- Character size must be selected by writing the Character Size bit group in the Control B register (`CTRLB.CHSIZE`)
- Data direction must be selected by writing the Data Order bit in the Control A register (`CTRLA.DORD`)
- If the SPI is used in master mode, the Baud register (`BAUD`) must be written to generate the desired baud rate
- If the SPI is used in master mode and Hardware SS control is required, the Master Slave Select Enable bit in `CTRLB` register (`CTRLB.MSSEN`) should be set to 1.
- The receiver can be enabled by writing a one to the Receiver Enable bit in the Control B register (`CTRLB.RXEN`)

### 32.6.2.2 Enabling, Disabling and Resetting

The SPI is enabled by writing a one to the Enable bit in the Control A register (`CTRLA.ENABLE`). The SPI is disabled by writing a zero to `CTRLA.ENABLE`.

The SPI is reset by writing a one to the Software Reset bit in the Control A register (`CTRLA.SWRST`). All registers in the SPI, except `DBGCTRL`, will be reset to their initial state, and the SPI will be disabled. Refer to `CTRLA` for details.

### 32.6.2.3 Clock Generation

In SPI master operation (`CTRLA.MODE` is 0x3), the serial clock (SCK) is generated internally using the SERCOM baud-rate generator. When used in SPI mode, the baud-rate generator is set to synchronous mode, and the 8-bit Baud register (`BAUD`) value is used to generate SCK, clocking the shift register. Refer to [“Clock Generation – Baud-Rate Generator” on page 495](#) for more details.

In SPI slave operation (`CTRLA.MODE` is 0x2), the clock is provided by an external master on the SCK pin. This clock is used to directly clock the SPI shift register.

#### 32.6.2.4 Data Register

The SPI Transmit Data register (TxDATA) and SPI Receive Data register (RxDATA) share the same I/O address, referred to as the SPI Data register (DATA). Writing the DATA register will update the Transmit Data register. Reading the DATA register will return the contents of the Receive Data register.

#### 32.6.2.5 SPI Transfer Modes

There are four combinations of SCK phase and polarity with respect to the serial data. The SPI data transfer modes are shown in [Table 32-2](#) and [Figure 32-3](#). SCK phase is selected by the Clock Phase bit in the Control A register (CTRLA.CPHA). SCK polarity is selected by the Clock Polarity bit in the Control A register (CTRLA.CPOL). Data bits are shifted out and latched in on opposite edges of the SCK signal, ensuring sufficient time for the data signals to stabilize.

**Table 32-2. SPI Transfer Modes**

| Mode | CPOL | CPHA | Leading Edge    | Trailing Edge   |
|------|------|------|-----------------|-----------------|
| 0    | 0    | 0    | Rising, sample  | Falling, setup  |
| 1    | 0    | 1    | Rising, setup   | Falling, sample |
| 2    | 1    | 0    | Falling, sample | Rising, setup   |
| 3    | 1    | 1    | Falling, setup  | Rising, sample  |

Leading edge is the first clock edge in a clock cycle, while trailing edge is the second clock edge in a clock cycle.

**Figure 32-3. SPI Transfer Modes**

### 32.6.2.6 Transferring Data

#### Master

When configured as a master (CTRLA.MODE is 0x3), if Master Slave Select Enable (CTRLB.MSEN) is set to zero the `_SS` line can be located at any general purpose I/O pin, and must be configured as an output. When the SPI is ready for a data transaction, software must pull the `_SS` line low. If Master Slave Enable Select (CTRLB.MSEN) is set to one, hardware controls the `_SS` line.

When writing a character to the Data register (DATA), the character will be transferred to the shift register when the shift register is empty. Once the contents of TxDATA have been transferred to the shift register, the Data Register Empty flag in the Interrupt Flag Status and Clear register (INTFLAG.DRE) is set, and a new character can be written to DATA.

As each character is shifted out from the master, another character is shifted in from the slave. If the receiver is enabled (CTRLA.RXEN is one), the contents of the shift register will be transferred to the two-level receive buffer. The transfer takes place in the same clock cycle as the last data bit is shifted in, and the Receive Complete Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.RXC) will be set. The received data can be retrieved by reading DATA.

When the last character has been transmitted and there is no valid data in DATA, the Transmit Complete Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.TXC) is set. When the transaction is finished, the master must indicate this to the slave by pulling the `_SS` line high. If Master Slave Select Enable (CTRLB.MSEN) is set to zero, the software must pull the `_SS` line high.

### Slave

When configured as a slave (CTRLA.MODE is 0x2), the SPI interface will remain inactive, with the MISO line tri-stated as long as the `_SS` pin is pulled high. Software may update the contents of DATA at any time, as long as the Data Register Empty flag in the Interrupt Status and Clear register (INTFLAG.DRE) is set.

When `_SS` is pulled low and SCK is running, the slave will sample and shift out data according to the transaction mode set. When the contents of TxDATA have been loaded into the shift register, INTFLAG.DRE is set, and new data can be written to DATA. Similar to the master, the slave will receive one character for each character transmitted. On the same clock cycle as the last data bit of a character is received, the character will be transferred into the two-level receive buffer. The received character can be retrieved from DATA when Receive Complete interrupt flag (INTFLAG.RXC) is set.

When the master pulls the `_SS` line high, the transaction is done and the Transmit Complete Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.TXC) is set.

Once DATA is written, it takes up to three SCK clock cycles before the content of DATA is ready to be loaded into the shift register. When the content of DATA is ready to be loaded, this will happen on the next character boundary. As a consequence, the first character transferred in a SPI transaction will not be the content of DATA. This can be avoided by using the preloading feature.

Refer to [“Preloading of the Slave Shift Register” on page 549](#).

When transmitting several characters in one SPI transaction, the data has to be written to DATA while there are at least three SCK clock cycles left in the current character transmission. If this criteria is not met, then the previous character received will be transmitted.

After the DATA register is empty, it takes three CLK\_SERCOM\_APB cycles for INTFLAG.DRE to be set.

#### 32.6.2.7 Receiver Error Bit

The SPI receiver has one error bit: the Buffer Overflow bit (BUFOVF), which can be read from the Status register (STATUS). Upon error detection, the bit will be set until it is cleared by writing a one to it. The bit is also automatically cleared when the receiver is disabled.

There are two methods for buffer overflow notification. When the immediate buffer overflow notification bit (CTRLA.IBON) is set, STATUS.BUFOVF is set immediately upon buffer overflow. Software can then empty the receive FIFO by reading RxDATA until the receive complete interrupt flag (INTFLAG.RXC) goes low.

When CTRLA.IBON is zero, the buffer overflow condition travels with data through the receive FIFO. After the received data is read, STATUS.BUFOVF and INTFLAG.ERROR will be set along with INTFLAG.RXC, and RxDATA will be zero.

### 32.6.3 Additional Features

#### 32.6.3.1 Address Recognition

When the SPI is configured for slave operation (CTRLA.MODE is 0x2) with address recognition (CTRLA.FORM is 0x2), the SERCOM address recognition logic is enabled. When address recognition is enabled, the first character in a transaction is checked for an address match. If there is a match, then the Receive Complete Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.RXC) is set, the MISO output is enabled and the transaction is processed. If there is no match, the transaction is ignored.

If the device is in sleep mode, an address match can wake up the device in order to process the transaction. If the address does not match, then the complete transaction is ignored. If a 9-bit frame format is selected, only the lower 8 bits of the shift register are checked against the Address register (ADDR).

Refer to [“Address Match and Mask” on page 498](#) for further details.

### 32.6.3.2 Preloading of the Slave Shift Register

When starting a transaction, the slave will first transmit the contents of the shift register before loading new data from DATA. The first character sent can be either the reset value of the shift register (if this is the first transmission since the last reset) or the last character in the previous transmission. Preloading can be used to preload data to the shift register while `_SS` is high and eliminate sending a dummy character when starting a transaction.

In order to guarantee enough set-up time before the first SCK edge, enough time must be given between `_SS` going low and the first SCK sampling edge, as shown in Figure 32-4.

Preloading is enabled by setting the Slave Data Preload Enable bit in the Control B register (`CTRLB.PLOADEN`).

Figure 32-4. Timing Using Preloading

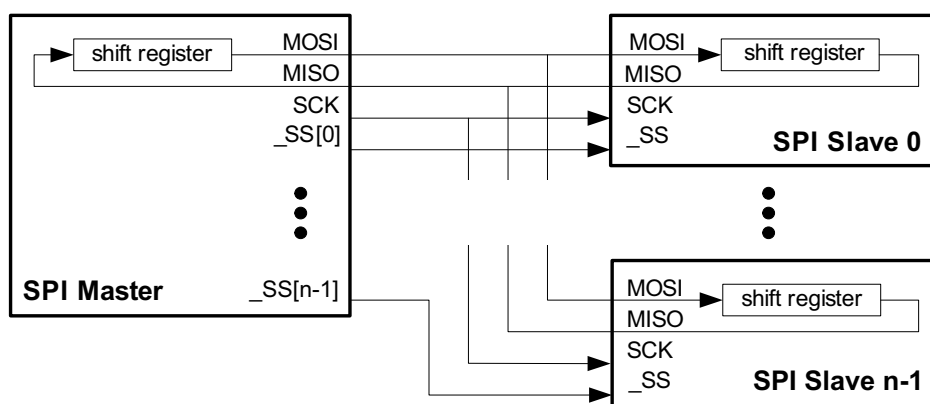

Only one data character written to DATA will be preloaded into the shift register while the synchronized `_SS` signal (see Figure 32-4) is high. The next character written to DATA before `_SS` is pulled low will be stored in DATA until transfer begins. If the shift register is not preloaded, the current contents of the shift register will be shifted out.

### 32.6.3.3 Master with Several Slaves

Master with multiple slaves in parallel feature is available only when Master Slave Select Enable (`CTRLB.MSEN`) is set to zero and hardware `_SS` control is disabled. If the bus consists of several SPI slaves, an SPI master can use general purpose I/O pins to control the `_SS` line to each of the slaves on the bus, as shown in Figure 32-5. In this configuration, the single selected SPI slave will drive the tri-state MISO line.

Figure 32-5. Multiple Slaves in Parallel

An alternate configuration is shown in Figure 32-6. In this configuration, all  $n$  attached slaves are connected in series. A common `_SS` line is provided to all slaves, enabling them simultaneously. The master must shift  $n$  characters for a complete transaction. Depending on the Master Slave Select Enable bit (`CTRLB.MSEN`), `_SS` line is controlled either by hardware or by user software and normal GPIO

**Figure 32-6. Multiple Slaves in Series**

#### 32.6.3.4 Loop-back Mode

By configuring the Data In Pinout (CTRLA.DIPO) and Data Out Pinout (CTRLA.DOPO) to use the same data pins for transmit and receive, loop-back is achieved. The loop-back is through the pad, so the signal is also available externally.

#### 32.6.3.5 Hardware Controlled \_SS

In master mode, a single \_SS chip select can be controlled by hardware by setting the Master Slave Select Enable (CTRLB.MSSEN) bit to one. In this mode, the \_SS pin is driven low for a minimum of one baud cycle before transmission begins, and stays low for a minimum of one baud cycle after transmission completes. If back-to-back frames are transmitted, the \_SS pin will always be driven high for a minimum of one baud cycle between frames.

In [Figure 32-7](#), the time T is between one and two baud cycles depending on the SPI transfer mode.

**Figure 32-7. Hardware Controlled \_SS**

When MSSEN is set to zero, the \_SS pin(s) is/are controlled by user software and normal GPIO.

#### 32.6.3.6 Slave Select Low Detection

In slave mode the SPI is capable of waking the CPU when the slave select (\_SS) goes low. When the Slave Select Low Detect is enabled (CTRLB.SSDE=1), a high to low transition will set the Slave Select Low interrupt flag (INTFLAG.SSL) and the device will wake if applicable.

## 32.6.4 DMA, Interrupts and Events

Table 32-3. Module Request for SERCOM SPI

| Condition           | Interrupt request | Event output | Event input | DMA request | DMA request is cleared |
|---------------------|-------------------|--------------|-------------|-------------|------------------------|
| Data Register Empty | x                 |              |             | x           | When data is written   |
| Transmit Complete   | x                 |              |             |             |                        |
| Receive Complete    | x                 |              |             | x           | When data is read      |
| Slave Select low    | x                 |              |             |             |                        |
| Error               | x                 |              |             |             |                        |

### 32.6.4.1 DMA Operation

The SPI generates the following DMA requests:

- Data received (RX): The request is set when data is available in the receive FIFO. The request is cleared when DATA is read.
- Data transmit (TX): The request is set when the transmit buffer (TX DATA) is empty. The request is cleared when DATA is written.

### 32.6.4.2 Interrupts

The SPI has the following interrupt sources:

- Error
- Slave Select Low
- Receive Complete
- Transmit Complete
- Data Register Empty

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the SPI is reset. See the register description for details on how to clear interrupt flags.

The SPI has one common interrupt request line for all the interrupt sources. The user must read INTFLAG to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 for details.

For details on clearing interrupt flags, refer to [INTFLAG](#).

### 32.6.4.3 Events

Not applicable.

### 32.6.5 Sleep Mode Operation

During master operation, the generic clock will continue to run in idle sleep mode. If the Run In Standby bit in the Control A register (CTRLA.RUNSTDBY) is one, the GCLK\_SERCOM\_CORE will also be enabled in standby sleep mode. Any interrupt can wake up the device.

If CTRLA.RUNSTDBY is zero during master operation, GLK\_SERCOMx\_CORE will be disabled when the ongoing transaction is finished. Any interrupt can wake up the device.

During slave operation, writing a one to CTRLA.RUNSTDBY will allow the Receive Complete interrupt to wake up the device.

If CTRLA.RUNSTDBY is zero during slave operation, all reception will be dropped, including the ongoing transaction.

### 32.6.6 Synchronization

Due to the asynchronicity between CLK\_SERCOMx\_APB and GCLK\_SERCOMx\_CORE, some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding Synchronization Busy bit in the Synchronization register (SYNCBUSY) will be set immediately, and cleared when synchronization is complete.

If an operation that requires synchronization is executed while the corresponding SYNCBUSY bit is one, a peripheral bus error is generated.

The following bits need synchronization when written:

- Software Reset bit in the Control A register (CTRLA.SWRST). SYNCBUSY.SWRST is set to one while synchronization is in progress.
- Enable bit in the Control A register (CTRLA.ENABLE). SYNCBUSY.ENABLE is set to one while synchronization is in progress.
- Receiver Enable bit in the Control B register (CTRLB.RXEN). SYNCBUSY.CTRLB is set to one while synchronization is in progress.

CTRLB.RXEN behaves somewhat differently than described above. Refer to CTRLB for details.

Write-synchronization is denoted by the Write-Synchronized property in the register description.

## 32.7 Register Summary

| Offset | Name     | Bit Pos. |            |         |           |           |           |             |           |       |  |
|--------|----------|----------|------------|---------|-----------|-----------|-----------|-------------|-----------|-------|--|
| 0x00   | CTRLA    | 7:0      | RUNSTDBY   |         |           | MODE[2:0] |           |             | ENABLE    | SWRST |  |
| 0x01   |          | 15:8     |            |         |           |           |           |             |           | IBON  |  |
| 0x02   |          | 23:16    |            |         | DIPO[1:0] |           |           |             | DOPO[1:0] |       |  |
| 0x03   |          | 31:24    |            | DORD    | CPOL      | CPHA      | FORM[3:0] |             |           |       |  |
| 0x04   | CTRLB    | 7:0      |            | PLOADEN |           |           |           | CHSIZE[2:0] |           |       |  |
| 0x05   |          | 15:8     | AMODE[1:0] |         | MSSSEN    |           |           |             | SSDE      |       |  |
| 0x06   |          | 23:16    |            |         |           |           |           |             | RXEN      |       |  |
| 0x07   |          | 31:24    |            |         |           |           |           |             |           |       |  |
| 0x08   | Reserved |          |            |         |           |           |           |             |           |       |  |
| 0x09   | Reserved |          |            |         |           |           |           |             |           |       |  |
| 0x0A   | Reserved |          |            |         |           |           |           |             |           |       |  |
| 0x0B   | Reserved |          |            |         |           |           |           |             |           |       |  |
| 0x0C   | BAUD     | 7:0      | BAUD[7:0]  |         |           |           |           |             |           |       |  |

## 32.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Refer to [“Register Access Protection” on page 544](#) for details.

Some registers require synchronization when read and/or written. Write-synchronization is denoted by the Write-Synchronized property in each individual register description. Refer to [“Synchronization” on page 552](#) for details.

Some registers are enable-protected, meaning they can only be written when the USART is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 32.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

| Reset  | 0        | 0    | 0         | 0         | 0         | 0   | 0         | 0     |

- Bit 31 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 30 – DORD: Data Order**  
 This bit indicates the data order when a character is shifted out from the Data register.  
 0: MSB is transferred first.  
 1: LSB is transferred first.  
 This bit is not synchronized.
- Bit 29 – CPOL: Clock Polarity**  
 In combination with the Clock Phase bit (CPHA), this bit determines the SPI transfer mode.  
 0: SCK is low when idle. The leading edge of a clock cycle is a rising edge, while the trailing edge is a falling edge.  
 1: SCK is high when idle. The leading edge of a clock cycle is a falling edge, while the trailing edge is a rising edge.  
 This bit is not synchronized.
- Bit 28 – CPHA: Clock Phase**  
 In combination with the Clock Polarity bit (CPOL), this bit determines the SPI transfer mode.

- 0: The data is sampled on a leading SCK edge and changed on a trailing SCK edge.
  - 1: The data is sampled on a trailing SCK edge and changed on a leading SCK edge.
- This bit is not synchronized.

**Table 32-4. SPI Transfer Modes**

| Mode | CPOL | CPHA | Leading Edge    | Trailing Edge   |
|------|------|------|-----------------|-----------------|
| 0x0  | 0    | 0    | Rising, sample  | Falling, change |
| 0x1  | 0    | 1    | Rising, change  | Falling, sample |
| 0x2  | 1    | 0    | Falling, sample | Rising, change  |
| 0x3  | 1    | 1    | Falling, change | Rising, sample  |

- **Bits 27:24 – FORM[3:0]: Frame Format**

Table 32-5 shows the various frame formats supported by the SPI. When a frame format with address is selected, the first byte received is checked against the ADDR register.

**Table 32-5. Frame Format**

| FORM[3:0] | Name     | Description            |
|-----------|----------|------------------------|
| 0x0       | SPI      | SPI frame              |
| 0x1       | -        | Reserved               |
| 0x2       | SPI_ADDR | SPI frame with address |
| 0x3-0xF   | -        | Reserved               |

- **Bits 23:22 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 21:20 – DIPO[1:0]: Data In Pinout**

These bits define the data in (DI) pad configurations.

In master operation, DI is MISO.

In slave operation, DI is MOSI.

These bits are not synchronized.

**Table 32-6. Data In Pinout**

| DIPO[1:0] | Name   | Description                         |
|-----------|--------|-------------------------------------|
| 0x0       | PAD[0] | SERCOM PAD[0] is used as data input |
| 0x1       | PAD[1] | SERCOM PAD[1] is used as data input |
| 0x2       | PAD[2] | SERCOM PAD[2] is used as data input |
| 0x3       | PAD[3] | SERCOM PAD[3] is used as data input |

- **Bits 19:18 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 17:16 – DOPO: Data Out Pinout**

This bit defines the available pad configurations for data out (DO) and the serial clock (SCK). In slave operation, the slave select line ( $\_SS$ ) is controlled by DOPO, while in master operation the  $\_SS$  line is controlled by the port configuration.

In master operation, DO is MOSI.

In slave operation, DO is MISO.

These bits are not synchronized.

**Table 32-7. Data Out Pinout**

| DOPO | DO     | SCK    | Slave_SS | Master_SS            |
|------|--------|--------|----------|----------------------|
| 0x0  | PAD[0] | PAD[1] | PAD[2]   | System configuration |
| 0x1  | PAD[2] | PAD[3] | PAD[1]   | System configuration |
| 0x2  | PAD[3] | PAD[1] | PAD[2]   | System configuration |
| 0x3  | PAD[0] | PAD[3] | PAD[1]   | System configuration |

- **Bits 15:9 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 8 – IBON: Immediate Buffer Overflow Notification**

This bit controls when the buffer overflow status bit (STATUS.BUFOVF) is asserted when a buffer overflow occurs.  
0: STATUS.BUFOVF is asserted when it occurs in the data stream.

1: STATUS.BUFOVF is asserted immediately upon buffer overflow.

This bit is not synchronized.

- **Bit 7 – RUNSTDBY: Run In Standby**

This bit defines the functionality in standby sleep mode.

These bits are not synchronized.

**Table 32-8. Run In Standby Configuration**

| RUNSTDBY | Slave  | Master   |
|----------|--|--|
| 0x0      | Disabled. All reception is dropped, including the ongoing transaction. | Generic clock is disabled when ongoing transaction is finished. All interrupts can wake up the device. |
| 0x1      | Wake on Receive Complete interrupt.                                    | Generic clock is enabled while in sleep modes. All interrupts can wake up the device.                  |

- **Bits 6:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 4:2 – MODE: Operating Mode**

These bits must be written to 0x2 or 0x3 to select the SPI serial communication interface of the SERCOM.

0x2: SPI slave operation

0x3: SPI master operation

These bits are not synchronized.

- **Bit 1 – ENABLE: Enable**

0: The peripheral is disabled or being disabled.

1: The peripheral is enabled or being enabled.

Due to synchronization, there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Synchronization Enable Busy bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE is cleared when the operation is complete.

This bit is not enable-protected.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the SERCOM, except DBGCTRL, to their initial state, and the SERCOM will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded. Any register write access during the ongoing reset will result in an APB error. Reading any register will return the reset value of the register.

Due to synchronization, there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

This bit is not enable-protected.

### 32.8.2 Control B

**Name:** CTRLB

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

| Bit    | 15         | 14      | 13   | 12 | 11 | 10          | 9    | 8   |
|        | AMODE[1:0] |         | MSEN |    |    |             | SSDE |     |
| Access | R/W        | R/W     | R/W  | R  | R  | R           | R/W  | R   |
| Reset  | 0          | 0       | 0    | 0  | 0  | 0           | 0    | 0   |
| Bit    | 7          | 6       | 5    | 4  | 3  | 2           | 1    | 0   |
|        |            | PLOADEN |      |    |    | CHSIZE[2:0] |      |     |
| Access | R          | R/W     | R    | R  | R  | R/W         | R/W  | R/W |
| Reset  | 0          | 0       | 0    | 0  | 0  | 0           | 0    | 0   |

- **Bits 31:18 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 17 – RXEN: Receiver Enable**

0: The receiver is disabled or being enabled.

1: The receiver is enabled or it will be enabled when SPI is enabled.

Writing a zero to this bit will disable the SPI receiver immediately. The receive buffer will be flushed, data from ongoing receptions will be lost and STATUS.BUFOVF will be cleared.

Writing a one to CTRLB.RXEN when the SPI is disabled will set CTRLB.RXEN immediately. When the SPI is enabled, CTRLB.RXEN will be cleared, SYNCBUSY.CTRLB will be set and remain set until the receiver is enabled. When the receiver is enabled CTRLB.RXEN will read back as one.

Writing a one to CTRLB.RXEN when the SPI is enabled will set SYNCBUSY.CTRLB, which will remain set until the receiver is enabled, and CTRLB.RXEN will read back as one.

This bit is not enable-protected.

- **Bit 16 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bits 15:14 – AMODE: Address Mode**  
These bits set the slave addressing mode when the frame format (CTRLA.FORM) with address is used. They are unused in master mode.

**Table 32-9. Address Mode**

| AMODE[1:0] | Name    | Description   |
|------------|---------|---|
| 0x0        | MASK    | ADDRMASK is used as a mask to the ADDR register   |
| 0x1        | 2_ADDRS | The slave responds to the two unique addresses in ADDR and ADDRMASK   |
| 0x2        | RANGE   | The slave responds to the range of addresses between and including ADDR and ADDRMASK. ADDR is the upper limit |
| 0x3        |         | Reserved  |

- **Bit 13 – MSSEN: Master Slave Select Enable**  
This bit enables hardware slave select (\_SS) control.  
0: Hardware \_SS control is disabled.  
1: Hardware \_SS control is enabled.
- **Bits 12:10 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 9 – SSDE: Slave Select Low Detect Enable**  
This bit enables wake up when the slave select (\_SS) pin transitions from high to low.  
0: \_SS low detector is disabled.  
1: \_SS low detector is enabled.
- **Bits 8:7 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 6 – PLOADEN: Slave Data Preload Enable**  
Setting this bit will enable preloading of the slave shift register when there is no transfer in progress. If the \_SS line is high when DATA is written, it will be transferred immediately to the shift register.
- **Bits 5:3 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 2:0 – CHSIZE[2:0]: Character Size**

**Table 32-10. Character Size**

| CHSIZE[2:0] | Name | Description |
|-------------|------|-------------|
| 0x0         | 8BIT | 8 bits      |
| 0x1         | 9BIT | 9 bits      |
| 0x2-0x7     |      | Reserved    |

32.8.3 Baud Rate

**Name:** BAUD  
**Offset:** 0x0C  
**Reset:** 0x00  
**Property:** Write-Protected, Enable-Protected

|        |           |     |     |     |     |     |     |     |
|--------|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | BAUD[7:0] |     |     |     |     |     |     |     |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- Bits 7:0 – BAUD: Baud Register**  
These bits control the clock generation, as described in the SERCOM [“Clock Generation – Baud-Rate Generator”](#) on page 495.

### 32.8.4 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x14

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5 | 4 | 3   | 2   | 1   | 0   |
|--------|-------|---|---|---|-----|-----|-----|-----|
|        | ERROR |   |   |   | SSL | RXC | TXC | DRE |
| Access | R/W   | R | R | R | R/W | R/W | R/W | R/W |
| Reset  | 0     | 0 | 0 | 0 | 0   | 0   | 0   | 0   |

- **Bit 7– ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Error Interrupt Enable bit, which disables the Error interrupt.

- **Bits 6:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3– SSL: Slave Select Low Interrupt Enable**

0: Slave Select Low interrupt is disabled.

1: Slave Select Low interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Slave Select Low Interrupt Enable bit, which disables the Slave Select Low interrupt.

- **Bit 2 – RXC: Receive Complete Interrupt Enable**

0: Receive Complete interrupt is disabled.

1: Receive Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Receive Complete Interrupt Enable bit, which disables the Receive Complete interrupt.

- **Bit 1 – TXC: Transmit Complete Interrupt Enable**

0: Transmit Complete interrupt is disabled.

1: Transmit Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Transmit Complete Interrupt Enable bit, which disable the Transmit Complete interrupt.

- **Bit 0 – DRE: Data Register Empty Interrupt Enable**

0: Data Register Empty interrupt is disabled.

1: Data Register Empty interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Data Register Empty Interrupt Enable bit, which disables the Data Register Empty interrupt.

### 32.8.5 Interrupt Enable Set

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x16

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5 | 4 | 3   | 2   | 1   | 0   |
|--------|-------|---|---|---|-----|-----|-----|-----|
|        | ERROR |   |   |   | SSL | RXC | TXC | DRE |
| Access | R/W   | R | R | R | R/W | R/W | R/W | R/W |
| Reset  | 0     | 0 | 0 | 0 | 0   | 0   | 0   | 0   |

- **Bit 7 – ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Error Interrupt Enable bit, which enables the Error interrupt.

- **Bits 6:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3 – SSL: Slave Select Low Interrupt Enable**

0: Slave Select Low interrupt is disabled.

1: Slave Select Low interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Slave Select Low Interrupt Enable bit, which enables the Slave Select Low interrupt.

- **Bit 2 – RXC: Receive Complete Interrupt Enable**

0: Receive Complete interrupt is disabled.

1: Receive Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Receive Complete Interrupt Enable bit, which enables the Receive Complete interrupt.

- **Bit 1 – TXC: Transmit Complete Interrupt Enable**

0: Transmit Complete interrupt is disabled.

1: Transmit Complete interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Transmit Complete Interrupt Enable bit, which enables the Transmit Complete interrupt.

- **Bit 0 – DRE: Data Register Empty Interrupt Enable**

0: Data Register Empty interrupt is disabled.

1: Data Register Empty interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Data Register Empty Interrupt Enable bit, which enables the Data Register Empty interrupt.

### 32.8.6 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x18

**Reset:** 0x00

**Property:** -

| Bit    | 7     | 6 | 5 | 4 | 3   | 2   | 1   | 0   |
|--------|-------|---|---|---|-----|-----|-----|-----|
|        | ERROR |   |   |   | SSL | RXC | TXC | DRE |
| Access | R/W   | R | R | R | R/W | R   | R/W | R   |
| Reset  | 0     | 0 | 0 | 0 | 0   | 0   | 0   | 0   |

- **Bit 7 – ERROR: Error**

This flag is cleared by writing a one to it.

This bit is set when any error is detected. Errors that will set this flag have corresponding status flags in the STATUS register. The BUFOVF error will set this interrupt flag.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bits 6:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3 – SSL: Slave Select Low**

This flag is cleared by writing a one to it.

This bit is set when a high to low transition is detected on the \_SS pin in slave mode and Slave Select Low Detect (CTRLB.SSDE) is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bit 2 – RXC: Receive Complete**

This flag is cleared by reading the Data (DATA) register or by disabling the receiver.

This flag is set when there are unread data in the receive buffer. If address matching is enabled, the first data received in a transaction will be an address.

Writing a zero to this bit has no effect.

Writing a one to this bit has no effect.

- **Bit 1 – TXC: Transmit Complete**

This flag is cleared by writing a one to it or by writing new data to DATA.

In master mode, this flag is set when the data have been shifted out and there are no new data in DATA.

In slave mode, this flag is set when the \_SS pin is pulled high. If address matching is enabled, this flag is only set if the transaction was initiated with an address match.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bit 0 – DRE: Data Register Empty**

This flag is cleared by writing new data to DATA.

This flag is set when DATA is empty and ready for new data to transmit.

Writing a zero to this bit has no effect.

Writing a one to this bit has no effect.

### 32.8.7 Status

**Name:** STATUS

**Offset:** 0x1A

**Reset:** 0x0000

**Property:** –

|        |    |    |    |    |    |        |   |   |
|--------|----|----|----|----|----|--------|---|---|
| Bit    | 15 | 14 | 13 | 12 | 11 | 10     | 9 | 8 |
|        |    |    |    |    |    |        |   |   |
| Access | R  | R  | R  | R  | R  | R      | R | R |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0      | 0 | 0 |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2      | 1 | 0 |
|        |    |    |    |    |    | BUFOVF |   |   |
| Access | R  | R  | R  | R  | R  | R/W    | R | R |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0      | 0 | 0 |

- **Bits 15:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – BUFOVF: Buffer Overflow**

Reading this bit before reading DATA will indicate the error status of the next character to be read.

This bit is cleared by writing a one to the bit or by disabling the receiver.

This bit is set when a buffer overflow condition is detected. An overflow condition occurs if the two-level receive buffer is full when the last bit of the incoming character is shifted into the shift register. All characters shifted into the shift registers before the overflow condition is eliminated by reading DATA will be lost.

When set, the corresponding RxDATA will be 0.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear it.

- **Bits 1:0 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

### 32.8.8 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x1C

**Reset:** 0x00000000

**Property:**

|        |    |    |    |    |    |       |        |       |
|--------|----|----|----|----|----|-------|--------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26    | 25     | 24    |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18    | 17     | 16    |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10    | 9      | 8     |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2     | 1      | 0     |
|        |    |    |    |    |    | CTRLB | ENABLE | SWRST |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2– CTRLB: CTRLB Synchronization Busy**

Writing CTRLB when the SERCOM is enabled requires synchronization. When written, the SYNCBUSY.CTRLB bit will be set until synchronization is complete. If CTRLB is written while SYNCBUSY.CTRLB is asserted, an APB error will be generated.

0: CTRLB synchronization is not busy.

1: CTRLB synchronization is busy.

- **Bit 1 – ENABLE: SERCOM Enable Synchronization Busy**

Enabling and disabling the SERCOM (CTRLA.ENABLE) requires synchronization. When written, the SYNCBUSY.ENABLE bit will be set until synchronization is complete.

Writes to any register (except for CTRLA.SWRST) while enable synchronization is on-going will be discarded and an APB error will be generated.

0: Enable synchronization is not busy.

1: Enable synchronization is busy.

- **Bit 0 – SWRST: Software Reset Synchronization Busy**

Resetting the SERCOM (CTRLA.SWRST) requires synchronization. When written, the SYNCBUSY.SWRST bit will be set until synchronization is complete.

Writes to any register while synchronization is on-going will be discarded and an APB error will be generated.

0: SWRST synchronization is not busy.

1: SWRST synchronization is busy.

### 32.8.9 Address

**Name:** ADDR

**Offset:** 0x24

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |               |     |     |     |     |     |     |     |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31            | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        |               |     |     |     |     |     |     |     |
| Access | R             | R   | R   | R   | R   | R   | R   | R   |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23            | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | ADDRMASK[7:0] |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15            | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        |               |     |     |     |     |     |     |     |
| Access | R             | R   | R   | R   | R   | R   | R   | R   |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | ADDR[7:0]     |     |     |     |     |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- Bits 31:24 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 23:16 – ADDRMASK[7:0]: Address Mask**  
 These bits hold the address mask when the transaction format (CTRLA.FORM) with address is used.
- Bits 15:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 7:0 – ADDR[7:0]: Address**  
 These bits hold the address when the transaction format (CTRLA.FORM) with address is used.

### 32.8.10 Data

**Name:** DATA  
**Offset:** 0x28  
**Reset:** 0x0000  
**Property:** –

|        |           |     |     |     |     |     |     |         |
|--------|-----------|-----|-----|-----|-----|-----|-----|---------|
| Bit    | 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8       |
|        |           |     |     |     |     |     |     | DATA[8] |
| Access | R         | R   | R   | R   | R   | R   | R   | R/W     |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0       |
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0       |
|        | DATA[7:0] |     |     |     |     |     |     |         |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W     |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0       |

- **Bits 15:9 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 8:0 – DATA[8:0]: Data**

Reading these bits will return the contents of the receive data buffer. The register should be read only when the Receive Complete Interrupt Flag bit in the Interrupt Flag Status and Clear register (INTFLAG.RXC) is set.

Writing these bits will write the transmit data buffer. This register should be written only when the Data Register Empty Interrupt Flag bit in the Interrupt Flag Status and Clear register (INTFLAG.DRE) is set.

### 32.8.11 Debug Control

**Name:** DBGCTRL

**Offset:** 0x30

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0       |
|--------|---|---|---|---|---|---|---|---------|
|        |   |   |   |   |   |   |   | DBGSTOP |
| Access | R | R | R | R | R | R | R | R/W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0       |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGSTOP: Debug Stop Mode**

This bit controls the functionality when the CPU is halted by an external debugger.

0: The baud-rate generator continues normal operation when the CPU is halted by an external debugger.

1: The baud-rate generator is halted when the CPU is halted by an external debugger.

## 33. SERCOM I<sup>2</sup>C – SERCOM Inter-Integrated Circuit

### 33.1 Overview

The inter-integrated circuit (I<sup>2</sup>C) interface is one of the available modes in the serial communication interface (SERCOM). Refer to “[SERCOM – Serial Communication Interface](#)” on page 492 for details.

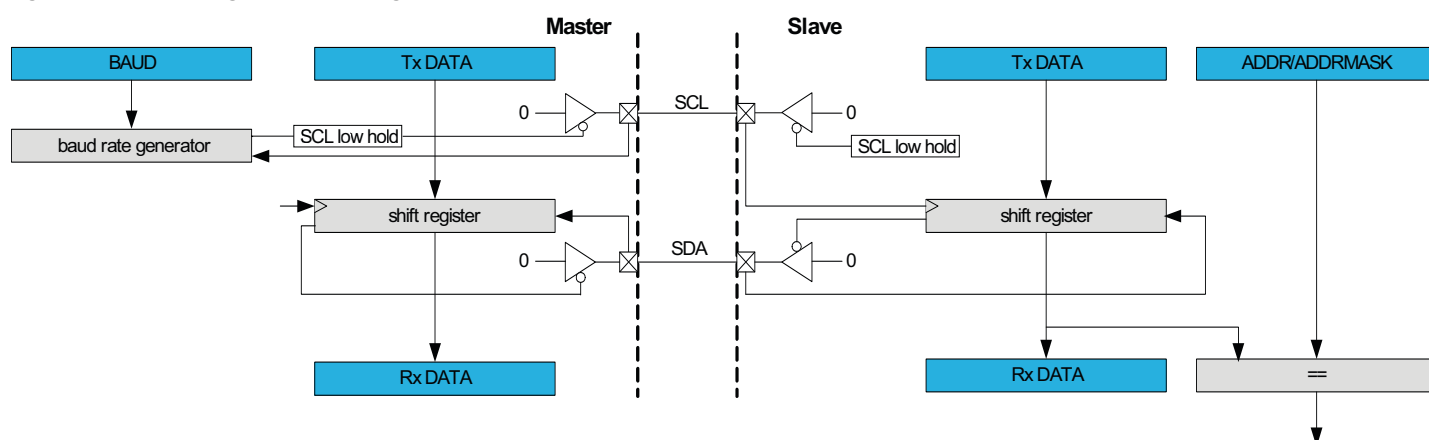

The I<sup>2</sup>C interface uses the SERCOM transmitter and receiver configured as shown in [Figure 33-1](#). Fields shown in capital letters are registers accessible by the CPU, while lowercase fields are internal to the SERCOM. Each side, master and slave, depicts a separate I<sup>2</sup>C interface containing a shift register, a transmit buffer and a receive buffer. In addition, the I<sup>2</sup>C master uses the SERCOM baud-rate generator, while the I<sup>2</sup>C slave uses the SERCOM address match logic.

### 33.2 Features

- Master or slave operation
- Can be used with DMA
- Philips I<sup>2</sup>C compatible
- SMBus™ compatible
- PMBus compatible
- 100kHz and 400kHz, 1MHz and 3.4MHz support at low system clock frequencies
- Physical interface includes:
  - Slew-rate limited outputs
  - Filtered inputs
- Slave operation:
  - Operation in all sleep modes
  - Wake-up on address match
  - 7-bit and 10-bit Address match in hardware for:
    - Unique address and/or 7-bit general call address
    - Address range
    - Two unique addresses can be used with DMA

### 33.3 Block Diagram

Figure 33-1. I<sup>2</sup>C Single-Master Single-Slave Interconnection

## 33.4 Signal Description

| Signal Name | Type        | Description      |
|-------------|-------------|------------------|
| PAD[0]      | Digital I/O | SDA              |
| PAD[1]      | Digital I/O | SCL              |
| PAD[2]      | Digital I/O | SDA_OUT (4-wire) |
| PAD[3]      | Digital I/O | SDC_OUT (4-wire) |

Refer to [“I/O Multiplexing and Considerations” on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins. Note that not all the pins are I<sup>2</sup>C pins. Refer to [Table 6-1](#) for details on the pin type for each pin.

## 33.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 33.5.1 I/O Lines

Using the SERCOM's I/O lines requires the I/O pins to be configured. Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

### 33.5.2 Power Management

The I<sup>2</sup>C will continue to operate in any sleep mode where the selected source clock is running. I<sup>2</sup>C interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 33.5.3 Clocks

The SERCOM bus clock (CLK\_SERCOMx\_APB, where x represents the specific SERCOM instance number) can be enabled and disabled in the Main Clock module, and the default state of CLK\_SERCOMx\_APB can be found in the Peripheral Clock Masking section in [Table 17-1](#).

Two generic clocks are used by the SERCOM (GCLK\_SERCOMx\_CORE and GCLK\_SERCOM\_SLOW). The core clock (GCLK\_SERCOMx\_CORE) is required to clock the SERCOM while operating as a master, while the slow clock (GCLK\_SERCOM\_SLOW) is required only for certain functions. These clocks must be configured and enabled in the Generic Clock Controller (GCLK) before using the SERCOM. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

These generic clocks are asynchronous to the SERCOM bus clock (CLK\_SERCOMx\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to the [“Synchronization” on page 593](#) section for further details.

### 33.5.4 DMA

The DMA request lines are connected to the DMA controller (DMAC). Using the SERCOM DMA requests, requires the DMA controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details.

### 33.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the I<sup>2</sup>C interrupts requires the Interrupt Controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 33.5.6 Events

Not applicable.

### 33.5.7 Debug Operation

When the CPU is halted in debug mode, the I<sup>2</sup>C interface continues normal operation. If the I<sup>2</sup>C interface is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging. The I<sup>2</sup>C interface can be forced to halt operation during debugging.

Refer to the [DBGCTRL](#) register for details.

### 33.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the Peripheral Access Controller (PAC), except the following registers:

- Interrupt Flag Status and Clear register (INTFLAG)
- Status register (STATUS)
- Address register (ADDR)
- Data register (DATA)

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to “[PAC – Peripheral Access Control](#)” on [page 33](#) for details.

### 33.5.9 Analog Connections

Not applicable.

## 33.6 Functional Description

### 33.6.1 Principle of Operation

The I<sup>2</sup>C interface uses two physical lines for communication:

- Serial Data Line (SDA) for packet transfer
- Serial Clock Line (SCL) for the bus clock

A transaction starts with the start condition, followed by a 7-bit address and a direction bit (read or write) sent from the I<sup>2</sup>C master. The addressed I<sup>2</sup>C slave will then acknowledge (ACK) the address, and data packet transactions can commence. Every 9-bit data packet consists of 8 data bits followed by a one-bit reply indicating whether the data was acknowledged or not. In the event that a data packet is not acknowledged (NACK), whether sent from the I<sup>2</sup>C slave or master, it will be up to the I<sup>2</sup>C master to either terminate the connection by issuing the stop condition, or send a repeated start if more data is to be transceived.

[Figure 33-2](#) illustrates the possible transaction formats and [Figure 33-3](#) explains the legend used.

## 33.6.2 Basic Operation

### 33.6.2.1 Initialization

The following registers are enable-protected, meaning they can be written only when the I<sup>2</sup>C interface is disabled (CTRLA.ENABLE is zero):

- Control A register (CTRLA), except Enable (CTRLA.ENABLE) and Software Reset (CTRLA.SWRST)
- Control B register (CTRLB), except Acknowledge Action (CTRLB.ACKACT) and Command (CTRLB.CMD)
- Baud Rate register (BAUD)
- Address register (ADDR) while in slave operation

Any writes to these bits or registers when the I<sup>2</sup>C interface is enabled or is being enabled (CTRLA.ENABLE is one) will be discarded. Writes to these registers while the I<sup>2</sup>C interface is being disabled will be completed after the disabling is complete.

Enable-protection is denoted by the Enable-Protection property in the register description.

Before the I<sup>2</sup>C interface is enabled, it must be configured as outlined by the following steps:

I<sup>2</sup>C mode in master or slave operation must be selected by writing 0x4 or 0x5 to the Operating Mode bit group in the Control A register (CTRLA.MODE)

- SCL low time-out can be enabled by writing to the SCL Low Time-Out bit in the Control A register (CTRLA.LOWTOUT)
- In master operation, the inactive bus time-out can be set in the Inactive Time-Out bit group in the Control A register (CTRLA.INACTOUT)
- Hold time for SDA can be set in the SDA Hold Time bit group in the Control A register (CTRLA.SDAHOLD)
- Smart operation can be enabled by writing to the Smart Mode Enable bit in the Control B register (CTRLB.SMEN)
- In slave operation, the address match configuration must be set in the Address Mode bit group in the Control B register (CTRLB.AMODE)
- In slave operation, the addresses must be set, according to the selected address configuration, in the Address and Address Mask bit groups in the Address register (ADDR.ADDR and ADDR.ADDRMASK)
- In master operation, the Baud Rate register (BAUD) must be written to generate the desired baud rate

### 33.6.2.2 Enabling, Disabling and Resetting

The I<sup>2</sup>C interface is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The I<sup>2</sup>C interface is disabled by writing a zero to CTRLA.ENABLE. The I<sup>2</sup>C interface is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the I<sup>2</sup>C interface, except DBGCTRL, will be reset to their initial state, and the I<sup>2</sup>C interface will be disabled. Refer to [CTRLA](#) for details.

### 33.6.2.3 I<sup>2</sup>C Bus State Logic

The bus state logic includes several logic blocks that continuously monitor the activity on the I<sup>2</sup>C bus lines in all sleep modes. The start and stop detectors and the bit counter are all essential in the process of determining the current bus state. The bus state is determined according to the state diagram shown in [Figure 33-4](#). Software can get the current bus state by reading the Master Bus State bits in the Status register (STATUS.BUSSTATE). The value of STATUS.BUSSTATE in the figure is shown in binary.

Figure 33-4. Bus State Diagram

The bus state machine is active when the I<sup>2</sup>C master is enabled. After the I<sup>2</sup>C master has been enabled, the bus state is unknown. From the unknown state, the bus state machine can be forced to enter the idle state by writing to STATUS.BUSSTATE accordingly. However, if no action is taken by software, the bus state will become idle if a stop condition is detected on the bus. If the inactive bus time-out is enabled, the bus state will change from unknown to idle on the occurrence of a time-out. Note that after a known bus state is established, the bus state logic will not re-enter the unknown state from either of the other states.

When the bus is idle it is ready for a new transaction. If a start condition is issued on the bus by another I<sup>2</sup>C master in a multimaster setup, the bus becomes busy until a stop condition is detected. The stop condition will cause the bus to re-enter the IDLE state. If the inactive bus time-out (SMBus) is enabled, the bus state will change from busy to idle on the occurrence of a time-out. If a start condition is generated internally by writing the Address bit group in the Address register (ADDR.ADDR) while in idle state, the owner state is entered. If the complete transaction was performed without interference, i.e., arbitration not lost, the I<sup>2</sup>C master is allowed to issue a stop condition, which in turn will cause a change of the bus state back to idle. However, if a packet collision is detected when in the owner state, the arbitration is assumed lost and the bus state becomes busy until a stop condition is detected.

A repeated start condition will change the bus state only if arbitration is lost while issuing a repeated start.

#### 33.6.2.4 Clock Generation (Standard-mode, Fast-mode and Fast-mode Plus Transfers)

The Master I<sup>2</sup>C clock (SCL) frequency is determined by a number of factors. The low ( $T_{LOW}$ ) and high ( $T_{HIGH}$ ) times are determined by the Baud Rate register (BAUD), while the rise ( $T_{RISE}$ ) and fall ( $T_{FALL}$ ) times are determined by the bus topology. Because of the wired-AND logic of the bus,  $T_{FALL}$  will be considered as part of  $T_{LOW}$ . Likewise,  $T_{RISE}$  will be in a state between  $T_{LOW}$  and  $T_{HIGH}$  until a high state has been detected.

Figure 33-5. SCL Timing

The following parameters are timed using the SCL low time period. This comes from the Master Baud Rate Low bit group in the Baud Rate register (BAUD.BAUDLOW) when non-zero, or the Master Baud Rate bit group in the Baud Rate register (BAUD.BAUD) when BAUD.BAUDLOW is zero.

- $T_{LOW}$  – Low period of SCL clock
- $T_{SU;STO}$  – Set-up time for stop condition
- $T_{BUF}$  – Bus free time between stop and start conditions
- $T_{HD;STA}$  – Hold time (repeated) start condition
- $T_{SU;STA}$  – Set-up time for repeated start condition
- $T_{HIGH}$  is timed using the SCL high time count from BAUD.BAUD
- $T_{RISE}$  is determined by the bus impedance; for internal pull-ups. Refer to “[Electrical Characteristics](#)” on page 903 for details.
- $T_{FALL}$  is determined by the open-drain current limit and bus impedance; can typically be regarded as zero. Refer to “[Electrical Characteristics](#)” on page 903 for details.

The SCL frequency is given by:

$$f_{SCL} = \frac{1}{T_{LOW} + T_{HIGH} + T_{RISE}}$$

When BAUD.BAUDLOW is zero, the BAUD.BAUD value is used to time both SCL high and SCL low. In this case the following formula will give the SCL frequency:

$$f_{SCL} = \frac{f_{GCLK}}{2(5 + BAUD) + f_{GCLK} T_{RISE}}$$

When BAUD.BAUDLOW is non-zero, the following formula is used to determine the SCL frequency:

$$f_{SCL} = \frac{f_{GCLK}}{10 + BAUD + BAUDLOW + f_{GCLK} T_{RISE}}$$

When BAUDLOW is non-zero, the following formula can be used to determine the SCL frequency:

$$f_{SCL} = \frac{f_{GCLK}}{10 + BAUD + BAUDLOW + f_{GCLK} T_{RISE}}$$

The following formulas can be used to determine the SCL  $T_{LOW}$  and  $T_{HIGH}$  times:

$$T_{low} = \frac{BAUD.BAUDLOW + 5}{f_{GCLK}}$$

$$T_{HIGH} = \frac{BAUD.BAUD + 5}{f_{GCLK}}$$

For Fast-mode Plus the nominal high to low SCL ratio is 1 to 2 and BAUD should be set accordingly. At a minimum, BAUD.BAUD and/or BAUD.BAUDLOW must be non-zero.

### 33.6.2.5 Master Clock Generation (High-speed mode Transfer)

For High-speed mode transfers, there is no SCL synchronization, so the SCL frequency is determined by the GCLK frequency and the High-speed BAUD setting. When HSBAUDLOW is zero, the HSBAUD value is used to time both SCL high and SCL low. In this case the following formula can be used to determine the SCL frequency.

$$f_{SCL} = \frac{f_{GCLK}}{2(1 + HSBAUD)}$$

When HSBAUDLOW is non-zero, the following formula can be used to determine the SCL frequency.

$$f_{SCL} = \frac{f_{GCLK}}{2 + HSBAUD + HSBAUDLOW}$$

For High-speed the nominal high to low SCL ratio is 1 to 2 and HSBAUD should be set accordingly. At a minimum, BAUD.BAUD and/or BAUD.BAUDLOW must be non-zero.

### 33.6.2.6 I<sup>2</sup>C Master Operation

The I<sup>2</sup>C master is byte-oriented and interrupt based. The number of interrupts generated is kept at a minimum by automatic handling of most events. Auto-triggering of operations and a special smart mode, which can be enabled by writing a one to the Smart Mode Enable bit in the Control A register (CTRLA.SMEN), are included to reduce software driver complexity and code size.

The I<sup>2</sup>C master has two interrupt strategies. When SCL Stretch Mode (CTRLA.SCLSM) is set to zero, SCL is stretched before or after the acknowledge bit. In this mode the I<sup>2</sup>C master operates according to the behavior diagram shown in [Figure 33-6](#). The circles with a capital letter M followed by a number (M1, M2... etc.) indicate which node in the figure the bus logic can jump to based on software or hardware interaction.

This diagram is used as reference for the description of the I<sup>2</sup>C master operation throughout the document.

Figure 33-6. I<sup>2</sup>C Master Behavioral Diagram (SCLSM=0)

In the second strategy (SCLSM=1), interrupts only occur after the ACK bit as shown in Figure 33-7. This strategy can be used when it is not necessary to check DATA before acknowledging.

Note that setting SCLSM to 1 is required for High-speed mode.

Figure 33-7. I<sup>2</sup>C Master Behavioral Diagram (SCLSM=1)

## Transmitting Address Packets

The I<sup>2</sup>C master starts a bus transaction by writing ADDR.ADDR with the I<sup>2</sup>C slave address and the direction bit. If the bus is busy, the I<sup>2</sup>C master will wait until the bus becomes idle before continuing the operation. When the bus is idle, the I<sup>2</sup>C master will issue a start condition on the bus. The I<sup>2</sup>C master will then transmit an address packet using the address written to ADDR.ADDR.

After the address packet has been transmitted by the I<sup>2</sup>C master, one of four cases will arise, based on arbitration and transfer direction.

### Case 1: Arbitration lost or bus error during address packet transmission

If arbitration was lost during transmission of the address packet, the Master on Bus bit in the Interrupt Flag register (INTFLAG.MB) and the Arbitration Lost bit in the Status register (STATUS.ARBLOST) are both set. Serial data output to SDA is disabled, and the SCL is released, which disables clock stretching. In effect the I<sup>2</sup>C master is no longer allowed to perform any operation on the bus until the bus is idle again. A bus error will behave similarly to the arbitration lost condition. In this case, the MB interrupt flag and Master Bus Error bit in the Status register (STATUS.BUSERR) are both set in addition to STATUS.ARBLOST.

The Master Received Not Acknowledge bit in the Status register (STATUS.RXNACK) will always contain the last successfully received acknowledge or not acknowledge indication.

In this case, software will typically inform the application code of the condition and then clear the interrupt flag before exiting the interrupt routine. No other flags have to be cleared at this point, because all flags will be cleared automatically the next time the ADDR.ADDR register is written.

### Case 2: Address packet transmit complete – No ACK received

If no I<sup>2</sup>C slave device responds to the address packet, then the INTFLAG.MB interrupt flag is set and STATUS.RXNACK is set. The clock hold is active at this point, preventing further activity on the bus.

The missing ACK response can indicate that the I<sup>2</sup>C slave is busy with other tasks or sleeping and, therefore, not able to respond. In this event, the next step can be either issuing a stop condition (recommended) or resending the address

packet by using a repeated start condition. However, the reason for the missing acknowledge can be that an invalid I<sup>2</sup>C slave address has been used or that the I<sup>2</sup>C slave is for some reason disconnected or faulty. If using SMBus logic, the slave must ACK the address, and hence no action means the slave is not available on the bus.

### **Case 3: Address packet transmit complete – Write packet, Master on Bus set**

If the I<sup>2</sup>C master receives an acknowledge response from the I<sup>2</sup>C slave, INTFLAG.MB is set and STATUS.RXNACK is cleared. The clock hold is active at this point, preventing further activity on the bus.

In this case, the software implementation becomes highly protocol dependent. Three possible actions can enable the I<sup>2</sup>C operation to continue. The three options are:

- The data transmit operation is initiated by writing the data byte to be transmitted into DATA.DATA.
- Transmit a new address packet by writing ADDR.ADDR. A repeated start condition will automatically be inserted before the address packet.
- Issue a stop condition, consequently terminating the transaction.

### **Case 4: Address packet transmit complete – Read packet, Slave on Bus set**

If the I<sup>2</sup>C master receives an ACK from the I<sup>2</sup>C slave, the I<sup>2</sup>C master proceeds to receive the next byte of data from the I<sup>2</sup>C slave. When the first data byte is received, the Slave on Bus bit in the Interrupt Flag register (INTFLAG.SB) is set and STATUS.RXNACK is cleared. The clock hold is active at this point, preventing further activity on the bus.

In this case, the software implementation becomes highly protocol dependent. Three possible actions can enable the I<sup>2</sup>C operation to continue. The three options are:

- Let the I<sup>2</sup>C master continue to read data by first acknowledging the data received. This is automatically done when reading DATA.DATA if the smart mode is enabled.
- Transmit a new address packet.
- Terminate the transaction by issuing a stop condition.

An ACK or NACK will be automatically transmitted for the last two alternatives if smart mode is enabled. The Acknowledge Action bit in the Control B register (CTRLB.ACKACT) determines whether ACK or NACK should be sent.

### **Transmitting Data Packets**

When an address packet with direction set to write has been successfully transmitted, INTFLAG.MB will be set and the I<sup>2</sup>C master can start transmitting data by writing to DATA.DATA. The I<sup>2</sup>C master transmits data via the I<sup>2</sup>C bus while continuously monitoring for packet collisions. If a collision is detected, the I<sup>2</sup>C master loses arbitration and STATUS.ARBLOST is set. If the transmit was successful, the I<sup>2</sup>C master automatically receives an ACK bit from the I<sup>2</sup>C slave and STATUS.RXNACK will be cleared. INTFLAG.MB will be set in both cases, regardless of arbitration outcome.

Testing STATUS.ARBLOST and handling the arbitration lost condition in the beginning of the I<sup>2</sup>C Master on Bus interrupt is recommended. This can be done, as there is no difference between handling address and data packet arbitration.

STATUS.RXNACK must be checked for each data packet transmitted before the next data packet transmission can commence. The I<sup>2</sup>C master is not allowed to continue transmitting data packets if a NACK is given from the I<sup>2</sup>C slave.

### **Receiving Data Packets (SCLSM=0)**

When INTFLAG.SB is set, the I<sup>2</sup>C master will already have received one data packet. The I<sup>2</sup>C master must respond by sending either an ACK or NACK. Sending a NACK might not be successfully executed as arbitration can be lost during the transmission. In this case, a loss of arbitration will cause INTFLAG.SB to not be set on completion. Instead, INTFLAG.MB will be used to indicate a change in arbitration. Handling of lost arbitration is the same as for data bit transmission.

### **Receiving Data Packets (SCLSM=1)**

When INTFLAG.SB is set, the I<sup>2</sup>C master will already have received one data packet and transmitted the ACKACT bit. At this point the ACKACT must be set to the correct value for the next ACK bit, and the transaction can continue by reading DATA and issuing a command if not in smart mode.

## High-speed Mode

High-speed transfers are a multi-step process as shown in Figure 33-8. First, a master code (0000 1nnn where nnn is a unique master code) is transmitted in Full-speed mode, followed by a NACK since no slave should acknowledge. Arbitration is performed only during the Full-speed Master Code phase. The master code is transmitted by writing the master code to the address register (ADDR) with the high-speed bit (ADDR.HS) written to zero.

After the Master Code and NACK have been transmitted, the master write interrupt will be asserted. At this point, the slave address can be written to the ADDR register with the ADDR.HS bit set to one. The master will then generate a repeated start followed by the slave address in High-speed mode. The bus will remain in High-speed mode until a stop is generated. If a repeated start is desired, the ADDR.HS bit must again be written to 1 along with the new address to be transmitted.

Figure 33-8. High Speed Transfer

Transmitting in High-speed mode requires the I2C master to be configured in High-speed mode (SPEED=0b10) and the SCL clock stretch mode (SCLSM) bit set to one.

## 10-Bit Addressing

When 10-bit addressing is enabled (TENBITEN=1) and the ADDR register is written, the two address bytes will be transmitted as shown in Figure 33-9. The addressed slave acknowledges the two address bytes and the transaction continues. Regardless of whether the transaction is a read or write, the master must start by sending the 10-bit address with the read/write bit (ADDR.ADDR[0]) equal to zero.

If the master receives a NACK after the first byte, then the write interrupt flag will be raised and the NACK bit will be set. If the first byte is acknowledged by one or more slaves, then the master will proceed to transmit the second address byte and the master will first see the write interrupt flag after the second byte is transmitted.

If the transaction is a read, the 10-bit address transmission must be followed by a repeated start and the first 7 bits of the address with the read/write bit equal to 1.

Figure 33-9. 10-Bit Address Transmission for a Read Transaction

This implies the following procedure for a 10-bit read operation:

- Write ADDR.ADDR[10:1] with the 10-bit address. ADDR.TENBITEN must be set (can be written simultaneously with ADDR) and read/write bit (ADDR.ADDR[0]) equal to 0.
- When the master write interrupt is asserted, write ADDR[7:0] register to “11110 address[9:8] 1”. ADDR.TENBITEN must be cleared (can be written simultaneously with ADDR).
- Proceed to transmit data.

### 33.6.2.7 I<sup>2</sup>C Slave Operation

The I<sup>2</sup>C slave is byte-oriented and interrupt-based. The number of interrupts generated is kept at a minimum by automatic handling of most events. Auto triggering of operations and a special smart mode, which can be enabled by writing a 1 to the Smart Mode Enable bit in the Control A register (CTRLA.SMEN), are included to reduce software's complexity and code size.

The I<sup>2</sup>C slave has two interrupt strategies. When SCL Stretch Mode (CTRLA.SCLSM) is set to zero, SCL is stretched before or after the acknowledge bit. In this mode, the I<sup>2</sup>C slave operates according to the behavior diagram shown in [Figure 33-10](#). The circles with a capital S followed by a number (S1, S2... etc.) indicate which node in the figure the bus logic can jump to based on software or hardware interaction.

This diagram is used as reference for the description of the I<sup>2</sup>C slave operation throughout the document.

**Figure 33-10. I<sup>2</sup>C Slave Behavioral Diagram (SCLSM=0)**

In the second strategy (SCLSM=1), interrupts only occur after the ACK bit as shown in [Figure 33-11](#). This strategy can be used when it is not necessary to check DATA before acknowledging. For master reads, an address and data interrupt will be issued simultaneously after the address acknowledge, while for master writes, the first data interrupt will be seen after the first data byte has been received by the slave and the acknowledge bit has been sent to the master.

Note that setting SCLSM to 1 is required for High-speed mode.

**Figure 33-11. Slave Behavioral Diagram (SCLSM=1)**

### Receiving Address Packets (SCLSM=0)

When SCLSM is zero, the I<sup>2</sup>C slave stretches the SCL line according to Figure 33-10. When the I<sup>2</sup>C slave is properly configured, it will wait for a start condition to be detected. When a start condition is detected, the successive address packet will be received and checked by the address match logic. If the received address is not a match, the packet is rejected and the I<sup>2</sup>C slave waits for a new start condition. The I<sup>2</sup>C slave Address Match bit in the Interrupt Flag register (INTFLAG.AMATCH) is set when a start condition followed by a valid address packet is detected. SCL will be stretched until the I<sup>2</sup>C slave clears INTFLAG.AMATCH. Because the I<sup>2</sup>C slave holds the clock by forcing SCL low, the software is given unlimited time to respond to the address.

The direction of a transaction is determined by reading the Read / Write Direction bit in the Status register (STATUS.DIR), and the bit will be updated only when a valid address packet is received.

If the Transmit Collision bit in the Status register (STATUS.COLL) is set, this indicates that the last packet addressed to the I<sup>2</sup>C slave had a packet collision. A collision causes the SDA and SCL lines to be released without any notification to software. The next AMATCH interrupt is, therefore, the first indication of the previous packet's collision. Collisions are intended to follow the SMBus Address Resolution Protocol (ARP).

After the address packet has been received from the I<sup>2</sup>C master, one of two cases will arise based on transfer direction.

#### Case 1: Address packet accepted – Read flag set

The STATUS.DIR bit is one, indicating an I<sup>2</sup>C master read operation. The SCL line is forced low, stretching the bus clock. If an ACK is sent, I<sup>2</sup>C slave hardware will set the Data Ready bit in the Interrupt Flag register (INTFLAG.DRDY), indicating data are needed for transmit. If not acknowledge is sent, the I<sup>2</sup>C slave will wait for a new start condition and address match.

Typically, software will immediately acknowledge the address packet by sending an ACK/NACK bit. The I<sup>2</sup>C slave command CTRLB.CMD = 3 can be used for both read and write operation as the command execution is dependent on the STATUS.DIR bit.

Writing a one to INTFLAG.AMATCH will also cause an ACK/NACK to be sent corresponding to the CTRLB.ACKACT bit.

#### Case 2: Address packet accepted – Write flag set

The STATUS.DIR bit is cleared, indicating an I<sup>2</sup>C master write operation. The SCL line is forced low, stretching the bus clock. If an ACK is sent, the I<sup>2</sup>C slave will wait for data to be received. Data, repeated start or stop can be received.

If not acknowledge is sent, the I<sup>2</sup>C slave will wait for a new start condition and address match.

Typically, software will immediately acknowledge the address packet by sending an ACK/NACK bit. The I<sup>2</sup>C slave command CTRLB.CMD = 3 can be used for both read and write operation as the command execution is dependent on STATUS.DIR.

Writing a one to INTFLAG.AMATCH will also cause an ACK/NACK to be sent corresponding to the CTRLB.ACKACT bit.

### Receiving Address Packets (SCLSM=1)

When SCLSM is one, the I<sup>2</sup>C slave only stretches the SCL line after an acknowledge according to [Figure 33-11](#). When the I<sup>2</sup>C slave is properly configured, it will wait for a start condition to be detected. When a start condition is detected, the successive address packet will be received and checked by the address match logic. If the received address is not a match, the packet is rejected and the I<sup>2</sup>C slave waits for a new start condition. If the address matches, the acknowledge action (CTRLB.ACKACT) is automatically sent and the Address Match bit in the Interrupt Flag register (INTFLAG.AMATCH) is set. SCL will be stretched until the I<sup>2</sup>C slave clears INTFLAG.AMATCH. Because the I<sup>2</sup>C slave holds the clock by forcing SCL low, the software is given unlimited time to respond to the address.

The direction of a transaction is determined by reading the Read / Write Direction bit in the Status register (STATUS.DIR), and the bit will be updated only when a valid address packet is received.

If the Transmit Collision bit in the Status register (STATUS.COLL) is set, this indicates that the last packet addressed to the I<sup>2</sup>C slave had a packet collision. A collision causes the SDA and SCL lines to be released without any notification to software. The next AMATCH interrupt is, therefore, the first indication of the previous packet's collision. Collisions are intended to follow the SMBus Address Resolution Protocol (ARP).

After the address packet has been received from the I<sup>2</sup>C master, a one can be written to INTFLAG.AMATCH to clear it.

### Receiving and Transmitting Data Packets (SCLSM=0)

After the I<sup>2</sup>C slave has received an address packet, it will respond according to the direction either by waiting for the data packet to be received or by starting to send a data packet by writing to DATA.DATA. When a data packet is received or sent, INTFLAG.DRDY will be set. Then, if the I<sup>2</sup>C slave was receiving data, it will send an acknowledge according to CTRLB.ACKACT.

#### Case 1: Data received

INTFLAG.DRDY is set, and SCL is held low pending SW interaction.

#### Case 2: Data sent

When a byte transmission is successfully completed, the INTFLAG.DRDY interrupt flag is set. If NACK is received, the I<sup>2</sup>C slave must expect a stop or a repeated start to be received. The I<sup>2</sup>C slave must release the data line to allow the I<sup>2</sup>C master to generate a stop or repeated start.

Upon stop detection, the Stop Received bit in the Interrupt Flag register (INTFLAG.PREC) will be set and the I<sup>2</sup>C slave will return to the idle state.

## High Speed Mode

When the I<sup>2</sup>C slave is configured in High-speed mode (CTRLA.SPEED=0x2) with SCLSM set to one, switching between Full-speed and High-speed modes is automatic. When the slave recognizes a START followed by a master code transmission and a NACK, it automatically switches to High-speed mode and sets the High-speed status bit (STATUS.HS). The slave will then remain in High-speed mode until a STOP is received.

## 10-Bit Addressing

When 10-bit addressing is enabled (ADDR.TENBITEN=1) the two address bytes following a START will be checked against the 10-bit slave address recognition. The first byte of the address will always be acknowledged and the second byte will raise the address interrupt flag as shown in [Figure 33-12](#).

If the transaction is a write, then the 10-bit address will be followed by N data bytes.

If the operation is a read, the 10-bit address will be followed by a repeated START and reception of “11110 ADDR[9:8] 1” and the second address interrupt will be received with the DIR bit set. The slave matches on the second address as it remembers that it was addressed by the previous 10-bit address.

**Figure 33-12.10-bit Addressing**

## PMBus Group Command

When the group command bit is set (CTRLB.GCMD) and 7-bit addressing is used, a STOP interrupt will be generated if the slave has been addressed since the last STOP condition.

The group command protocol is used to send commands to more than one device. The commands are sent in one continuous transmission with a single STOP condition at the end. When the STOP condition is detected by the slaves addressed during the group command, they all begin executing the command they received.

Figure 33-13 shows an example where this slave is addressed by ADDRESS 1. This slave is addressed after a repeated START condition. There can be multiple slaves addressed before and after, then at the end of the group command, a single STOP is generated by the master. At this point a STOP interrupt is asserted.

**Figure 33-13.PMBus Group Command Example**

## 33.6.3 Additional Features

### 33.6.3.1 SMBus

The I<sup>2</sup>C hardware incorporates three hardware SCL low time-outs which allows a time-out to occur for SMBus SCL low time-out, master extend time-out, and slave extend time-out. These time-outs are driven by the GCLK\_SERCOM\_SLOW clock. The GCLK\_SERCOM\_SLOW clock is used to accurately time the time-out and must be configured to used a 32kHz oscillator. The I<sup>2</sup>C interface also allows for an SMBus compatible SDA hold time.

- T<sub>TIMEOUT</sub>: SCL low time of 25-35 ms. – Measured for a single SCL low period. Enabled by bit CTRLA.LOWTOUTEN.

- $T_{\text{LOW:SEXT}}$ : Cumulative clock low extend time of 25 ms – Measured as the cumulative SCL low extend time by a slave device in a single message from the initial START to the STOP. Enabled by bit CTRLA.SEXTTOEN.
- $T_{\text{LOW:MEXT}}$ : Cumulative clock low extend time of 10 ms. – Measured as the cumulative SCL low extend time by the master device within a single byte from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. Enabled by bit (CTRLA.MEXTTOEN).

### 33.6.3.2 Smart Mode

The I<sup>2</sup>C interface incorporates a special smart mode that simplifies application code and minimizes the user interaction needed to keep hold of the I<sup>2</sup>C protocol. The smart mode accomplishes this by letting the reading of DATA.DATA automatically issue an ACK or NACK based on the state of CTRLB.ACKACT.

### 33.6.3.3 4-Wire Mode

Setting the Pin Usage bit in the Control A register (CTRLA.PINOUT) for master or slave to 4-wire mode enables operation as shown in Figure 33-14. In this mode, the internal I<sup>2</sup>C tri-state drivers are bypassed, and an external, I<sup>2</sup>C-compliant tri-state driver is needed when connecting to an I<sup>2</sup>C bus.

Figure 33-14. I<sup>2</sup>C Pad Interface

### 33.6.3.4 Quick Command

Setting the Quick Command Enable bit in the Control B register (CTRLB.QCEN) enables quick command. When quick command is enabled, the corresponding interrupt flag is set immediately after the slave acknowledges the address. At this point, the software can either issue a stop command or a repeated start by writing CTRLB.CMD or ADDR.ADDR.

### 33.6.4 DMA, Interrupts and Events

**Table 33-1. Module Request for SERCOM I<sup>2</sup>C Slave**

| Condition                                      | Interrupt request | Event output | Event input | DMA request | DMA request is cleared |
|--|-------------------|--------------|-------------|-------------|------------------------|
| Data Ready                                     | x                 |              |             |             |                        |
| Data received (Slave receive mode)             |                   |              |             | x           | when data is read      |
| Data needed for transmit (Slave transmit mode) |                   |              |             | x           | when data is written   |
| Address Match                                  | x                 |              |             |             |                        |
| Stop received                                  | x                 |              |             |             |                        |
| Error  | x                 |              |             |             |                        |

**Table 33-2. Module Request for SERCOM I<sup>2</sup>C Master**

| Condition                                       | Interrupt request | Event output | Event input | DMA request | DMA request is cleared |
|---|-------------------|--------------|-------------|-------------|------------------------|
| Master on Bus                                   | x                 |              |             |             |                        |
| Slave on Bus                                    | x                 |              |             |             |                        |
| Data received (Master receive mode)             |                   |              |             | x           | when data is read      |
| Data needed for transmit (Master transmit mode) |                   |              |             | x           | when data is written   |
| Error   | x                 |              |             |             |                        |

#### 33.6.4.1 DMA Operation

Smart mode (CTRLB.SMEN) must be enabled for DMA operation.

##### Slave DMA

When using the I<sup>2</sup>C slave with DMA, an address match will cause the address interrupt flag (INTFLAG.ADDRMATCH) to be raised. After the interrupt has been serviced, data transfer will be performed through DMA.

The I<sup>2</sup>C slave generates the following requests:

- Write data received (RX): The request is set when master write data is received. The request is cleared when DATA is read.
- Read data needed for transmit (TX): The request is set when data is needed for a master read operation. The request is cleared when DATA is written.

##### Master DMA

When using the I<sup>2</sup>C master with DMA, the ADDR register must be written with the desired address (ADDR.ADDR), transaction length (ADDR.LEN), and transaction length enable (ADDR.LENEN). When ADDR.LENEN is written to 1

along with ADDR.ADDR, ADDR.LEN determines the number of data bytes in the transaction from 0 to 255. DMA is then used to transfer ADDR.LEN bytes followed by an automatically generated NACK (for master reads) and a STOP.

If a NACK is received by the slave for a master write transaction before ADDR.LEN bytes, a STOP will be automatically generated and the length error (STATUS.LENERR) will be raised along with the INTFLAG.ERROR interrupt.

The I<sup>2</sup>C master generates the following requests:

- Read data received (RX): The request is set when master read data is received. The request is cleared when DATA is read.
- Write data needed for transmit (TX): The request is set when data is needed for a master write operation. The request is cleared when DATA is written.

#### 33.6.4.2 Interrupts

The I<sup>2</sup>C slave has the following interrupt sources:

- Error
- Data Ready
- Address Match
- Stop Received

The I<sup>2</sup>C master has the following interrupt sources:

- Error
- Slave on Bus
- Master on Bus

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the I<sup>2</sup>C is reset. See [INTFLAG](#) for details on how to clear interrupt flags.

The I<sup>2</sup>C has one common interrupt request line for all the interrupt sources. The user must read INTFLAG to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

#### 33.6.4.3 Events

Not applicable.

#### 33.6.5 Sleep Mode Operation

During I<sup>2</sup>C master operation, the generic clock (GCLK\_SERCOMx\_CORE) will continue to run in idle sleep mode. If the Run In Standby bit in the Control A register (CTRLA.RUNSTDBY) is one, the GLK\_SERCOMx\_CORE will also run in standby sleep mode. Any interrupt can wake up the device.

If CTRLA.RUNSTDBY is zero during I<sup>2</sup>C master operation, the GLK\_SERCOMx\_CORE will be disabled when an ongoing transaction is finished. Any interrupt can wake up the device.

During I<sup>2</sup>C slave operation, writing a one to CTRLA.RUNSTDBY will allow the Address Match interrupt to wake up the device.

In I<sup>2</sup>C slave operation, all receptions will be dropped when CTRLA.RUNSTDBY is zero.

#### 33.6.6 Synchronization

Due to the asynchronicity between CLK\_SERCOMx\_APB and GCLK\_SERCOMx\_CORE, some registers must be synchronized when accessed. A register can require:

- Synchronization when written

- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding Synchronization Busy bit in the Synchronization register (SYNCBUSY) will be set immediately, and cleared when synchronization is complete.

If an operation that requires synchronization is executed while the corresponding SYNCBUSY bit is one, a peripheral bus error is generated.

The following bits need synchronization when written:

- Software Reset bit in the Control A register (CTRLA.SWRST). SYNCBUSY.SWRST is set to one while synchronization is in progress.
- Enable bit in the Control A register (CTRLA.ENABLE). SYNCBUSY.ENABLE is set to one while synchronization is in progress.
- Write to Bus State bits in the Status register (STATUS.BUSSTATE). SYNCBUSY.SYSOP is set to one while synchronization is in progress.
- Address bits in the Address register (ADDR.ADDR) when in master operation. SYNCBUSY.SYSOP is set to one while synchronization is in progress.
- Data (DATA) when in master operation. SYNCBUSY.SYSOP is set to one while synchronization is in progress.

Write-synchronization is denoted by the Write-Synchronized property in the register description.

## 33.7 Register Summary

**Table 33-3. Register Summary – Slave Mode**

| Offset | Name     | Bit Pos. |            |         |              |               |       |        |            |        |
|--------|----------|----------|------------|---------|--------------|---------------|-------|--------|------------|--------|
| 0x00   | CTRLA    | 7:0      | RUNSTDBY   |         |              | MODE[2:0]=100 |       |        | ENABLE     | SWRST  |
| 0x01   |          | 15:8     |            |         |              |               |       |        |            |        |

## 33.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 577](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 593](#) for details.

Some registers are enable-protected, meaning they can only be written when the I<sup>2</sup>C is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

## 33.8.1 I<sup>2</sup>C Slave Register Description

### 33.8.1.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

| Bit    | 31       | 30      | 29           | 28            | 27    | 26  | 25         | 24     |
|--------|----------|---------|--------------|---------------|-------|-----|------------|--------|
|        |          | LOWTOUT |              |               | SCLSM |     | SPEED[1:0] |        |
| Access | R        | R/W     | R            | R             | R/W   | R   | R/W        | R/W    |
| Reset  | 0        | 0       | 0            | 0             | 0     | 0   | 0          | 0      |
| Bit    | 23       | 22      | 21           | 20            | 19    | 18  | 17         | 16     |
|        | SEXTTOEN |         | SDAHOLD[1:0] |               |       |     |            | PINOUT |
| Access | R/W      | R       | R/W          | R/W           | R     | R   | R          | R/W    |
| Reset  | 0        | 0       | 0            | 0             | 0     | 0   | 0          | 0      |
| Bit    | 15       | 14      | 13           | 12            | 11    | 10  | 9          | 8      |
|        |          |         |              |               |       |     |            |        |
| Access | R        | R       | R            | R             | R     | R   | R          | R      |
| Reset  | 0        | 0       | 0            | 0             | 0     | 0   | 0          | 0      |
| Bit    | 7        | 6       | 5            | 4             | 3     | 2   | 1          | 0      |
|        | RUNSTDBY |         |              | MODE[2:0]=100 |       |     | ENABLE     | SWRST  |
| Access | R/W      | R       | R            | R/W           | R/W   | R/W | R/W        | R/W    |
| Reset  | 0        | 0       | 0            | 0             | 0     | 0   | 0          | 0      |

- **Bit 31 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 30 – LOWTOUT: SCL Low Time-Out**

This bit enables the SCL low time-out. If SCL is held low for 25ms-35ms, the slave will release its clock hold, if enabled, and reset the internal state machine. Any interrupts set at the time of time-out will remain set.

0: Time-out disabled.

1: Time-out enabled.

- **Bits 29:28 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 27– SCLSM: SCL Clock Stretch Mode**

This bit controls when SCL will be stretch for software interaction.

0: SCL stretch according to [Figure 33-7](#)

1: SCL stretch only after ACK bit according to [Figure 33-10](#).

This bit is not synchronized.

- **Bit 26– Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 25:24 – SPEED[1:0]: Transfer Speed**

These bits define bus speed.

**Table 33-5. Transfer Speed**

| Value | Description   |
|-------|---|
| 0x0   | Standard-mode (Sm) up to 100 kHz and Fast-mode (Fm) up to 400 kHz |
| 0x1   | Fast-mode Plus (Fm+) up to 1 MHz                                  |
| 0x2   | High-speed mode (Hs-mode) up to 3.4 MHz                           |
| 0x3   | Reserved  |

These bits are not synchronized.

- **Bit 23 – SEXTTOEN: Slave SCL Low Extend Time-Out**

This bit enables the slave SCL low extend time-out. If SCL is cumulatively held low for greater than 25ms from the initial START to a STOP, the slave will release its clock hold if enabled and reset the internal state machine. Any interrupts set at the time of time-out will remain set. If the address was recognized, PREC will be set when a STOP is received.

0: Time-out disabled

1: Time-out enabled

This bit is not synchronized.

- **Bit 22 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 21:20 – SDAHOLD[1:0]: SDA Hold Time**

These bits define the SDA hold time with respect to the negative edge of SCL.

**Table 33-6. SDA Hold Time**

| Value | Name | Description         |
|-------|------|---------------------|
| 0x0   | DIS  | Disabled            |
| 0x1   | 75   | 50-100ns hold time  |
| 0x2   | 450  | 300-600ns hold time |
| 0x3   | 600  | 400-800ns hold time |

These bits are not synchronized.

- **Bits 19:17 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 16 – PINOUT: Pin Usage**  
 This bit sets the pin usage to either two- or four-wire operation:  
 0: 4-wire operation disabled  
 1: 4-wire operation enabled  
 This bit is not synchronized.
- **Bits 15:8 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 7 – RUNSTDBY: Run in Standby**  
 This bit defines the functionality in standby sleep mode.  
 0: Disabled – All reception is dropped.  
 1: Wake on address match, if enabled.  
 This bit is not synchronized.
- **Bits 6:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 4:2 – MODE[2:0]: Operating Mode**  
 These bits must be written to 0x04 to select the I<sup>2</sup>C slave serial communication interface of the SERCOM.  
 These bits are not synchronized.
- **Bit 1 – ENABLE: Enable**  
 0: The peripheral is disabled.  
 1: The peripheral is enabled.  
 Due to synchronization, there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Synchronization Enable Busy bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.  
 This bit is not enable-protected.
- **Bit 0 – SWRST: Software Reset**  
 0: There is no reset operation ongoing.  
 1: The reset operation is ongoing.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit resets all registers in the SERCOM, except DBGCTRL, to their initial state, and the SERCOM will be disabled.  
 Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded. Any register write access during the ongoing reset will result in an APB error. Reading any register will return the reset value of the register.  
 Due to synchronization, there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.  
 This bit is not enable-protected.

### 33.8.1.2 Control B

**Name:** CTRLB

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

| Reset  | 0          | 0   | 0  | 0  | 0  | 0      | 0        | 0    |

- **Bits 31:19 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 18 – ACKACT: Acknowledge Action**

0: Send ACK

1: Send NACK

The Acknowledge Action (ACKACT) bit defines the slave's acknowledge behavior after an address or data byte is received from the master. The acknowledge action is executed when a command is written to the CMD bits. If smart mode is enabled (CTRLB.SMEN is one), the acknowledge action is performed when the DATA register is read.

This bit is not enable-protected.

- **Bits 17:16 – CMD[1:0]: Command**

Writing the Command bits (CMD) triggers the slave operation as defined in [Table 33-7](#). The CMD bits are strobe bits, and always read as zero. The operation is dependent on the slave interrupt flags, INTFLAG.DRDY and INTFLAG.AMATCH, in addition to STATUS.DIR (See [Table 33-7](#)).

Interrupt flags INTFLAG.DRDY, INTFLAG.AMATCH and INTFLAG.PREC are automatically cleared when a command is given.

This bit is not enable-protected.

**Table 33-7. Command Description**

| CMD[1:0] | DIR   | Action   |
|----------|---|--|
| 0x0      | X   | (No action)  |
| 0x1      | X   | (Reserved)   |
| 0x2      | Used to complete a transaction in response to a data interrupt (DRDY) |  |
|          | 0 (Master write)  | Execute acknowledge action succeeded by waiting for any start (S/Sr) condition |
|          | 1 (Master read)   | Wait for any start (S/Sr) condition  |
| 0x3      | Used in response to an address interrupt (AMATCH)                     |  |
|          | 0 (Master write)  | Execute acknowledge action succeeded by reception of next byte                 |
|          | 1 (Master read)   | Execute acknowledge action succeeded by slave data interrupt                   |
|          | Used in response to a data interrupt (DRDY)                           |  |
|          | 0 (Master write)  | Execute acknowledge action succeeded by reception of next byte                 |
|          | 1 (Master read)   | Execute a byte read operation followed by ACK/NACK reception                   |

- **Bits 15:14 – AMODE[1:0]: Address Mode**

These bits set the addressing mode according to [Table 33-8](#).

**Table 33-8. Address Mode Description**

| Value | Name    | Description   |
|-------|---------|---|
| 0x0   | MASK    | The slave responds to the address written in ADDR.ADDR masked by the value in ADDR.ADDRMASK <sup>(1)</sup> .                  |
| 0x1   | 2_ADDRS | The slave responds to the two unique addresses in ADDR.ADDR and ADDR.ADDRMASK.  |
| 0x2   | RANGE   | The slave responds to the range of addresses between and including ADDR.ADDR and ADDR.ADDRMASK. ADDR.ADDR is the upper limit. |
| 0x3   | -       | Reserved.   |

Note: 1. See “[SERCOM – Serial Communication Interface](#)” on [page 492](#) for additional information.

These bits are not write-synchronized.

- **Bits 13:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 10– AACKEN: Automatic Acknowledge Enable**

This bit enables the address to be automatically acknowledged if there is an address match.

0: Automatic acknowledge is disabled.

1: Automatic acknowledge is enabled.

This bit is not write-synchronized.

- **Bit 9 – GCMD: PMBus Group Command**

This bit enables PMBus group command support. When enabled, a STOP interrupt will be generated if the slave has been addressed since the last STOP condition on the bus.

0: Group command is disabled.

1: Group command is enabled.

This bit is not write-synchronized.

- **Bit 8 – SMEN: Smart Mode Enable**

This bit enables smart mode. When smart mode is enabled, acknowledge action is sent when DATA.DATA is read.

0: Smart mode is disabled.

1: Smart mode is enabled.

This bit is not write-synchronized.

- **Bits 7:0 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

### 33.8.1.3 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x14

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5 | 4 | 3 | 2    | 1      | 0    |
|--------|-------|---|---|---|---|------|--------|------|
|        | ERROR |   |   |   |   | DRDY | AMATCH | PREC |
| Access | R/W   | R | R | R | R | R/W  | R/W    | R/W  |
| Reset  | 0     | 0 | 0 | 0 | 0 | 0    | 0      | 0    |

- **Bit 7– ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Error Interrupt Enable bit, which disables the Error interrupt.

- **Bits 6:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – DRDY: Data Ready Interrupt Enable**

0: The Data Ready interrupt is disabled.

1: The Data Ready interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Data Ready bit, which disables the Data Ready interrupt.

- **Bit 1 – AMATCH: Address Match Interrupt Enable**

0: The Address Match interrupt is disabled.

1: The Address Match interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Address Match Interrupt Enable bit, which disables the Address Match interrupt.

- **Bit 0 – PREC: Stop Received Interrupt Enable**

0: The Stop Received interrupt is disabled.

1: The Stop Received interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Stop Received bit, which disables the Stop Received interrupt.

### 33.8.1.4 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x16

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5 | 4 | 3 | 2    | 1      | 0    |
|--------|-------|---|---|---|---|------|--------|------|
|        | ERROR |   |   |   |   | DRDY | AMATCH | PREC |
| Access | R/W   | R | R | R | R | R/W  | R/W    | R/W  |
| Reset  | 0     | 0 | 0 | 0 | 0 | 0    | 0      | 0    |

- **Bit 7 – ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Error Interrupt Enable bit, which enables the Error interrupt.

- **Bits 6:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – DRDY: Data Ready Interrupt Enable**

0: The Data Ready interrupt is disabled.

1: The Data Ready interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Data Ready bit, which enables the Data Ready interrupt.

- **Bit 1 – AMATCH: Address Match Interrupt Enable**

0: The Address Match interrupt is disabled.

1: The Address Match interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Address Match Interrupt Enable bit, which enables the Address Match interrupt.

- **Bit 0 – PREC: Stop Received Interrupt Enable**

0: The Stop Received interrupt is disabled.

1: The Stop Received interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Stop Received bit, which enables the Stop Received interrupt.

### 33.8.1.5 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x18

**Reset:** 0x00

**Property:** -

| Bit    | 7     | 6 | 5 | 4 | 3 | 2    | 1      | 0    |
|--------|-------|---|---|---|---|------|--------|------|
|        | ERROR |   |   |   |   | DRDY | AMATCH | PREC |
| Access | R/W   | R | R | R | R | R/W  | R/W    | R/W  |
| Reset  | 0     | 0 | 0 | 0 | 0 | 0    | 0      | 0    |

- **Bit 7– ERROR: Error**

This flag is cleared by writing a one to it.

This bit is set when any error is detected. Errors that will set this flag have corresponding status flags in the STATUS register. Errors that will set this flag are SEXTTOUT, LOWTOUT, COLL, and BUSERR. Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bits 6:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – DRDY: Data Ready**

This flag is set when a I<sup>2</sup>C slave byte transmission is successfully completed.

The flag is cleared by hardware when either:

- Writing to the DATA register.
- Reading the DATA register with smart mode enabled.
- Writing a valid command to the CMD register.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Data Ready interrupt flag. Optionally, the flag can be cleared manually by writing a one to INTFLAG.DRDY.

- **Bit 1 – AMATCH: Address Match**

This flag is set when the I<sup>2</sup>C slave address match logic detects that a valid address has been received.

The flag is cleared by hardware when CTRL.CMD is written.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Address Match interrupt flag. Optionally the flag can be cleared manually by writing a one to INTFLAG.AMATCH. When cleared, an ACK/NACK will be sent according to CTRLB.ACKACT.

- **Bit 0 – PREC: Stop Received**

This flag is set when a stop condition is detected for a transaction being processed. A stop condition detected between a bus master and another slave will not set this flag.

This flag is cleared by hardware after a command is issued on the next address match.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Stop Received interrupt flag. Optionally, the flag can be cleared manually by writing a one to INTFLAG.PREC.

### 33.8.1.6 Status

**Name:** STATUS

**Offset:** 0x1A

**Reset:** 0x0000

**Property:** -

| Bit    | 15 | 14 | 13 | 12 | 11 | 10  | 9        | 8 |
|--------|----|----|----|----|----|-----|----------|---|
|        |    |    |    |    |    | HS  | SEXTTOUT |   |
| Access | R  | R  | R  | R  | R  | R/W | R/W      | R |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0   | 0        | 0 |

| Bit    | 7       | 6       | 5 | 4  | 3   | 2      | 1    | 0      |
|--------|---------|---------|---|----|-----|--------|------|--------|
|        | CLKHOLD | LOWTOUT |   | SR | DIR | RXNACK | COLL | BUSERR |
| Access | R       | R/W     | R | R  | R   | R      | R/W  | R/W    |
| Reset  | 0       | 0       | 0 | 0  | 0   | 0      | 0    | 0      |

- Bits 15:11 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 10 – HS: High-speed**  
 This bit is set if the slave detects a START followed by a Master Code transmission.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the status. However, this flag is automatically cleared when a STOP is received.
- Bit 9 – SEXTTOUT: Slave SCL Low Extend Time-Out**  
 This bit is set if a slave SCL low extend time-out occurs.  
 This bit is cleared automatically if responding to a new start condition with ACK or NACK (write 3 to CTRLB.CMD) or when INTFLAG.AMATCH is cleared.  
 0: No SCL low extend time-out has occurred.  
 1: SCL low extend time-out has occurred.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the status.
- Bit 8 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 7 – CLKHOLD: Clock Hold**  
 The slave Clock Hold bit (STATUS.CLKHOLD) is set when the slave is holding the SCL line low, stretching the I<sup>2</sup>C clock. Software should consider this bit a read-only status flag that is set when INTFLAG.DRDY or INTFLAG.AMATCH is set.  
 This bit is automatically cleared when the corresponding interrupt is also cleared.
- Bit 6 – LOWTOUT: SCL Low Time-out**  
 This bit is set if an SCL low time-out occurs.  
 This bit is cleared automatically if responding to a new start condition with ACK or NACK (write 3 to CTRLB.CMD) or when INTFLAG.AMATCH is cleared.

0: No SCL low time-out has occurred.

1: SCL low time-out has occurred.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the status.

- **Bit 5 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 4 – SR: Repeated Start**

When INTFLAG.AMATCH is raised due to an address match, SR indicates a repeated start or start condition.

0: Start condition on last address match

1: Repeated start condition on last address match

This flag is only valid while the INTFLAG.AMATCH flag is one.

- **Bit 3 – DIR: Read / Write Direction**

The Read/Write Direction (STATUS.DIR) bit stores the direction of the last address packet received from a master.

0: Master write operation is in progress.

1: Master read operation is in progress.

- **Bit 2 – RXNACK: Received Not Acknowledge**

This bit indicates whether the last data packet sent was acknowledged or not.

0: Master responded with ACK.

1: Master responded with NACK.

- **Bit 1 – COLL: Transmit Collision**

If set, the I<sup>2</sup>C slave was not able to transmit a high data or NACK bit, the I<sup>2</sup>C slave will immediately release the SDA and SCL lines and wait for the next packet addressed to it.

This flag is intended for the SMBus address resolution protocol (ARP). A detected collision in non-ARP situations indicates that there has been a protocol violation, and should be treated as a bus error.

Note that this status will not trigger any interrupt, and should be checked by software to verify that the data were sent correctly. This bit is cleared automatically if responding to an address match with an ACK or a NACK (writing 0x3 to CTRLB.CMD), or INTFLAG.AMATCH is cleared.

0: No collision detected on last data byte sent.

1: Collision detected on last data byte sent.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the status.

- **Bit 0 – BUSERR: Bus Error**

The Bus Error bit (STATUS.BUSERR) indicates that an illegal bus condition has occurred on the bus, regardless of bus ownership. An illegal bus condition is detected if a protocol violating start, repeated start or stop is detected on the I<sup>2</sup>C bus lines. A start condition directly followed by a stop condition is one example of a protocol violation. If a time-out occurs during a frame, this is also considered a protocol violation, and will set STATUS.BUSERR.

This bit is cleared automatically if responding to an address match with an ACK or a NACK (writing 0x3 to CTRLB.CMD) or INTFLAG.AMATCH is cleared.

0: No bus error detected.

1: Bus error detected.

Writing a one to this bit will clear the status.

Writing a zero to this bit has no effect.

### 33.8.1.7 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x1C

**Reset:** 0x00000000

**Property:**

|        |    |    |    |    |    |    |        |       |
|--------|----|----|----|----|----|----|--------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25     | 24    |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18 | 17     | 16    |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10 | 9      | 8     |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2  | 1      | 0     |
|        |    |    |    |    |    |    | ENABLE | SWRST |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |

- **Bits 31:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: SERCOM Enable Synchronization Busy**

Enabling and disabling the SERCOM (CTRLA.ENABLE) requires synchronization. When written, the SYNCBUSY.ENABLE bit will be set until synchronization is complete.

Writes to any register (except for CTRLA.SWRST) while enable synchronization is on-going will be discarded and an APB error will be generated.

0: Enable synchronization is not busy.

1: Enable synchronization is busy.

- **Bit 0 – SWRST: Software Reset Synchronization Busy**

Resetting the SERCOM (CTRLA.SWRST) requires synchronization. When written, the SYNCBUSY.SWRST bit will be set until synchronization is complete.

Writes to any register while synchronization is on-going will be discarded and an APB error will be generated.

0: SWRST synchronization is not busy.

1: SWRST synchronization is busy.

### 33.8.1.8 Address

**Name:** ADDR

**Offset:** 0x24

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected

|        |               |     |     |     |     |               |     |        |

| Reset  | 0             | 0   | 0   | 0   | 0   | 0             | 0   | 0      |

- **Bits 31:27 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 26:17 – ADDRMASK[9:0]: Address Mask**

The ADDRMASK bits acts as a second address match register, an address mask register or the lower limit of an address range, depending on the CTRLB.AMODE setting.

- **Bit 16– Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 15– TENBITEN: Ten Bit Addressing Enable**

Writing a one to TENBITEN enables 10-bit address recognition.

0: 10-bit address recognition disabled.

1: 10-bit address recognition enabled.

- **Bits 14:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 10:1 – ADDR[9:0]: Address**

The slave address (ADDR) bits contain the I<sup>2</sup>C slave address used by the slave address match logic to determine if a master has addressed the slave.

When using 7-bit addressing, the slave address is represented by ADDR.ADDR[6:0].

When using 10-bit addressing (ADDR.TENBITEN=1), the slave address is represented by ADDR.ADDR[9:0]

When the address match logic detects a match, INTFLAG.AMATCH is set and STATUS.DIR is updated to indicate whether it is a read or a write transaction.
- **Bit 0 – GENCEN: General Call Address Enable**

Writing a one to GENCEN enables general call address recognition. A general call address is an address of all zeroes with the direction bit written to zero (master write).

0: General call address recognition disabled.

1: General call address recognition enabled.

### 33.8.1.9 Data

**Name:** DATA

**Offset:** 0x28

**Reset:** 0x0000

**Property:** Write-Synchronized, Read-Synchronized

|        |           |     |     |     |     |     |     |     |
|--------|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        |           |     |     |     |     |     |     |     |
| Access | R         | R   | R   | R   | R   | R   | R   | R   |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | DATA[7:0] |     |     |     |     |     |     |     |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 7:0 – DATA[7:0]: Data**

The slave data register I/O location (DATA.DATA) provides access to the master transmit and receive data buffers. Reading valid data or writing data to be transmitted can be successfully done only when SCL is held low by the slave (STATUS.CLKHOLD is set). An exception occurs when reading the last data byte after the stop condition has been received.

Accessing DATA.DATA auto-triggers I<sup>2</sup>C bus operations. The operation performed depends on the state of CTRLB.ACKACT, CTRLB.SMEN and the type of access (read/write).

Writing or reading DATA.DATA when not in smart mode does not require synchronization.

## 33.8.2 I<sup>2</sup>C Master Register Description

### 33.8.2.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

|        |          |          |               |               |       |     |            |        |
|--------|----------|----------|---------------|---------------|-------|-----|------------|--------|
| Bit    | 31       | 30       | 29            | 28            | 27    | 26  | 25         | 24     |
|        |          | LOWTOUT  | INACTOUT[1:0] |               | SCLSM |     | SPEED[1:0] |        |
| Access | R        | R/W      | R/W           | R/W           | R/W   | R   | R/W        | R/W    |
| Reset  | 0        | 0        | 0             | 0             | 0     | 0   | 0          | 0      |
| Bit    | 23       | 22       | 21            | 20            | 19    | 18  | 17         | 16     |
|        | SEXTTOEN | MEXTTOEN | SDAHOLD[1:0]  |               |       |     |            | PINOUT |
| Access | R/W      | R/W      | R/W           | R/W           | R     | R   | R          | R/W    |
| Reset  | 0        | 0        | 0             | 0             | 0     | 0   | 0          | 0      |
| Bit    | 15       | 14       | 13            | 12            | 11    | 10  | 9          | 8      |
|        |          |          |               |               |       |     |            |        |
| Access | R        | R        | R             | R             | R     | R   | R          | R      |
| Reset  | 0        | 0        | 0             | 0             | 0     | 0   | 0          | 0      |
| Bit    | 7        | 6        | 5             | 4             | 3     | 2   | 1          | 0      |
|        | RUNSTDBY |          |               | MODE[2:0]=101 |       |     | ENABLE     | SWRST  |
| Access | R/W      | R        | R             | R/W           | R/W   | R/W | R/W        | R/W    |
| Reset  | 0        | 0        | 0             | 0             | 0     | 0   | 0          | 0      |

- **Bit 31 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 30 – LOWTOUT: SCL Low Time-Out**

This bit enables the SCL low time-out. If SCL is held low for 25ms-35ms, the master will release its clock hold, if enabled, and complete the current transaction. A stop condition will automatically be transmitted.

INTFLAG.SB or INTFLAG.MB will be set as normal, but the clock hold will be released. The STATUS.LOWTOUT and STATUS.BUSERR status bits will be set.

0: Time-out disabled.

1: Time-out enabled.

This bit is not synchronized.

- **Bits 29:28 – INACTOUT[1:0]: Inactive Time-Out**

If the inactive bus time-out is enabled and the bus is inactive for longer than the time-out setting, the bus state logic will be set to idle. An inactive bus arise when either an I<sup>2</sup>C master or slave is holding the SCL low. The available time-outs are given in [Table 33-9](#).

Enabling this option is necessary for SMBus compatibility, but can also be used in a non-SMBus set-up.

**Table 33-9. Inactive Timeout**

| Value | Name  | Description                          |
|-------|-------|--------------------------------------|
| 0x0   | DIS   | Disabled                             |
| 0x1   | 55US  | 5-6 SCL cycle time-out (50-60µs)     |
| 0x2   | 105US | 10-11 SCL cycle time-out (100-110µs) |
| 0x3   | 205US | 20-21 SCL cycle time-out (200-210µs) |

Calculated time-out periods are based on a 100kHz baud rate.

These bits are not synchronized.

- **Bit 27– SCLSM: SCL Clock Stretch Mode**

This bit controls when SCL will be stretch for software interaction.

0: SCL stretch according to [Figure 33-7](#).

1: SCL stretch only after ACK bit.

This bit is not synchronized.

- **Bit 26– Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 25:24 – SPEED[1:0]: Transfer Speed**

These bits define bus speed.

**Table 33-10. Transfer Speed**

| Value | Description   |
|-------|---|
| 0x0   | Standard-mode (Sm) up to 100 kHz and Fast-mode (Fm) up to 400 kHz |
| 0x1   | Fast-mode Plus (Fm+) up to 1 MHz                                  |
| 0x2   | High-speed mode (Hs-mode) up to 3.4 MHz                           |
| 0x3   | Reserved  |

These bits are not synchronized.

- **Bit 23 – SEXTTOEN: Slave SCL Low Extend Time-Out**

This bit enables the slave SCL low extend time-out. If SCL is cumulatively held low for greater than 25ms from the initial START to a STOP, the slave will release its clock hold if enabled and reset the internal state machine. Any interrupts set at the time of time-out will remain set. If the address was recognized, PREC will be set when a STOP is received.

0: Time-out disabled

1: Time-out enabled

This bit is not synchronized.

- **Bit 22 – MEXTTOEN: Master SCL Low Extend Time-Out**

This bit enables the master SCL low extend time-out. If SCL is cumulatively held low for greater than 10ms from START-to-ACK, ACK-to-ACK, or ACK-to-STOP the master will release its clock hold if enabled, and complete the current transaction. A STOP will automatically be transmitted.

SB or MB will be set as normal, but CLKHOLD will be release. The MEXTTOUT and BUSERR status bits will be set.

0: Time-out disabled

1: Time-out enabled

This bit is not synchronized.

- **Bits 21:20 – SDAHOLD[1:0]: SDA Hold Time**

These bits define the SDA hold time with respect to the negative edge of SCL.

**Table 33-11. SDA Hold Time**

| Value | Name  | Description         |
|-------|-------|---------------------|
| 0x0   | DIS   | Disabled            |
| 0x1   | 75NS  | 50-100ns hold time  |
| 0x2   | 450NS | 300-600ns hold time |
| 0x3   | 600NS | 400-800ns hold time |

These bits are not synchronized.

- **Bits 19:17 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 16 – PINOUT: Pin Usage**

This bit set the pin usage to either two- or four-wire operation:

0: 4-wire operation disabled.

1: 4-wire operation enabled.

This bit is not synchronized.

- **Bits 15:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 7 – RUNSTDBY: Run in Standby**

This bit defines the functionality in standby sleep mode.

0: GCLK\_SERCOMx\_CORE is disabled and the I<sup>2</sup>C master will not operate in standby sleep mode.

1: GCLK\_SERCOMx\_CORE is enabled in all sleep modes allowing the master to operate in standby sleep mode.

This bit is not synchronized.

- **Bits 6:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 4:2 – MODE[2:0]: Operating Mode**

These bits must be written to 0x5 to select the I<sup>2</sup>C master serial communication interface of the SERCOM.

These bits are not synchronized.

- **Bit 1 – ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Due to synchronization, there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the Enable bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

This bit is not enable-protected.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the SERCOM, except DBGCTRL, to their initial state, and the SERCOM will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded. Any register write access during the ongoing reset will result in an APB error. Reading any register will return the reset value of the register.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

This bit is not enable-protected.

### 33.8.2.2 Control B

**Name:** CTRLB

**Offset:** 0x04

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected, Write-Synchronized

|        |    |    |    |    |    |        |          |      |
|--------|----|----|----|----|----|--------|----------|------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26     | 25       | 24   |
|        |    |    |    |    |    |        |          |      |
| Access | R  | R  | R  | R  | R  | R      | R        | R    |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0      | 0        | 0    |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18     | 17       | 16   |
|        |    |    |    |    |    | ACKACT | CMD[1:0] |      |
| Access | R  | R  | R  | R  | R  | R/W    | R/W      | R/W  |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0      | 0        | 0    |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10     | 9        | 8    |
|        |    |    |    |    |    |        | QCEN     | SMEN |
| Access | R  | R  | R  | R  | R  | R      | R        | R/W  |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0      | 0        | 0    |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2      | 1        | 0    |
|        |    |    |    |    |    |        |          |      |
| Access | R  | R  | R  | R  | R  | R      | R        | R    |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0      | 0        | 0    |

- **Bits 31:19 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 18 – ACKACT: Acknowledge Action**

The Acknowledge Action (ACKACT) bit defines the I<sup>2</sup>C master's acknowledge behavior after a data byte is received from the I<sup>2</sup>C slave. The acknowledge action is executed when a command is written to CTRLB.CMD, or if smart mode is enabled (CTRLB.SMEN is written to one), when DATA.DATA is read.

0: Send ACK.

1: Send NACK.

This bit is not enable-protected.

This bit is not write-synchronized.

- **Bits 17:16 – CMD[1:0]: Command**

Writing the Command bits (CMD) triggers the master operation as defined in [Table 33-12](#). The CMD bits are strobe bits, and always read as zero. The acknowledge action is only valid in master read mode. In master write mode, a command will only result in a repeated start or stop condition. The CTRLB.ACKACT bit and the CMD bits

can be written at the same time, and then the acknowledge action will be updated before the command is triggered.

Commands can only be issued when the Slave on Bus interrupt flag (INTFLAG.SB) or Master on Bus interrupt flag (INTFLAG.MB) is one.

If CMD 0x1 is issued, a repeated start will be issued followed by the transmission of the current address in ADDR.ADDR. If another address is desired, ADDR.ADDR must be written instead of the CMD bits. This will trigger a repeated start followed by transmission of the new address.

Issuing a command will set System Operation bit in the Synchronization Busy register (SYNCBUSY.SYSOP).

**Table 33-12. Command Description**

| CMD[1:0] | Direction | Action   |
|----------|-----------|--|
| 0x0      | X         | (No action)  |
| 0x1      | X         | Execute acknowledge action succeeded by repeated Start           |
| 0x2      | 0 (Write) | No operation   |
|          | 1 (Read)  | Execute acknowledge action succeeded by a byte read operation    |
| 0x3      | X         | Execute acknowledge action succeeded by issuing a stop condition |

These bits are not enable-protected.

- **Bits 15:10 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 9 – QCEN: Quick Command Enable**  
Setting the Quick Command Enable bit (QCEN) enables quick command.  
0: Quick Command is disabled.  
1: Quick Command is enabled.  
This bit is not write-synchronized.
- **Bit 8 – SMEN: Smart Mode Enable**  
This bit enables smart mode. When smart mode is enabled, acknowledge action is sent when DATA.DATA is read.  
0: Smart mode is disabled.  
1: Smart mode is enabled.  
This bit is not write-synchronized.
- **Bits 7:0 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

### 33.8.2.3 Baud Rate

**Name:** BAUD

**Offset:** 0x0C

**Reset:** 0x0000

**Property:** Write-Protected, Enable-Protected

|        |                |     |     |     |     |     |     |     |
|--------|----------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31             | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | HSBAUDLOW[7:0] |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23             | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | HSBAUD[7:0]    |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15             | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | BAUDLOW[7:0]   |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7              | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | BAUD[7:0]      |     |     |     |     |     |     |     |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 31:24 – HSBAUDLOW[7:0]: High Speed Master Baud Rate Low**  
**HSBAUDLOW not equal to 0**

HSBAUDLOW indicates the SCL low time according to the following formula.

$$HSBAUDLOW = f_{GCLK} T_{LOW} - 1$$

**HSBAUDLOW equal to 0**

The HSBAUD register is used to time  $T_{LOW}$ ,  $T_{HIGH}$ ,  $T_{SU;STO}$ ,  $T_{HD;STA}$  and  $T_{SU;STA}$ .  $T_{BUF}$  is timed by the BAUD register.

- **Bits 23:16 – HSBAUD[7:0]: High Speed Master Baud Rate**

The HSBAUD register indicates the SCL high time according to the following formula. When HSBAUDLOW is zero,  $T_{LOW}$ ,  $T_{HIGH}$ ,  $T_{SU;STO}$ ,  $T_{HD;STA}$  and  $T_{SU;STA}$  are derived using this formula.  $T_{BUF}$  is timed by the BAUD register.

$$BAUD = f_{GCLK} T_{HIGH} - 1$$

- **Bits 15:8 – BAUDLOW[7:0]: Master Baud Rate Low**

If the Master Baud Rate Low bit group (BAUDLOW) has a non-zero value, the SCL low time will be described by the value written.

For more information on how to calculate the frequency, see [“SERCOM I2C – SERCOM Inter-Integrated Circuit” on page 575](#).

- **Bits 7:0 – BAUD[7:0]: Master Baud Rate**

The Master Baud Rate bit group (BAUD) is used to derive the SCL high time if BAUD.BAUDLOW is non-zero. If BAUD.BAUDLOW is zero, BAUD will be used to generate both high and low periods of the SCL.

For more information on how to calculate the frequency, see [“SERCOM I2C – SERCOM Inter-Integrated Circuit” on page 575](#).

### 33.8.2.4 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x14

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5 | 4 | 3 | 2 | 1   | 0   |
|--------|-------|---|---|---|---|---|-----|-----|
|        | ERROR |   |   |   |   |   | SB  | MB  |
| Access | R/W   | R | R | R | R | R | R/W | R/W |
| Reset  | 0     | 0 | 0 | 0 | 0 | 0 | 0   | 0   |

- **Bit 7– ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Error Interrupt Enable bit, which disables the Error interrupt.

- **Bits 6:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – SB: Slave on Bus Interrupt Enable**

0: The Slave on Bus interrupt is disabled.

1: The Slave on Bus interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Slave on Bus Interrupt Enable bit, which disables the Slave on Bus interrupt.

- **Bit 0 – MB: Master on Bus Interrupt Enable**

0: The Master on Bus interrupt is disabled.

1: The Master on Bus interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Master on Bus Interrupt Enable bit, which disables the Master on Bus interrupt.

### 33.8.2.5 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x16

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7     | 6 | 5 | 4 | 3 | 2 | 1   | 0   |
|--------|-------|---|---|---|---|---|-----|-----|
|        | ERROR |   |   |   |   |   | SB  | MB  |
| Access | R/W   | R | R | R | R | R | R/W | R/W |
| Reset  | 0     | 0 | 0 | 0 | 0 | 0 | 0   | 0   |

- **Bit 7 – ERROR: Error Interrupt Enable**

0: Error interrupt is disabled.

1: Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Error Interrupt Enable bit, which enables the Error interrupt.

- **Bits 6:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – SB: Slave on Bus Interrupt Enable**

0: The Slave on Bus interrupt is disabled.

1: The Slave on Bus interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Slave on Bus Interrupt Enable bit, which enables the Slave on Bus interrupt.

- **Bit 0 – MB: Master on Bus Interrupt Enable**

0: The Master on Bus interrupt is disabled.

1: The Master on Bus interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Master on Bus Interrupt Enable bit, which enables the Master on Bus interrupt.

### 33.8.2.6 Interrupt Flag Status and Clear

**Name:** INTFLAG

**Offset:** 0x18

**Reset:** 0x00

**Property:** -

| Bit    | 7     | 6 | 5 | 4 | 3 | 2 | 1   | 0   |
|--------|-------|---|---|---|---|---|-----|-----|
|        | ERROR |   |   |   |   |   | SB  | MB  |
| Access | R/W   | R | R | R | R | R | R/W | R/W |
| Reset  | 0     | 0 | 0 | 0 | 0 | 0 | 0   | 0   |

- **Bit 7– ERROR: Error**

This flag is cleared by writing a one to it.

This bit is set when any error is detected. Errors that will set this flag have corresponding status flags in the STATUS register. Errors that will set this flag are LENERR, SEXTTOUT, MEXTTOUT, LOWTOUT, ARBLOST, and BUSERR.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the flag.

- **Bits 6:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – SB: Slave on Bus**

The Slave on Bus flag (SB) is set when a byte is successfully received in master read mode, i.e., no arbitration lost or bus error occurred during the operation. When this flag is set, the master forces the SCL line low, stretching the I<sup>2</sup>C clock period. The SCL line will be released and SB will be cleared on one of the following actions:

- Writing to ADDR.ADDR
- Writing to DATA.DATA
- Reading DATA.DATA when smart mode is enabled (CTRLB.SMEN)
- Writing a valid command to CTRLB.CMD

Writing a one to this bit location will clear the SB flag. The transaction will not continue or be terminated until one of the above actions is performed.

Writing a zero to this bit has no effect.

- **Bit 0 – MB: Master on Bus**

The Master on Bus flag (MB) is set when a byte is transmitted in master write mode. The flag is set regardless of the occurrence of a bus error or an arbitration lost condition. MB is also set when arbitration is lost during sending of NACK in master read mode, and when issuing a start condition if the bus state is unknown. When this flag is set and arbitration is not lost, the master forces the SCL line low, stretching the I<sup>2</sup>C clock period. The SCL line will be released and MB will be cleared on one of the following actions:

- Writing to ADDR.ADDR
- Writing to DATA.DATA
- Reading DATA.DATA when smart mode is enabled (CTRLB.SMEN)
- Writing a valid command to CTRLB.CMD

If arbitration is lost, writing a one to this bit location will clear the MB flag.

If arbitration is not lost, writing a one to this bit location will clear the MB flag. The transaction will not continue or be terminated until one of the above actions is performed.

Writing a zero to this bit has no effect.

### 33.8.2.7 Status

**Name:** STATUS

**Offset:** 0x1A

**Reset:** 0x0000

**Property:** Write-Synchronized

| Bit    | 15      | 14      | 13            | 12  | 11 | 10     | 9        | 8        |
|--------|---------|---------|---------------|-----|----|--------|----------|----------|
|        |         |         |               |     |    | LENERR | SEXTTOUT | MEXTTOUT |
| Access | R       | R       | R             | R   | R  | R/W    | R/W      | R/W      |
| Reset  | 0       | 0       | 0             | 0   | 0  | 0      | 0        | 0        |
| Bit    | 7       | 6       | 5             | 4   | 3  | 2      | 1        | 0        |
|        | CLKHOLD | LOWTOUT | BUSSTATE[1:0] |     |    | RXNACK | ARBLOST  | BUSERR   |
| Access | R       | R/W     | R             | R/W | R  | R      | R/W      | R/W      |
| Reset  | 0       | 0       | 0             | 0   | 0  | 0      | 0        | 0        |

- **Bits 15:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 10 – LENERR: Transaction Length Error**

This bit is set when automatic length is used for a DMA transaction and the slave sends a NACK before ADDR.LEN bytes have been written by the master.

Writing a one to this bit location will clear STATUS.LENERR. This flag is automatically cleared when writing to the ADDR register.

Writing a zero to this bit has no effect.

This bit is not write-synchronized.

- **Bit 9 – SEXTTOUT: Slave SCL Low Extend Time-Out**

This bit is set if a slave SCL low extend time-out occurs.

Writing a one to this bit location will clear STATUS.SEXTTOUT. Normal use of the I<sup>2</sup>C interface does not require the STATUS.SEXTTOUT flag to be cleared by this method. This flag is automatically cleared when writing to the ADDR register.

Writing a zero to this bit has no effect.

This bit is not write-synchronized.

- **Bit 8 – MEXTTOUT: Master SCL Low Extend Time-Out**

This bit is set if a master SCL low time-out occurs.

Writing a one to this bit location will clear STATUS.MEXTTOUT. Normal use of the I<sup>2</sup>C interface does not require the STATUS.MEXTTOUT flag to be cleared by this method. This flag is automatically cleared when writing to the ADDR register.

Writing a zero to this bit has no effect.

This bit is not write-synchronized.

- **Bit 7 – CLKHOLD: Clock Hold**

The Master Clock Hold flag (STATUS.CLKHOLD) is set when the master is holding the SCL line low, stretching the I<sup>2</sup>C clock. Software should consider this bit a read-only status flag that is set when INTFLAG.SB or INT-

FLAG.MB is set. When the corresponding interrupt flag is cleared and the next operation is given, this bit is automatically cleared.

Writing a zero to this bit has no effect.

Writing a one to this bit has no effect.

This bit is not write-synchronized.

- **Bit 6 – LOWTOUT: SCL Low Time-Out**

This bit is set if an SCL low time-out occurs.

Writing a one to this bit location will clear STATUS.LOWTOUT. Normal use of the I<sup>2</sup>C interface does not require the LOWTOUT flag to be cleared by this method. This flag is automatically cleared when writing to the ADDR register.

Writing a zero to this bit has no effect.

This bit is not write-synchronized.

- **Bits 5:4 – BUSSTATE[1:0]: Bus State**

These bits indicate the current I<sup>2</sup>C bus state as defined in [Table 33-13](#). After enabling the SERCOM as an I<sup>2</sup>C master, the bus state will be unknown.

**Table 33-13. Bus State**

| Value | Name    | Description   |
|-------|---------|---|
| 0x0   | Unknown | The bus state is unknown to the I <sup>2</sup> C master and will wait for a stop condition to be detected or wait to be forced into an idle state by software |
| 0x1   | Idle    | The bus state is waiting for a transaction to be initialized  |
| 0x2   | Owner   | The I <sup>2</sup> C master is the current owner of the bus   |
| 0x3   | Busy    | Some other I <sup>2</sup> C master owns the bus   |

When the master is disabled, the bus-state is unknown. When in the unknown state, writing 0x1 to BUSSTATE forces the bus state into the idle state. The bus state cannot be forced into any other state.

Writing BUSSTATE to idle will set SYNCBUSY.SYSOP.

- **Bit 3 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 2 – RXNACK: Received Not Acknowledge**

This bit indicates whether the last address or data packet sent was acknowledged or not.

0: Slave responded with ACK.

1: Slave responded with NACK.

Writing a zero to this bit has no effect.

Writing a one to this bit has no effect.

This bit is not write-synchronized.

- **Bit 1 – ARBLOST: Arbitration Lost**

The Arbitration Lost flag (STATUS.ARBLOST) is set if arbitration is lost while transmitting a high data bit or a NACK bit, or while issuing a start or repeated start condition on the bus. The Master on Bus interrupt flag (INT-FLAG.MB) will be set when STATUS.ARBLOST is set.

Writing the ADDR.ADDR register will automatically clear STATUS.ARBLOST.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear it.

This bit is not write-synchronized.

- **Bit 0 – BUSERR: Bus Error**

The Bus Error bit (STATUS.BUSERR) indicates that an illegal bus condition has occurred on the bus, regardless of bus ownership. An illegal bus condition is detected if a protocol violating start, repeated start or stop is detected on the I<sup>2</sup>C bus lines. A start condition directly followed by a stop condition is one example of a protocol violation. If a time-out occurs during a frame, this is also considered a protocol violation, and will set BUSERR.

If the I<sup>2</sup>C master is the bus owner at the time a bus error occurs, STATUS.ARBLOST and INTFLAG.MB will be set in addition to BUSERR.

Writing the ADDR.ADDR register will automatically clear the BUSERR flag.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear it.

This bit is not write-synchronized.

### 33.8.2.8 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x1C

**Reset:** 0x00000000

**Property:** -

|        |    |    |    |    |    |       |        |       |
|--------|----|----|----|----|----|-------|--------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26    | 25     | 24    |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18    | 17     | 16    |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10    | 9      | 8     |
|        |    |    |    |    |    |       |        |       |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2     | 1      | 0     |
|        |    |    |    |    |    | SYSOP | ENABLE | SWRST |
| Access | R  | R  | R  | R  | R  | R     | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0     | 0      | 0     |

- **Bits 31:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2– SYSOP: System Operation Synchronization Busy**

Writing CTRLB, STATUS.BUSSTATE, ADDR, or DATA when the SERCOM is enabled requires synchronization. When written, the SYNCBUSY.SYSOP bit will be set until synchronization is complete.

0: System operation synchronization is not busy.

1: System operation synchronization is busy.

- **Bit 1 – ENABLE: SERCOM Enable Synchronization Busy**

Enabling and disabling the SERCOM (CTRLA.ENABLE) requires synchronization. When written, the SYNCBUSY.ENABLE bit will be set until synchronization is complete.

Writes to any register (except for CTRLA.SWRST) while enable synchronization is on-going will be discarded and an APB error will be generated.

0: Enable synchronization is not busy.

1: Enable synchronization is busy.

- **Bit 0 – SWRST: Software Reset Synchronization Busy**

Resetting the SERCOM (CTRLA.SWRST) requires synchronization. When written, the SYNCBUSY.SWRST bit will be set until synchronization is complete.

Writes to any register while synchronization is on-going will be discarded and an APB error will be generated.

0: SWRST synchronization is not busy.

1: SWRST synchronization is busy.

### 33.8.2.9 Address

**Name:** ADDR  
**Offset:** 0x24  
**Reset:** 0x0000  
**Property:** Write-Synchronized

|        |           |     |       |     |     |            |     |     |
|--------|-----------|-----|-------|-----|-----|------------|-----|-----|
| Bit    | 31        | 30  | 29    | 28  | 27  | 26         | 25  | 24  |
|        |           |     |       |     |     |            |     |     |
| Access | R         | R   | R     | R   | R   | R          | R   | R   |
| Reset  | 0         | 0   | 0     | 0   | 0   | 0          | 0   | 0   |
| Bit    | 23        | 22  | 21    | 20  | 19  | 18         | 17  | 16  |
|        | LEN[7:0]  |     |       |     |     |            |     |     |
| Access | R/W       | R/W | R/W   | R/W | R/W | R/W        | R/W | R/W |
| Reset  | 0         | 0   | 0     | 0   | 0   | 0          | 0   | 0   |
| Bit    | 15        | 14  | 13    | 12  | 11  | 10         | 9   | 8   |
|        | TENBITEN  | HS  | LENEN |     |     | ADDR[10:8] |     |     |
| Access | R/W       | R/W | R/W   | R   | R   | R/W        | R/W | R/W |
| Reset  | 0         | 0   | 0     | 0   | 0   | 0          | 0   | 0   |
| Bit    | 7         | 6   | 5     | 4   | 3   | 2          | 1   | 0   |
|        | ADDR[7:0] |     |       |     |     |            |     |     |
| Access | R/W       | R/W | R/W   | R/W | R/W | R/W        | R/W | R/W |
| Reset  | 0         | 0   | 0     | 0   | 0   | 0          | 0   | 0   |

- Bits 31:24 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 23:16 – LEN[7:0]: Transaction Length**  
 For DMA operation, this field represents the data length of the transaction from 0 to 255 bytes. The transaction length enable (ADDR.LENEN) must be written to 1 for automatic transaction length to be used. After ADDR.LEN bytes have been transmitted or received, a NACK (for master reads) and STOP are automatically generated.
- Bit 15 – TENBITEN: Ten Bit Addressing Enable**  
 This bit enables 10-bit addressing. This bit can be written simultaneously with ADDR to indicate a 10-bit or 7-bit address transmission.  
 0: 10-bit addressing disabled.  
 1: 10-bit addressing enabled.
- Bit 14 – HS: High Speed**  
 This bit enables High-speed mode for the current transfer from repeated START to STOP. This bit can be written simultaneously with ADDR for a high speed transfer.  
 0: High-speed transfer disabled.

1: High-speed transfer enabled.

- **Bit 13 – LENEN: Transfer Length Enable**

This bit enables automatic transfer length.

0: Automatic transfer length disabled.

1: Automatic transfer length enabled.

- **Bits 12:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 10:0 – ADDR[10:0]: Address**

When ADDR is written, the consecutive operation will depend on the bus state:

Unknown: INTFLAG.MB and STATUS.BUSERR are set, and the operation is terminated.

Busy: The I<sup>2</sup>C master will await further operation until the bus becomes idle.

Idle: The I<sup>2</sup>C master will issue a start condition followed by the address written in ADDR. If the address is acknowledged, SCL is forced and held low, and STATUS.CLKHOLD and INTFLAG.MB are set.

Owner: A repeated start sequence will be performed. If the previous transaction was a read, the acknowledge action is sent before the repeated start bus condition is issued on the bus. Writing ADDR to issue a repeated start is performed while INTFLAG.MB or INTFLAG.SB is set.

Regardless of winning or losing arbitration, the entire address will be sent. If arbitration is lost, only ones are transmitted from the point of losing arbitration and the rest of the address length.

STATUS.BUSERR, STATUS.ARBLOST, INTFLAG.MB and INTFLAG.SB will be cleared when ADDR is written.

The ADDR register can be read at any time without interfering with ongoing bus activity, as a read access does not trigger the master logic to perform any bus protocol related operations.

The I<sup>2</sup>C master control logic uses bit 0 of ADDR as the bus protocol's read/write flag (R/W); 0 for write and 1 for read.

- **Bits 31:24 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 23:16 – LEN[7:0]: Transaction Length**

For DMA operation, this field represents the data length of the transaction from 0 to 255 bytes. The transaction length enable (ADDR.LENEN) must be written to 1 for automatic transaction length to be used. After ADDR.LEN bytes have been transmitted or received, a NACK (for master reads) and STOP are automatically generated.

- **Bit 15 – TENBITEN: Ten Bit Addressing Enable**

This bit enables 10-bit addressing. This bit can be written simultaneously with ADDR to indicate a 10-bit or 7-bit address transmission.

0: 10-bit addressing disabled.

1: 10-bit addressing enabled.

- **Bit 14 – HS: High Speed**

This bit enables High-speed mode for the current transfer from repeated START to STOP. This bit can be written simultaneously with ADDR for a high speed transfer.

0: High-speed transfer disabled.

1: High-speed transfer enabled.

- **Bit 13 – LENEN: Transfer Length Enable**

This bit enables automatic transfer length.

0: Automatic transfer length disabled.

1: Automatic transfer length enabled.

- **Bits 12:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 10:0 – ADDR[10:0]: Address**

When ADDR is written, the consecutive operation will depend on the bus state:

Unknown: INTFLAG.MB and STATUS.BUSERR are set, and the operation is terminated.

Busy: The I<sup>2</sup>C master will await further operation until the bus becomes idle.

Idle: The I<sup>2</sup>C master will issue a start condition followed by the address written in ADDR. If the address is acknowledged, SCL is forced and held low, and STATUS.CLKHOLD and INTFLAG.MB are set.

Owner: A repeated start sequence will be performed. If the previous transaction was a read, the acknowledge action is sent before the repeated start bus condition is issued on the bus. Writing ADDR to issue a repeated start is performed while INTFLAG.MB or INTFLAG.SB is set.

Regardless of winning or losing arbitration, the entire address will be sent. If arbitration is lost, only ones are transmitted from the point of losing arbitration and the rest of the address length.

STATUS.BUSERR, STATUS.ARBLOST, INTFLAG.MB and INTFLAG.SB will be cleared when ADDR is written.

The ADDR register can be read at any time without interfering with ongoing bus activity, as a read access does not trigger the master logic to perform any bus protocol related operations.

The I<sup>2</sup>C master control logic uses bit 0 of ADDR as the bus protocol's read/write flag (R/W); 0 for write and 1 for read.

### 33.8.2.10 Data

**Name:** DATA

**Offset:** 0x18

**Reset:** 0x0000

**Property:** Write-Synchronized, Read-Synchronized

|        |           |     |     |     |     |     |     |     |
|--------|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        |           |     |     |     |     |     |     |     |
| Access | R         | R   | R   | R   | R   | R   | R   | R   |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7         | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | DATA[7:0] |     |     |     |     |     |     |     |
| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 7:0 – DATA[7:0]: Data**

The master data register I/O location (DATA) provides access to the master transmit and receive data buffers. Reading valid data or writing data to be transmitted can be successfully done only when SCL is held low by the master (STATUS.CLKHOLD is set). An exception occurs when reading the last data byte after the stop condition has been sent.

Accessing DATA.DATA auto-triggers I<sup>2</sup>C bus operations. The operation performed depends on the state of CTRLB.ACKACT, CTRLB.SMEN and the type of access (read/write).

Writing or reading DATA.DATA when not in smart mode does not require synchronization.

### 33.8.2.11 Debug Control

**Name:** DBGCTRL

**Offset:** 0x30

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0       |
|--------|---|---|---|---|---|---|---|---------|
|        |   |   |   |   |   |   |   | DBGSTOP |
| Access | R | R | R | R | R | R | R | R/W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0       |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGSTOP: Debug Stop Mode**

This bit controls functionality when the CPU is halted by an external debugger.

0: The baud-rate generator continues normal operation when the CPU is halted by an external debugger.

1: The baud-rate generator is halted when the CPU is halted by an external debugger.

## 34. TC – Timer/Counter

### 34.1 Overview

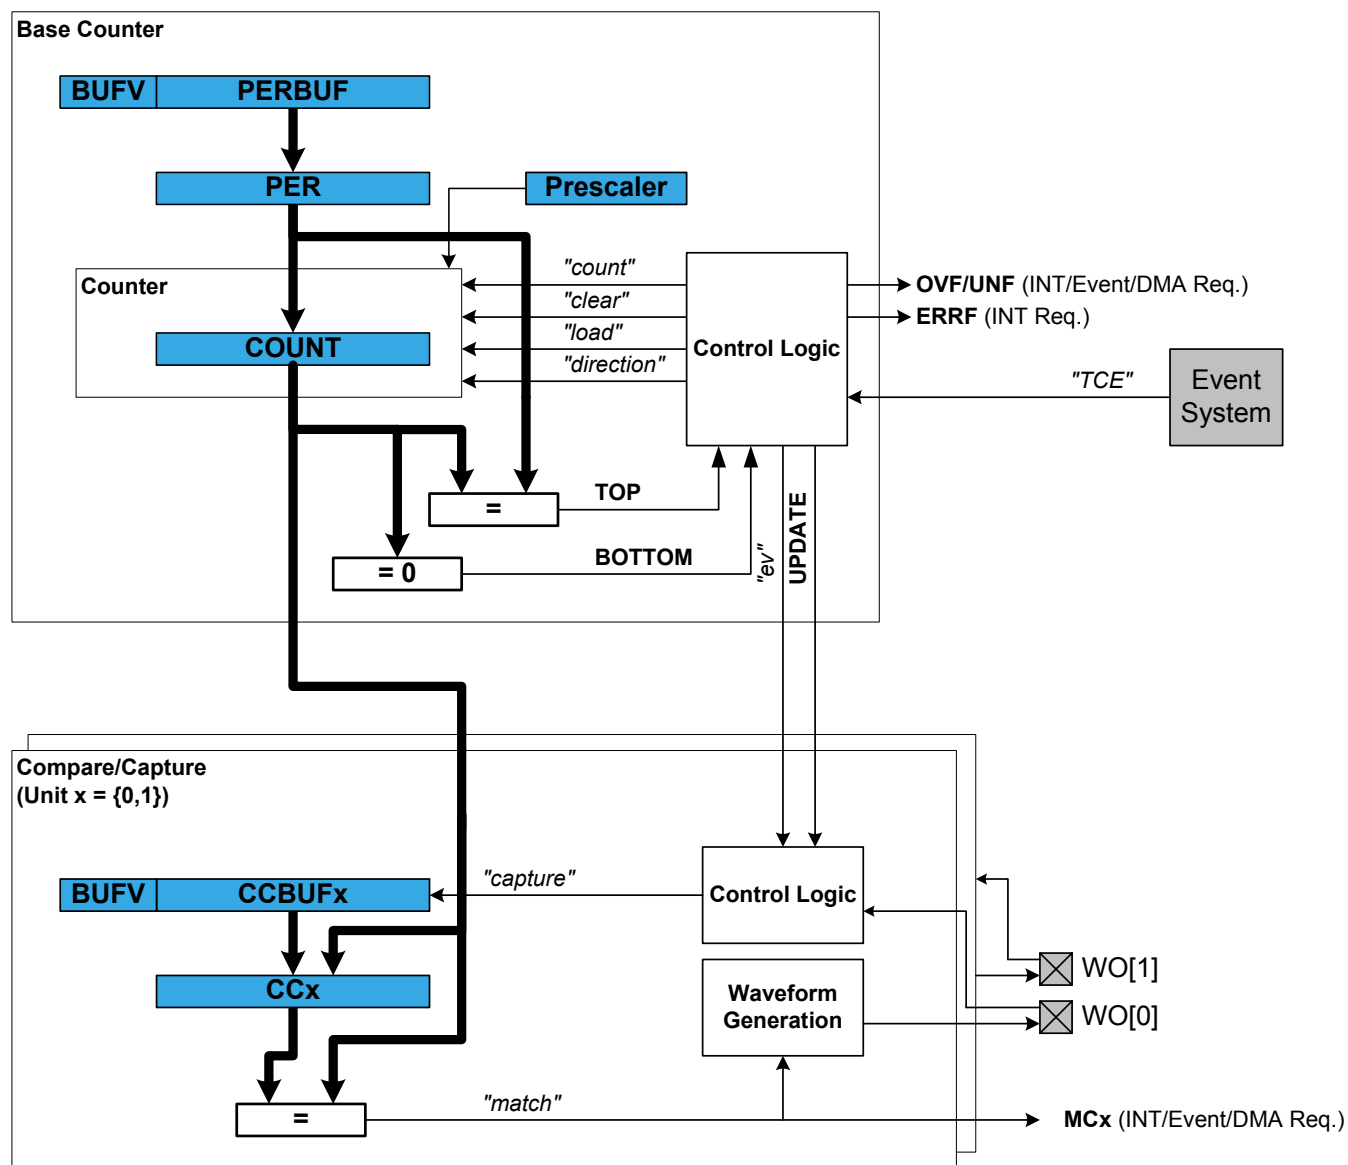

The TC consists of a counter, a prescaler, compare/capture channels and control logic. The counter can be set to count events, or clock pulses. The counter, together with the compare/capture channels, can be configured to timestamp input event or IO pin edges, allowing capture of frequency and pulse width. It can also perform waveform generation, such as frequency generation and pulse-width modulation.

### 34.2 Features

- Selectable configuration
  - 8-, 16- or 32-bit TC, with compare/capture channels
- 2 compare/capture channels (CC) with:
  - Double buffered timer period setting (in 8-bit mode only)
  - Double buffered compare channel
- Waveform generation
  - Frequency generation
  - Single-slope pulse-width modulation
- Input capture
  - Event / IO pin edge capture
  - Frequency capture
  - Pulse-width capture
  - Time-stamp capture
- One input event
- Interrupts/output events on:
  - Counter overflow/underflow
  - Compare match or capture
- Internal prescaler
- Can be used with DMA and to trigger DMA transactions

## 34.3 Block Diagram

Figure 34-1. Timer/Counter Block Diagram

## 34.4 Signal Description

| Signal Name | Type           | Description     |
|-------------|----------------|-----------------|
| WO[1:0]     | Digital output | Waveform output |
|             | Digital input  | Capture input   |

Refer to ["I/O Multiplexing and Considerations" on page 13](#) for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 34.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 34.5.1 I/O Lines

Using the TC's I/O lines requires the I/O pins to be configured. Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

### 34.5.2 Power Management

The TC can continue to operate in any sleep mode where the selected source clock is running. The TC interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 34.5.3 Clocks

The TC bus clock (CLK\_TCx\_APB, where x represents the specific TC instance number) can be enabled and disabled in the Main Clock module, and the default state of CLK\_TCx\_APB can be found in the Peripheral Clock Masking section in [Table 17-1](#).

Tc master - slave pair uses the same generic clock, GCLK\_TCx. This means that TC instances in a TC master - slave pair, cannot be set to use different clock frequencies.

This generic clock is asynchronous to the user interface clock (CLK\_TCx\_APB). Due to this asynchronicity, accessing certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 652](#) for further details.

### 34.5.4 DMA

The DMA request lines (or line if only one request) are connected to the DMA Controller (DMAC). Using the TC DMA requests requires the DMA Controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details.

### 34.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the TC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 34.5.6 Events

To use the TC event functionality, the corresponding events need to be configured in the event system. Refer to [“EVSYS – Event System” on page 467](#) for details.

### 34.5.7 Debug Operation

When the CPU is halted in debug mode the TC will halt normal operation. The TC can be forced to continue operation during debugging. Refer to the [DBGCTRL](#) register for details.

### 34.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag register (INTFLAG)
- Status register (STATUS)
- Count register (COUNT)
- Period register (PER/PERBUF)
- Compare/Capture Value registers (CCx/CCBUFx)

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details.

### 34.5.9 Analog Connections

Not applicable.

## 34.6 Functional Description

### 34.6.1 Principle of Operation

The counter in the TC can be set to count on events from the Event System, or on the GCLK\_TCx clock. The pulses from GCLK\_TCx will go through the prescaler, where it is possible to divide the clock frequency.

The value in the counter is passed to the compare/capture channels, where it can either be compared with user defined values or captured when capture operations are enabled.

Mode settings determines the maximum range of the counter. The counter register (COUNT) and compare and capture registers with buffers (CCx and CCBUFx) can be configured as 8-, 16- or 32-bit registers. Each buffer register has a buffer valid (BUFV) flag that indicates when the buffer contains a new value. The counter range combined with the operating frequency will determine the maximum time resolution achievable with the TC peripheral. When the 8-bit mode is selected, a period register with buffer (PER, PERBUF) is also available.

The TC can be set to count up or down. During normal operation, the counter value is continuously compared to the TOP and to ZERO value to determine whether the counter has reached TOP or BOTTOM, to request DMA transactions or generate interrupts or events for the Event System.

The counter value is also compared to the CCx registers. These comparisons can be used to request DMA transactions or generate interrupt requests or events for the Event System. The waveform generator modes use these comparisons to set the waveform period or pulse width.

Capture operation can be enabled to perform input signal period and pulse width measurements, or to capture selectable edges from an IO pin or internal event from Event System.

### 34.6.2 Basic Operation

#### 34.6.2.1 Initialization

The following registers are enable-protected, meaning that they can only be written when the TC is disabled (CTRLA.ENABLE is zero):

- Control A register (CTRLA), except the Enable (ENABLE) and Software Reset (SWRST) bits
- Drive Control register (DRVCTRL)
- Wave register (WAVE)
- Event Control register (EVCTRL)

Enable-protected bits in CTRLA register can be written at the same time as CTRLA.ENABLE is written to one, but not at the same time as CTRLA.ENABLE is written to zero.

Enable-protection is denoted by Enable-Protected property in the register description.

Before enabling the TC, the module must be configured as outlined by the following steps:

- The TC bus clock (CLK\_TCx\_APB) must be enabled
- The mode (8, 16 or 32 bits) of the TC must be selected in the TC Mode bit group in the Control A register (CTRLA.MODE). The default mode is 16 bits
- One of the wave generation operations must be selected in the Waveform Generation Operation bit group in the WAVE register (WAVE.WAVEGEN)

- If the GCLK\_TCx clock should be prescaled, this can be selected in the Prescaler bit group in the Control A register (CTRLA.PRESCALER)
- If the prescaler is used, one of the prescaler synchronization operation must be chosen in the Prescaler and Counter Synchronization bit group in the Control A register (CTRLA.PRESYNC)
- One-shot operation can be selected by writing a one to the One-Shot bit in the Control B Set register (CTRLBSET.ONESHOT)
- If the counter should count down from the top value, write a one to the Counter Direction bit in the Control B Set register (CTRLBSET.DIR)
- If capture operations are to be used, the individual channels must be enabled for capture in the Capture Channel x Enable bit group in the Control A register (CTRLA.CAPTEN)
- The waveform output or IO pin input signal for individual channels can be inverted using the Invert Enable bit group in the Drive Control register (DRVCTRL.INVEN)

#### 34.6.2.2 Enabling, Disabling and Resetting

The TC is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The TC is disabled by writing a zero to CTRLA.ENABLE.

The TC is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the TC, except DBGCTRL, will be reset to their initial state, and the TC will be disabled. Refer to the [CTRLA](#) register for details.

The TC should be disabled before the TC is reset to avoid undefined behavior.

#### 34.6.2.3 Prescaler Selection

The GCLK\_TC is fed into the internal prescaler. Prescaler outputs from 1 to 1/1024 are directly available for selection by the timer/counter and all selections are available in Control A register (CTRLA.PRESCALER). If the prescaler value is higher than one, the counter update condition can be optionally executed on the next GCLK\_TC clock pulse or the next prescaled clock pulse. For further details, refer to Control A Prescaler and Counter Synchronization (CTRLA.PRESYNCH) description.

If the counter is set to count events, the internal prescaler is bypassed and GCLK\_TC clock is automatically selected during operation.

**Figure 34-2. Prescaler**

#### 34.6.2.4 Counter Mode

The counter mode is selected with the Mode bit group in the Control A register (CTRLA.MODE). By default, the counter is enabled in the 16-bit counter resolution.

Three counter resolutions are available:

- COUNT8: The 8-bit TC has its own Period with buffer register (PER, PERBUF). This register is used to store the period value that can be used as the top value for waveform generation.
- COUNT16: This is the default counter resolution. There is no dedicated period register in this mode.
- COUNT32: This mode is achieved by pairing two 16-bit TC peripherals, as explained in [“Clocks” on page 640](#). When paired, the TC instance acting as slave will set to one the Slave bit in STATUS register (STATUS.SLAVE). The registers of the slave will not reflect the registers of the 32-bit counter. Writing to any of the slave registers will not affect the 32-bit counter. Normal access to the slave COUNT and CCx registers is not allowed.

### 34.6.2.5 Counter Operations

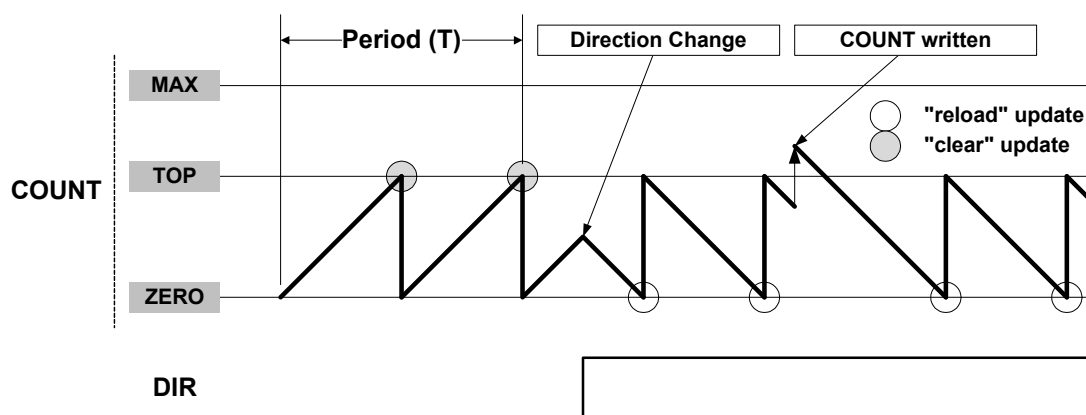

Depending on the mode of operation, the counter is cleared, reloaded, incremented, or decremented at each timer/counter clock input.

The counter will count in the direction set by the direction (DIR) bit for each clock until it reaches TOP or ZERO. When up-counting and TOP is reached, the counter will be set to zero when the next clock is given. When down-counting, the counter is reloaded with the TOP value when ZERO is reached.

This comparison will set the Overflow/Underflow Interrupt Flag in the Interrupt Flag Status and Clear register (INTFLAG.OVF) and can be used to trigger an interrupt, a DMA request, or an event. This comparison will stop the counting operation as well if ONESHOT bit in the Control B Set register (CTRLBSET.ONESHOT) is set.

Up-counting operation is enabled by writing to one the Direction bit in Control B Clear register (CTRLBCLR.DIR). Down-counting operation is enabled by writing to one the Direction bit in Control B Set register (CTRLBSET.DIR).

Figure 34-3. Counter Operation

As shown in Figure 34-3, it is possible to change the counter value when the counter is running. The write access has higher priority than count, clear, or reload. The COUNT value will always be zero when starting the TC, unless other value has been written to it or the TC has been stopped at a value other than zero. The direction of the counter can also be changed during normal operation. Due to asynchronous clock domains, the internal counter settings are written when the synchronization is complete.

#### Stop Command

A stop command can be enabled by software in the Control B Set register (CTRLBSET.CMD). When a stop is detected while the counter is running, the counter will be cleared or reloaded with the TOP value, depending on direction setting (DIR). All waveforms are cleared and the Stop bit in the Status register is set (STATUS.STOP).

#### Re-trigger Command and Event Action

A re-trigger command can be enabled by software in the Control B Set register (CTRLBSET.CMD) or when re-trigger event action is configured in Event Control register (EVCTRL.EVACT) and an event is detected by hardware.

When the command is detected during counting operation, the counter will be reloaded or cleared, depending on the counting direction (DIR). If the re-trigger command is detected when the counter is stopped, the counter will resume counting operation from the value in the COUNT register.

**Note:** When re-trigger event action is enabled, enabling the counter will not start the counter. The counter will start on the next incoming event and restart on any following event.

#### Count Event Action

The count action can be selected in the Event Control register (EVCTRL.EVACT) and can be used to count external events. When an event is received, the counter increments or decrements the value, depending on direction settings (DIR).

## Start Event Action

The start action can be selected in the Event Control register (EVCTRL.EVACT) and can be used to start the counting operation when previously stopped. As consequence, the event has no effect if the counter is already counting. When the module is enabled, the counter operation starts when the event is received or when a re-trigger software command is applied.

### 34.6.2.6 Compare Operations

When using the TC and the Compare/Capture Value registers (CCx) for compare operations, the counter value is continuously compared to the values in the CCx registers. This can be used for timer or for waveform operation.

The compare buffer register provides double buffer capability. The double buffering synchronizes the update of the CCx register with the buffer value at the UPDATE condition. For further details, refer to [“Double Buffering” on page 646](#). The synchronization prevents the occurrence of odd-length, non-symmetrical pulses and ensure glitch-free output.

## Waveform Output Operations

The compare channels can be used for waveform generation on output port pins. To make the waveform visible on the connected pin, the following requirements must be fulfilled:

1. Choose a waveform generation mode in the WAVE register (WAVE.WAVEGEN)
2. Optionally invert the waveform output WO[x] by writing the corresponding IO Invert Enable bit in the Driver Control register (DRVCTRL.INVENx)
3. Configure the pins with the I/O Pin Controller Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

The counter value is continuously compared with each CCx value. When a compare match occurs, the Match or Capture Channel x Interrupt Flag in the Interrupt Flag Status and Clear register (INTFLAG.MCx) is set on the next zero-to-one transition of CLK\_TC\_CNT (see [Figure 34-4](#)). An interrupt and/or event can be generated on the same condition if INTENSET.MCx and/or Match or Capture Event Output EVCTRL.MCEOx is one. The same conditions generate DMA requests.

One of four configurations in the Waveform Generation Operation bit group in the WAVE register (WAVE.WAVEGEN) must be chosen to perform waveform generation. This will influence how the waveform is generated and impose restrictions on the top value. The four configurations are:

- Normal frequency (NFRQ)
- Match frequency (MFRQ)
- Normal PWM (NPWM)
- Match PWM (MPWM)

When using NPWM or NFRQ, the top value is determined by the counter resolution. In 8-bit mode, the Period register (PER) is used as the top value and the top value can be changed by writing to the PER register. In 16- and 32-bit mode, the top value is fixed to the maximum (MAX) value of the counter.

## Normal Frequency Generation

For normal frequency generation, the period time (T) is controlled by the period register (PER). The waveform generation output (WO[x]) is toggled on each compare match between the COUNT and CCx registers, and the corresponding Match or Capture Channel x Interrupt Flag will be set.

Figure 34-4. Normal Frequency Operation

### Match Frequency Generation

For match frequency generation, the period time (T) is controlled by the CC0 register instead of TOP value. WO[0] toggles and a one-cycle negative pulse is generated on each update condition

Figure 34-5. Match Frequency Operation

### Normal PWM Operation

For single-slope PWM generation, the period (T) is controlled by TOP value (MAX, PER or CC0), while CCx registers control the duty cycle of the WG output. When up-counting, the WO[x] is set at start or compare match between the COUNT and TOP values, and cleared on compare match between COUNT and Channel Compare register values (CCx). When down-counting, the WO[x] is cleared at start or compare match between the COUNT and TOP values, and set on compare match between COUNT and Channel Compare register values (CCx).

The following equation is used to calculate the exact period for a single-slope PWM ( $R_{PWM\_SS}$ ) waveform:

$$R_{PWM\_SS} = \frac{\log(TOP + 1)}{\log(2)}$$

$$f_{PWM\_SS} = \frac{f_{GCLK\_TC}}{N(TOP + 1)}$$

where N represent the prescaler divider used (1, 2, 4, 8, 16, 64, 256, 1024).

### Match PWM Operation

In match operation (MPWM), a one-cycle negative pulse is generated on WO[0], on every overflow/underflow.

Figure 34-6. Match PWM Operation

The table below shows the update counter and overflow event/interrupt generation conditions in different operation modes.

Table 34-1. Counter Update and Overflow Event/interrupt Conditions

| Description      |                        |                          |                           |
|------------------|------------------------|--------------------------|---------------------------|
| Operation        | Top                    | Output Waveform On Match | Output Waveform On Update |
| Normal Frequency | PER/MAX <sup>(1)</sup> | Toggle                   | No action                 |
| Match Frequency  | CC0                    | Toggle                   | No action                 |
| Normal PWM       | PER/MAX <sup>(1)</sup> | Set                      | Clear                     |
| Match PWM        | CC0                    | Set                      | Clear                     |

Note: 1. This depends on the TC mode. In 8-bit mode, the top value is the Period Value register (PER). In 16- and 32-bit mode it is the maximum value.

#### 34.6.2.7 Double Buffering

Period (PER) and the compare channels (CCx) registers are all double buffered. Each buffer register has a buffer valid (PERBUFV or CCBUFVx) flag, which indicates that the buffer register contains a new valid value, waiting to be copied into the corresponding register. As long as the buffer valid status flag is set to one (PERBUFV, CCBUFVx), an access to the corresponding PER or CCx register generates an error.

When the buffer valid flag is one and a double buffering is enabled (CTRLB.LUPD=0), the data from buffer registers will be copied into the corresponding register on UPDATE condition, including the software update command (CTRLB.CMD). The buffer valid flags are automatically cleared by hardware when the data is copied from the buffer to the corresponding register, or by software.

This is shown for a compare register in Figure 34-7.

Figure 34-7. Compare Channel Double Buffering

Both the PER/CCx and PERBUF/CCBUFx registers are available in the I/O register map. This allows initialization and bypassing of the buffer register, and the double buffering feature.

Note: In FREQ or PWM down-counting counter mode (CTRLB.DIR=1), the PER register is written at the same time as the PERBUF register is written, if CTRLB.LUPD is 0 or as soon as CTRLB.LUPD becomes 0.

### Changing the Period

The counter period is changed by writing a new TOP value to the period register (PER or CC0, depending on waveform generation mode). If double buffering is not used, any period update is effective after the synchronization delay.

Figure 34-8. Unbuffered Single-Slope Up-Counting Operation

Figure 34-9. Unbuffered Single-Slope Down-Counting Operation

A counter wraparound can occur in any mode of operation when up-counting without buffering, as shown in [Figure 34-9](#). This is due to the fact that COUNT and PER (or CC0) are continuously compared, and if a new TOP value that is lower than current COUNT is written to PER (or CC0), it will wrap before a compare match happens.

**Figure 34-10. Changing the Period Using Buffering**

### 34.6.2.8 Capture Operations

To enable and use capture operations, the corresponding Capture Channel x Enable bit in CTRLA register must be set to one (CTRLA.CAPTENx). Capture trigger on channel x, can be provided through asynchronous IO pin WO[x] for each capture channel or through TC event. To enable the capture from the IO pin, the Capture On Pin Enable bit in CTRLA register (CTRLA.COPENx) must be set to one. Note the Retrigger, Count and Start event actions are available only with an event from the Event System.

By default, a capture operation is done when a rising edge is detected on the input signal. If a capture on falling edge is needed, the user must write one to the corresponding Invert Enable bit in Drive Control register (DRVCTRL.INVEN) when the channel is used with the corresponding IO pin, or write one to the TC Event Input Invert Enable bit in Event Control register (EVCTRL.TCINV) when the channel is used with an event from Event System.

#### Event Capture Action

The compare/capture channels can be used as input capture channels to capture events from the Event System or from the corresponding IO pin, and give them a timestamp.

[Figure 34-11](#) shows four capture events for one capture channel.

**Figure 34-11. Input Capture Timing**

The TC can detect capture overflow of the input capture channels. When the Capture Interrupt flag is set and a new capture event is detected, there is nowhere to store the new timestamp. As a result, the Error Interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG.ERR) is set.

## Period and Pulse-Width Capture Action

The TC can perform two input captures and restart the counter on one of the edges. This enables the TC to measure the pulse width and period. This can be used to characterize the frequency and duty cycle of an input signal:

$$f = \frac{1}{T} \quad \text{dutyCycle} = \frac{t_p}{T}$$

When using PPW event action, the period (T) will be captured into CC0 and the pulse width (tp) in CC1. In PWP event action, the pulse width (tp) will be captured in CC0 and the period (T) in CC1. Note that the corresponding capture is done only if the channel is enabled in capture mode (CTRLA.CAPTENx = 1). If not, the capture action is ignored and the channel is enabled in compare mode of operation.

Figure 34-12.PWP Capture

Selecting PWP (pulse-width, period) or PPW (period, pulse-width) in the Event Action bit group in the Event Control register (EVCTRL.EVACT) enables the TC to perform two capture actions, one on the rising edge and one on the falling edge.

The TC Event Input Invert Enable bit in the Event Control register (EVCTRL.TCEINV) is used to select whether the wraparound should occur on the rising edge or the falling edge. If EVCTRL.TCEINV is written to one, the wraparound will happen on the falling edge.

Note that the corresponding capture is done only if the channel is enabled in capture mode (CTRLA.CAPTENx = 1). If not, the capture action is ignored and the channel is enabled in compare mode of operation. As consequence, to fully characterize the frequency and duty cycle of the input signal, both channels must be enabled in capture mode (CTRLA.CAPTENx = 1).

The TC can detect capture overflow of the input capture channels. When the Capture Interrupt flag is set and a new capture event is detected, there is nowhere to store the new timestamp. As a result, INTFLAG.ERR is set.

## Pulse-Width Capture Action

The TC performs the input capture on the falling edge of the input signal. When the edge is detected, the counter value is cleared and the TC stops counting. When a rising edge is detected on the input signal, the counter restarts the counting operation. To enable the operation on the opposite edges, the input signal to capture must be inverted (refer to DRVCTRL.INVEN or EVCTRL.TCEINV).

**Figure 34-13. Pulse-Width Capture on Channel 0**

The TC can detect capture overflow of the input capture channel. When the Capture Interrupt flag is set and a new capture event is detected, there is nowhere to store the new timestamp. As a result, INTFLAG.ERR is set.

### 34.6.3 Additional Features

#### 34.6.3.1 One-Shot Operation

When one-shot is enabled, the counter automatically stops on the next counter overflow or underflow condition. When the counter is stopped, STOP status bit in STATUS register (STATUS.STOP) is automatically set by hardware and the waveform outputs are set to zero.

One-shot operation can be enabled by writing a one to the ONESHOT bit in the Control B Set register (CTRLBSET.ONESHOT) and disabled by writing a one to the ONESHOT bit in the Control B Clear register (CTRLBCLR.ONESHOT). When enabled, the TC will count until an overflow or underflow occurs and stops counting operation. The one-shot operation can be restarted by using retrigger software command, a retrigger event or a start event.

When the Counter restarts its operation, the STOP bit in the Status register (STATUS.STOP) is automatically cleared by hardware.

#### 34.6.3.2 Time-stamp Capture

This feature is enabled when the STAMP Event Action in Event Control register (EVCTRL.EVACT) is selected. The counter TOP value must be programmed as follow:

$$TOP < MAX$$

When a capture event is detected, the COUNT value is copied into the corresponding capture channel CC register (CCx). If the overflow condition is detected, MAX value is copied into the corresponding capture channel CC register (CCx).

When a valid captured value is present in the capture channel register, the corresponding channel Capture Interrupt flag is set to one (INTFLAG.MCx). When the Capture Interrupt flag is set and a new capture event is detected, there is nowhere to store the new timestamp. As a result, the Error Interrupt Flag (INTFLAG.ERR) will be set to one.

**Figure 34-14. Time-stamp**

### 34.6.4 DMA Operation

The TC can generate the following DMA requests:

- Overflow (OVF): the request is set when an update condition (overflow, underflow or re-trigger) is detected. The request is cleared when writing one of the PER/PERBUF or CCx/CCBUFx registers.
- Channel Match or Capture (MCx): for a compare channel, the request is set on each compare match detection and cleared when CCx/CCBUFx register is written. For a capture channel, the request is set when valid data is present in CCx register, and cleared when CCx register is read.

### 34.6.5 Interrupts

The TC has the following interrupt sources:

- Overflow/Underflow (OVF)
- Compare Match or Capture Channels (MCx)
- Capture Overflow Error (ERR)

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear register (INTFLAG) is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set register (INTENSET), and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear register (INTENCLR). An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled or the TC is reset. See the [INTFLAG](#) register for details on how to clear interrupt flags.

The TC has one common interrupt request line for all the interrupt sources. The user must read the INTFLAG register to determine which interrupt condition is present. Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 for details.

### 34.6.6 Events

The TC can generate the following output events:

- Overflow/Underflow (OVF)
- Compare Match or Capture (MCx)

Writing a one to an Event Output bit in the Event Control register (EVCTRL.MCEx) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event.

To enable one of the following event actions, write to the Event Action bit group (EVCTRL.EVACT).

- Start the counter
- Retrigger counter
- Increment or decrement counter (depends on counter direction)
- Capture event

- Capture period
- Capture pulse width

Writing a one to the TC Event Input bit in the Event Control register (EVCTRL.TCEI) enables input events to the TC. Writing a zero to this bit disables input events to the TC. The TC requires only asynchronous event inputs. For further details on how configuring the asynchronous events, refer to “[EVSYS – Event System](#)” on page 467.

### 34.6.7 Sleep Mode Operation

The TC can be configured to operate in any sleep mode. To be able to run in standby, the RUNSTDBY bit in the Control A register (CTRLA.RUNSTDBY) must be written to one. The TC can wake up the device using interrupts from any sleep mode or perform actions through the Event System.

If the ONDEMAND bit in CTRLA register (CTRLA.ONDEMAND) is set to one, the module stops requesting the clocks when STOP bit in STATUS register (STATUS.STOP) is set to one. When retrigger or start conditions are detected, the TC requests the clock before the operation starts.

### 34.6.8 Synchronization

Due to the asynchronicity between the main clock domain (CLK\_TCx\_APB) and the peripheral clock domain (GCLK\_TCx) some registers are synchronized when written. When a write-synchronized register is written, the corresponding bit in the Synchronization Busy register (SYNCBUSY) is set immediately. When the write-synchronization is complete, this bit is cleared. Reading a write-synchronized register while the synchronization is ongoing will return the value written, and not the current value in the peripheral clock domain. To read the current value in the peripheral clock domain after writing a register, the user must wait for the corresponding SYNCBUSY bit to be cleared before reading the value.

If a register is written while the corresponding bit in SYNCBUSY is one, the write is discarded and an error is generated.

The following bits and registers are write-synchronized:

- Software Reset and Enable bits in Control A register (CTRLA.SWRST and CTRLA.ENABLE)
- Capture Channel Buffer Valid bit in STATUS register (STATUS.CCBUFVx)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

The following registers need synchronization when written:

- Control B Clear and Control B Set registers (CTRLBCLR and CTRLBSET)
- Count Value register (COUNT)
- Period Value register (PER)
- Compare/Capture Value registers (CCx)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

The following register needs synchronization when read:

- Count Value register (COUNT): synchronization is done on demand through READSYNC command (CTRLBSET.CMD).

Read-synchronization is denoted by the Read-Synchronized property in the register description.

## 34.7 Register Summary

**Table 34-2. COUNT8 - Mode Register Summary**

| Offset              | Name     | Bit Pos. |            |          |                |         |           |                |              |         |
|---------------------|----------|----------|------------|----------|----------------|---------|-----------|----------------|--------------|---------|
| 0x00                | CTRLA    | 7:0      | ONDEMAND   | RUNSTDBY | PRESCSYNC[1:0] |         | MODE[1:0] |                | ENABLE       | SWRST   |

## 34.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 640](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 652](#) for details.

Some registers are enable-protected, meaning they can only be written when the TC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 34.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00000000

**Access:** Read-Write

**Property:** Enable-Protected, Write-Protected

- **Bits 31:22 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 21:20 – COPENx [x=1..0]: Capture On Pin x Enable**

This bit is used to enable the capture operation from Event System or I/O pin.

0: Event from Event System is selected as trigger source for capture operation on channel x.

1: I/O pin is selected as trigger source for capture operation on channel x.

- **Bits 19:18 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 17:16 – CAPTENx [x=1..0]: Capture Channel x Enable**

These bits are used to select whether channel x is a capture or a compare channel.

Writing a one to CAPTENx enables capture on channel x.

Writing a zero to CAPTENx disables capture on channel x.

These bits are not synchronized.

- **Bits 15:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 11 – ALOCK: Auto Lock**

When this bit is set, Lock bit update (LUPD) is set to one on each overflow/underflow or re-trigger event.

0: The LUPD bit is not affected on overflow/underflow, and re-trigger event.

1: The LUPD bit is set on each overflow/underflow or re-trigger event.

This bit is not synchronized.

- **Bits 10:8 – PRESCALER[2:0]: Prescaler**

These bits select the counter prescaler factor, as shown in [Table 34-5 on page 658](#).

These bits are not synchronized.

**Table 34-5. Prescaler**

| PRESCALER[2:0] | Name    | Description             |
|----------------|---------|-------------------------|
| 0x0            | DIV1    | Prescaler: GCLK_TC      |
| 0x1            | DIV2    | Prescaler: GCLK_TC/2    |
| 0x2            | DIV4    | Prescaler: GCLK_TC/4    |
| 0x3            | DIV8    | Prescaler: GCLK_TC/8    |
| 0x4            | DIV16   | Prescaler: GCLK_TC/16   |
| 0x5            | DIV64   | Prescaler: GCLK_TC/64   |
| 0x6            | DIV256  | Prescaler: GCLK_TC/256  |
| 0x7            | DIV1024 | Prescaler: GCLK_TC/1024 |

- **Bit 7 – ONDEMAND: Clock On Demand**

The On Demand operation mode allows the TC to continue to request the GCLK clock when stopped (STATUS.STOP = 1). If On Demand is disabled, the TC continues to request the clock when its operation is stopped. When On Demand is enabled, the TC will not request the clock when its operation is stopped. The clock is requested when a software retrigger command is applied or when an event with start/retrigger action is detected. In standby mode, this On Demand operation is forced disabled if RUNSTDBY bit (CTRLA.RUNSTDBY) is set to zero.

0: The On Demand is disabled.

1: The On Demand is enabled.

This bit is not synchronized.

- **Bit 6 – RUNSTDBY: Run during Standby**

This bit is used to keep the TC running in standby mode:

0: The TC is halted in standby.

1: The TC continues to run in standby.

This bit is not synchronized.

- **Bits 5:4 – PRESCSYNC[1:0]: Prescaler and Counter Synchronization**

These bits select whether the counter should wrap around on the next GCLK\_TCx clock or the next prescaled GCLK\_TCx clock. It also makes it possible to reset the prescaler.

The options are as shown in [Table 34-6 on page 659](#).

These bits are not synchronized.

**Table 34-6. Prescaler and Counter Synchronization**

| PRESCSYNC[1:0] | Name   | Description   |
|----------------|--------|---|
| 0x0            | GCLK   | Reload or reset the counter on next generic clock                                 |
| 0x1            | PRESC  | Reload or reset the counter on next prescaler clock                               |
| 0x2            | RESYNC | Reload or reset the counter on next generic clock and reset the prescaler counter |
| 0x3            |        | Reserved  |

- **Bits 3:2 – MODE[1:0]: Timer Counter Mode**

These bits select the counter mode, as shown in [Table 34-7 on page 659](#).

These bits are not synchronized.

**Table 34-7. Timer Counter Mode**

| MODE[1:0] | Name    | Description            |
|-----------|---------|------------------------|
| 0x0       | COUNT16 | Counter in 16-bit mode |
| 0x1       | COUNT8  | Counter in 8-bit mode  |
| 0x2       | COUNT32 | Counter in 32-bit mode |
| 0x3       |         | Reserved               |

- **Bit 1 – ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Due to synchronization, there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately, and the ENABLE Synchronization Busy bit in the SYNCBUSY register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the TC, except DBGCTRL, to their initial state, and the TC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence; all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 34.8.2 Control B Clear

**Name:** CTRLBCLR

**Offset:** 0x04

**Reset:** 0x00

**Access:** Read-Write

**Property:** Read-Synchronized, Write-Protected, Write-Synchronized

| Bit    | 7        | 6   | 5   | 4 | 3 | 2       | 1    | 0   |
|--------|----------|-----|-----|---|---|---------|------|-----|
|        | CMD[2:0] |     |     |   |   | ONESHOT | LUPD | DIR |
| Access | R/W      | R/W | R/W | R | R | R/W     | R/W  | R/W |
| Reset  | 0        | 0   | 0   | 0 | 0 | 0       | 0    | 0   |

This register allows the user to change this register without doing a read-modify-write operation. Changes in this register will also be reflected in the Control B Set (CTRLBSET) register.

- **Bits 7:5 – CMD[2:0]: Command**

These bits are used for software control of retriggering and stopping the TC. When a command has been executed, the CMD bit group will read back as zero. The commands are executed on the next prescaled GCLK\_TC clock cycle.

Writing a zero to one of these bits has no effect.

Writing a one to one of these bits will clear the pending command.

**Table 34-8. Command**

| CMD[2:0] | Name      | Description                              |
|----------|-----------|--|
| 0x0      | NONE      | No action                                |
| 0x1      | RETRIGGER | Force a start, restart or retrigger      |
| 0x2      | STOP      | Force a stop                             |
| 0x3      | UPDATE    | Force update of double-buffered register |
| 0x4      | READSYNC  | Force a read synchronization of COUNT    |
| 0x5-0x7  |           | Reserved                                 |

- **Bits 4:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – ONESHOT: One-Shot on Counter**

This bit controls one-shot operation of the TC. When in one-shot operation, the TC will stop counting on the next overflow/underflow condition or a stop command.

0: The TC will wrap around and continue counting on an overflow/underflow condition.

1: The TC will wrap around and stop on the next underflow/overflow condition.

Writing a zero to this bit has no effect

Writing a one to this bit will disable one-shot operation.

- **Bit 1 – LUPD: Lock Update**

This bit controls the update operation of the TC buffered registers. When this bit is set, no update of the buffered registers is performed, even though an UPDATE condition has occurred. Locking the update ensures that all buffers registers are valid before an update is performed.

This bit has no effect when input capture operation is enabled.

0: The CCBUFx and PERBUF buffer registers value are not copied into the corresponding CCx, and PER registers.

1: The CCBUFx, and PERBUF buffer registers value are copied into the corresponding CCx and PER registers on counter update condition.

- **Bit 0 – DIR: Counter Direction**

This bit is used to change the direction of the counter.

0: The timer/counter is counting up (incrementing).

1: The timer/counter is counting down (decrementing).

Writing a zero to this bit has no effect.

Writing a one to this bit will make the counter count up.

### 34.8.3 Control B Set

**Name:** CTRLBSET

**Offset:** 0x05

**Reset:** 0x00

**Access:** Read-Write

**Property:** Read-Synchronized, Write-Protected, Write-Synchronized

|        |          |     |     |   |   |         |      |     |
|--------|----------|-----|-----|---|---|---------|------|-----|
| Bit    | 7        | 6   | 5   | 4 | 3 | 2       | 1    | 0   |
|        | CMD[2:0] |     |     |   |   | ONESHOT | LUPD | DIR |
| Access | R/W      | R/W | R/W | R | R | R/W     | R/W  | R/W |
| Reset  | 0        | 0   | 0   | 0 | 0 | 0       | 0    | 0   |

This register allows the user to change this register without doing a read-modify-write operation. Changes in this register will also be reflected in the Control B Set (CTRLBCLR) register.

- Bits 7:5 – CMD[2:0]: Command**

These bits are used for software control of retriggering and stopping the TC. When a command has been executed, the CMD bit group will be read back as zero. The commands are executed on the next prescaled GCLK\_TC clock cycle.

Writing a zero to one of these bits has no effect.

Writing a one to one of these bits will set a command.

**Table 34-9. Command**

| CMD[2:0] | Name      | Description                              |
|----------|-----------|--|
| 0x0      | NONE      | No action                                |
| 0x1      | RETRIGGER | Force a start, restart or retrigger      |
| 0x2      | STOP      | Force a stop                             |
| 0x3      | UPDATE    | Force update of double-buffered register |
| 0x4      | READSYNC  | Force a read synchronization of COUNT    |
| 0x5-0x7  |           | Reserved                                 |

- Bits 4:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- Bit 2 – ONESHOT: One-Shot on Counter**

This bit controls one-shot operation of the TC. When active, the TC will stop counting on the next overflow/underflow condition or a stop command.

0: The TC will wrap around and continue counting on an overflow/underflow condition.

1: The timer/counter will wrap around and stop on the next underflow/overflow condition.

Writing a zero to this bit has no effect.

Writing a one to this bit will enable one-shot operation.

- **Bit 1 – LUPD: Lock Update**

This bit controls the update operation of the TC buffered registers. When this bit is set, no update of the buffered registers is performed, even though an UPDATE condition has occurred. Locking the update ensures that all buffers registers, are valid before an update is performed.

This bit has no effect when input capture operation is enabled.

0: The CCBUFx and PERBUF buffer registers value are not copied into CCx and PER registers.

1: The CCBUFx and PERBUF buffer registers value are copied into CCx and PER registers on counter update condition.

- **Bit 0 – DIR: Counter Direction**

This bit is used to change the direction of the counter.

0: The timer/counter is counting up (incrementing).

1: The timer/counter is counting down (decrementing).

Writing a zero to this bit has no effect

Writing a one to this bit will make the counter count down.

### 34.8.4 Event Control

**Name:** EVCTRL

**Offset:** 0x06

**Reset:** 0x0000

**Access:** Read-Write

**Property:** Enable-Protected, Write-Protected

| Bit    | 15 | 14 | 13    | 12    | 11 | 10 | 9 | 8     |
|--------|----|----|-------|-------|----|----|---|-------|
|        |    |    | MCEO1 | MCEO0 |    |    |   | OVFEO |
| Access | R  | R  | R/W   | R/W   | R  | R  | R | R/W   |
| Reset  | 0  | 0  | 0     | 0     | 0  | 0  | 0 | 0     |

| Bit    | 7 | 6 | 5    | 4     | 3 | 2          | 1   | 0   |
|--------|---|---|------|-------|---|------------|-----|-----|
|        |   |   | TCEI | TCINV |   | EVACT[2:0] |     |     |
| Access | R | R | R/W  | R/W   | R | R/W        | R/W | R/W |
| Reset  | 0 | 0 | 0    | 0     | 0 | 0          | 0   | 0   |

- Bits 15:14 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 13:12 – MCEOx [x=1..0]: MC Event Output Enable x**  
 These bits control whether event match or capture on channel x is enabled or not and generated for every match or capture.  
 0: Match/Capture event on channel x is disabled and will not be generated.  
 1: Match/Capture event on channel x is enabled and will be generated for every compare/capture.
- Bits 11:9 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 8 – OVFEO: Event Output Enable**  
 This bit is used to enable the Overflow/Underflow event. When enabled an event will be generated when the counter overflows/underflows.  
 0: Overflow/Underflow event is disabled and will not be generated.  
 1: Overflow/Underflow event is enabled and will be generated for every counter overflow/underflow.
- Bits 7:6 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 5 – TCEI: TC Event Enable**  
 This bit is used to enable asynchronous input events to the TC.  
 0: Incoming events are disabled.  
 1: Incoming events are enabled.
- Bit 4 – TCINV: TC Event Input Polarity**  
 This bit inverts the asynchronous input event source.  
 0: Input event source is not inverted.

1: Input event source is inverted.

- **Bit 3 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 2:0 – EVACT[2:0]: Event Action**

These bits define the event action the TC will perform on an event, as shown in [Table 34-10 on page 665](#).

**Table 34-10. Event Action**

| EVACT[2:0] | Name      | Description                                |
|------------|-----------|--|
| 0x0        | OFF       | Event action disabled                      |
| 0x1        | RETRIGGER | Start, restart or retrigger TC on event    |
| 0x2        | COUNT     | Count on event                             |
| 0x3        | START     | Start TC on event                          |
| 0x4        | STAMP     | Time stamp capture                         |
| 0x5        | PPW       | Period captured in CC0, pulse width in CC1 |
| 0x6        | PWP       | Period captured in CC1, pulse width in CC0 |
| 0x7        | PW        | Pulse width capture                        |

### 34.8.5 Interrupt Enable Clear

**Name:** INTENCLR  
**Offset:** 0x08  
**Reset:** 0x00  
**Access:** Read-Write  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5   | 4   | 3 | 2 | 1   | 0   |
|--------|---|---|-----|-----|---|---|-----|-----|
|        |   |   | MC1 | MC0 |   |   | ERR | OVF |
| Access | R | R | R/W | R/W | R | R | R/W | R/W |
| Reset  | 0 | 0 | 0   | 0   | 0 | 0 | 0   | 0   |

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

- Bits 7:6 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 5:4 – MCx [x=1..0]: MC Interrupt Disable x**  
 0: The Match or Capture Channel x interrupt is disabled.  
 1: The Match or Capture Channel x interrupt is enabled.  
 Writing a zero to MCx has no effect.  
 Writing a one to MCx will clear the corresponding Match or Capture Channel x Interrupt Enable bit, which disables the Match or Capture Channel x interrupt.
- Bits 3:2 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 1 – ERR: ERR Interrupt Disable**  
 0: The Error interrupt is disabled.  
 1: The Error interrupt is enabled.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Error Interrupt Enable bit, which disables the Error interrupt.
- Bit 0 – OVF: OVF Interrupt Disable**  
 0: The Overflow interrupt is disabled.  
 1: The Overflow interrupt is enabled.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit will clear the Overflow Interrupt Enable bit, which disables the Overflow interrupt.

### 34.8.6 Interrupt Enable Set

**Name:** INTENSET

**Offset:** 0x09

**Reset:** 0x00

**Access:** Read-Write

**Property:** Write-Protected

| Bit    | 7 | 6 | 5   | 4   | 3 | 2 | 1   | 0   |
|--------|---|---|-----|-----|---|---|-----|-----|
|        |   |   | MC1 | MC0 |   |   | ERR | OVF |
| Access | R | R | R/W | R/W | R | R | R/W | R/W |
| Reset  | 0 | 0 | 0   | 0   | 0 | 0 | 0   | 0   |

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

- **Bits 7:6 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 5:4 – MCx [x=1..0]: MC Interrupt Enable x**  
0: The Match or Capture Channel x interrupt is disabled.  
1: The Match or Capture Channel x interrupt is enabled.  
Writing a zero to MCx has no effect.  
Writing a one to MCx will set the corresponding Match or Capture Channel x Interrupt Enable bit, which enables the Match or Capture Channel x interrupt.
- **Bits 3:2 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 1 – ERR: ERR Interrupt Enable**  
0: The Error interrupt is disabled.  
1: The Error interrupt is enabled.  
Writing a zero to this bit has no effect.  
Writing a one to this bit will set the Error Interrupt Enable bit, which enables the Error interrupt.
- **Bit 0 – OVF: OVF Interrupt Enable**  
0: The Overflow interrupt is disabled.  
1: The Overflow interrupt is enabled.  
Writing a zero to this bit has no effect.  
Writing a one to this bit will set the Overflow Interrupt Enable bit, which enables the Overflow interrupt.

### 34.8.7 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x0A  
**Reset:** 0x00  
**Access:** Read-Write  
**Property:** -

| Bit    | 7 | 6 | 5   | 4   | 3 | 2 | 1   | 0   |
|--------|---|---|-----|-----|---|---|-----|-----|
|        |   |   | MC1 | MC0 |   |   | ERR | OVF |
| Access | R | R | R/W | R/W | R | R | R/W | R/W |
| Reset  | 0 | 0 | 0   | 0   | 0 | 0 | 0   | 0   |

- **Bits 7:6 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 5:4 – MCx [x=1..0]: MC Interrupt Flag x**  
This flag is set on the next CLK\_TC\_CNT cycle after a match with the compare condition or once CCx register contain a valid capture value, and will generate an interrupt request if the corresponding Match or Capture Channel x Interrupt Enable bit in the Interrupt Enable Set register (INTENSET.MCx) is one.  
Writing a zero to one of these bits has no effect.  
Writing a one to one of these bits will clear the corresponding Match or Capture Channel x interrupt flag  
In capture operation, this flag is automatically cleared when CCx register is read.
- **Bits 3:2 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 1 – ERR: ERR Interrupt Flag**  
This flag is set if a new capture occurs on a channel when the corresponding Match or Capture Channel x interrupt flag is one, in which case there is nowhere to store the new capture.  
Writing a zero to this bit has no effect.  
Writing a one to this bit clears the Error interrupt flag.
- **Bit 0 – OVF: OVF Interrupt Flag**  
This flag is set on the next CLK\_TC\_CNT cycle after an overflow condition occurs, and will generate an interrupt if INTENCLR/SET.OVF is one.  
Writing a zero to this bit has no effect.  
Writing a one to this bit clears the Overflow interrupt flag.

### 34.8.8 Status

**Name:** STATUS

**Offset:** 0x0B

**Reset:** 0x01

**Access:** Read-Write

**Property:** Read-Synchronized, Write-Protected

| Bit    | 7 | 6 | 5       | 4       | 3       | 2 | 1     | 0    |
|--------|---|---|---------|---------|---------|---|-------|------|
|        |   |   | CCBUFV1 | CCBUFV0 | PERBUFV |   | SLAVE | STOP |
| Access | R | R | R/W     | R/W     | R/W     | R | R     | R    |
| Reset  | 0 | 0 | 0       | 0       | 0       | 0 | 0     | 1    |

- **Bits 7:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:4 – CCBUFVx [x=1..0]: Compare channel buffer x valid**

For a compare channel, the bit is set when a new value is written to the corresponding CCBUFx register. The bit is cleared by writing a one to the corresponding location or automatically cleared by hardware on UPDATE condition. For a capture channel, the bit is set when a valid capture value is stored in the CCBUFx register. The bit is automatically cleared when the CCx register is read.

- **Bit 3 – PERBUFV: Synchronization Busy Status**

This bit is set when a new value is written to the PERBUF register. The bit is cleared by writing a one to the corresponding location or automatically cleared by hardware on UPDATE condition. This bit is available only in 8-bit mode and always read zero in 16- and 32-bit modes.

- **Bit 2 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 1 – SLAVE: Slave Status Flag**

This bit is available on TC slave only. The bit is set when the associated master TC is set to run in 32-bit mode.

- **Bit 0 – STOP: Stop Status Flag**

This bit is set when the TC is disabled, on a Stop command or on an overflow/underflow condition when the One-Shot bit in the Control B Set register (CTRLBSET.ONESHOT) is one.

0: Counter is running.

1: Counter is stopped.

### 34.8.9 Waveform Generation Control

**Name:** WAVE

**Offset:** 0x0C

**Reset:** 0x00

**Access:** Read-Write

**Property:** Enable-Protected, Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1            | 0   |
|--------|---|---|---|---|---|---|--------------|-----|
|        |   |   |   |   |   |   | WAVEGEN[1:0] |     |
| Access | R | R | R | R | R | R | R/W          | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0            | 0   |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – WAVEGEN[1:0]: Waveform Generation Mode**

These bits select the waveform generation operation, as shown in the table below. The settings impact the top value and select the frequency/PWM mode.

These bits are not synchronized.

**Table 34-11. Waveform Generation Mode**

| WAVEGEN[1:0] | Name | Description      |
|--------------|------|------------------|
| 0x0          | NFRQ | Normal frequency |
| 0x1          | MFRQ | Match frequency  |
| 0x2          | NPWM | Normal PWM       |
| 0x3          | MPWM | Match PWM        |

### 34.8.10 Control C

**Name:** DRVCTRL

**Offset:** 0x0D

**Reset:** 0x00

**Access:** Read-Write

**Property:** Enable-Protected, Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0      |
|--------|---|---|---|---|---|---|--------|--------|
|        |   |   |   |   |   |   | INVEN1 | INVEN0 |
| Access | R | R | R | R | R | R | R/W    | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0      | 0      |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – INVENx [x=1..0]: Output Waveform Invert Enable x**

These bits are used to select inversion on the output or capture trigger input of channel x.

Writing a one to INVENx inverts the WO[x] output and IO input pin.

Writing a zero to INVENx disables inversion of the WO[x] output and IO input pin.

### 34.8.11 Debug Control

**Name:** DBGCTRL

**Offset:** 0x0F

**Reset:** 0x00

**Access:** Read-Write

**Property:** Write-Protected

|        |   |   |   |   |   |   |   |        |
|--------|---|---|---|---|---|---|---|--------|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
|        |   |   |   |   |   |   |   | DBGRUN |
| Access | R | R | R | R | R | R | R | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGRUN: Run During Debug**

This bit is not affected by a software reset, and should not be changed by software while the TC is enabled.

0: The TC is halted when the device is halted in debug mode.

1: The TC continues normal operation when the device is halted in debug mode.

### 34.8.12 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x10

**Reset:** 0x00000000

**Access:** Read-Only

**Property:** -

|        |     |     |     |       |        |       |        |       |

| Reset  | 0   | 0   | 0   | 0     | 0      | 0     | 0      | 0     |
| Bit    | 7   | 6   | 5   | 4     | 3      | 2     | 1      | 0     |
|        | CC1 | CC0 | PER | COUNT | STATUS | CTRLB | ENABLE | SWRST |
| Access | R   | R   | R   | R     | R      | R     | R      | R     |
| Reset  | 0   | 0   | 0   | 0     | 0      | 0     | 0      | 0     |

- **Bits 31:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 7:6 – CCx [x=1..0]: Compare Channel x**

This bit is cleared when the synchronization of Compare/Capture Channel x register between the clock domains is complete.

This bit is set when the synchronization of Compare/Capture Channel x register between clock domains is started. CCx bit is available only for existing Compare/Capture Channels. For details on CC channels number, refer to each TC feature list.

This bit is set when the synchronization of CCx register between clock domains is started.

This bit is also set when the CCBUFx register is written, and cleared on update condition. The bit is automatically cleared when the STATUS.CCBUFx bit is cleared.

- **Bit 5 – PER: Period**

This bit is cleared when the synchronization of PER register between the clock domains is complete.

This bit is set when the synchronization of PER register between clock domains is started.

This bit is also set when the PER register is written, and cleared on update condition. The bit is automatically cleared when the STATUS.PERBUF bit is cleared.

- **Bit 4 – COUNT: Counter**

This bit is cleared when the synchronization of COUNT register between the clock domains is complete.

This bit is set when the synchronization of COUNT register between clock domains is started.

- **Bit 3 – STATUS: STATUS**

This bit is cleared when the synchronization of STATUS register between the clock domains is complete.

This bit is set when a one is written to the Capture Channel Buffer Valid status flags (STATUS.CCBUFVx and the synchronization of STATUS register between clock domains is started.

- **Bit 2 – CTRLB: CTRLB**

This bit is cleared when the synchronization of CTRLB register between the clock domains is complete.

This bit is set when the synchronization of CTRLB register between clock domains is started.

- **Bit 1 – ENABLE: enable**

This bit is cleared when the synchronization of ENABLE register bit between the clock domains is complete.

This bit is set when the synchronization of ENABLE register bit between clock domains is started.

- **Bit 0 – SWRST: swrst**

This bit is cleared when the synchronization of SWRST register bit between the clock domains is complete.

This bit is set when the synchronization of SWRST register bit between clock domains is started.

34.8.13 Count - COUNT8

**Name:** COUNT  
**Offset:** 0x14  
**Reset:** 0x00  
**Access:** Read-Write  
**Property:** Read-Synchronized, Write-Protected, Write-Synchronized

## 35. TCC – Timer/Counter for Control Applications

### 35.1 Overview

The Timer/Counter for Control applications (TCC) consists of a counter, a prescaler, compare/capture channels and control logic. The counter can be set to count events or clock pulses. The counter together with the compare/capture channels can be configured to time stamp input events, allowing capture of frequency and pulse-width. It can also perform waveform generation such as frequency generation and pulse-width modulation.

Waveform extensions are intended for motor control, ballast, LED, H-bridge, power converters, and other types of power control applications. It enables low- and high-side output with optional dead-time insertion. It can also generate a synchronized bit pattern across the waveform output pins. The fault options enable fault protection for safe and deterministic handling, disabling and/or shut down of external drivers.

The Timer/Counter Block diagram ([Figure 35-1 on page 692](#)) shows all the features in TCC but table below shows the configuration of the TCC. Note that the number of CC registers (CC\_NUM) for each TCC corresponds to the number of compare/capture channels, so that a TCC can have more Waveform Outputs (WO\_NUM) than CC registers.

**Table 35-1. TCC Configuration Summary**

| TCC# | Channels (CC_NUM) | Waveform Output (WO_NUM) | Counter size | Fault | Dithering | Output matrix | Dead Time Insertion (DTI) | SWAP | Pattern generation |
|------|-------------------|--------------------------|--------------|-------|-----------|---------------|---------------------------|------|--------------------|
| 0    | 4                 | 8                        | 24-bit       | X     | X         | X             | X                         | X    | X                  |

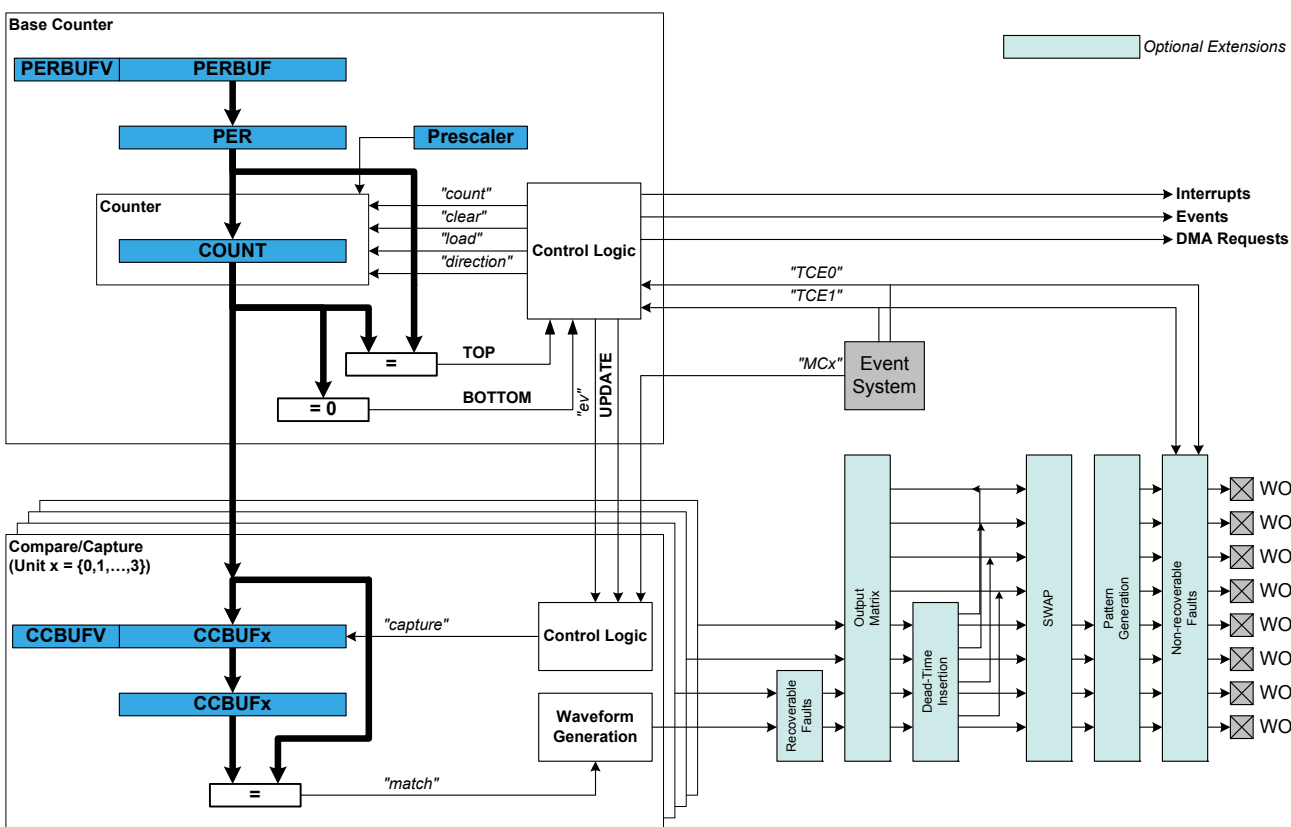

### 35.2 Features

- Up to four compare/capture channels (CC) with:
  - Double buffered period setting
  - Double buffered compare or capture channel
  - Circular buffer on period and compare channel registers
- Waveform generation:
  - Frequency generation
  - Single-slope pulse-width modulation (PWM)
  - Dual-slope pulse-width modulation with half-cycle reload capability
- Input capture:
  - Event capture
  - Frequency capture
  - Pulse-width capture
- Waveform extensions:
  - Configurable distribution of compare channels outputs across port pins
  - Low- and high-side output with programmable dead-time insertion
  - Waveform swap option with double buffer support
  - Pattern generation with double buffer support
  - Dithering support
- Fault protection for safe drivers disabling:
  - Two recoverable fault sources
  - Two non-recoverable fault sources
  - Debugger can be source of non-recoverable fault
- Input event:
  - Two input events for counter
  - One input event for each channel
- Output event:
  - Timer event output on overflow/re-trigger condition
  - One compare match or input capture event output per CC channel

- Event output on fault detection
- Interrupts:
  - Overflow and Retrigger interrupt
  - Compare Match/Input Capture interrupt
  - Interrupt on fault detection
- Can be used with DMA and can trigger DMA transactions.

## 35.3 Block Diagram

Figure 35-1. Timer/Counter Block Diagram

## 35.4 Signal Description

| Pin Name          | Type           | Description                       |
|-------------------|----------------|-----------------------------------|
| TCCx/WO[0]        | Digital output | Compare channel 0 waveform output |
| TCCx/WO[1]        | Digital output | Compare channel 1 waveform output |
| ...               | ...            | ...                               |
| TCCx/WO[WO_NUM-1] | Digital output | Compare channel n waveform output |

Refer to [Table 6-1](#) in the “I/O Multiplexing and Considerations” on page 13 for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 35.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 35.5.1 I/O Lines

Using the TCC's I/O lines requires the I/O pins to be configured. Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

### 35.5.2 Power Management

The TCC will continue to operate in any sleep mode where the selected source clock is running. The TCC's interrupts can be used to wake up the device from sleep modes. Events connected to the event system can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 35.5.3 Clocks

The TCC bus clock (CLK\_TCCx\_APB) is enabled by default, and can be enabled and disabled in the Main Clock. Refer to [Table 17-1](#) for details.

A generic clock (GCLK\_TCCx) is required to clock the TCC. This clock must be configured and enabled in the generic clock controller before using the TCC. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

This generic clock is asynchronous to the bus clock (CLK\_TCCx\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 725](#) for further details.

### 35.5.4 DMA

The DMA request lines are connected to the DMA Controller (DMAC). Using the TCC DMA requests, requires the DMA Controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details.

### 35.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the TCC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 35.5.6 Events

The events are connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

### 35.5.7 Debug Operation

When the CPU is halted in debug mode the TCC will halt normal operation. The TCC can be forced to continue operation during debugging. Refer to [DBGCTRL](#) for details.

### 35.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag register (INTFLAG)
- Status register (STATUS)
- Period and Period Buffer registers (PER, PERBUF)
- Compare/Capture and Compare/Capture Buffer registers (CCx, CCBUFx)
- Control Waveform and Control Waveform Buffer registers (WAVE, WAVEBUF)
- Pattern Generation Value and Pattern Generation Value Buffer registers (PATT, PATTBUF)

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to the [“PAC – Peripheral Access Control” on page 33](#) for details.

## 35.5.9 Analog Connections

Not applicable.

## 35.6 Functional Description

### 35.6.1 Principle of Operation

Each TCC instance has up to eight compare/capture channels (CCx).

The following definitions are used throughout the documentation:

**Figure 35-2. Timer/counter definitions**

| Name   | Description  |
|--------|--|
| TOP    | The counter reaches TOP when it becomes equal to the highest value in the count sequence. The TOP value can be equal to the period (PER) or the compare channel A (CCA) register setting. This is selected by the waveform generator mode. |
| BOTTOM | The counter reaches BOTTOM when it becomes zero  |
| MAX    | The counter reaches maximum when it becomes all ones   |
| UPDATE | The timer/counter signals an update when it reaches BOTTOM or TOP, depending on the direction settings.  |

In general, the term “timer” is used when the timer/counter clock control is handled by an internal source, and the term “counter” is used when the clock control is handled externally (e.g. counting external events). When used for compare operations, the CC channels are referred to as “compare channels.” When used for capture operations, the CC channels are referred to as “capture channels.”

The counter register (COUNT), period registers with buffer (PER and PERBUF), and compare and capture registers with buffers (CCx and CCxBUF) are 16-, 24- or 32-bit registers, depending on each TCC instance. Each buffer register has a buffer valid (BV) flag that indicates when the buffer contains a new value. During normal operation, the counter value is continuously compared to the Period (TOP) and to ZERO value to determine whether the counter has reached TOP or ZERO.

The counter value is also compared to the CCx registers. These comparisons can be used to generate interrupt requests, request DMA transactions or generate events for the event system. The waveform generator modes use these comparisons to set the waveform period or pulse width.

A prescaled generic clock (GCLK\_TCCx) and events from the event system can be used to control the counter. The event system is also used as a source to the input capture.

The recoverable fault module extension enables event controlled waveforms by acting directly on the generated waveforms from TCC compare channels output. These events can restart, halt the timer/counter period or shorten the output pulse active time, or disable waveform output as long as the fault condition is present. This can typically be used for current sensing regulation or zero crossing and demagnetization retriggering.

The MCE0 and MCE1 event sources are shared with the recoverable fault module. Only asynchronous events are used internally when fault unit extension is enabled. For further details on how to configure asynchronous events routing, refer to section [“EVSYS – Event System” on page 467](#).

By using digital filtering and/or input blanking, qualification options (as detailed in [“Recoverable Faults” on page 711](#)), recoverable fault sources can be filtered and/or windowed to avoid false triggering, for example from I/O pin glitches.

In addition as shown in [Figure 35-1 on page 692](#), six optional independent and successive units primarily intended for use with different types of motor control, ballast, LED, H-bridge, power converter, and other types of power switching applications, are implemented in some of TCC instances.

The output matrix (OTMX) can distribute and route out the TCC waveform outputs across the port pins in different configurations, each optimized for different application types.

The dead time insertion (DTI) unit splits the four lower OTMX outputs into two non-overlapping signals, the non-inverted low side (LS) and inverted high side (HS) of the waveform output with optional dead-time insertion between LS and HS switching.

The swap (SWAP) unit can be used to swap the LS and HS pin outputs, and can be used for fast decay motor control.

The pattern generation unit can be used to generate synchronized waveforms with constant logic level on TCC update conditions. This is for example useful for easy stepper motor and full bridge control.

The non-recoverable fault module enables event controlled fault protection by acting directly on the generated waveforms from timer/counter compare channels output. When a non-recoverable fault condition is detected, the output waveforms are forced to a safe and pre-configured value that is safe for the application. This is typically used for instant and predictable shut down and disabling high current or voltage drives.

The count event sources (TCE0 and TCE1) are shared with the non-recoverable fault extension. The events can be optionally filtered. If the filter options are not used, the non-recoverable faults provide an immediate asynchronous action on waveform output, even for cases where the clock is not present. For further details on how to configure asynchronous events routing, refer to section [“EVSYS – Event System” on page 467](#).

## 35.6.2 Basic Operation

### 35.6.2.1 Initialization

The following registers are enable-protected, meaning that it can only be written when the TCC is disabled (CTRLA.ENABLE is zero):

- Control A (CTRLA) register, except Run Standby (RUNSTDBY), Enable (ENABLE) and Software Reset (SWRST) bits.
- Recoverable Fault n Control register (FCTRLA and FCTRLB).
- Waveform Extension Control register (WEXCTRL).
- Drive Control register (DRVCTRL).
- Event Control register.

Enable-protected bits in the CTRLA register can be written at the same time as CTRLA.ENABLE is written to one, but not at the same time as CTRLA.ENABLE is written to zero.

Enable-protection is denoted by the Enable-Protected property in the register description.

Before the TCC is enabled, it must be configured as outlined by the following steps:

- Select PRESCALER setting in the Control A register (CTRLA.PRESCALER)
- Select Prescaler Synchronization setting in Control A register (CTRLA.PRESCSYNC)
- A channel is enabled in capture mode by writing a one to Capture Enable bit in Control A register (CTRLA.CAPTEN)
- If down-counting operation must be enabled, write a one to the Counter Direction bit in the Control B Set register (CTRLBSET.DIR)
- Select the Waveform Generation operation in WAVE register (WAVE.WAVEGEN)
- Select the Waveform Output Polarity in the WAVE register (WAVE.POL)
- The waveform output can be inverted for the individual channels using the Waveform Output Invert Enable bit group in the Driver register (DRVCTRL.INVEN)

### 35.6.2.2 Enabling, Disabling and Resetting

The TCC is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The TCC is disabled by writing a zero to CTRLA.ENABLE.

The TCC is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the TCC, except DBGCTRL, will be reset to their initial state, and the TCC will be disabled. Refer to the CTRLA register for details.

The TCC should be disabled before the TCC is reset to avoid undefined behavior.

### 35.6.2.3 Prescaler Selection

The GCLK\_TCCx is fed into the internal prescaler. Prescaler output intervals from 1 to 1/1024 are available. For a complete list of available prescaler outputs, see the register description for the Prescaler bit group in the Control A register (CTRLA.PRESCALER).

The prescaler consists of a counter that counts to the selected prescaler value, whereupon the output of the prescaler toggles. When the prescaler is set to a value greater than one, it is necessary to choose whether the prescaler should reset its value to zero or continue counting from its current value on the occurrence of an external re-trigger. It is also necessary to choose whether the TCC counter should wrap around on the next GCLK\_TCC clock pulse or the next prescaled clock pulse (CLK\_TCC\_CNT in Figure 35-3). To do this, use the Prescaler and Counter synchronization bit group in the Control A register (CTRLA.PRESYNC). If the counter is set to count events from the event system, these will not pass through the prescaler

Figure 35-3. Prescaler

### 35.6.2.4 Counter Operation

Depending on the mode of operation, the counter is cleared, reloaded, incremented, or decremented at each TCC clock cycle (CLK\_TCC\_CNT). A counter clear or reload marks the end of current counter cycle and the start of a new one.

The counter will count in the direction set by the direction (CTRLBSET.DIR or CTRLBCLR.DIR) bit for each clock until it reaches TOP or ZERO. A clear operation occurs when the TOP is reached while up-counting, the counter will be set to ZERO (cleared) on the next clock cycle. A reload operation occurs when the ZERO is reached while down-counting, the counter is reloaded with the period register (PER) value.

The counter value is continuously compared with the period (PER) and ZERO value to determine if the counter has reached TOP or ZERO. Based on this comparison, the Overflow Interrupt Flag in the Interrupt Flag Status and Clear register (INTFLAG.OVF) is set whenever the counter value matches with TOP / ZERO. This can be used to trigger an interrupt, a DMA request, or an event. If the One-Shot bit in the Control B Set register (CTRLBSET.ONESHOT) is set, the compare match (with TOP/ZERO) will stop the counting operation.

Up-counting is enabled by writing a one to the Direction bit in the Control B Clear register (CTRLBCLR.DIR). Down-counting is enabled by writing a one to the Direction bit in the Control B Set register (CTRLBSET.DIR).

Figure 35-4. Counter Operation

As shown in Figure 35-4, it is possible to change the counter value when the counter is running. The write access has higher priority than count, clear, or reload. The direction of the counter can also be changed during normal operation. Due to asynchronous clock domains, the internal counter settings are written when the synchronization is complete.

Normal operation must be used when using the counter as timer base for the capture channels.

### Stop Command and Event Action

A stop command can be issued from software by using TCC Command bits in Control B Set register (CTRLBSET.CMD = STOP) or when the stop event action is configured in the Input Event1 Action bits in Event Control register (EVCTRL.EVACT1 = STOP).

When a stop is detected while the counter is running, the counter will maintain its current value. If waveform generation (WG) is used, all waveforms are set to a state defined in Non-Recoverable State x Output Enable bit and Non-Recoverable State x Output Value bit in the Driver Control register (DRVCTRL.NRE and DRVCTRL.NRV) and the Stop bit in the Status register is set (STATUS.STOP).

### Retrigger Command and Event Action

A retrigger command can be issued from software by using TCC Command bits in Control B Set register (CTRLBSET.CMD = RETRIGGER) or when the retrigger event action is configured in the Input Event0/1 Action bits in Event Control register (EVCTRL.EVACT1 = RETRIGGER).

When the command is detected during counting operation, the counter will be reloaded or cleared, depending on the counting direction (CTRLSET.DIR or CTRLBCLR.DIR). The Retrigger bit will be set in the Interrupt Flag Status and Clear register (INTFLAG.TRG). It is also possible to generate an event by writing a one to the Retrigger Event Output Enable bit in the Event Control register (EVCTRL.TRGEO).

If the retrigger command is detected when the counter is stopped, the counter will resume counting operation from the value in COUNT.

**Note:** When re-trigger event action is enabled, enabling the counter will not start the counter. The counter will start on the next incoming event and restart on corresponding following event.

### Start Event Action

The start action can be selected in the Event Control register (EVCTRL.EVACT0) and can be used to start the counting operation when stopped. As consequence, the event has no effect if the counter is already counting. When the module is enabled, the counter operation starts when the event is received or when a retrigger software command is applied. When retrigger or start event action is enabled, enabling counter will not start the counter. The counter will start on the next incoming event and restart on corresponding following event. If the event action is disabled, enabling counter will start the counter.

### Count Event Action

The count action can be selected in the Event Control register (EVCTRL.EVACT0) and can be used to count external events (from pins for example). When an event is received, the counter is incremented or decremented, depending on direction settings (CTRLBSET.DIR or CTRLBCLR.DIR).

### Direction Event Action

The direction event action can be selected in the Event Control register (EVCTRL.EVACT1). When this event is used, the asynchronous event path specified in the event system must be configured or selected. The direction event action can be used to control the direction of the counter operation, depending on external events level. When received, the event level overrides the Direction settings (CTRLBSET.DIR or CTRLBCLR.DIR) and the direction bit value is updated accordingly.

### Increment Event Action

The increment event action can be selected in the Event Control register (EVCTRL.EVACT0) and can be used to change the counter state when an event is received. When the TCE0 event is received, the counter increments, whatever direction settings (CTRLBSET.DIR or CTRLBCLR.DIR) is.

### Decrement Event Action

The decrement event action can be selected in the Event Control register (EVCTRL.EVACT1) and can be used to change the counter state when an event is received. When the TCE1 event is received, the counter decrements, whatever direction settings (CTRLBSET.DIR or CTRLBCLR.DIR) is.

### Non-recoverable Fault Event Action

Non-recoverable fault actions can be selected in the Event Control register (EVCTRL.EVACT0 or EVCTRL.EVACT1).

When received, the counter will be stopped and compare channels outputs are overridden according to DRVCTRL register settings (Non-Recoverable State x Output Enable bits and Non-Recoverable State x Output Value bits).

TCE0 and TCE1 must be configured as asynchronous events.

## 35.6.2.5 Compare Operations

By default, Compare/Capture channel is configured for Compare operations. To perform capture operations, it must be re-configured.

When using the TCC with the Compare/Capture Value registers (CCx) configured for compare operations, the counter value is continuously compared to the values in the CCx registers. This can be used for timer or for waveform operation.

The compare buffer (CCBUFx) register provides double buffer capability. The double buffering synchronizes the update of the CCx register with the buffer value at the UPDATE condition. For further details, refer to [“Double Buffering” on page 703](#). The synchronization prevents the occurrence of odd-length, non-symmetrical pulses and ensures glitch-free output.

If Compare/Capture channel is not configured for capture operation (Control A register), then compare operation will be enabled.

### Waveform Output Generation Operations

The compare channels can be used for waveform generation on output port pins. To make the waveform visible on the connected pin, the following requirements must be fulfilled:

1. Choose a waveform generation mode in the Waveform Control register (WAVE.WAVEGEN)
2. Optionally invert the waveform output WO[x] by writing the corresponding Waveform Output Invert Enable bit in the Driver Control register (DRVCTRL.INVENx)
3. Configure the pins with the I/O Pin Controller. Refer to [“PORT – IO Pin Controller” on page 437](#) for details.

The counter value is continuously compared with each CCx value. When a compare match occurs, the Match or Capture Channel x bit in the Interrupt Flag Status and Clear register (INTFLAG.MCx) is set on the next zero-to-one transition of CLK\_TCC\_COUNT. If Match/Capture occurs, interrupt can be generated when INTENSET.MCX is set. If

Compare/Match occurs, an event can be triggered when EVCTRL.MCEOx is set to one. Both interrupt and event can be generated simultaneously. . The same condition generates a DMA request.

Six waveform configurations are available through the Waveform Generation (WG) bit group in the Waveform Control register (WAVE.WAVEGEN):

- Normal Frequency (NFRQ)
- Match Frequency (MFRQ)
- Single-slope PWM (NPWM)
- Dual-slope, interrupt/event at Top (DSTOP)
- Dual-slope, interrupt/event at ZERO (DSBOTTOM)
- Dual-slope, interrupt/event at Top and ZERO (DSBOTH)
- Dual-slope, critical interrupt/event at ZERO (DSCRITICAL)

When using MFRQ, the top value is defined by the CC0 register value, for all other waveforms operation the top value is defined by Period (PER) register value.

For dual slope waveform operations update time occurs when counter reaches the zero value. For all other waveforms generation modes, the update time occurs on counter wraparound, on overflow, underflow or retrigger.

### Normal Frequency Generation

For normal frequency generation, the period time is controlled by the period register (PER). The waveform generation output (WO[x]) is toggled on each compare match between COUNT and CCx, and the corresponding Match or Capture Channel x will be set.

**Figure 35-5. Normal Frequency Operation**

### Match Frequency Generation

For match frequency generation, the period time is controlled by CC0 instead of PER. WO[0] toggles on each update condition.

Figure 35-6. Match Frequency Operation

### Single-Slope PWM Generation

For single-slope PWM generation, the period time is controlled by PER, while CCx control the duty cycle of the generated waveform output. When up-counting, WO[x] is set at start or compare match between the COUNT and TOP values, and cleared on compare match between COUNT and CCx register values.

When down-counting, WO[x] is cleared at start or compare match between the COUNT and TOP values, and set on compare match between COUNT and CCx register values.

Figure 35-7. Single-Slope PWM Operation

The following equation calculates the exact resolution for a single-slope PWM ( $R_{PWM\_SS}$ ) waveform:

$$R_{PWM\_SS} = \frac{\log(TOP+1)}{\log(2)}$$

The PWM frequency depends on the Period register value (PER) and the peripheral clock frequency ( $f_{GCLK\_TCC}$ ), and can be

calculated by the following equation:

$$f_{PWM\_SS} = \frac{f_{GCLK\_TCC}}{N(TOP+1)}$$

Where N represent the prescaler divider used (1, 2, 4, 8, 16, 64, 256, 1024).

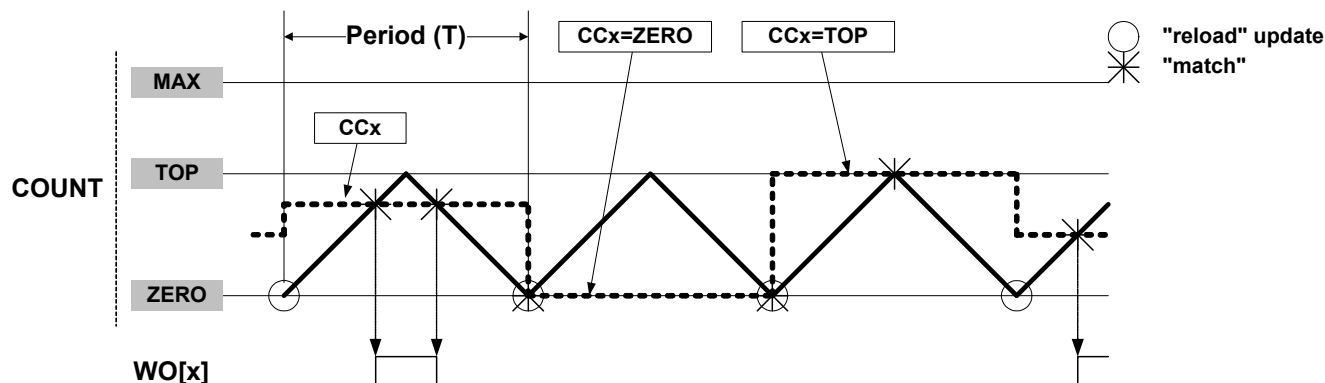

### Dual-Slope PWM Generation

For dual-slope PWM generation, the period (TOP) is controlled by PER, while CCx control the duty cycle of the WG output. Figure 35-8 shows how for dual-slope PWM the counter counts repeatedly from ZERO to TOP and then from

TOP to ZERO. The waveform generator output is set on compare match when up-counting, and cleared on compare match when down-counting.

**Figure 35-8. Dual-Slope Pulse Width Modulation**

Using dual-slope PWM results in a lower maximum operation frequency compared to single-slope PWM operation.

The period (TOP) defines the PWM resolution. The minimum resolution is 1 bits (TOP=0x00000001).

The following equation calculates the exact resolution for dual-slope PWM ( $R_{PWM\_DS}$ ):

$$R_{PWM\_DS} = \frac{\log(TOP+1)}{\log(2)}$$

The PWM frequency depends on the period setting (TOP) and the peripheral clock frequency ( $f_{GCLK\_TCC}$ ), and can be calculated by the following equation:

$$f_{PWM\_DS} = \frac{f_{GCLK\_TCC}}{2N \cdot TOP}$$

N represents the prescaler divider used. The waveform generated will have a maximum frequency of half of the TCC clock frequency ( $f_{GCLK\_TCC}$ ) when TOP is set to one (0x00000001) and no prescaling is used.

The pulse width (PPWM\_DS) depends on the compare channel (CCx) register value and the peripheral clock frequency ( $f_{GCLK\_TCC}$ ), and can be calculated by the following equation:

$$P_{PWM\_DS} = \frac{2N \cdot (TOP - CCx)}{f_{GCLK\_TCC}}$$

Where N represents the prescaler divider used. In PWM operation, the pulse can be inhibited.

Note: In dual-slope PWM operation, the CCx MSB bit defines the ramp (rising if CCx[MSB] is 0, or falling if CCx[MSB] is 1) on which the CCx Match interrupt or event is generated.

#### Dual-Slope Critical PWM Generation

Critical mode operation allows generation of non-aligned centered pulses. In this mode, the period time is controlled by PER, while CCx control the generated waveform output edge during up-counting and CC(x+CC\_NUM/2) control the generated waveform output edge during down-counting.

Figure 35-9. Dual-Slope Critical Pulse Width Modulation (N=CC\_NUM)

The table below shows the update counter and overflow event/interrupt generation conditions in different operation modes.

Table 35-2. Counter Update and Overflow Event/interrupt Conditions

| Name       | Operation        | Top | Update     | Description                    |                                 |                   |               |
|------------|------------------|-----|------------|--------------------------------|---------------------------------|-------------------|---------------|
|            |                  |     |            | Output<br>Waveform<br>On Match | Output<br>Waveform<br>On Update | OVFIF/Event<br>Up | Event<br>Down |

| DSBOTH     | Dual-slope PWM   | PER | TOP & ZERO |                                |                                 | TOP               | ZERO          |
| DSTOP      | Dual-slope PWM   | PER | ZERO       |                                |                                 | TOP               | -             |

### Output Polarity

The polarity (WAVE.POLx) is available in all waveform output generation. In single-slope and dual-slope PWM generation, it is possible to invert individually the pulse edge alignment on start or end of PWM cycle for each compare channels. [Table 35-3](#) shows the waveform output set/clear conditions, depending on timer/counter settings, direction and polarity setting.

**Table 35-3. Waveform Generation Set/Clear Conditions**

| Waveform Generation operation | DIR | POLx | Waveform Generation Output Updates           |  |
|-------------------------------|-----|------|--|--|
|                               |     |      | Set  | Clear  |
| Single-Slope PWM              | 0   | 0    | Timer/counter matches TOP                    | Timer/counter matches CCx                    |
|                               |     | 1    | Timer/counter matches CCx                    | Timer/counter matches TOP                    |
|                               | 1   | 0    | Timer/counter matches CCx                    | Timer/counter matches ZERO                   |
|                               |     | 1    | Timer/counter matches ZERO                   | Timer/counter matches CCx                    |
| Dual-Slope PWM                | x   | 0    | Timer/counter matches CCx when counting up   | Timer/counter matches CCx when counting down |
|                               |     | 1    | Timer/counter matches CCx when counting down | Timer/counter matches CCx when counting up   |

In Normal and Match Frequency, the WAVE.POLx value represents the initial state of the waveform output.

### 35.6.2.6 Double Buffering

The Pattern (PATT), Waveform (WAVE), Period (PER) and the Compare Channels (CCx) registers are all double buffered. Each buffer register has a Buffer Valid (PATTBUFV, WAVEBUFV, PERBUFV or CCBUFVx) bit in the STATUS register, which indicates that the buffer register contains a value that can be copied into the corresponding register. When double buffering is enabled by writing a one to the Lock Update bit in the Control B Clear register (CTRLBCLR.LUPD) and the PER and CCx are used for a compare operation, the Buffer Valid bit is set when data has been written to a buffer register and cleared on an update condition.

This is shown for a compare register in [Figure 35-10](#).

**Figure 35-10. Compare Channel Double Buffering**

As both the register (PATT/WAVE/PER/CCx) and corresponding buffer register (PATTBUF/WAVEBUF/PERBUF/CCBUFx) are available in the I/O register map, the double buffering feature is not mandatory. The double buffering is disabled by writing a one to CTRLSET.LUPD. This allows initialization and bypassing of the buffer register, and the double buffering feature.

**Note:** In normal frequency (NFRQ), match frequency (MFRQ) or PWM down-counting counter mode (CTRLBSET.DIR is one), PER is written at the same time as PERB is written if CTRLB.LUPD is zero or as soon as CTRLB.LUPD becomes zero.

## Changing the Period

The counter period is changed by writing a new value to the Period register or the Period Buffer register. If double buffering is not used, any update of PER is effective after the synchronization delay.

Figure 35-11. Unbuffered Single-Slope Up-Counting Operation

Figure 35-12. Unbuffered Single-Slope Down-Counting Operation

A counter wraparound can occur in any mode of operation when up-counting without buffering, as shown in [Figure 34-10](#). This is due to the fact that COUNT and TOP are continuously compared, and if a new value that is lower than the current COUNT is written to TOP, COUNT will wrap before a compare match happens.

Figure 35-13. Unbuffered Dual-Slope Operation

When double buffering is used, the buffer can be written at any time and the counter will still maintain correct operation. The period register is always updated on the update condition, as shown for dual-slope operation in [Figure 35-14](#). This prevents wraparound and the generation of odd waveforms.

Figure 35-14. Changing the Period Using Buffering

### 35.6.2.7 Capture Operations

To enable and use capture operations, the Match or Capture Channel x Event Input Enable (MCEIx) bit must be enabled in the Event Control register (EVCTRL.MCEIx). The capture channels to be used must also be enabled in the Capture Channel x Enable bit in the Control A register (CTRLA.CAPTENx) before capture can be performed.

#### Event Capture Action

The capture channels can be used to capture the COUNT value upon reception of any event. Since there is one event line per capture channel, multiple capture operations can be enabled at the same time.

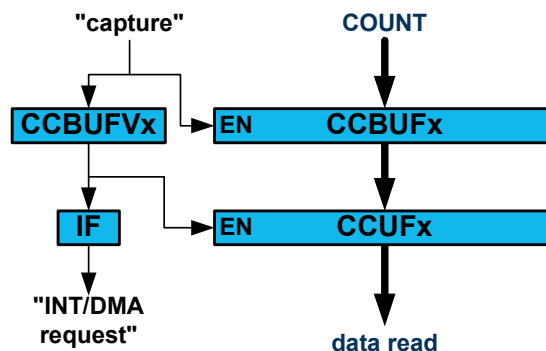

[Figure 35-15](#) shows four capture events for one capture channel.

Figure 35-15. Input Capture Timing

For input capture, the buffer register and the corresponding CCx act like a FIFO. When CCx is empty or read, any content in CCBUFx is transferred to CCx. The buffer valid flag is passed to set the CCx interrupt flag (IF) and generate the optional interrupt, event or DMA request.

Figure 35-16. Capture Double Buffering

When the Capture x (MCx) bit and the buffer valid flag are set and a new capture event is detected, there is nowhere to store the new timestamp. In that case the Error bit in the Interrupt Flag Status and Clear register (INTFLAG.ERR) is set.

### Period and Pulse-Width Capture Action

The TCC can perform two input captures and restart the counter on one of the edges. This enables the TCC to measure the pulse-width and period. This can be used to characterize an input signal in frequency and duty cycle:

$$f = \frac{1}{T} \quad \text{dutyCycle} = \frac{tp}{T}$$

When using PPW (Period, Pulse-width) event action, period (TOP) will be captured into CC0 and pulse-width (tp) into CC1. In PWP (Pulse-width, Period) event action, pulse-width (tp) will be captured into CC0 and period (TOP) into CC1.

Figure 35-17.PWP Capture

Selecting PWP or PPW in the Event Action bit group in the Event Control register (EVCTRL.EVACT1) enables the TCC to perform two capture actions, one on the rising edge and one on the falling edge.

The Timer/Counter Inverted Event 1 Input Enable bit in Event Control register (EVCTRL.TCEINV1) is used to select which event input edge the counter restarts operation. The event source to be captured must be an asynchronous event.

For a full characterization of input signal in frequency and duty cycle, enable capture on CC0 and CC1 channels by writing a one to the Capture Channel x Enable bit in the Control A register (CTRLA.CAPTENx). When only one of these measurements is required, the second channel can be used for other purposes.

The TCC can detect capture overflow of the input capture channels. When the Capture Interrupt Flag is set and a new capture event is detected, there is nowhere to store the new timestamp. In that case INTFLAG.ERR is set.

Note: In dual-slope PWM operation, the CCx MSB captures the CTRLB.DIR state to identify the ramp (rising if CCx[MSB] is zero, or falling if CCx[MSB] is one) on which the Counter capture has been done.

### 35.6.3 Additional Features

#### 35.6.3.1 One-Shot Operation

When one-shot is enabled, the counter automatically stops on the next counter overflow or underflow condition. When the counter is stopped, STATUS.STOP is set and the waveform outputs are set to the value defined by the Non-Recoverable State x Output Enable (NREx) and Non-Recoverable State x Output Value (NRVx) bits in the Drive Control register (DRVCTRL.NREx and DRVCTRL.NRVx).

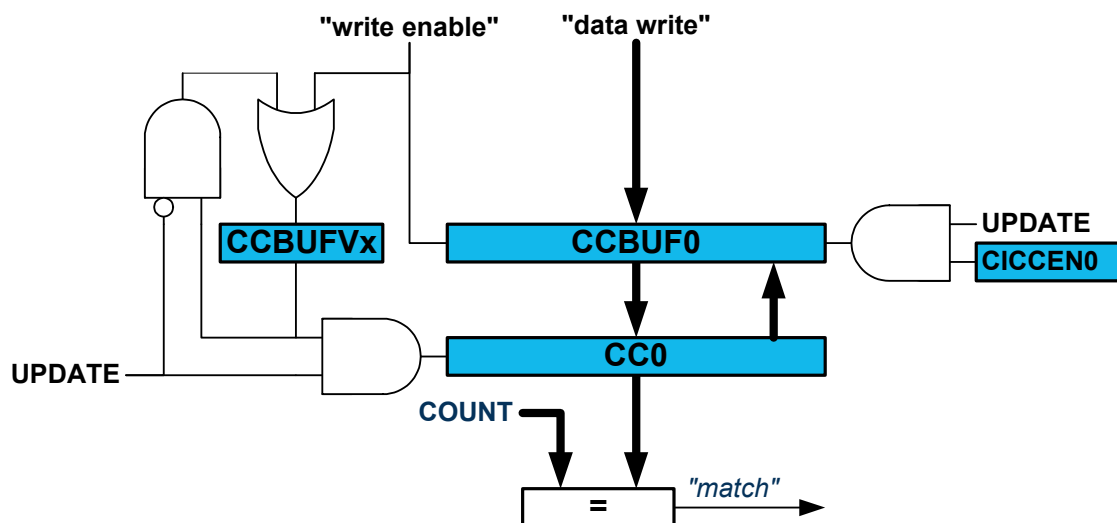

One-shot operation can be enabled by writing a one to the One-Shot bit in the Control B Set register (CTRLBSET.ONESHOT) and disabled by writing a one to the One-Shot bit in the Control B Clear register (CTRLBCLR.ONESHOT). When enabled, the TCC will count until an overflow or underflow occurs and stop counting. The one-shot operation can be restarted by using retrigger software command, a retrigger event or a start event.

When the counter restarts its operation, the Stop bit in the Status register (STATUS.STOP) is cleared.

#### 35.6.3.2 Circular Buffer

The Period register (PER) and the compare channels register (CC0 to CC3) support circular buffer operation. When circular buffer operation is enabled, at each update condition, the (PER) or CCx values are copied into the corresponding buffer registers. Circular buffer are dedicated to RAMP2, RAMP2A, and DSBOTH operations.

Figure 35-18. Circular Buffer on Channel 0

### 35.6.3.3 Dithering Operation

The TCC supports dithering on Pulse-width or Period on a 16, 32 or 64 PWM cycles frame.

Dithering consists in adding some extra clock cycles in a frame of several PWM cycles, improving the accuracy of the average output pulses width or period. The extra clock cycles are added on some of the compare match signals, one at a time, through a "blue noise" process that minimizes the flickering on the resulting dither patterns.

Dithering makes possible to improve the accuracy of the average output pulse width or period.

Dithering is enabled by writing the corresponding configuration in the Enhanced Resolution bits in CTRLA register (CTRLA.RESOLUTION):

- DITH4 enable dithering every 16 PWM frames.
- DITH5 enable dithering every 32 PWM frames.
- DITH6 enable dithering every 64 PWM frames.

The DITHERCY bits of COUNT, PER and CCx define the number of extra cycles to add into the frame (DITHERCY bits from the respective COUNT, PER or CCx registers). The remaining bits of COUNT, PER, CCx define the compare value itself.

The pseudo code, giving the extra cycles insertion regarding the cycle is:

```

int extra_cycle(resolution, dithercy, cycle){
    int MASK;
    int value
    switch (resolution){
        DITH4: MASK = 0x0f;
        DITH5: MASK = 0x1f;
        DITH6: MASK = 0x3f;
    }
    value = cycle * dithercy;
    if (((MASK & value) + dithercy) > MASK)
        return 1;
    return 0;
}

```

### 1.7.3.3.1: Dithering on Period

Writing DITHERCY in PER will lead to an average PWM period configured by the following formula:

DITH4 mode:

$$PwmPeriod = \left( \frac{DITHER}{16} + PER \right) \left( \frac{1}{f_{GCLK\_TCC}} \right)$$

DITH5 mode:

$$PwmPeriod = \left( \frac{DITHER}{32} + PER \right) \left( \frac{1}{f_{GCLK\_TCC}} \right)$$

DITH6 mode:

$$PwmPeriod = \left( \frac{DITHER}{64} + PER \right) \left( \frac{1}{f_{GCLK\_TCC}} \right)$$

### 1.7.3.3.2: Dithering on Pulse Width

Writing DITHERCY in CCx will lead to an average PWM pulse width configured by the following formula:

DITH4 mode:

$$PwmPulseWidth = \left( \frac{DITHER}{16} + CCx \right) \left( \frac{1}{f_{GCLK\_TCC}} \right)$$

DITH5 mode:

$$PwmPulseWidth = \left( \frac{DITHER}{32} + CCx \right) \left( \frac{1}{f_{GCLK\_TCC}} \right)$$

DITH6 mode:

$$PwmPulsewidth = \left( \frac{DITHER}{64} + CCx \right) \left( \frac{1}{f_{GCLK\_TCC}} \right)$$

Note that the PWM period remains static in this case.

## 35.6.3.4 Ramp Operations

Three ramp operations are supported and all require the TCC running in single-slope PWM generation.

### RAMP1 Operation

This is the default PWM operation, described in [“Single-Slope PWM Generation” on page 700](#).

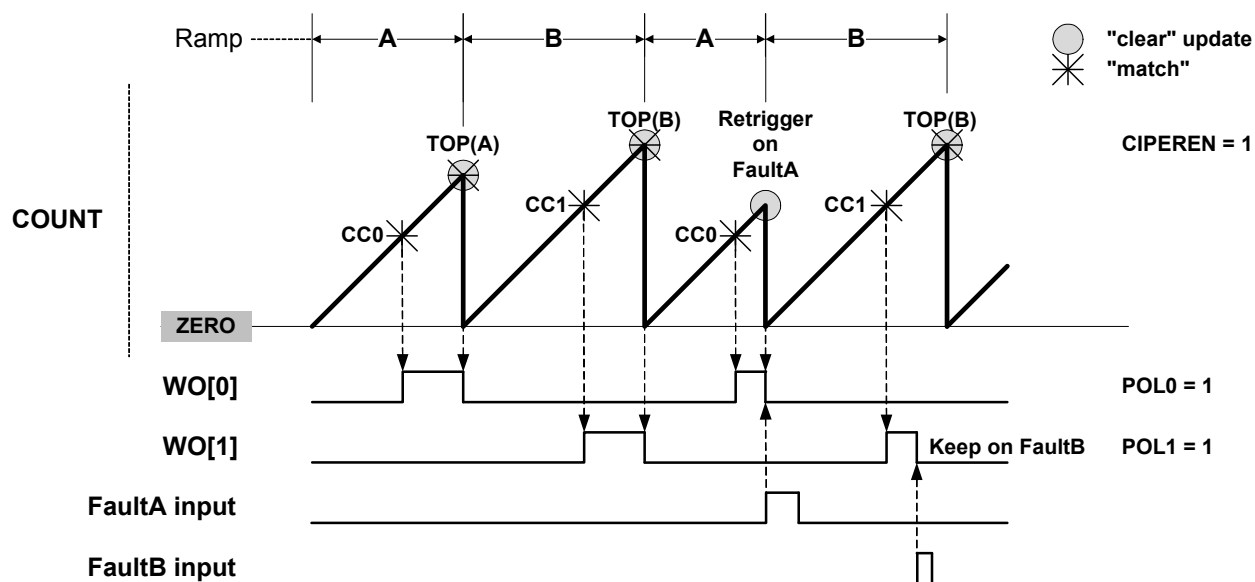

### RAMP2 Operation

These operations are dedicated for PFC, Half-Bridge and Push-Pull SMPS topologies, where two consecutive timer/counter cycles are interleaved, as shown in [Figure 35-19](#). In cycle A, odd channels output are disabled, and in cycle B, even channels output are disabled. The ramp index changes after each update, but can be software modified using the the cycle index command bits in Control B Set register (CTRLBSET.IDXCMD).

### Standard RAMP2 (RAMP2) Operation

Ramp A and B periods are controlled through PER register value. Period register value can have different values on each ramp by enabling the circular buffer option (CIPEREN). This mode allows use of a two channels TCC to generate two output signals, or one output signal with another CC channel enabled in capture mode.

Figure 35-19.RAMP2 Standard Operation

### Alternate RAMP2 (RAMP2A) Operation

Alternate RAMP2 operation is similar to RAMP2 with the difference that CC0 register controls both WO[0]/WO[1] waveforms when the corresponding circular buffer option is enabled. The waveform polarity is the same on both outputs, and the channel 1 can be used in capture mode.

Figure 35-20.RAMP2 Alternate Operation

### Critical RAMP2 (RAMP2C) Operation

Critical RAMP2 operation provides a way to cover RAMP2 operation requirements without the update constraint associated to the use of circular buffers. When this mode is enabled, CC0 control the ramp A period and PER the ramp B period. WO[0] output toggle control is done regarding CC2 value on TCC with more than 2 channels. On TCC with 2 channels a pulse can take place during all rampA period, if WAVE.POL0 is clear.

Figure 35-21.RAMP2 Critical Operation with more than 2 channels

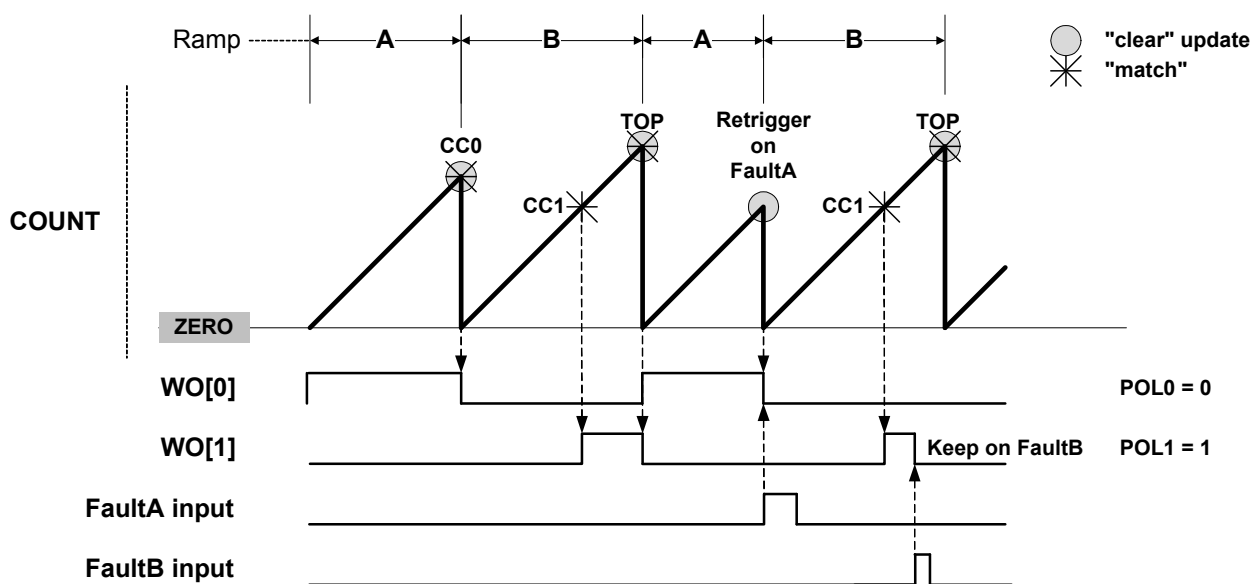

Figure 35-22.RAMP2 Critical Operation with 2 channels

### 35.6.3.5 Recoverable Faults

Recoverable faults can restart or halt the timer/counter. Two faults, called Fault A and Fault B, can trigger recoverable fault actions on compare channels CC0 and CC1 from the corresponding timer/counter. The compare channels outputs can be clamped to inactive state as long as the fault condition is present, or from the first valid fault condition detection and until the end of the timer/counter cycle.

#### Fault inputs

The first two channel input events (MC\_EV0 and MC\_EV1) can be used as Fault A and Fault B inputs respectively. Event system channel connected to these fault inputs must be configured as asynchronous. In two ramp (RAMP2, RAMP2A) operation.

## Fault filtering

Three filtering types are available. The recoverable faults can use all three filters independently or various filter combinations.

- **Input filtering:** By default, the event detection is asynchronous. When the event occurs, the fault system will immediately and asynchronously performs the selected fault action on the compare channel output, including system power modes where the clock is not available. To avoid false fault detection on external events (e.g. a glitch on I/O port) a digital filter can be enabled and set in FILTERVAL bits in the corresponding recoverable Fault Control n register (FCTRLn.FILTERVAL). In this case, the event detection is synchronous, and event action delayed by the selected digital filter value clock cycles.
- **Fault blanking:** Provides a way to disable fault input just after a selected waveform output edge to prevent false fault triggering because of signal bouncing on fault signal, as shown in [Figure 35-23](#). The fault Blank Value is set in the corresponding recoverable Fault Control n register (FCTRLn.BLANKVAL), and the start of the blanking time can be set in the BLANK bits in the corresponding recoverable Fault Control n register (FCTRLn.BLANK). The blank counter can be prescaled by a x64 factor. The maximum blanking time is:  
 $256 / (96 \times 10^6) = 2.66\mu s$  for 96MHz peripheral clock frequency  
 $256 * 64 / (32 * 10^6) = 170\mu s$  for prescaled and 96MHz peripheral clock frequency  
 $256 / (1 \times 10^6) = 256\mu s$  for 1MHz peripheral clock frequency

Figure 35-23. Fault Blanking in RAMP1 Operation with Inverted Polarity

- **Fault Qualification:** When the recoverable fault qualification is enabled (FCTRLn.QUAL), the fault input is disabled all the time the corresponding channel output has an inactive level, as shown in [Figure 35-24](#).

Figure 35-24. Fault Qualification in RAMP1 Operation

Figure 35-25. Fault Qualification in RAMP2 Operation with Inverted Polarity

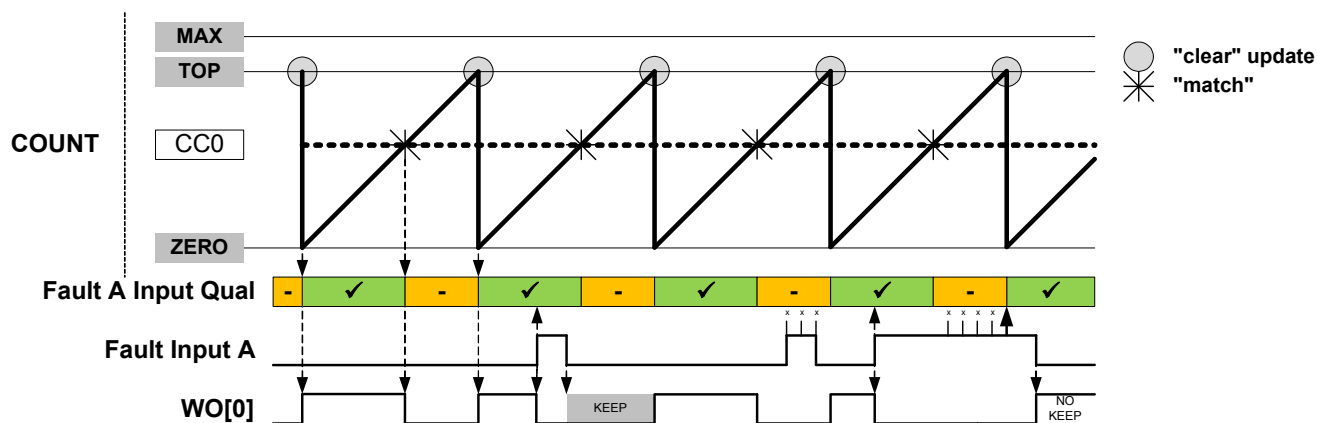

### Fault actions

Different fault actions can be configured individually for Fault A and Fault B. Most fault actions are not mutually exclusive; hence two or more actions can be enabled at the same time to achieve a result that is a combination of fault actions.

- **Keep action:** When the keep action (FCTRLn.KEEP) is enabled, the corresponding channel output will be clamped to zero when the fault condition is present. The clamp will be released on the start of the first cycle after the fault condition is no longer present, as shown in Figure 35-26.

Figure 35-26. Waveform Generation with Fault Qualification and Keep Action

- Restart action: When the restart action (FCTRLn.RESTART) is enabled, the timer/counter will be restarted when the corresponding fault condition is present. The ongoing cycle is stopped and the timer/counter starts a new cycle, as shown in Figure 35-27. When the new cycle starts, the compare outputs will be clamped to inactive level as long as the fault condition is present. Note that in RAMP2 operation, when a new timer/counter cycle starts, the cycle index will change automatically, as shown in Figure 35-28. Fault A and Fault B are qualified only during the cycle A and cycle B respectively, i.e. the faultA and faultB is disabled during cycle B or cycle A respectively.

Figure 35-27. Waveform Generation in RAMP1 mode with Restart Action

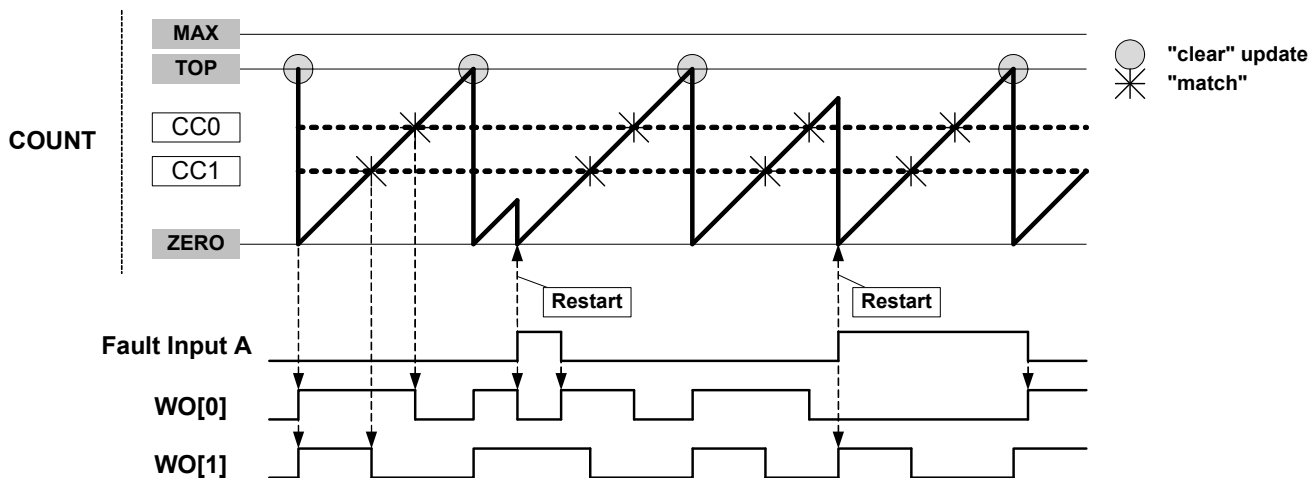

Figure 35-28. Waveform Generation in RAMP2 mode with Restart Action

- Capture action: When one of the capture operations (FCTRLn.CAPTURE) is selected, the corresponding fault is time stamped. Several capture operations are available:
  - Capture on fault (CAPT): is equivalent to a standard capture operation, for further details refer to [“Capture Operations” on page 705](#)
  - Minimum capture (CAPTMIN): allows to get the minimum time stamped value, with notification through event or interrupt on each new local minimum captured value detection.
  - Maximum capture (CAPTMAX): allows to get the maximum time stamped value, with notification through event or IT on each new local maximum captured value, as shown in [Figure](#) .
  - Minimum local detection (LOCMIN): notifies through event or IT a local minimum captured value is detected.
  - Maximum local detection (LOCMAx): notifies through event or IT a local maximum captured value is detected.
  - Minimum and maximum local detection (DERIV0): notifies through event or IT when a local minimum or maximum captured value is detected, as shown in [Figure 35-30](#).
  - Capture with ramp index as MSB value (CAPTMARK): this capture mode can be used only in double-ramp modes of operation. The MSB bit of the captured value represents the ramp index at captured time.

In CAPTMIN and CAPTMAX mode CCx keeps the minimum and maximum values respectively, as show in [Figure](#) ., while in LOCMIN, LOCMAx or DERIV0 modes, CCx follows counter value at fault time, as show in [Figure 35-30](#).

Figure 35-29. Capture Action “CAPTMAX”

Figure 35-30. Capture Action “DERIV0”

- Hardware halt action: When hardware halt action is enabled (FCTRLn.HALT = HW), the timer/counter is halted and the cycle is extended as long as the corresponding fault is present. Figure 35-31 shows an example where restart and hardware halt actions are enabled for Fault A. The compare channel 0 output is clamped to inactive level as long as the TCC is halted. The TCC resumes the counting operation as soon as the fault condition is no longer present. If the restart action is enabled, the timer/counter is halted as long as the fault condition is present and restarted when the fault condition is no longer present, as shown in Figure 35-32. Note that in RAMP2 and RAMP2A operations, when a new timer/counter cycle starts, the cycle index will automatically change.

Figure 35-31. Waveform Generation with Halt and Restart Actions

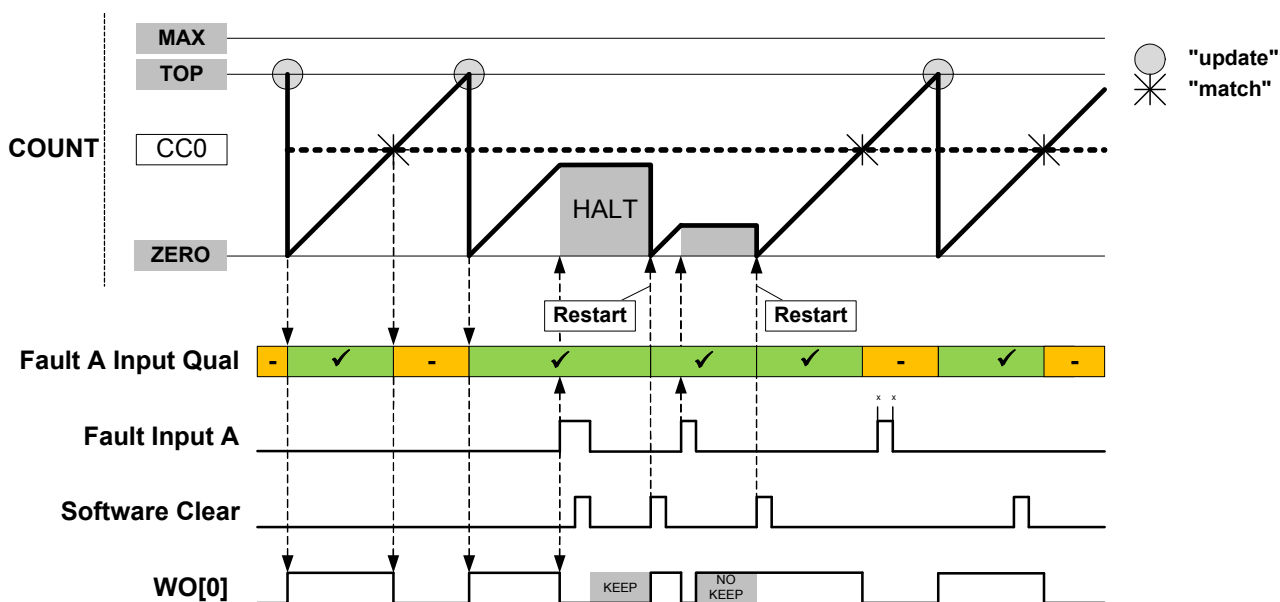

Figure 35-32. Waveform Generation with Fault Qualification, Halt and Restart Actions

- The software halt action (FCTRLn.HALT = SWHALT) is similar to hardware halt action with one exception. To restart the timer/counter, the corresponding fault condition should no longer be present and the corresponding FAULTn bit in STATUS register must be cleared.

Figure 35-33. Waveform Generation with Software Halt, Fault Qualification, Keep and Restart Actions

### 35.6.3.6 Non Recoverable Faults

The non-recoverable fault action will force all the compare outputs to a pre-defined level programmed into the Driver Control register (DRVCTRL.NRE and DRVCTRL.NRV). The non recoverable fault input (EV0 and EV1) actions are enabled in Event Control register (EVCTRL.EVACT0 and EVCTRL.EVACT1). To avoid false fault detection on external events (e.g. a glitch on an I/O port) a digital filter can be enabled in the Driver Control register (DRVCTRL.FILTERVALn). In this case, the event detection is synchronous, and event action is delayed by the selected digital filter value clock cycles.

If Fault Detection on Debug Break Detection bit is enabled in Debug Control register (DGBCTRL.FDDBD = 1), a non-recoverable Debug Faults State and an interrupt (DFS) are generated when the system goes in debug operation.

A non recoverable Update Fault State and the respective interrupt (UFS) are generated in RAMP2, RAMP2A or DSBOTh operation if the CTRLB.LUPD bit is set and ramp index or counter direction changes.

### 35.6.3.7 Time-stamp Capture

This feature is enabled when the STAMP Event Action 0 in Event Control register (EVCTRL.EVACT0) is selected. The counter TOP value must be programmed as follow:

$$TOP < MAX$$

When a capture event is detected, the COUNT value is copied into the corresponding capture channel CC register (CCx). If the overflow condition is detected, MAX value is copied into the corresponding capture channel CC register (CCx).

When a valid captured value is present in the capture channel register, the corresponding channel Capture Interrupt flag is set to one (INTFLAG.MCx). When the Capture Interrupt flag is set and a new capture event is detected, there is nowhere to store the new timestamp. As a result, the Error Interrupt Flag (INTFLAG.ERR) will be set to one.

**Figure 35-34. Time-stamp**

### 35.6.3.8 Waveform Extension

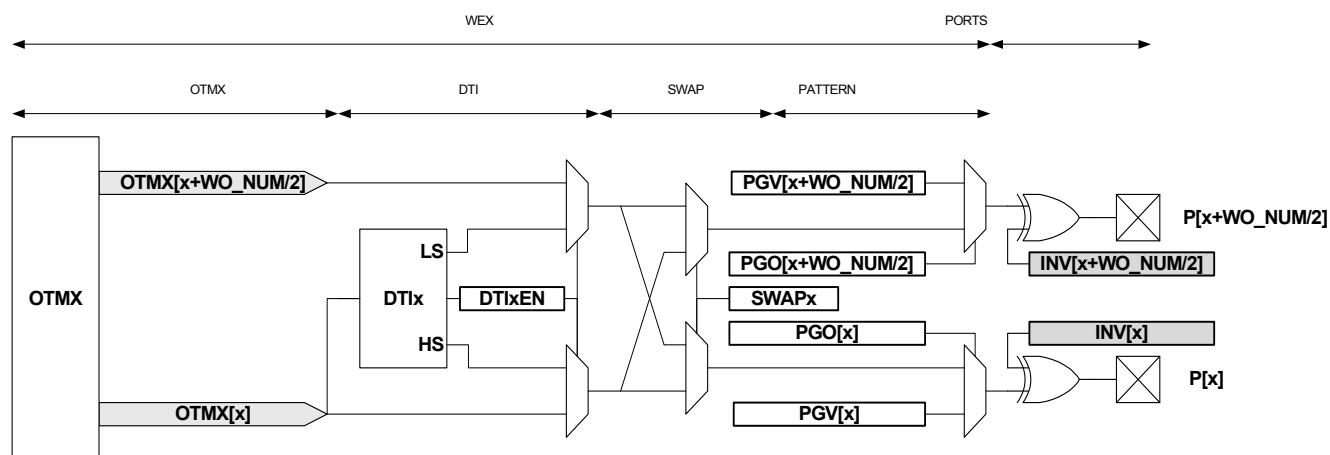

Figure 35-35 shows a schematic diagram of action of the four optional units following the recoverable fault stage, on a port pin pair. The DTI and SWAP units can be seen as a four port pair slices:

- Slice 0 DTI0 / SWAP0 acting on port pins (WO[0], WO[WO\_NUM/2 +0])
- Slice 1 DTI1 / SWAP1 acting on port pins (WO[1], WO[WO\_NUM/2 +1])

And more generally:

- Slice n DTIx / SWAPx acting on port pins (WO[x], WO[WO\_NUM/2 +x])

**Figure 35-35. Waveform Extension Stage Details**

The output matrix (OTMX) unit distributes “compare channels”, according to the selectable configurations, as shown in [Table 35-4](#).

**Table 35-4. Output Matrix Channel Pin Routing Configuration**

| Value | OTMX[x] |     |     |     |     |     |     |     |
|-------|---------|-----|-----|-----|-----|-----|-----|-----|
| 0x0   | CC3     | CC2 | CC1 | CC0 | CC3 | CC2 | CC1 | CC0 |
| 0x1   | CC1     | CC0 | CC1 | CC0 | CC1 | CC0 | CC1 | CC0 |
| 0x2   | CC0     | CC0 | CC0 | CC0 | CC0 | CC0 | CC0 | CC0 |
| 0x3   | CC1     | CC1 | CC1 | CC1 | CC1 | CC1 | CC1 | CC0 |

- Configuration 0x0 is default configuration. The channel location is the default one and channels are distributed on outputs module. Channel 0 is routed to the Output matrix output OTMX[0], Channel 1 to OTMX[1]. If there are more outputs than channels, then channel 0 is duplicated to the Output matrix output OTMX[CC\_NUM], channel 1 to OTMX[CC\_NUM+1] and so on.
- Configuration 0x1 distributes the channels on output module half the number of channels, this gives the lower channels twice the number of output locations than the default configuration. This provides for example, control of the four transistors of a full bridge using only two compare channels. Using pattern generation, some of these four outputs can be overwritten by a constant level, enabling flexible drive of a full bridge in all quadrant configurations.
- Configuration 0x2 distributes the compare channel 0 (CC0) to all port pins. When using pattern generation, this configuration can control a stepper motor.
- Configuration 0x3 distributes the compare channel CC0 to first output and the channel CC1 to all other outputs. This, together with pattern generation and the fault extension will for example, control up to seven LED strings, with a boost stage.

**Table 35-5. Example of 4 compare channels on 4 outputs:**

| Value | OTMX[3] | OTMX[2] | OTMX[1] | OTMX[0] |
|-------|---------|---------|---------|---------|
| 0x0   | CC3     | CC2     | CC1     | CC0     |
| 0x1   | CC1     | CC0     | CC1     | CC0     |
| 0x2   | CC0     | CC0     | CC0     | CC0     |
| 0x3   | CC1     | CC1     | CC1     | CC0     |

The dead-time insertion (DTI) unit generates OFF time with the non-inverted low side (LS) and inverted high side (HS) of the WG output forced at low level. This OFF time is called dead time, and dead-time insertion ensures that the LS and HS will never switch simultaneously.

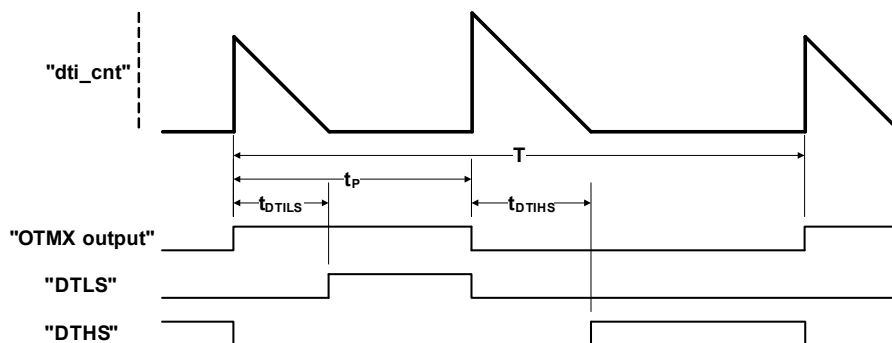

The DTI stage consists of four equal dead-time insertion generators; one for each of the first four compare channels. [Figure 35-36](#) shows the block diagram of one DTI generator. The four channels have a common register which controls the dead time and is independent of high side and low side setting.

**Figure 35-36. Dead-Time Generator Block Diagram**

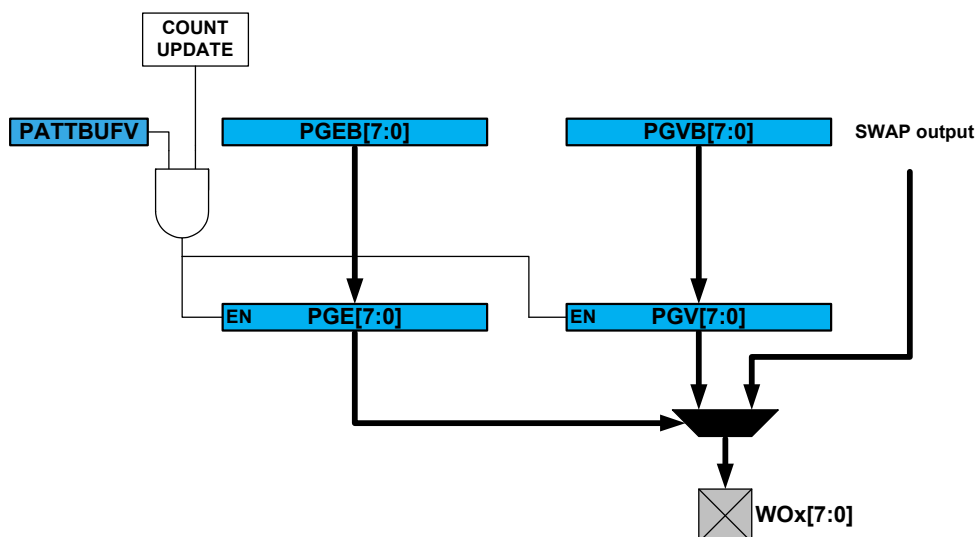

As shown in [Figure 35-37](#), the 8-bit dead-time counter is decremented by one for each peripheral clock cycle, until it reaches zero. A nonzero counter value will force both the low side and high side outputs into their OFF state. When the output matrix (OTMX) output changes, the dead-time counter is reloaded according to the edge of the input. When the output changes from low to high (positive edge) it initiates counter reload of the DTLS register, and when the output changes from high to low (negative edge) reload the DTHS register.

**Figure 35-37. Dead-Time Generator Timing Diagram**

The pattern generator unit produces a synchronized bit pattern across the port pins it is connected to. The pattern generation features are primarily intended for handling the commutation sequence in brushless DC motor (BLDC), stepper motor and full bridge control. A block diagram of the pattern generator is shown in [Figure 35-38](#).

Figure 35-38. Pattern Generator Block Diagram

As with other double buffered timer/counter registers, the register update is synchronized to the UPDATE condition set by the timer/counter waveform generation operation. If the synchronization is not required by the application, the software can simply access directly the PATT.PGE, PATT.PGV bits registers.

### 35.6.4 DMA, Interrupts and Events

Table 35-6. Module request for TCC

| Condition                        | Interrupt request | Event output | Event input      | DMA request      | DMA request is cleared   |
|----------------------------------|-------------------|--------------|------------------|------------------|--|
| Overflow / Underflow             | X                 | X            |                  | X <sup>(1)</sup> | Cleared when PER/PERB, CCx/CCBx, PATT/PATTB or WAVE/WAVEB register is written.   |
| Channel Compare Match or Capture | X                 | X            | X <sup>(2)</sup> | X                | For compare channel:<br>Cleared when CCBx register is written.<br><br>For capture channel:<br>Cleared when CCx register is read. |
| Retrigger                        | X                 | X            |                  |                  |  |
| Count                            | X                 | X            |                  |                  |  |
| Capture Overflow Error           | X                 |              |                  |                  |  |
| Synchronization Ready            | X                 |              |                  |                  |  |
| Debug Fault State                | X                 |              |                  |                  |  |
| Update Fault State               | X                 |              |                  |                  |  |
| Recoverable Faults               | X                 |              |                  |                  |  |

**Table 35-6. Module request for TCC (Continued)**

| Condition              | Interrupt request | Event output | Event input      | DMA request | DMA request is cleared |
|------------------------|-------------------|--------------|------------------|-------------|------------------------|
| Non-Recoverable Faults | X                 |              |                  |             |                        |
| TCCx Event 0 input     |                   |              | X <sup>(3)</sup> |             |                        |
| TCCx Event 1 input     |                   |              | X <sup>(4)</sup> |             |                        |

- Notes:
1. DMA request set on overflow, underflow or retrigger conditions.
  2. Can perform capture or generate recoverable fault on an event input.
  3. Can retrigger counter / control counter direction / stop the counter / decrement the counter / perform period and pulse width capture / generate non-recoverable fault on an event input.
  4. Can retrigger counter / increment or decrement counter depending on direction / start the counter / increment or decrement counter based on direction / increment counter regardless of direction / generate non-recoverable fault on an event input.

### 35.6.5 DMA Operation

The TCC generates the following DMA requests:

- Overflow (OVF): the request is set when an update condition (overflow, underflow or re-trigger) is detected. The request is cleared when a write to the PER/PERBUF, CCx/CCBUFx, PATT/PATTBUF or WAVE/WAVEBUF register is performed.
- Compare Match or Capture (MCx): for a compare channel, the request is set on each compare match detection and cleared when CCBUFx register is written. For a capture channel, the request is set when valid data is present in CCx register, and cleared when CCx register is read.

#### DMA Operation with Circular Buffer

When circular buffer option is enabled, the buffer registers must be written in a correct order and synchronised to the update times of the timer. TCC's DMA triggers provide a way to ensure a safe and correct update of circular buffers.

Note: Circular buffer are intended to be used with RAMP2, RAMP2A and DSBOTH operations.

#### DMA operation with circular buffer in RAMP and RAMP2A mode

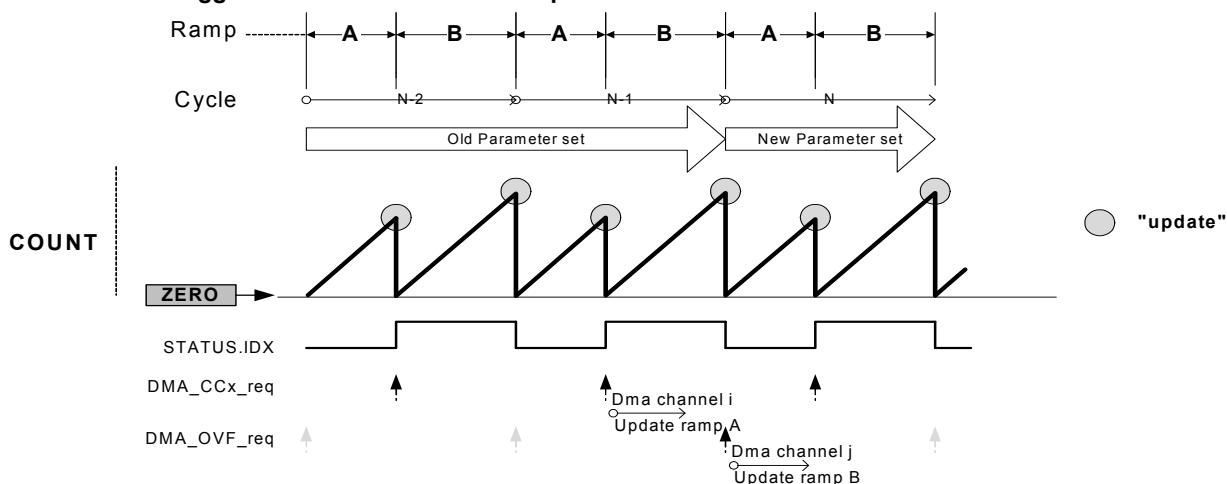

When a CC channel is selected as a circular buffer, the related DMA request is not set on a compare match detection, but on start of ramp B.

If at least one circular buffer is enabled, the DMA overflow request is conditioned to the start of ramp A with an effective DMA transfer on previous ramp B.

The update of all circular buffer values for ramp A, can be done through a DMA channel triggered on a MC trigger. The update of all circular buffer values for ramp B, can be done through a second DMA channel triggered by the overflow DMA request.

Note: When an update of TCC value is required, the channel triggered by DMA overflow trigger must be enabled first.

**Figure 35-39.DMA Triggers in RAMP and RAMP2A Operation Mode and Circular Buffer Enabled**

### DMA operation with circular buffer in DSBOTH mode

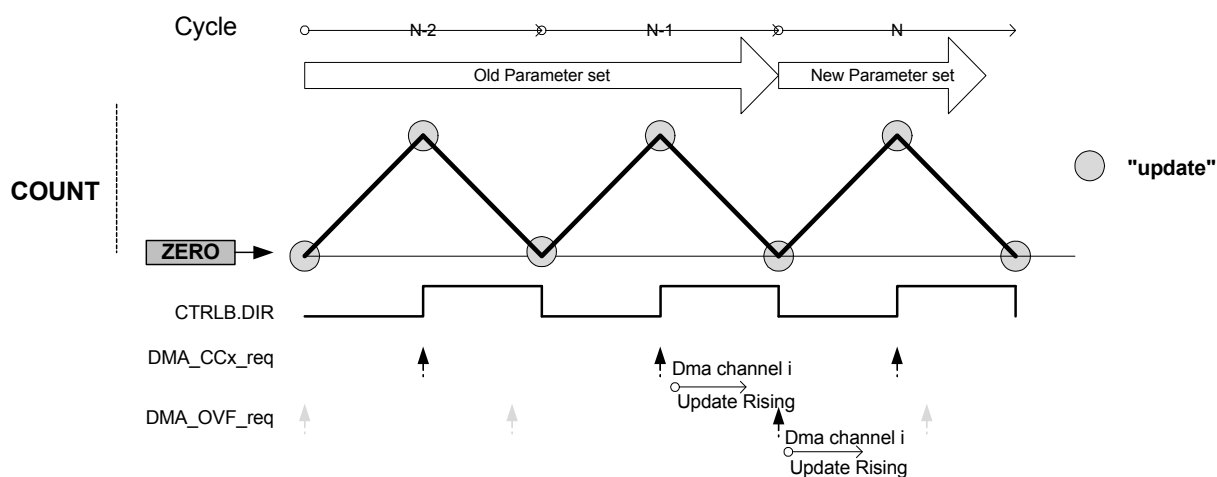

When a CC channel is selected as a circular buffer, the related DMA request is not set on a compare match detection, but on start of down-counting phase.

If at least one circular buffer is enabled, the DMA overflow request is conditioned to the start of up-counting phase with an effective DMA transfer on previous down-counting phase.

The update of all circular buffers value for up-counting phase can be done through a DMA channel triggered by MC trigger. The update of all circular buffer value for down-counting phase, can be done through a second DMA channel, triggered by the OVF DMA request.

Note: When an update of TCC value is required the channel triggered by DMA overflow trigger must be enable first.

**Figure 35-40.DMA Triggers in DSBOTH Operation Mode and Circular Buffer Enabled**

### 35.6.6 Interrupts

The TCC has the following interrupt sources:

- Overflow/Underflow: OVF
- Retrigger: TRG
- Count: CNT. For further details, refer to [EVCTRL.CNTSEL](#) description.
- Capture Overflow Error: ERR
- Non-Recoverable Update Fault: UFS

- Debug Fault State: DFS
- Recoverable Faults: FAULTn
- Non-recoverable Faults: FAULTx
- Compare Match or Capture Channels: MCx

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the TCC is reset. See the [INTFLAG](#) for details on how to clear interrupt flags. The TCC has one common interrupt request line for all the interrupt sources. Refer to the Processor and Architecture chapter for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to the Processor and Architecture chapter for details.

### 35.6.7 Events

The TCC can generate the following output events:

- Overflow/Underflow: OVF
- Trigger: TRG
- Counter: CNT. For further details, refer to [EVCTRL.CNTSEL](#) description.
- Compare Match or Capture on compare/capture channels: MCx

Writing a one to an Event Output bit in the Event Control Register (EVCTRL.xxEO) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to the Event System chapter for details on configuring the event system.

The TCC can take the following actions on a channel input event (MCx):

- Capture event
- Generate a recoverable fault

The TCC can take the following actions on counter event 1 (TCCx EV1):

- Counter retrigger
- Counter direction control
- Stop the counter
- Decrement the counter on event
- Period and pulse width capture
- Non-recoverable fault

The TCC can take the following actions on counter event 0 (TCCx EV0):

- Counter retrigger
- Count on event (increment or decrement, depending on counter direction)
- Counter start. Start counting on the event rising edge. Further events will not restart the counter; it keeps on counting using prescaled GCLK\_TCCx, until it reaches TOP or Zero depending on the direction.
- Counter increment on event. This will increment the counter irrespective of the counter direction.
- Count during active state of an asynchronous event (increment or decrement, depending on counter direction). In this case, the counter will be incremented or decremented on each cycle of the prescaled clock, as long as the event is active.
- Non-recoverable fault

The counter Event Actions are available in Event Control register (EVCTRL.EVACT0 and EVCTRL.EVACT1). For further details, refer to [EVCTRL](#) register description.

Writing a one to an Event Input bit in the Event Control register (EVCTRL.MCEIx or EVCTRL.TCEIx) enables the corresponding action on input event. Writing a zero to this bit disables the corresponding action on input event. Note that if several events are connected to the TCC, the enabled action will apply for each the incoming event. Refer to the Event System chapter for details on how to configure the event system.

### 35.6.8 Sleep Mode Operation

The TCC can be configured to operate in any sleep mode. To be able to run in standby the RUNSTDBY bit (CTRLA.RUNSTDBY) must be written to one. The TCC can wake up the device using interrupts from any sleep mode or performs internal actions through the event system.

### 35.6.9 Synchronization

Due to the asynchronicity between CLK\_TCCx\_APB and GCLK\_TCCx some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When a register requiring synchronization is accessed, the corresponding synchronization bit is set in Synchronization Busy register (SYNCBUSY) and cleared when the synchronization is complete.

An access to a register with synchronization busy bit set, will trigger an hardware interrupt

The following bits need synchronization when written:

- Software Reset and Enable bits in Control A register (CTRLA.SWRST and CTRLA.ENABLE)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

The following registers require synchronization when written:

- Control B Clear and Control B Set registers (CTRLBCLR and CTRLBSET)
- Status register (STATUS)
- Pattern and Pattern Buffer registers (PATT and PATTBUF)
- Waveform and Waveform Buffer registers (WAVE and WAVEBUF)
- Count Value register (COUNT)
- Period Value and Period Buffer Value registers (PER and PERBUF)
- Compare/Capture Value and Compare/Capture Buffer Value registers (CCx and CCBUFx)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

## 35.7 Register Summary

Table 35-7. Register Summary

| Offset | Name     | Bit Pos. |                 |                 |                |             |                |                 |           |        |  |
|--------|----------|----------|-----------------|-----------------|----------------|-------------|----------------|-----------------|-----------|--------|--|
| 0x00   | CTRLA    | 7:0      |                 | RESOLUTION[1:0] |                |             |                |                 | ENABLE    | SWRST  |  |
| 0x01   |          | 15:8     |                 | ALOCK           | PRESCSYNC[1:0] |             | RUNSTDBY       | PRESCALER[2:0]  |           |        |  |
| 0x02   |          | 23:16    |                 |                 |                |             |                |                 |           |        |  |
| 0x03   |          | 31:24    |                 |                 |                |             | CPTEN3         | CPTEN2          | CPTEN1    | CPTEN0 |  |

| 0x72                |          | 23:16    | CCBUF[23:16]  |       |            |       |          |               |          |          |
| 0x73                |          | 31:24    |               |       |            |       |          |               |          |          |
| 0x74                | CCBUF1   | 7:0      | CCBUF[7:0]    |       |            |       |          |               |          |          |
| 0x75                |          | 15:8     | CCBUF[15:8]   |       |            |       |          |               |          |          |
| 0x76                |          | 23:16    | CCBUF[23:16]  |       |            |       |          |               |          |          |
| 0x77                |          | 31:24    |               |       |            |       |          |               |          |          |
| 0x78                | CCBUF2   | 7:0      | CCBUF[7:0]    |       |            |       |          |               |          |          |
| 0x79                |          | 15:8     | CCBUF[15:8]   |       |            |       |          |               |          |          |
| 0x7A                |          | 23:16    | CCBUF[23:16]  |       |            |       |          |               |          |          |
| 0x7B                |          | 31:24    |               |       |            |       |          |               |          |          |
| 0x7C                | CCBUF3   | 7:0      | CCBUF[7:0]    |       |            |       |          |               |          |          |
| 0x7D                |          | 15:8     | CCBUF[15:8]   |       |            |       |          |               |          |          |
| 0x7E                |          | 23:16    | CCBUF[23:16]  |       |            |       |          |               |          |          |
| 0x7F                |          | 31:24    |               |       |            |       |          |               |          |          |

## 35.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16-, and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to the [“Register Access Protection” on page 693](#) and the PAC chapter for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or Read-Synchronized property in each individual register description. Please refer to the [“Synchronization” on page 725](#) for details.

Some registers are enable-protected, meaning they can only be written when the TCC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 35.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Reset:** 0x00000000

**Property:** Write-Protected, Write-Synchronized

|        |    |    |    |    |        |        |        |        |
|--------|----|----|----|----|--------|--------|--------|--------|
| Bit    | 31 | 30 | 29 | 28 | 27     | 26     | 25     | 24     |
|        |    |    |    |    | CPTEN3 | CPTEN2 | CPTEN1 | CPTEN0 |
| Access | R  | R  | R  | R  | R/W    | R/W    | R/W    | R/W    |
| Reset  | 0  | 0  | 0  | 0  | 0      | 0      | 0      | 0      |

|        |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|
| Bit    | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        |    |    |    |    |    |    |    |    |
| Access | R  | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

|        |    |       |               |     |          |                |     |     |
|--------|----|-------|---------------|-----|----------|----------------|-----|-----|
| Bit    | 15 | 14    | 13            | 12  | 11       | 10             | 9   | 8   |
|        |    | ALOCK | PRESCSYN[1:0] |     | RUNSTDBY | PRESCALER[2:0] |     |     |
| Access | R  | R/W   | R/W           | R/W | R/W      | R/W            | R/W | R/W |
| Reset  | 0  | 0     | 0             | 0   | 0        | 0              | 0   | 0   |

|        |   |                 |     |   |   |   |        |       |
|--------|---|-----------------|-----|---|---|---|--------|-------|
| Bit    | 7 | 6               | 5   | 4 | 3 | 2 | 1      | 0     |
|        |   | RESOLUTION[1:0] |     |   |   |   | ENABLE | SWRST |
| Access | R | R/W             | R/W | R | R | R | R/W    | R/W   |
| Reset  | 0 | 0               | 0   | 0 | 0 | 0 | 0      | 0     |

- **Bits 31:28 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 27:24 – CPTENx [x=3..0]: Capture Channel x Enable**

These bits are used to select the capture or compare operation on channel x. The number of available channels depend on the TCC instance.

Writing a one to CAPTENx enables capture on channel x.

Writing a zero to CAPTENx disables capture on channel x.

These bits are not synchronized.

- **Bits 23:15 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 14 – ALOCK: Auto Lock**

When this bit is set, Lock Update (LUPD) is set to one on each overflow/underflow or re-trigger event.

0: The LUPD bit is not affected on overflow/underflow, and re-trigger event.

1: The LUPD bit is set on each overflow/underflow or re-trigger event.

This bit is not synchronized.

- **Bits 13:12 – PRESCSYNC[1:0]: Prescaler and Counter Synchronization Selection**

These bits select if on retrigger event, the Counter should be cleared or reloaded on the next GCLK\_TCCx clock or on the next prescaled GCLK\_TCCx clock. It also makes possible to reset the prescaler on retrigger event, as shown in the following table.

These bits are not synchronized.

**Table 35-8. Prescaler and Counter Synchronization Selection**

| PRESCSYNC[1:0] | Name   | Description  |
|----------------|--------|--|
| 0x0            | GCLK   | Reload or reset counter on next GCLK                             |
| 0x1            | PRESC  | Reload or reset counter on next prescaler clock                  |
| 0x2            | RESYNC | Reload or reset counter on next GCLK and reset prescaler counter |
| 0x3            |        | Reserved   |

- **Bit 11 – RUNSTDBY: Run in Standby**

This bit is used to keep the TCC running in standby mode:

0: The TCC is halted in standby.

1: The TCC continues to run in standby.

This bit is not synchronized.

- **Bits 10:8 – PRESCALER[2:0]: Prescaler**

These bits select the Counter prescaler factor as shown in the following table.

These bits are not synchronized.

**Table 35-9. Prescaler**

| PRESCALER[2:0] | Name    | Description    |
|----------------|---------|----------------|
| 0x0            | DIV1    | No division    |
| 0x1            | DIV2    | Divide by 2    |
| 0x2            | DIV4    | Divide by 4    |
| 0x3            | DIV8    | Divide by 8    |
| 0x4            | DIV16   | Divide by 16   |
| 0x5            | DIV64   | Divide by 64   |
| 0x6            | DIV256  | Divide by 256  |
| 0x7            | DIV1024 | Divide by 1024 |

- **Bit 7 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 6:5 – RESOLUTION[1:0]: Enhanced Resolution**

These bits increase the TCC resolution by enabling the dithering options, according to the following table.

These bits are not synchronized.

**Table 35-10. Enhanced Resolution**

| RESOLUTION[1:0] | Name  | Description                           |
|-----------------|-------|---------------------------------------|
| 0x0             | NONE  | Dithering is disabled                 |
| 0x1             | DITH4 | Dithering is done every 16 PWM frames |
| 0x2             | DITH5 | Dithering is done every 32 PWM frames |
| 0x3             | DITH6 | Dithering is done every 64 PWM frames |

- **Bits 4:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the ENABLE bit in the SYNCBUSY register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the TCC, except DBGCTRL, to their initial state, and the TCC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence; all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 35.8.2 Control B Clear

This register allows the user to change the below mentioned functionalities without doing a read-modify-write operation. Changes in this register will also be reflected in the Control B Set (CTRLBSET) register.

**Name:** CTRLBCLR

**Offset:** 0x04

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7        | 6   | 5   | 4           | 3   | 2       | 1    | 0   |
|--------|----------|-----|-----|-------------|-----|---------|------|-----|
|        | CMD[2:0] |     |     | IDXCMD[1:0] |     | ONESHOT | LUPD | DIR |
| Access | R/W      | R/W | R/W | R/W         | R/W | R/W     | R/W  | R/W |
| Reset  | 0        | 0   | 0   | 0           | 0   | 0       | 0    | 0   |

- Bits 7:5 – CMD[2:0]: TCC Command**

These bits can be used for software control of re-triggering and stop commands of the TCC. When a command has been executed, the CMD bit field will read back zero. The commands are executed on the next prescaled GCLK\_TCC clock cycle.

Writing a zero to this bit group has no effect.

Writing a valid value to these bits will clear the corresponding pending command.

**Table 35-11. TCC Command**

| CMD[2:0] | Name      | Description                               |
|----------|-----------|---|
| 0x0      | NONE      | No action                                 |
| 0x1      | RETRIGGER | Clear start, restart or retrigger         |
| 0x2      | STOP      | Force stop                                |
| 0x3      | UPDATE    | Force update or double buffered registers |
| 0x4      | READSYNC  | Force COUNT read synchronization          |
| 0x5-0x7  |           | Reserved                                  |

- Bits 4:3 – IDXCMD[1:0]: Ramp Index Command**

These bits can be used to force cycle A and cycle B changes in RAMP2 and RAMP2A operation, according to the following table. On timer/counter update condition, the command is executed, the IDX flag in STATUS register is updated and the IDXCMD command is cleared.

Writing a zero to this field has no effect.

Writing a valid value to this field will clear the pending command.

**Table 35-12. Ramp Index Command**

| IDXCMD[1:0] | Name    | Description  |
|-------------|---------|--|
| 0x0         | DISABLE | Command disabled: Index toggles between cycles A and B |

| IDXCMD[1:0] | Name  | Description  |
|-------------|-------|--|
| 0x1         | SET   | Set index: cycle B will be forced in the next cycle              |
| 0x2         | CLEAR | Clear index: cycle A will be forced in the next cycle            |
| 0x3         | HOLD  | Hold index: the next cycle will be the same as the current cycle |

- **Bit 2 – ONESHOT: One-Shot**

This bit controls one-shot operation of the TCC. When one-shot operation is enabled, the TCC will stop counting on the next overflow/underflow condition or on a stop command.

0: The TCC will update the counter value on overflow/underflow condition and continues operation.

1: The TCC will stop counting on the next underflow/overflow condition.

Writing a zero to this bit has no effect

Writing a one to this bit will disable the one-shot operation.

- **Bit 1 – LUPD: Lock Update**

This bit controls the update operation of the TCC buffered registers. When this bit is set, no update of the buffered registers is performed, even though an UPDATE condition has occurred. Locking the update ensures that all buffers registers are valid before an update is performed.

This bit has no effect when input capture operation is enabled.

1: The CCBUFx, PERBUF, PGVB, PGOB, and SWAPBx buffer registers value are not copied into the corresponding CCx, PER, PGV, PGO and SWAPx registers.

0: The CCBUFx, PERBUF, PGVB, PGOB, and SWAPBx buffer registers value are copied into the corresponding CCx, PER, PGV, PGO and SWAPx registers on counter update condition.

- **Bit 0 – DIR: Counter Direction**

This bit is used to change the direction of the counter.

0: The timer/counter is counting up (incrementing).

1: The timer/counter is counting down (decrementing).

Writing a zero to this bit has no effect

Writing a one to this bit will make the counter count up.

### 35.8.3 Control B Set

This register allows the user to change the below mentioned functionalities without doing a read-modify-write operation. Changes in this register will also be reflected in the Control B Clear (CTRLBCLR) register.

**Name:** CTRLBSET

**Offset:** 0x05

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7        | 6   | 5   | 4           | 3   | 2       | 1    | 0   |
|--------|----------|-----|-----|-------------|-----|---------|------|-----|
|        | CMD[2:0] |     |     | IDXCMD[1:0] |     | ONESHOT | LUPD | DIR |
| Access | R/W      | R/W | R/W | R/W         | R/W | R/W     | R/W  | R/W |
| Reset  | 0        | 0   | 0   | 0           | 0   | 0       | 0    | 0   |

- **Bits 7:5 – CMD[2:0]: TCC Command**

These bits can be used for software control of re-triggering and stop commands of the TCC. When a command has been executed, the CMD field will be read back as zero. The commands are executed on the next prescaled GCLK\_TCC clock cycle.

Writing a zero to this bit group has no effect

Writing a valid value into this bit group will set the associated command, as shown in the table below.

**Table 35-13. TCC Command**

| CMD[2:0] | Name      | Description                               |
|----------|-----------|---|
| 0x0      | NONE      | No action                                 |
| 0x1      | RETRIGGER | Clear start, restart or retrigger         |
| 0x2      | STOP      | Force stop                                |
| 0x3      | UPDATE    | Force update or double buffered registers |
| 0x4      | READSYNC  | Force COUNT read synchronization          |
| 0x5-0x7  |           | Reserved                                  |

- **Bits 4:3 – IDXCMD[1:0]: Ramp Index Command**

These bits can be used to force cycle A and cycle B changes in RAMP2 and RAMP2A operation, according to the table below. On timer/counter update condition, the command is executed, the IDX flag in STATUS register is updated and the IDXCMD command is cleared.

Writing a zero to this field has no effect.

Writing a valid value into this field will set a command.

**Table 35-14. Ramp Index Command**

| IDXCMD[1:0] | Name    | Description  |
|-------------|---------|--|
| 0x0         | DISABLE | Command disabled: Index toggles between cycles A and B |

| IDXCMD[1:0] | Name  | Description  |
|-------------|-------|--|
| 0x1         | SET   | Set index: cycle B will be forced in the next cycle              |
| 0x2         | CLEAR | Clear index: cycle A will be forced in the next cycle            |
| 0x3         | HOLD  | Hold index: the next cycle will be the same as the current cycle |

- **Bit 2 – ONESHOT: One-Shot**

This bit controls one-shot operation of the TCC. When in one-shot operation, the TCC will stop counting on the next overflow/underflow condition or a stop command.

0: The TCC will count continuously.

1: The TCC will stop counting on the next underflow/overflow condition.

Writing a zero to this bit has no effect.

Writing a one to this bit will disable the one-shot operation.

- **Bit 1 – LUPD: Lock Update**

This bit controls the update operation of the TCC buffered registers. When this bit is set, no update of the buffered registers is performed, even though an UPDATE condition has occurred. Locking the update can be used to ensure that all buffer registers are loaded with the desired values, before an update is performed. After all the buffer registers are loaded correctly, the buffered registers can be unlocked.

This bit has no effect when input capture operation is enabled.

1: The CCBUFx, PERBUF, PGVB, PGOB, and SWAPBx buffer registers value are not copied into CCx, PER, PGV, PGO and SWAPx registers.

0: The CCBUFx, PERBUF, PGVB, PGOB, and SWAPBx buffer registers value are copied into CCx, PER, PGV, PGO and SWAPx registers on timer Overflow/underflow or retrigger condition.

- **Bit 0 – DIR: Counter Direction**

This bit is used to change the direction of the counter.

0: The timer/counter is counting up (incrementing).

1: The timer/counter is counting down (decrementing).

Writing a zero to this bit has no effect

Writing a one to this bit will make the counter count down.

### 35.8.4 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x08

**Reset:** 0x00000000

**Property:** -

- **Bits 31:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 – CCx [x=3..0]: Compare Channel x Busy**

This bit is cleared when the synchronization of Compare/Capture Channel x register between the clock domains is complete.

This bit is set when the synchronization of Compare/Capture Channel x register between clock domains is started. CCx bit is available only for existing Compare/Capture Channels. For details on CC channels number, refer to each TCC feature list.

This bit is set when the synchronization of CCx register between clock domains is started.

- **Bit 7 – PER: Period Busy**

This bit is cleared when the synchronization of PER register between the clock domains is complete.

This bit is set when the synchronization of PER register between clock domains is started.

- **Bit 6 – WAVE: Wave Busy**

This bit is cleared when the synchronization of WAVE register between the clock domains is complete.

This bit is set when the synchronization of WAVE register between clock domains is started.

- **Bit 5 – PATT: Pattern Busy**  
This bit is cleared when the synchronization of PATT register between the clock domains is complete.  
This bit is set when the synchronization of PATT register between clock domains is started.
- **Bit 4 – COUNT: Count Busy**  
This bit is cleared when the synchronization of COUNT register between the clock domains is complete.  
This bit is set when the synchronization of COUNT register between clock domains is started.
- **Bit 3 – STATUS: Status Busy**  
This bit is cleared when the synchronization of STATUS register between the clock domains is complete.  
This bit is set when the synchronization of STATUS register between clock domains is started.
- **Bit 2 – CTRLB: Ctrlb Busy**  
This bit is cleared when the synchronization of CTRLB register between the clock domains is complete.  
This bit is set when the synchronization of CTRLB register between clock domains is started.
- **Bit 1 – ENABLE: Enable Busy**  
This bit is cleared when the synchronization of ENABLE register bit between the clock domains is complete.  
This bit is set when the synchronization of ENABLE register bit between clock domains is started.
- **Bit 0 – SWRST: Swrst Busy**  
This bit is cleared when the synchronization of SWRST register bit between the clock domains is complete.  
This bit is set when the synchronization of SWRST register bit between clock domains is started.

- Bits 31:28 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 27:24 – FILTERVAL[3:0]: Fault A Filter Value**  
 These bits define the filter value applied on MCEx (x=0,1) event input line. The value must be set to zero when MCEx event is used as synchronous event.
- Bits 23:16 – BLANKVAL[7:0]: Fault A Blanking Time**  
 These bits are used to ignore potential glitches after selectable waveform edge is detected. The edge selection is available in BLANK bits (FCTRLA.BLANK). When enabled, the fault input source is internally disabled during BLANKVAL \* prescaled GCLK\_TCC periods after the detection of the waveform edge.
- Bit 15 – BLANKPRESC: Fault A Blanking Prescaler**  
 This bit enables a 64 prescaler factor on BLANKVAL value.  
 0: Blank time is BLANKVAL \* prescaled GCLK\_TCC.  
 1: Blank time is BLANKVAL \* 64 \* prescaled GCLK\_TCC.
- Bits 14:12 – CAPTURE[2:0]: Fault A Capture Action**  
 These bits select the capture and Fault A interrupt/event conditions, as defined in the table below.

**Table 35-15. Fault A Capture Action**

| CAPTURE[2:0] | Name     | Description                          |
|--------------|----------|--------------------------------------|
| 0x0          | DISABLE  | No capture                           |
| 0x1          | CAPT     | Capture on fault                     |
| 0x2          | CAPTMIN  | Minimum capture                      |
| 0x3          | CAPTMAX  | Maximum capture                      |
| 0x4          | LOCMIN   | Minimum local detection              |
| 0x5          | LOCMAX   | Maximum local detection              |
| 0x6          | DERIV0   | Minimum and maximum local detection  |
| 0x7          | CAPTMARK | Capture with ramp index as MSB value |

- **Bits 11:10 – CHSEL[1:0]: Fault A Capture Channel**

These bits select the channel for capture operation triggered by recoverable Fault A, as defined in the table below.

**Table 35-16. Fault A Capture Channel**

| CHSEL[1:0] | Name | Description                       |
|------------|------|-----------------------------------|
| 0x0        | CC0  | Capture value stored in channel 0 |
| 0x1        | CC1  | Capture value stored in channel 1 |
| 0x2        | CC2  | Capture value stored in channel 2 |
| 0x3        | CC3  | Capture value stored in channel 3 |

- **Bits 9:8 – HALT[1:0]: Fault A Halt Mode**

These bits select the halt action for recoverable Fault A as defined in the table below.

**Table 35-17. Fault A Halt Mode**

| HALT[1:0] | Name    | Description           |
|-----------|---------|-----------------------|
| 0x0       | DISABLE | Halt action disabled  |
| 0x1       | HW      | Hardware halt action  |
| 0x2       | SW      | Software halt action  |
| 0x3       | NR      | Non-recoverable fault |

- **Bit 7 – RESTART: Fault A Restart**

Setting this bit enables restart action for Fault A.

0: Fault A restart action is disabled.

1: Fault A restart action is enabled.

- **Bits 6:5 – BLANK[1:0]: Fault A Blanking Mode**

These bits, select the blanking start point for recoverable Fault A as defined in the table below.

**Table 35-18. Fault A Blanking Mode**

| BLANK[1:0] | Name  | Description   |
|------------|-------|---|
| 0x0        | START | Blanking applied from start of the ramp                   |
| 0x1        | RISE  | Blanking applied from rising edge of the output waveform  |
| 0x2        | FALL  | Blanking applied from falling edge of the output waveform |
| 0x3        | BOTH  | Blanking applied from each toggle of the output waveform  |

- **Bit 4 – QUAL: Fault A Qualification**

Setting this bit, enables the recoverable Fault A input qualification.

0: The recoverable Fault A input is not disabled on CMPx value condition.

1: The recoverable Fault A input is disabled when output signal is at inactive level (CMPx == 0).

- **Bit 3 – KEEP: Fault A Keeper**

Setting this bit enables the Fault A keep action.

0: The Fault A state is released as soon as the recoverable Fault A is released.

1: The Fault A state is released at the end of TCC cycle.

- **Bit 2 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 1:0 – SRC[1:0]: Fault A Source**

These bits select the TCC event input for recoverable Fault A, as defined in the table below.

Event system channel connected to MCEx event input, must be configured to route the event asynchronously, when used as a recoverable Fault A input.

**Table 35-19. Fault A Source**

| SRC[1:0] | Name     | Description  |
|----------|----------|--|
| 0x0      | DISABLE  | Fault input disabled   |
| 0x1      | ENABLE   | MCEx (x=0,1) event input   |
| 0x2      | INVERT   | Inverted MCEx (x=0,1) event input                                |
| 0x3      | ALTFAULT | Alternate fault (A or B) state at the end of the previous period |

### 35.8.6 Recoverable Fault B Configuration

|        | RESTART       | BLANK[1:0]   |     | QUAL | KEEP           |     | SRC[1:0]  |     |
| Access | R/W           | R/W          | R/W | R/W  | R/W            | R   | R/W       | R/W |
| Reset  | 0             | 0            | 0   | 0    | 0              | 0   | 0         | 0   |

- **Bits 31:28 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 27:24 – FILTERVAL[3:0]: Fault B Filter Value**

These bits define the filter value applied on MCE<sub>x</sub> (x=0,1) event input line. The value must be set to zero when MCE<sub>x</sub> event is used as synchronous event.

- **Bits 23:16 – BLANKVAL[7:0]: Fault B Blanking Time**

These bits are used to ignore potential glitches after selectable waveform edge is detected. The edge selection is available in BLANK bits (FCTRLB.BLANK). When enabled, the fault input source is internally disabled during BLANKVAL \* prescaled GCLK\_TCC periods after the detection of the edge.

- **Bit 15 – BLANKPRESC: Fault B Blanking Prescaler**

This bit enables a 64 prescaler factor on BLANKVAL value.

0: Blank time is BLANKVAL \* prescaled GCLK\_TCC.

1: Blank time is BLANKVAL \* 64 \* prescaled GCLK\_TCC.

- **Bits 14:12 – CAPTURE[2:0]: Fault B Capture Action**

These bits select the capture and Fault B interrupt/event conditions, as defined in table below.

**Table 35-20. Fault B Capture Action**

| CAPTURE[2:0] | Name     | Description                          |
|--------------|----------|--------------------------------------|
| 0x0          | DISABLE  | No capture                           |
| 0x1          | CAPT     | Capture on fault                     |
| 0x2          | CAPTMIN  | Minimum capture                      |
| 0x3          | CAPTMAX  | Maximum capture                      |
| 0x4          | LOCMIN   | Minimum local detection              |
| 0x5          | LOCMAX   | Maximum local detection              |
| 0x6          | DERIV0   | Minimum and maximum local detection  |
| 0x7          | CAPTMARK | Capture with ramp index as MSB value |

- **Bits 11:10 – CHSEL[1:0]: Fault B Capture Channel**

These bits select the channel for capture operation triggered by recoverable Fault B, as defined in the table below.

**Table 35-21. Fault B Capture Channel**

| CHSEL[1:0] | Name | Description                       |
|------------|------|-----------------------------------|
| 0x0        | CC0  | Capture value stored in channel 0 |
| 0x1        | CC1  | Capture value stored in channel 1 |
| 0x2        | CC2  | Capture value stored in channel 2 |
| 0x3        | CC3  | Capture value stored in channel 3 |

- **Bits 9:8 – HALT[1:0]: Fault B Halt Mode**

These bits select the halt action for recoverable Fault B as defined in the table below.

**Table 35-22. Fault B Halt Mode**

| HALT[1:0] | Name    | Description           |
|-----------|---------|-----------------------|
| 0x0       | DISABLE | Halt action disabled  |
| 0x1       | HW      | Hardware halt action  |
| 0x2       | SW      | Software halt action  |
| 0x3       | NR      | Non-recoverable fault |

- **Bit 7 – RESTART: Fault B Restart**

Setting this bit enables restart action for Fault B.

0: Fault B restart action is disabled.

1: Fault B restart action is enabled.

- **Bits 6:5 – BLANK[1:0]: Fault B Blanking Mode**

These bits, select the blanking start point for recoverable Fault B as defined in the table below.

**Table 35-23. Fault B Blanking Mode**

| BLANK[1:0] | Name  | Description   |
|------------|-------|---|
| 0x0        | START | Blanking applied from start of the ramp                   |
| 0x1        | RISE  | Blanking applied from rising edge of the output waveform  |
| 0x2        | FALL  | Blanking applied from falling edge of the output waveform |
| 0x3        | BOTH  | Blanking applied from each toggle of the output waveform  |

- **Bit 4 – QUAL: Fault B Qualification**

Setting this bit, enables the recoverable Fault B input qualification.

0: The recoverable Fault B input is not disabled on CMPx value condition.

1: The recoverable Fault B input is disabled when output signal is at inactive level (CMPx == 0).

- **Bit 3 – KEEP: Fault B Keeper**

Setting this bit enables the Fault B keep action.

0: The Fault B state is released as soon as the recoverable Fault B is released.

1: The Fault B state is released at the end of TCC cycle.

- **Bit 2 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 1:0 – SRC[1:0]: Fault B Source**

These bits select the TCC event input for recoverable Fault B, as defined in the table below.

Event system channel connected to MCEx event input, must be configured to route the event asynchronously, when used as a recoverable Fault B input.

**Table 35-24. Fault B Source**

| SRC[1:0] | Name     | Description  |
|----------|----------|--|
| 0x0      | DISABLE  | Fault input disabled   |
| 0x1      | ENABLE   | MCEx (x=0,1) event input   |
| 0x2      | INVERT   | Inverted MCEx (x=0,1) event input                                |
| 0x3      | ALTFAULT | Alternate fault (A or B) state at the end of the previous period |

### 35.8.7 Waveform Extension Configuration

**Name:** WEXCTRL

**Offset:** 0x14

- Bits 31:24 – DTHS[7:0]: Dead-time High Side Outputs Value**  
 This register holds the number of GCLK\_TCC clock cycles for the dead-time high side.
- Bits 23:16 – DTLS[7:0]: Dead-time Low Side Outputs Value**  
 This register holds the number of GCLK\_TCC clock cycles for the dead-time low side.
- Bits 15:12 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 11:8 – DTIENx [x=3..0]: Dead-time Insertion Generator x Enable**  
 Setting any of these bits enables the dead-time insertion generator for the corresponding output matrix. This will override the output matrix [x] and [x+WO\_NUM/2], with the low side and high side waveform respectively.  
 0: No dead-time insertion override.  
 1: Dead time insertion override on signal outputs[x] and [x+WO\_NUM/2], from matrix outputs[x] signal.
- Bits 7:2 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – OTMX[1:0]: Output Matrix**

These bits define the matrix routing of the TCC waveform generation outputs to the port pins, according to [Table 35-4](#).

- Bits 31:28 – FILTERVAL1[3:0]: Non-Recoverable Fault Input 1 Filter Value**  
 These bits define the filter value applied on TCEx event input line. This value must be 0 when TCEx event input line is configured as asynchronous event.
- Bits 27:24 – FILTERVAL0[3:0]: Non-Recoverable Fault Input 0 Filter Value**  
 These bits define the filter value applied on TCEx event input line. This value must be 0 when TCEx event input line is configured as asynchronous event.
- Bits 23:16 – INVENx [x=7..0]: Output Waveform x Inversion**  
 These bits are used to select inversion on the output of channel x.  
 Writing a one to INVENx inverts output from WO[x].  
 Writing a zero to INVENx disables inversion of output from WO[x].  
 These bits define the value of the enabled override outputs, under non-recoverable fault condition.
- Bits 15:8 – NRVx [x=7..0]: Non-Recoverable State x Output Value**  
 These bits define the value of the enabled override outputs, under non-recoverable fault condition.
- Bits 7:0 – NREx [x=7..0]: Non-Recoverable State x Output Enable**  
 These bits enable the override of individual outputs by NRVx value, under non-recoverable fault condition.

- 0: Non-recoverable fault tri-state the output.
- 1: Non-recoverable faults set the output to NRVx level.

### 35.8.9 Debug Control

**Name:** DBGCTRL

**Offset:** 0x1E

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2     | 1 | 0      |
|--------|---|---|---|---|---|-------|---|--------|
|        |   |   |   |   |   | FDDBD |   | DBGRUN |
| Access | R | R | R | R | R | R/W   | R | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0     | 0 | 0      |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – FDDBD: Fault Detection on Debug Break Detection**

This bit is not affected by software reset and should not be changed by software while the TCC is enabled.

By default this bit is zero, the on-chip debug (OCD) fault protection is enabled. OCD break request from the OCD system will trigger non-recoverable fault. When this bit is set, OCD fault protection is disabled and OCD break request will not trigger a fault.

0: No faults are generated when TCC is halted in debug mode.

1: A non recoverable fault is generated and DFS flag is set when TCC is halted in debug mode.

- **Bit 1 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 0 – DBGRUN: Debug Running Mode**

This bit is not affected by software reset and should not be changed by software while the TCC is enabled.

0: The TCC is halted when the device is halted in debug mode.

1: The TCC continues normal operation when the device is halted in debug mode.

|        | CNTSEL[1:0] |       | EVACT1[2:0] |        |       | EVACT0[2:0] |       |       |
| Access | R/W         | R/W   | R/W         | R/W    | R/W   | R/W         | R/W   | R/W   |
| Reset  | 0           | 0     | 0           | 0      | 0     | 0           | 0     | 0     |

- **Bits 31:28 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 27:24 – MCEOx [x=3..0]: Match or Capture Channel x Event Output Enable**

These bits control if the Match/capture event on channel x is enabled and will be generated for every match or capture.

0: Match/capture x event is disabled and will not be generated.

1: Match/capture x event is enabled and will be generated for every compare/capture on channel x.

- **Bits 23:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 19:16 – MCEIx [x=3..0]: Match or Capture Channel x Event Input Enable**

These bits indicate if the Match/capture x incoming event is enabled

These bits are used to enable match or capture input events to the CCx channel of TCC.

0: Incoming events are disabled.

1: Incoming events are enabled.

- Bits 15:14 – TCEIx [x=1..0]: Timer/counter Event x Input Enable**  
 This bit is used to enable input event x to the TCC.  
 0: Incoming event x is disabled.  
 1: Incoming event x is enabled.
- Bits 13:12 – TCINVx [x=1..0]: Inverted Event x Input Enable**  
 This bit inverts the event x input.  
 0: Input event source x is not inverted.  
 1: Input event source x is inverted.
- Bit 11 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 10 – CNTEO: Timer/counter Output Event Enable**  
 This bit is used to enable the counter cycle event. When enabled, an event will be generated on begin or end of counter cycle depending of CNTSEL[1:0] settings.  
 0: Counter cycle output event is disabled and will not be generated.  
 1: Counter cycle output event is enabled and will be generated depend of CNTSEL[1:0] value.
- Bit 9 – TRGEO: Retrigger Output Event Enable**  
 This bit is used to enable the counter retrigger event. When enabled, an event will be generated when the counter retriggers operation.  
 0: Counter retrigger event is disabled and will not be generated.  
 1: Counter retrigger event is enabled and will be generated for every counter retrigger.
- Bit 8 – OVFE0: Overflow/Underflow Output Event Enable**  
 This bit is used to enable the overflow/underflow event. When enabled, an event will be generated when the counter reaches the TOP or the ZERO value.  
 0: Overflow/underflow counter event is disabled and will not be generated.  
 1: Overflow/underflow counter event is enabled and will be generated for every counter overflow/underflow.
- Bits 7:6 – CNTSEL[1:0]: Timer/counter Output Event Mode**  
 These bits define on which part of the counter cycle the counter event output is generated.

**Table 35-25. Timer/counter Output Event Mode**

| CNTSEL[1:0] | Name     | Description  |
|-------------|----------|--|
| 0x0         | START    | An interrupt/event is generated when a new counter cycle   |
| 0x1         | END      | An interrupt/event is generated when a counter cycle ends  |
| 0x2         | BETWEEN  | An interrupt/event is generated when a counter cycle ends, |
| 0x3         | BOUNDARY | An interrupt/event is generated when a new counter cycle   |

- Bits 5:3 – EVACT1[2:0]: Timer/counter Input Event1 Action**  
 These bits define the action the TCC will perform on TCCx EV1 event input, as shown in the table below.

**Table 35-26. Timer/counter Input Event1 Action**

| EVACT1[2:0] | Name      | Description   |
|-------------|-----------|---|
| 0x0         | OFF       | Event action disabled   |
| 0x1         | RETRIGGER | Re-trigger counter on event   |
| 0x2         | DIR       | Direction control   |
| 0x3         | STOP      | Stop counter on event   |
| 0x4         | DEC       | Decrement counter on event  |
| 0x5         | PPW       | Period capture value in CC0 register, pulse width capture value in CC1 register |
| 0x6         | PWP       | Period capture value in CC1 register, pulse width capture value in CC0 register |
| 0x7         | FAULT     | Non-recoverable fault   |

- **Bits 2:0 – EVACT0[2:0]: Timer/counter Input Event0 Action**

These bits define the action the TCC will perform on TCCx EV0 event input 0, as shown in the table below.

**Table 35-27. Timer/counter Input Event0 Action**

| EVACT0[2:0] | Name      | Description                                   |
|-------------|-----------|---|
| 0x0         | OFF       | Event action disabled                         |
| 0x1         | RETRIGGER | Start, restart or re-trigger counter on event |
| 0x2         | COUNTEV   | Count on event                                |
| 0x3         | START     | Start counter on event                        |
| 0x4         | INC       | Increment counter on event                    |
| 0x5         | COUNT     | Count on active state of asynchronous event   |
| 0x6         | STAMP     | Stamp capture                                 |
| 0x7         | FAULT     | Non-recoverable fault                         |

### 35.8.11 Interrupt Enable Clear

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set (INTENSET) register.

**Name:** INTENCLR

**Offset:** 0x24

**Reset:** 0x00000000

| Reset  | 0 | 0 | 0 | 0 | 0   | 0   | 0   | 0   |

- **Bits 31:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 19:16 – MCx [x=3..0]: Match or Capture Channel x Interrupt Enable**

0: The Match or Capture Channel x interrupt is disabled.

1: The Match or Capture Channel x interrupt is enabled.

Writing a zero to MCx has no effect.

Writing a one to MCx will clear the corresponding Match or Capture Channel x Interrupt Disable/Enable bit, which disables the Match or Capture Channel x interrupt.

- **Bit 15 – FAULT1: Non-Recoverable Fault 1 Interrupt Enable**

0: The Non-Recoverable Fault 1 interrupt is disabled.

1: The Non-Recoverable Fault 1 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Non-Recoverable Fault 1 Interrupt Disable/Enable bit, which disables the Non-Recoverable Fault 1 interrupt.

- **Bit 14 – FAULT0: Non-Recoverable Fault 0 Interrupt Enable**

0: The Non-Recoverable Fault 0 interrupt is disabled.

1: The Non-Recoverable Fault 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Non-Recoverable Fault 0 Interrupt Disable/Enable bit, which disables the Non-Recoverable Fault 0 interrupt.

- **Bit 13 – FAULTB: Recoverable Fault B Interrupt Enable**

0: The Recoverable Fault B interrupt is disabled.

1: The Recoverable Fault B interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Recoverable Fault B Interrupt Disable/Enable bit, which disables the Recoverable Fault B interrupt.

- **Bit 12 – FAULTA: Recoverable Fault A Interrupt Enable**

0: The Recoverable Fault A interrupt is disabled.

1: The Recoverable Fault A interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Recoverable Fault A Interrupt Disable/Enable bit, which disables the Recoverable Fault A interrupt.

- **Bit 11 – DFS: Non-Recoverable Debug Fault Interrupt Enable**

0: The Debug Fault State interrupt is disabled.

1: The Debug Fault State interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Debug Fault State Interrupt Disable/Enable bit, which disables the Debug Fault State interrupt.

- **Bit 10 – UFS: Non-Recoverable Update Fault Interrupt Enable**

0: The Non-Recoverable Update Fault interrupt is disabled.

1: The Non-Recoverable Update Fault interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Non-Recoverable Update Fault Interrupt Disable/Enable bit, which disables the Non-Recoverable Update Fault interrupt.

- **Bits 9:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3 – ERR: Error Interrupt Enable**

0: The Error interrupt is disabled.

1: The Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Error Interrupt Disable/Enable bit, which disables the Error interrupt.

- **Bit 2 – CNT: Counter Interrupt Enable**

0: The Counter interrupt is disabled.

1: The Counter interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Counter Interrupt Disable/Enable bit, which disables the Counter interrupt.

- **Bit 1 – TRG: Retrigger Interrupt Enable**

0: The Retrigger interrupt is disabled.

1: The Retrigger interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Retrigger Interrupt Disable/Enable bit, which disables the Retrigger interrupt.

- **Bit 0 – OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Overflow Interrupt Disable/Enable bit, which disables the Overflow interrupt.

### 35.8.12 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear (INTENCLR) register.

**Name:** INTENSET

**Offset:** 0x28

**Reset:** 0x00000000

- **Bits 31:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 19:16 – MCx [x=3..0]: Match or Capture Channel x Interrupt Enable**

0: The Match or Capture Channel x interrupt is disabled.

1: The Match or Capture Channel x interrupt is enabled.

Writing a zero to MCx has no effect.

Writing a one to MCx will set the corresponding Match or Capture Channel x Interrupt Disable/Enable bit, which enables the Match or Capture Channel x interrupt.

- **Bit 15 – FAULT1: Non-Recoverable Fault 1 Interrupt Enable**

0: The Non-Recoverable Fault 1 interrupt is disabled.

1: The Non-Recoverable Fault 1 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Non-Recoverable Fault 1 Interrupt Disable/Enable bit, which enables the Non-Recoverable Fault 1 interrupt.

- **Bit 14 – FAULT0: Non-Recoverable Fault 0 Interrupt Enable**

0: The Non-Recoverable Fault 0 interrupt is disabled.

1: The Non-Recoverable Fault 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Non-Recoverable Fault 0 Interrupt Disable/Enable bit, which enables the Non-Recoverable Fault 0 interrupt.

- **Bit 13 – FAULTB: Recoverable Fault B Interrupt Enable**

0: The Recoverable Fault B interrupt is disabled.

1: The Recoverable Fault B interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Recoverable Fault B Interrupt Disable/Enable bit, which enables the Recoverable Fault B interrupt.

- **Bit 12 – FAULTA: Recoverable Fault A Interrupt Enable**

0: The Recoverable Fault A interrupt is disabled.

1: The Recoverable Fault A interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Recoverable Fault A Interrupt Disable/Enable bit, which enables the Recoverable Fault A interrupt.

- **Bit 11 – DFS: Non-Recoverable Debug Fault Interrupt Enable**

0: The Debug Fault State interrupt is disabled.

1: The Debug Fault State interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Debug Fault State Interrupt Disable/Enable bit, which enables the Debug Fault State interrupt.

- **Bit 10 – UFS: Non-Recoverable Update Fault Interrupt Enable**

0: The Non-Recoverable Update Fault interrupt is disabled.

1: The Non-Recoverable Update Fault interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Non-Recoverable Update Fault Interrupt Disable/Enable bit, which enables the Non-Recoverable Update Fault interrupt.

- **Bits 9:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3 – ERR: Error Interrupt Enable**

0: The Error interrupt is disabled.

1: The Error interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Error Interrupt Disable/Enable bit, which enables the Error interrupt.

- **Bit 2 – CNT: Counter Interrupt Enable**

0: The Counter interrupt is disabled.

1: The Counter interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Retrigger Interrupt Disable/Enable bit, which enables the Counter interrupt.

- **Bit 1 – TRG: Retrigger Interrupt Enable**

0: The Retrigger interrupt is disabled.

1: The Retrigger interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Retrigger Interrupt Disable/Enable bit, which enables the Retrigger interrupt.

- **Bit 0 – OVF: Overflow Interrupt Enable**

0: The Overflow interrupt is disabled.

1: The Overflow interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Overflow Interrupt Disable/Enable bit, which enables the Overflow interrupt.

### 35.8.13 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x2C  
**Reset:** 0x00000000  
**Property:** -

| Reset  | 0 | 0 | 0 | 0 | 0   | 0   | 0   | 0   |

- Bits 31:20 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 19:16 – MCx [x=3..0]: Match or Capture x**  
 This flag is set on the next CLK\_TCC\_COUNT cycle after a match with the compare condition or once CCx register contain a valid capture value.  
 Writing a zero to one of these bits has no effect.  
 Writing a one to one of these bits will clear the corresponding Match or Capture Channel x interrupt flag  
 In Capture operation, this flag is automatically cleared when CCx register is read.
- Bit 15 – FAULT1: Non-Recoverable Fault 1**  
 This flag is set on the next CLK\_TCC\_COUNT cycle after a Non-Recoverable Fault 1 occurs.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Non-Recoverable Fault 1 interrupt flag.
- Bit 14 – FAULT0: Non-Recoverable Fault 0**  
 This flag is set on the next CLK\_TCC\_COUNT cycle after a Non-Recoverable Fault 0 occurs.  
 Writing a zero to this bit has no effect.

Writing a one to this bit clears the Non-Recoverable Fault 0 interrupt flag.

- **Bit 13 – FAULTB: Recoverable Fault B**

This flag is set on the next CLK\_TCC\_COUNT cycle after a Recoverable Fault B occurs.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Recoverable Fault B interrupt flag.

- **Bit 12 – FAULTA: Recoverable Fault A**

This flag is set on the next CLK\_TCC\_COUNT cycle after a Recoverable Fault A occurs.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Recoverable Fault A interrupt flag.

- **Bit 11 – DFS: Non-Recoverable Debug Fault**

This flag is set on the next CLK\_TCC\_COUNT cycle after an Debug Fault State occurs.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Debug Fault State interrupt flag.

- **Bit 10 – UFS: Non-Recoverable Update Fault**

This flag is set when the RAMP index changes and the Lock Update bit is set (CTRLBSET.LUPD).

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Non-Recoverable Update Fault interrupt flag.

- **Bits 9:4 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 3 – ERR: Error**

This flag is set if a new capture occurs on a channel when the corresponding Match or Capture Channel x interrupt flag is one. In which case there is nowhere to store the new capture.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Error interrupt flag.

- **Bit 2 – CNT: Counter**

This flag is set on the next CLK\_TCC\_COUNT cycle after a counter event occurs.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the CNT interrupt flag.

- **Bit 1 – TRG: Retrigger**

This flag is set on the next CLK\_TCC\_COUNT cycle after a counter retrigger occurs.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Retrigger interrupt flag.

- **Bit 0 – OVF: Overflow**

This flag is set on the next CLK\_TCC\_COUNT cycle after an overflow condition occurs.

Writing a zero to this bit has no effect.

Writing a one to this bit clears the Overflow interrupt flag.

### 35.8.14 Status

| Reset  | 0       | 0        | 0        | 0 | 0   | 0   | 0   | 1    |

- Bits 31:28 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 27:24 – CMPx [x=3..0]: Compare Channel x Value**  
 This bit reflects the channel x output compare value.  
 0: Channel compare output value is 0.  
 1: Channel compare output value is 1.
- Bits 23:20 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 19:16 – CCBUFVx [x=3..0]: Compare Channel x Buffer Valid**  
 For a compare channel, the bit is set when a new value is written to the corresponding CCBUFx register. The bit is cleared by writing a one to the corresponding location or automatically cleared on an UPDATE condition.  
 For a capture channel, the bit is set when a valid capture value is stored in the CCBUFx register. The bit is automatically cleared when the CCx register is read.

- **Bit 15 – FAULT1: Non-Recoverable Fault 1 State**  
 This bit is set by hardware as soon as non-recoverable Fault 1 condition occurs.  
 This bit is cleared by writing a one to this bit and when the corresponding FAULT1IN status bit is low.  
 Once this bit is clear, the timer/counter will restart from the last COUNT value. To restart the timer/counter from BOTTOM, the timer/counter restart command must be executed before clearing the corresponding FAULT1 bit.  
 For further details on timer/counter commands, refer to available commands description ([CTRLBSET.CMD](#)).
- **Bit 14 – FAULT0: Non-Recoverable Fault 0 State**  
 This bit is set by hardware as soon as non-recoverable Fault 0 condition occurs.  
 This bit is cleared by writing a one to this bit and when the corresponding FAULT0IN status bit is low.  
 Once this bit is clear, the timer/counter will restart from the last COUNT value. To restart the timer/counter from BOTTOM, the timer/counter restart command must be executed before clearing the corresponding FAULT0 bit.  
 For further details on timer/counter commands, refer to available commands description ([CTRLBSET.CMD](#)).
- **Bit 13 – FAULTB: Recoverable Fault B State**  
 This bit is set by hardware as soon as recoverable Fault B condition occurs.  
 This bit is cleared by hardware when Fault B action is resumed, or by writing a one to this bit when the corresponding FAULTBIN bit is low. If software halt command is enabled (FCTRLB.HALT=SW), clearing this bit release the timer/counter.
- **Bit 12 – FAULTA: Recoverable Fault A State**  
 This bit is set by hardware as soon as recoverable Fault A condition occurs.  
 This bit is cleared by hardware when Fault A action is resumed, or by writing a one to this bit when the corresponding FAULTAIN bit is low. If software halt command is enabled (FCTRLA.HALT=SW), clearing this bit release the timer/counter.
- **Bit 11 – FAULT1IN: Non-Recoverable Fault1 Input**  
 This bit is set while an active Non-Recoverable Fault 1 input is present.
- **Bit 10 – FAULT0IN: Non-Recoverable Fault0 Input**  
 This bit is set while an active Non-Recoverable Fault 0 input is present.
- **Bit 9 – FAULTBIN: Recoverable Fault B Input**  
 This bit is set while an active Recoverable Fault B input is present.
- **Bit 8 – FAULTAIN: Recoverable Fault A Input**  
 This bit is set while an active Recoverable Fault A input is present.
- **Bit 7 – PERBUFV: Period Buffer Valid**  
 This bit is set when a new value is written to the PERBUF register. This bit is automatically cleared by hardware on UPDATE condition or by writing a one to this bit.
- **Bit 6 – WAVEBUFV: Wave Buffer Valid**  
 This bit is set when a new value is written to the WAVEBUF register. This bit is automatically cleared by hardware on UPDATE condition or by writing a one to this bit.
- **Bit 5 – PATTBUFV: Pattern Buffer Valid**  
 This bit is set when a new value is written to the PATTBUF register. This bit is automatically cleared by hardware on UPDATE condition or by writing a one to this bit.
- **Bits 4 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- Bit 3 – DFS: Non-Recoverable Debug Fault State**  
 This bit is set by hardware in debug mode when DBGCTRL.FDDBD bit is set. The bit is cleared by writing a one to this bit and when the TCC is not in debug mode.  
 When the bit is set, the counter is halted and the waveforms state depend on DRVCTRL.NRE and DRVCTRL.NRV registers.
- Bit 2 – UFS: Non-recoverable Update Fault State**  
 This bit is set by hardware when the RAMP index changes and the Lock Update bit is set (CTRLBSET.LUPD). The bit is cleared by writing a one to this bit.  
 When the bit is set, the waveforms state depend on DRVCTRL.NRE and DRVCTRL.NRV registers.
- Bit 1 – IDX: Ramp**  
 In RAMP2 and RAMP2A operation, the bit is cleared during the cycle A and set during the cycle B. In RAMP1 operation, the bit is always read zero. For details on ramp operations, refer to [“Ramp Operations” on page 709](#).
- Bit 0 – STOP: Stop**  
 This bit is set when the TCC is disabled, on a STOP command or on an UPDATE condition when One-Shot operation mode is enabled (CTRLBSET.ONESHOT = 1).  
 This bit is clear on the next incoming counter increment or decrement.  
 0: Counter is running.  
 1: Counter is stopped.

| Reset  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

- Bits 15:8 – PGVx [x=7..0]: Pattern Generator x Output Value**  
 This register holds the values of pattern for each waveform output.
- Bits 7:0 – PGE<sub>x</sub> [x=7..0]: Pattern Generator x Output Enable**  
 This register holds the enables of pattern generation for each waveform output. A bit position at one, overrides the corresponding SWAP output with the corresponding PGV<sub>x</sub> value.

### 35.8.17 Waveform Control

**Name:** WAVE

**Offset:** 0x3C

**Reset:** 0x00000000

| Reset  | 0       | 0 | 0         | 0   | 0 | 0            | 0   | 0   |

- **Bits 31:28 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 27:24 – SWAPx [x=3..0]: Swap DTI Output Pair x**

Setting these bits enables output swap of DTI outputs [x] and [x+WO\_NUM/2]. Note the DTIxEN settings will not affect the swap operation.

- **Bits 23:20 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 19:16 – POLx [x=3..0]: Channel x Polarity**

Setting these bits enable the output polarity in single-slope and dual-slope PWM operations.

In single-slope PWM waveform generation:

0: Compare output is initialized to ~DIR and set to DIR when TCC counter matches CCx value

1: Compare output is initialized to DIR and set to ~DIR when TCC counter matches CCx value.

In dual-slope PWM waveform generation:

0: Compare output is set to ~DIR when TCC counter matches CCx value

1: Compare output is set to DIR when TCC counter matches CCx value.

- **Bits 15:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 – CICCENx [x=3..0]: Circular Channel x Enable**

Setting these bits enable the compare circular buffer option on channel. When the bit is set, CCx register value is copied-back into the CCx register on UPDATE condition.

- **Bit 7 – CIPEREN: Circular period Enable**

Setting these bits enable the period circular buffer option. When the bit field is set, the PER register value is copied-back into the PERBUF register on UPDATE condition.

- **Bit 6 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 5:4 – RAMP[1:0]: Ramp Mode**

These bits select Ramp operation (RAMP), as shown in the table below. These bits are not synchronized.

**Table 35-28. Ramp Mode**

| RAMP[1:0] | Name   | Description                 |
|-----------|--------|-----------------------------|
| 0x0       | RAMP1  | RAMP1 operation             |
| 0x1       | RAMP2A | Alternative RAMP2 operation |
| 0x2       | RAMP2  | RAMP2 operation             |
| 0x3       | RAMP2C | Critical RAMP2 operation    |

- **Bit 3 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 2:0 – WAVEGEN[2:0]: Waveform Generation**

These bits select the waveform generation operation, as shown in the table below. The settings impact the top value and select the frequency/PWM mode. These bits are not synchronized.

**Table 35-29. Waveform Generation**

| WAVEGEN[2:0] | Name       | Description         |
|--------------|------------|---------------------|
| 0x0          | NFRQ       | Normal frequency    |
| 0x1          | MFRQ       | Match frequency     |
| 0x2          | NPWM       | Normal PWM          |
| 0x3          |            | Reserved            |
| 0x4          | DSCRITICAL | Dual-slope critical |

| WAVEGEN[2:0] | Name     | Description  |
|--------------|----------|--|
| 0x5          | DSBOTTOM | Dual-slope with interrupt/event condition when COUNT reaches ZERO        |
| 0x6          | DSBOTH   | Dual-slope with interrupt/event condition when COUNT reaches ZERO or TOP |
| 0x7          | DSTOP    | Dual-slope with interrupt/event condition when COUNT reaches TOP         |

## 35.8.19 Compare/Capture Channel x

### 35.8.19.1 CTRLA.RESOLUTION = NONE

The CCx register represents the 16-, 24- or 32-bit value, CCx. The register has two functions, depending of the mode of operation. For capture operation, this register represents the second buffer level and access point for the CPU and DMA. For compare operation, this register is continuously compared to the counter value. Normally, the output from the comparator is then used for generating waveforms. CCx register is updated with the buffer value from their corresponding CCBUFx register when an UPDATE condition occurs. In addition, in match frequency operation, the CC0 register controls the counter period.

**Name:** CCx

- Bits 31:24 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 23:5 – CC[18:0]: Channel Compare/Capture Value**  
 These bits hold the value of the Channel x compare/capture register.  
 The number of bits in this field corresponds to the size of the counter.  
 CCx[31:24] are read zero when TCC is configured as 16- or 24-bits timer/counter.  
 CCx[23:16] are read zero when TCC is configured as 16-bits timer/counter.
- Bits 4:0 – DITHER[4:0]: Dithering Cycle Number**  
 These bits hold the number of extra cycles that are added on the PWM pulse width every 32 PWM frames.

### 35.8.19.4 CTRLA.RESOLUTION = DITH6

The CCx register represents the 16-, 24- or 32-bit value, CCx. The register has two functions, depending of the mode of operation. For capture operation, this register represents the second buffer level and access point for the CPU and DMA. For compare operation, this register is continuously compared to the counter value. Normally, the output from the comparator is then used for generating waveforms. CCx register is updated with the buffer value from their corresponding CCBx register when an UPDATE condition occurs. In addition, in match frequency operation, the CC0 register controls the counter period.

**Name:** ICCx

**Offset:** 0x44+x\*0x4 [x=0..3]

| Access | R/W      | R | R/W        | R/W | R | R/W           | R/W | R/W |
| Reset  | 0        | 0 | 0          | 0   | 0 | 0             | 0   | 0   |

- Bits 31:28 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 27:24 – SWAPBx [x=3..0]: Swap DTI Output Pair x Buffer**  
 These bits represent the SWAP buffers. When the double buffering is enable, SWAPB bits value is copied to the SWAP bits on an UPDATE condition.
- Bits 23:20 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 19:16 – POLBx [x=3..0]: Channel x Polarity Buffer**  
 These bits represent the POL buffers. When the double buffering is enable, POLB bits value is copied to the POL bits on an UPDATE condition.
- Bits 15:12 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:8 – CICCENBx [x=3..0]: Circular Channel x Enable Buffer**  
These bits represent the CICCEN buffers. When the double buffering is enable, CICCENB bits value is copied to the CICCEN bits on an UPDATE condition.
- **Bit 7 – CIPERENB: Circular Period Enable Buffer**  
This bit represents the CIPEREN buffer. When the double buffering is enable, CIPERENB bit value is copied to the CIPEREN bit on an UPDATE condition.
- **Bit 6 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bits 5:4 – RAMPB[1:0]: Ramp Mode Buffer**  
These bits represent the RAMP buffers. When the double buffering is enable, RAMPB bits value is copied to the RAMP bits on an UPDATE condition.
- **Bit 3 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bits 2:0 – WAVEGENB[2:0]: Waveform Generation Buffer**  
These bits represent the WAVEGEN buffers. When the double buffering is enable, WAVEGENB bits value is copied to the WAVEGEN bits on an UPDATE condition.

**Table 35-30. Waveform Generation Buffer**

| WAVEGENB[2:0] | Name       | Description  |
|---------------|------------|--|
| 0x0           | NFRQ       | Normal frequency   |
| 0x1           | MFRQ       | Match frequency  |
| 0x2           | NPWM       | Normal PWM   |
| 0x3           |            | Reserved   |
| 0x4           | DSCRITICAL | Dual-slope critical  |
| 0x5           | DSBOTTOM   | Dual-slope with interrupt/event condition when COUNT reaches ZERO        |
| 0x6           | DSBOTH     | Dual-slope with interrupt/event condition when COUNT reaches ZERO or TOP |
| 0x7           | DSTOP      | Dual-slope with interrupt/event condition when COUNT reaches TOP         |

## 35.8.22 Period Buffer Value

### 35.8.22.1 CTRLA.RESOLUTION = NONE

**Name:** PERBUF

**Offset:** 0x6C

**Reset:** 0xFFFFFFFF

**Property:** Write-Synchronized, Read-Synchronized

- **Bits 31:24 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 23:5 – PERBUF[18:0]: Period Buffer Value**

These bits hold the value of the period register.

The number of bits in this field corresponds to the size of the counter.

PERBUF[31:24] are read zero when TCC is configured as 16- or 24-bits timer/counter.

PERBUF[23:16] are read zero when TCC is configured as 16-bits timer/counter.

- **Bits 4:0 – DITHERBUF[4:0]: Dithering Buffer Cycle Number**

These bits represent the PER.DITHER bits buffer. When the double buffering is enable, DITHERBUF bits value is copied to the PER.DITHER bits on an UPDATE condition.

The number of bits in this field corresponds to the size of the counter.

CCBUF[31:24] are read zero when TCC is configured as 16- or 24-bits timer/counter.

CCBUF[23:16] are read zero when TCC is configured as 16-bits timer/counter.

- **Bits 5:0 – DITHERBUF[5:0]: Dithering Buffer Cycle Number**

These bits represent the CCx.DITHER bits buffer. When the double buffering is enable, DITHERBUF bits value is copied to the CCx.DITHER bits on an UPDATE condition.

## 36. CCL – Configurable Custom Logic

### 36.1 Features

- Glue logic for general purpose PCB design
- Up to four Programmable LookUp Tables (LUT)
- Combinatorial Logic Functions
  - AND, NAND, OR, NOR, XOR, XNOR, NOT
- Sequential Logic Functions
  - Gated D Flip-Flop, JK Flip-Flop, gated D Latch, RS Latch
- Flexible LookUp Table Inputs Selection
  - I/Os
  - Events
  - Internal Peripherals
  - Subsequent LUT Output
- Output can be connected to IO pins or Event System
- Optional synchronizer, filter or edge detector available on each LUT output

### 36.2 Overview

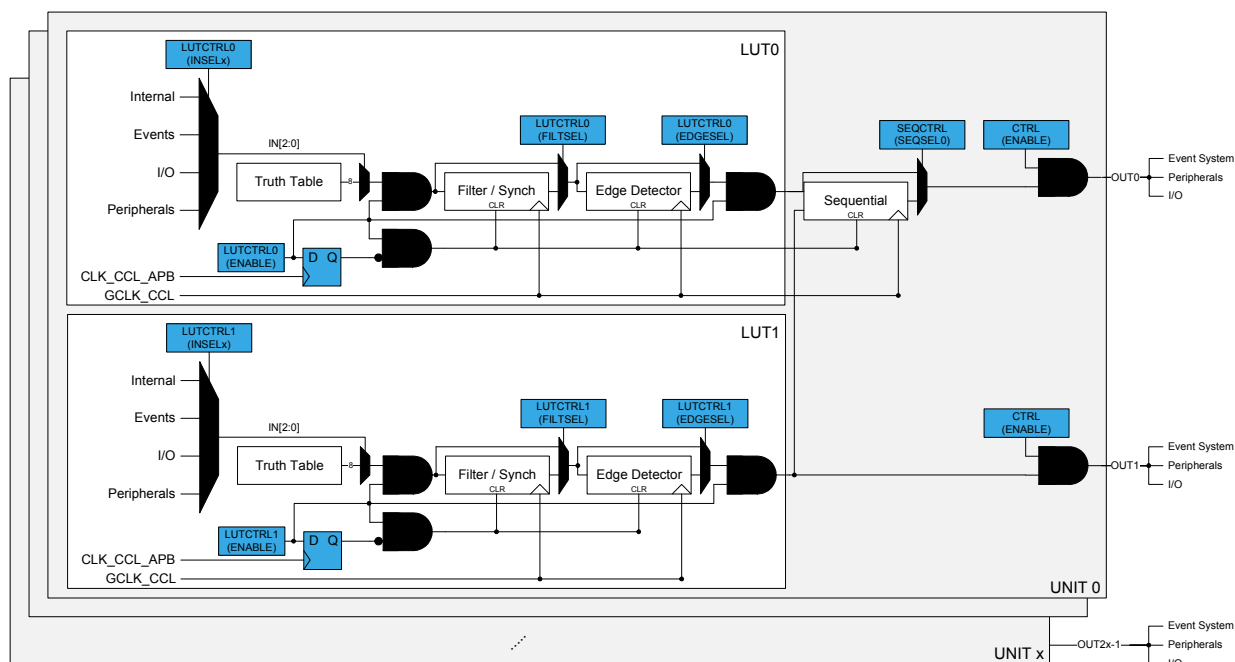

The Configurable Custom Logic (CCL) contains programmable logic which can be connected to the device pins, events or internal peripherals. This allows the user to eliminate logic gates for simple glue logic functions on the PCB.

Each LUT consists of three inputs, a truth table and optional synchronizer, filter and edge detector. Each LUT can generate an output as a user programmable logic expression with three inputs. Inputs can be individually masked.

The output can be combinatorially generated from the inputs, or filtered to remove spike. An optional sequential module can be enabled. The inputs of sequential module are individually controlled by two independent, adjacent LUT (LUT0/LUT1, LUT2/LUT3 etc) outputs, enabling complex waveform generation.

### 36.3 Block Diagram

Figure 36-1. Configurable Custom Logic.

## 36.4 Signal Description

Table 36-1. Signal Description

| Pin Name | Type           | Description                |
|----------|----------------|----------------------------|
| OUT0     | Digital output | Output from lookup table 0 |
| OUT1     | Digital output | Output from lookup table 1 |
| OUT2     | Digital output | Output from lookup table 2 |
| OUT3     | Digital output | Output from lookup table 3 |
| IN0      | Digital input  | Input 0 to lookup table 0  |
| IN1      | Digital input  | Input 1 to lookup table 0  |
| IN2      | Digital input  | Input 2 to lookup table 0  |
| IN3      | Digital input  | Input 0 to lookup table 1  |
| IN4      | Digital input  | Input 1 to lookup table 1  |
| IN5      | Digital input  | Input 2 to lookup table 1  |
| IN6      | Digital input  | Input 0 to lookup table 2  |
| IN7      | Digital input  | Input 1 to lookup table 2  |
| IN8      | Digital input  | Input 2 to lookup table 2  |
| IN9      | Digital input  | Input 0 to lookup table 3  |
| IN10     | Digital input  | Input 1 to lookup table 3  |
| IN11     | Digital input  | Input 2 to lookup table 3  |

Refer to the Peripheral Multiplexing on I/O Lines section in the Pinout and Block Diagram chapter for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 36.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 36.5.1 I/O Lines

Using the CCL I/O lines requires the I/O pins to be configured. Refer to the PORT chapter for details.

### 36.5.2 Power Management

The CCL will continue to operate in any sleep mode where the selected source clock is running. Events connected to the event system can trigger other operations in the system without exiting sleep modes. Refer to the Power Manager chapter for details on the different sleep modes.

### 36.5.3 Clocks

The CCL bus clock (CLK\_CCL\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_CCL\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

A generic clock (GCLK\_CCL) is optionally required to clock the CCL. This clock must be configured and enabled in the generic clock controller before using the sequential sub-module of CCL. The GCLK\_CCL clock is required when input events, filter, edge detector or sequential sub-module are enabled. Refer to the Generic Clock Controller chapter for details.

This generic clock is asynchronous to the user interface clock (CLK\_CCL\_APB).

#### 36.5.4 DMA

Not applicable.

#### 36.5.5 Interrupts

Not applicable.

#### 36.5.6 Events

The events are connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

#### 36.5.7 Debug Operation

When the CPU is halted in debug mode the CCL continues normal operation. If the CCL is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

#### 36.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC).

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to the Peripheral Access Controller chapter for details.

#### 36.5.9 Analog Connections

Not applicable.

### 36.6 Functional Description

#### 36.6.1 Principle of Operation

Configurable Custom Logic is a block which can be used to add logic to the device port pin or to generate internal events. This increases the reliability of PCB, reduces its complexity and enables more powerful functions.

#### 36.6.2 Basic Operation

##### 36.6.2.1 Initialization

The following bits are enable-protected, meaning that they can only be written when the corresponding even LUT is disabled (LUTCTRLx.ENABLE is zero):

- Sequential Selection in Sequential Control x register (SEQCTRLx.SEQSEL)

The following register is enable-protected, meaning that it can only be written when the corresponding LUT is disabled (LUTCTRLx.ENABLE is zero):

- LUT Control x register, except ENABLE bit (LUTCTRLx)

Enable-protected bits in the LUTCTRLx registers can be written at the same time as LUTCTRLx.ENABLE is written to one, but not at the same time as LUTCTRLx.ENABLE is written to zero.

Enable-protection is denoted by the Enable-Protected property in the register description.

##### 36.6.2.2 Enabling, Disabling and Resetting

The CCL is enabled by writing a one to the Enable bit in the Control register (CTRL.ENABLE). The CCL is disabled by writing a zero to CTRL.ENABLE.

Each LUT is enabled by writing a one to the Enable bit in the LUT Control x register (LUTCTRLx.ENABLE). Each LUT is disabled by writing a zero to LUTCTRLx.ENABLE.

The CCL is reset by writing a one to the Software Reset bit in the Control register (CTRL.SWRST). All registers in the CCL will be reset to their initial state, and the CCL will be disabled. Refer to [CTRL](#) for details.

### 36.6.2.3 Lookup Table Logic

The lookup table in each LUT unit can generate any logic expression OUT as a function of three inputs (IN[2:0]), as shown in [Figure 36-2](#). One or more inputs can be masked. The truth table for the expression is defined by TRUTH bits in LUT Control x register (LUTCTRLx.TRUTH).

**Figure 36-2. Truth Table Output Value Selection**

**Table 36-2. Truth Table of LUT**

| IN[2] | IN[1] | IN[0] | OUT      |
|-------|-------|-------|----------|
| 0     | 0     | 0     | TRUTH[0] |
| 0     | 0     | 1     | TRUTH[1] |
| 0     | 1     | 0     | TRUTH[2] |
| 0     | 1     | 1     | TRUTH[3] |
| 1     | 0     | 0     | TRUTH[4] |
| 1     | 0     | 1     | TRUTH[5] |
| 1     | 1     | 0     | TRUTH[6] |
| 1     | 1     | 1     | TRUTH[7] |

### 36.6.2.4 Truth Table Inputs Selection

The inputs can be individually:

- Masked
- Driven by peripherals
  - Analog comparator output (AC)
  - Timer/Counters waveform outputs (T/C)
  - Serial Communication output transmit interface (SERCOM)
- Driven by internal events from Event System
- Internal CCL sub-modules

The Input Selection for each LUT input is available in the corresponding LUT Control register (LUTCTRLx.INSELx).

### Masked Inputs (MASK)

When a LUT input is masked, the corresponding TRUTH input (IN) is internally tied to zero, as shown in Figure 36-3:

Figure 36-3. Masked Input Selection

### Internal Feedback Inputs (FEEDBACK)

When selected, the Sequential (SEQ) output is used as input for the corresponding LUT

The output from internal Sequential sub-module can be used as input source for one or both of the two LUTs that act as input to the SEQ block. Figure 36-4 shows an example for LUT0 and LUT1. The Sequential selection for each LUT follows the formula:

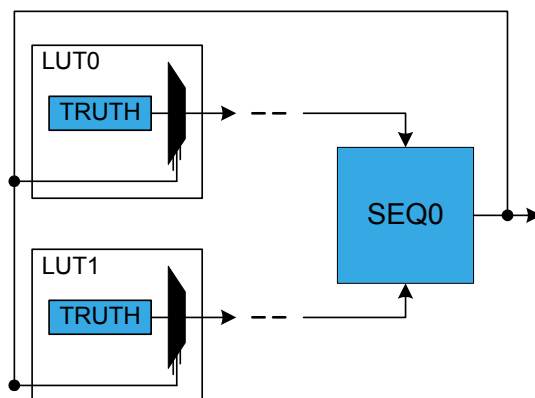

$$IN[2N][i] = SEQ[N]$$

$$IN[2N+1][i] = SEQ[N]$$

Where N represents the LUT number and i represents the LUT input index (i=0,1,2).

For details on Sequential sub-module, refer to “Sequential Logic” on page 802.

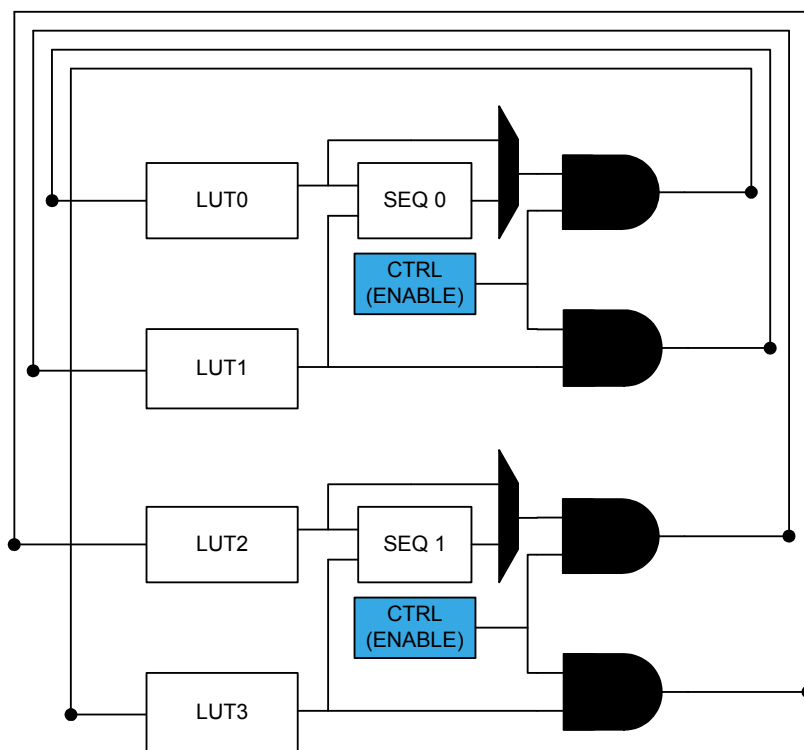

Figure 36-4. Feedback Selection

### Linked LUT (LINK)

When selected, the LUT input is connected to the sub-sequent LUT output, as shown in [Figure 36-5](#):

**Figure 36-5. Linked LUT Selection**

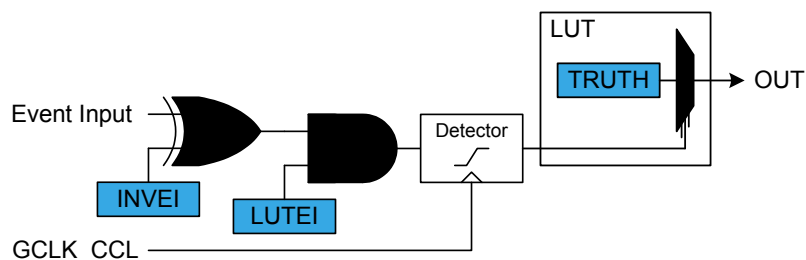

### Internal Events Inputs (EVENT)

Asynchronous events from Event System can be used as input selection, as shown in [Figure 36-6](#). One event input line is available for each LUT and can be selected on each LUT input. Before enabling the event selection, the Event System must be configured first. For details, refer to “[EVSYS – Event System](#)” on page 467.

The CCL includes an edge detector. When the event is received, an internal strobe is generated when the rising edge is detected. The pulse duration is one GCLK\_CCL clock cycle. To ensure the proper operation, the following steps must be followed:

- Enable the GCLK\_CCL clock
- Configure Event System to route the desired event asynchronously
- Set the Inverted Event Input Enable bit in LUT Control register (LUTCTRLx.INVEI = 1) if a strobe must be generated on the event input falling edge
- Set the Event Input Enable bit in LUT Control register (LUTCTRLx.LUTEI = 1)

**Figure 36-6. Event Selection**

## I/O Pin Inputs (IO)

Refer to “PORT – IO Pin Controller” on page 437 for details on how to configure the I/O pins. When the IO pin is selected as LUT input, the corresponding LUT input will be connected to the pin, as shown in Figure 36-7. Refer to Table 36-1 for details on available IO pins for each LUT unit.

Figure 36-7. IO Pin Input Selection

## Analog Comparator Inputs (AC)

The AC outputs can be used as input source for the LUT. Comparator 0 output selection is available on each even LUT (LUT2x) and the comparator 1 output selection is available on each odd LUT (LUT2x+1), as shown in Figure 36-8. More general, the analog comparator outputs are distributed following the formula:

$$IN[N][i] = AC[N\%ComparatorOutput\_Number]$$

Where N represents the LUT number and i represents the LUT input index (i=0,1,2).

Before selecting the comparator output, the AC must be configured first. For further details, refer to “AC – Analog Comparators” on page 852.

Figure 36-8. AC Selection

## Timer/Counter Inputs (TC)

The TC waveform output can be used as input source for the LUT. TCx and the sub-sequent TC(x+1) instances are available as default and alternative timer/counter selections (ie TC0 and TC1 are sources for LUT0, TC1 and TC2 are sources for LUT1, etc). Figure 36-9 shows an example for LUT0. More general, the Timer/Counter selection for each LUT follows the formula:

$$IN[N][i] = DefaultTC[N\%TC\_InstanceNumber]$$

$$IN[N][i] = AlternativeTC[(N+1)\%TC\_InstanceNumber]$$

Where N represents the LUT number and i represents the LUT input index (i=0,1,2)

Before selecting the waveform outputs, the TC must be configured first. For further details, refer to “TC – Timer/Counter” on page 638.

**Figure 36-9. TC Selection**

### Timer/Counter for Control Application Inputs (TCC)

The timer/counter waveforms output can be used as input source for the LUT. Only WO[2:0] outputs can be selected and routed to the respective LUT input (ie IN0 is connected to WO0, IN1 to WO1 and IN2 to WO2), as shown in [Figure 36-10](#). The TCC selection for each LUT follows the formula:

$$IN[N] = TCC[N\%TCC\_InstanceNumber]$$

Where N represents the LUT number.

Before selecting the waveform outputs, the TCC must be configured first. For further details, refer to “[TCC – Timer/Counter for Control Applications](#)” on page 691.

**Figure 36-10. TCC Selection**

### Serial Communication Output Transmit Inputs (SERCOM)

The serial engine transmitter output from Serial Communication Interface (SERCOM) can be used as input source for the LUT. [Figure 36-11](#) shows an example for LUT0 and LUT1. The SERCOM selection for each LUT follows the formula:

$$IN[N][i] = SERCOM[N\%SERCOM\_InstanceNumber]$$

Where N represents the LUT number and i represents the LUT input index (i=0,1,2)

Before selecting the SERCOM as input source, the SERCOM must be configured first. For further details, refer to “[SERCOM – Serial Communication Interface](#)” on page 492.

**Figure 36-11. SERCOM Selection**

### 36.6.2.5 Filter

The LUT output is a combinatorial function of the LUT inputs (INx), by default. This may cause some short glitches to occur when the inputs change value. Depending on application needs, it is also possible to clock the output through a filter to remove glitches. Synchronizer or digital filter options are available, and defined by Filter Selection bits in LUT Control register (LUTCTRLx.FILTSEL). When the filter is enabled, the OUT output will be delayed by two to five GCLK cycles, depending on configuration. One APB clock after the corresponding LUT is disabled, all internal Filter logic is cleared. Note if events are used as LUT input selection and the filter is selected, the event will be filtered.

**Figure 36-12.Filter**

### 36.6.2.6 Edge Detector

The edge detector can be enabled to generate a pulse when a rising edge on its input is detected. To detect a falling edge, the TRUTH table should be programmed in a way to provide the opposite levels. The edge detector is enabled by writing to one the Edge Selection bit in LUT Control register (LUTCTRLx.EDGESEL). When enabled, and to avoid unpredictable behavior, a valid filter option must be enabled as well.

One APB clock after the corresponding LUT is disabled, all internal Edge Detector logic is cleared.

**Figure 36-13.Edge Detector**

36.6.2.7 Sequential Logic

Each LUT pair can be connected to internal Sequential logic. D flip flop, JK flip flop, gated D-latch or RS-latch can be selected by writing the corresponding Sequential Selection bits in Sequential Control x register (SEQCTRLx.SEQSEL). Before using sequential logic, the GCLK clock and optionally each LUT filter or edge detector, must be enabled.

Gated D Flip-Flop (DFF)

When this configuration is selected, the D-input is driven by the even LUT output (LUT2x), since the G-input is driven by the odd LUT output (LUT2x+1), as shown in Figure 36-14.

Figure 36-14.D Flip Flop

When the even LUT is disabled (LUTCTRL2x.ENABLE is set to zero), the flip-flop is asynchronously cleared. The reset command (R) is kept enabled one APB clock cycle. In all other cases, the flip-flop output (OUT) is refreshed on rising edge of the GCLK\_CCL, as shown in Table 36-3.

Table 36-3. DFF Characteristics

| R | G | D | OUT                    |
|---|---|---|------------------------|
| 1 | X | X | Clear                  |
| 0 | 1 | 1 | Set                    |
|   |   | 0 | Clear                  |
|   | 0 | X | Hold state (no change) |

JK Flip-Flop (JK)

When this configuration is selected, the J-input is driven by the even LUT output (LUT2x), since the K-input is driven by the odd LUT output (LUT2x+1), as shown in Figure 36-15.

Figure 36-15.JK Flip Flop

When the even LUT is disabled (LUTCTRL2x.ENABLE is set to zero), the flip-flop is asynchronously cleared. The reset command (R) is kept enabled one APB clock cycle. In all other cases, the flip-flop output (OUT) is refreshed on rising edge of the GCLK\_CCL, as shown in Table 36-4.

**Table 36-4. JK Characteristics**

| R | J | K | OUT                    |
|---|---|---|------------------------|
| 1 | X | X | Clear                  |
| 0 | 0 | 0 | Hold state (no change) |
| 0 | 0 | 1 | Clear                  |
| 0 | 1 | 0 | Set                    |
| 0 | 1 | 1 | Toggle                 |

**Gated D-Latch (DLATCH)**

When this configuration is selected, the D-input is driven by the even LUT output (LUT2x), since the G-input is driven by the odd LUT output (LUT2x+1), as shown in [Figure 36-16](#).

**Figure 36-16.D-Latch**

When the even LUT is disabled (LUTCTRL2x.ENABLE is set to zero), the latch output will be cleared. The G-input is forced enabled one APB clock cycle and D-input to zero. In all other cases, the latch output (OUT) is refreshed as shown in [Table 36-4](#).

**Table 36-5. D-latch Characteristics**

| G | D | OUT                    |
|---|---|------------------------|
| 0 | X | Hold state (no change) |
| 1 | 0 | Clear                  |
| 1 | 1 | Set                    |

**RS Latch (RS)**

When this configuration is selected, the S-input is driven by the even LUT output (LUT2x), and the R-input is driven by the odd LUT output (LUT2x+1), as shown in [Figure 36-17](#).

**Figure 36-17.RS-Latch**

When the even LUT is disabled (LUTCTRL2x.ENABLE is set to zero), the latch output will be cleared. The R-input is forced enabled one APB clock cycle and S-input to zero. In all other cases, the latch output (OUT) is refreshed as shown in [Table 36-6](#).

**Table 36-6. RS-latch Characteristics**

| S | R | OUT                    |
|---|---|------------------------|
| 0 | 0 | Hold state (no change) |
| 0 | 1 | Clear                  |
| 1 | 0 | Set                    |
| 1 | 1 | Forbidden state        |

### 36.6.3 Events

The CCL can generate the following output events:

- LUTOUTx: Lookup Table Output Value

Writing a one to the LUT Control Event Output Enable bit (LUTCTRLx.LUTEO) enabled the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to Event System for details on configuration.

The CCL can take the following actions on an input event:

- INx: Event is used as input for the TRUTH table. For further details refer to [“Internal Events Inputs \(EVENT\)” on page 798](#).

Writing a one to the LUT Control Event Input Enable bit (LUTCTRLx.LUTEI) enables the corresponding action on input event. Writing a zero to this bit disables the corresponding action on input event. Refer to Event System for details on configuration.

### 36.6.4 Sleep Mode Operation

When using the GCLK\_CCL internal clocking, writing the Run In Standby bit in the Control register (CTRL.RUNSTDBY) to one will allow GCLK\_CCL to be enabled in all sleep modes.

If CTRL.RUNSTDBY is zero, the GCLK\_CCL will be disabled. If the Filter, Edge Detector or Sequential logic are enabled, the LUT output will be forced to zero in STANDBY mode. In all other cases, the TRUTH table decoder will continue operation and LUT output will be refreshed accordingly.

## 36.7 Register Summary

| Offset | Name     | Bit pos. |             |          |              |       |             |  |        |       |
|--------|----------|----------|-------------|----------|--------------|-------|-------------|--|--------|-------|
| 0x00   | CTRL     | 7:0      |             | RUNSTDBY |              |       |             |  | ENABLE | SWRST |
| 0x01   | Reserved | 7:0      |             |          |              |       |             |  |        |       |
| 0x02   | Reserved | 7:0      |             |          |              |       |             |  |        |       |
| 0x03   | Reserved | 7:0      |             |          |              |       |             |  |        |       |
| 0x04   | SEQCTRL0 | 7:0      |             |          |              |       | SEQSEL[3:0] |  |        |       |
| 0x05   | SEQCTRL1 | 7:0      |             |          |              |       | SEQSEL[3:0] |  |        |       |
| 0x06   | SEQCTRL2 | 7:0      |             |          |              |       | SEQSEL[3:0] |  |        |       |
| 0x07   | SEQCTRL3 | 7:0      |             |          |              |       | SEQSEL[3:0] |  |        |       |
| 0x08   | LUTCTRL0 | 7:0      | EDGESEL     |          | FILTSEL[1:0] |       |             |  | ENABLE |       |
| 0x09   |          | 15:8     | INSEL1[3:0] |          |              |       | INSEL0[3:0] |  |        |       |
| 0x0A   |          | 23:16    |             | LUTEO    | LUTEI        | INVEI | INSEL2[3:0] |  |        |       |
| 0x0B   |          | 31:24    | TRUTH[7:0]  |          |              |       |             |  |        |       |
| 0x0C   | LUTCTRL1 | 7:0      | EDGESEL     |          | FILTSEL[1:0] |       |             |  | ENABLE |       |
| 0x0D   |          | 15:8     | INSEL1[3:0] |          |              |       | INSEL0[3:0] |  |        |       |
| 0x0E   |          | 23:16    |             | LUTEO    | LUTEI        | INVEI | INSEL2[3:0] |  |        |       |
| 0x0F   |          | 31:24    | TRUTH[7:0]  |          |              |       |             |  |        |       |
| 0x10   | LUTCTRL2 | 7:0      | EDGESEL     |          | FILTSEL[1:0] |       |             |  | ENABLE |       |
| 0x11   |          | 15:8     | INSEL1[3:0] |          |              |       | INSEL0[3:0] |  |        |       |
| 0x12   |          | 23:16    |             | LUTEO    | LUTEI        | INVEI | INSEL2[3:0] |  |        |       |
| 0x13   |          | 31:24    | TRUTH[7:0]  |          |              |       |             |  |        |       |
| 0x14   | LUTCTRL3 | 7:0      | EDGESEL     |          | FILTSEL[1:0] |       |             |  | ENABLE |       |
| 0x15   |          | 15:8     | INSEL1[3:0] |          |              |       | INSEL0[3:0] |  |        |       |
| 0x16   |          | 23:16    |             | LUTEO    | LUTEI        | INVEI | INSEL2[3:0] |  |        |       |

## 36.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16-, and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 795](#) for details.

Some registers are enable-protected, meaning they can only be written when the module is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 36.8.1 Control

**Name:** CTRL

**Offset:** 0x00

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7   | 6        | 5 | 4 | 3 | 2 | 1      | 0     |
|--------|-----|----------|---|---|---|---|--------|-------|
|        |     | RUNSTDBY |   |   |   |   | ENABLE | SWRST |
| Access | R/W | R/W      | R | R | R | R | R/W    | R/W   |
| Reset  | 0   | 0        | 0 | 0 | 0 | 0 | 0      | 0     |

- **Bit 7 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit indicates if the GCLK\_CCL clock must be kept running in standby mode. The setting is ignored for configurations where the generic clock is not required. For details refer to [“Sleep Mode Operation” on page 804](#).

0: Generic clock is not required in standby sleep mode.

1: Generic clock is required in standby sleep mode.

- **Bits 5:2– Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the CCL to their initial state.

### 36.8.2 Sequential Control x

**Name:** SEQCTRLx

**Offset:** 0x04 + x (x = 0,...,3)

**Reset:** 0x00

**Property:** Write-Protected, Enable-Protected

| Bit    | 7 | 6 | 5 | 4 | 3            | 2   | 1   | 0   |
|--------|---|---|---|---|--------------|-----|-----|-----|
|        |   |   |   |   | SEQSEL0[3:0] |     |     |     |
| Access | R | R | R | R | R/W          | R/W | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0            | 0   | 0   | 0   |

- Bits 7:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 3:0 – SEQSEL[3:0]: Sequential Selection**  
 These bits select the sequential configuration, as shown in [Table 36-7](#):

**Table 36-7. Sequential Selection**

| Value     | Name    | Description                  |
|-----------|---------|------------------------------|
| 0x0       | DISABLE | Sequential logic is disabled |
| 0x1       | DFF     | D flip flop                  |
| 0x2       | JK      | JK flip flop                 |
| 0x3       | LATCH   | D latch                      |
| 0x4       | RS      | RS latch                     |
| 0x5 - 0xF | –       | Reserved                     |

### 36.8.3 LUT Control x

**Name:** LUTCTRLx

**Offset:** 0x08 + 4\*x (x = 0,...,7)

**Reset:** 0x00000000

**Property:** Write-Protected, Enable-Protected (except LUTEN)

|        |             |       |              |       |             |     |        |     |
|--------|-------------|-------|--------------|-------|-------------|-----|--------|-----|
| Bit    | 31          | 30    | 29           | 28    | 27          | 26  | 25     | 24  |
|        | TRUTH[7:0]  |       |              |       |             |     |        |     |
| Access | R/W         | R/W   | R/W          | R/W   | R/W         | R/W | R/W    | R/W |
| Reset  | 0           | 0     | 0            | 0     | 0           | 0   | 0      | 0   |
| Bit    | 23          | 22    | 21           | 20    | 19          | 18  | 17     | 16  |
|        |             | LUTEO | LUTEI        | INVEI | INSEL2[3:0] |     |        |     |
| Access | R           | R/W   | R/W          | R/W   | R/W         | R/W | R/W    | R/W |
| Reset  | 0           | 0     | 0            | 0     | 0           | 0   | 0      | 0   |
| Bit    | 15          | 14    | 13           | 12    | 11          | 10  | 9      | 8   |
|        | INSEL1[3:0] |       |              |       | INSEL0[3:0] |     |        |     |
| Access | R/W         | R/W   | R/W          | R/W   | R/W         | R/W | R/W    | R/W |
| Reset  | 0           | 0     | 0            | 0     | 0           | 0   | 0      | 0   |
| Bit    | 7           | 6     | 5            | 4     | 3           | 2   | 1      | 0   |
|        | EDGESEL     |       | FILTSEL[1:0] |       |             |     | ENABLE |     |
| Access | R/W         | R     | R/W          | R/W   | R           | R   | R/W    | R   |
| Reset  | 0           | 0     | 0            | 0     | 0           | 0   | 0      | 0   |

- **Bits 31:24 – TRUTH[7:0]: Truth Table**  
These bits define the value of truth logic as a function of inputs IN[2:0].
- **Bit 23 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bit 22 – LUTEO: LUT Event Output Enable**  
0: LUT event output is disabled.  
1: LUT event output is enabled.
- **Bit 21 – LUTEI: LUT Event Input Enable**  
0: LUT incoming event is disabled.  
1: LUT incoming event is enabled.
- **Bit 20 – INVEI: Inverted Event Input Enable**  
This bit indicates if the LUT event input must be inverted before use:  
0: Incoming event is not inverted.  
1: Incoming event is inverted.

- **Bits 19:8 – INSELx[3:0]: LUT Input x Source Selection**  
These bits select the LUT input x source, as shown in [Table 36-8](#):

**Table 36-8. LUT Input Source Selection**

| Value     | Name     | Description                 |
|-----------|----------|-----------------------------|
| 0x0       | MASK     | Masked input                |
| 0x1       | FEEDBACK | Feedback input source       |
| 0x2       | LINK     | Linked LUT input source     |
| 0x3       | EVENT    | Event input source          |
| 0x4       | IO       | I/O pin input source        |
| 0x5       | AC       | AC input source             |
| 0x6       | TC       | TC input source             |
| 0x7       | ALTTC    | Alternative TC input source |
| 0x8       | TCC      | TCC input source            |
| 0x9       | SERCOM   | SERCOM input source         |
| 0xA - 0xF | –        | Reserved                    |

- **Bit 7 – EDGESEL: Edge Selection**  
0: Edge detector is disabled.  
1: Edge detector is enabled.
- **Bit 6 – Reserved**  
This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- **Bits 5:4 – FILTSEL[1:0]: Filter Selection**  
These bits select the LUT output filter options, as shown in [Table 36-9](#):

**Table 36-9. Filter Selection**

| Value | Name    | Description          |
|-------|---------|----------------------|
| 0x0   | DISABLE | Filter disabled      |
| 0x1   | SYNCH   | Synchronizer enabled |
| 0x2   | FILTER  | Filter enabled       |
| 0x3   | –       | Reserved             |

- **Bits 3:2 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 1 – ENABLE: LUT Enable**  
0: The LUT is disabled.  
1: The LUT is enabled.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

## 37. ADC – Analog-to-Digital Converter

### 37.1 Overview

The Analog-to-Digital Converter (ADC) converts analog signals to digital values. The ADC has 12-bit resolution, and is capable of converting up to 1MSPS. The input selection is flexible, and both differential and single-ended measurements can be performed. In addition, several internal signal inputs are available. The ADC can provide both signed and unsigned results.

ADC measurements can be started by either application software or an incoming event from another peripheral in the device. ADC measurements can be started with predictable timing, and without software intervention.

Both internal and external reference voltages can be used.

The bandgap voltage as well as the scaled I/O and core voltages can also be measured by the ADC.

The ADC has a compare function for accurate monitoring of user-defined thresholds, with minimum software intervention required.

The ADC may be configured for 8-, 10- or 12-bit results, reducing the conversion time. ADC conversion results are provided left- or right-adjusted, which eases calculation when the result is represented as a signed value. It is possible to use DMA to move ADC results directly to memory or peripherals when conversions are done.

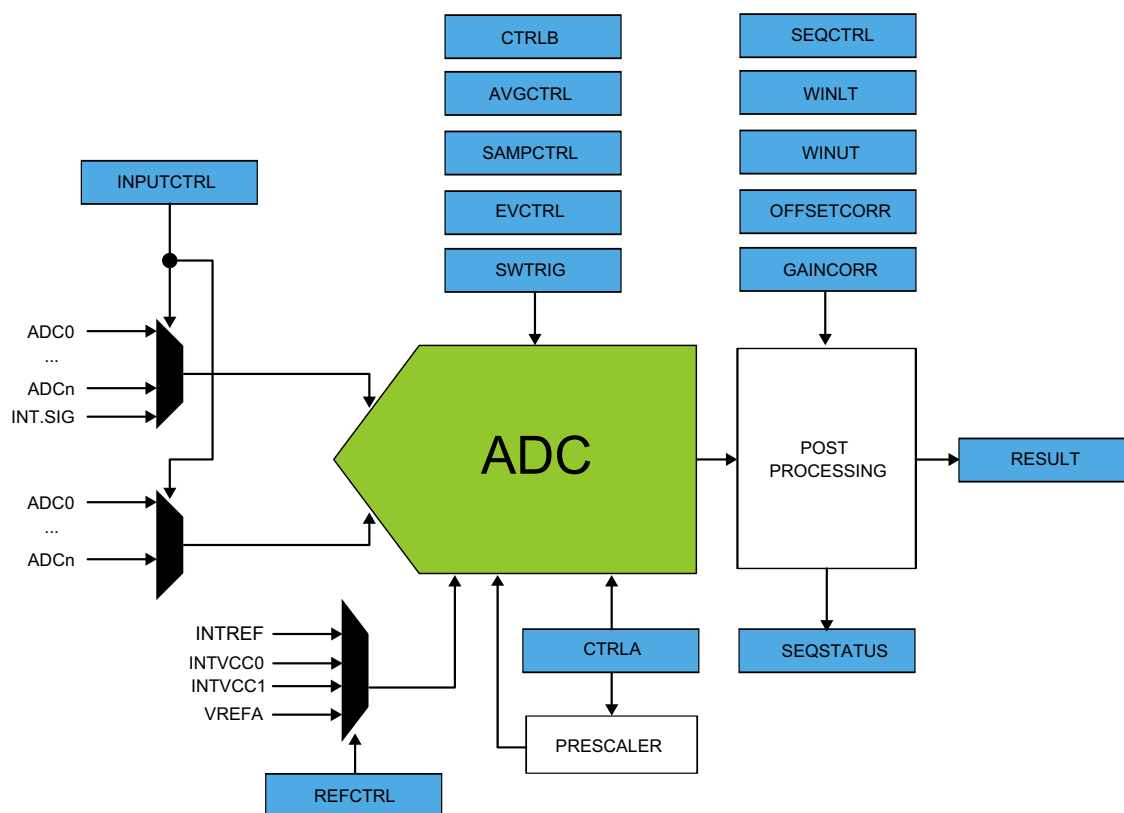

### 37.2 Features

- 8-, 10- or 12-bit resolution
- Up to 1,000,000 samples per second (1 MSPS)
- Differential and single-ended inputs
  - Up to 12 analog inputs
    - 16 positive and 7 negative, including internal and external
- Three internal inputs
  - Bandgap voltage
  - Scaled core supply
  - Scaled I/O supply
- Single, continuous and sequencing options
- Windowing monitor with selectable channel
- Conversion range:
  - $V_{ref}$  [2.0V to  $VDD_{ANA}$ ]
- Built-in internal reference and external reference options
- Event-triggered conversion for accurate timing (one event input)
- Optional DMA transfer of conversion settings or result
- Hardware gain and offset compensation
- Averaging and oversampling with decimation to support up to 16-bit result
- Selectable sampling time
- Flexible Power / Throughput rate management

## 37.3 Block Diagram

Figure 37-1. ADC Block Diagram

## 37.4 Signal Description

| Signal                    | Description  | Type                         |
|---------------------------|--------------|------------------------------|
| VREFA                     | Analog input | External reference voltage A |
| ADC[11..0] <sup>(1)</sup> | Analog input | Analog input channels        |

Note: 1. Refer to "Configuration Summary" on page 3 for details on exact number of analog input channels.

Refer to "I/O Multiplexing and Considerations" on page 13 for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 37.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 37.5.1 I/O Lines

Using the ADC's I/O lines requires the I/O pins to be configured using the port configuration (PORT).

Refer to "PORT – IO Pin Controller" on page 437 for details.

### 37.5.2 Power Management

The ADC can continue to operate in any sleep mode where the selected source clock is running. The ADC interrupts can be used to wake up the device from sleep modes. The events can trigger other operations in the system without exiting sleep modes. Refer to [“PM – Power Manager” on page 148](#) for details on the different sleep modes.

### 37.5.3 Clocks

The ADC bus clock (CLK\_ADCx\_APB, where x represents the specific ADC instance number) can be enabled and disabled in the Main Clock module, and the default state of CLK\_ADCx\_APB can be found in the Peripheral Clock Masking section in [Table 17-1](#).

A generic clock (GCLK\_ADCx) is required to clock the ADC. This clock must be configured and enabled in the Generic Clock Controller (GCLK) before using the ADC. Refer to [“GCLK – Generic Clock Controller” on page 109](#) for details.

This generic clock is asynchronous to the user interface clock (CLK\_ADCx\_APB). Due to this asynchronicity, accessing certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 822](#) for further details.

### 37.5.4 DMA

The DMA request line is connected to the DMA Controller (DMAC). Using the ADC DMA request requires the DMA Controller to be configured first. Refer to [“DMAC – Direct Memory Access Controller” on page 321](#) for details.

### 37.5.5 Interrupts

The interrupt request line is connected to the Interrupt Controller. Using the ADC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 37.5.6 Events

To use the ADC event functionality, the corresponding events need to be configured in the event system. Refer to [“EVSYS – Event System” on page 467](#) for details.

### 37.5.7 Debug Operation

When the CPU is halted in debug mode the ADC will halt normal operation. The ADC can be forced to continue operation during debugging. Refer to the [DBGCTRL](#) register for details.

### 37.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Interrupt Flag Status and Clear (INTFLAG) register

Write-protection is denoted by the Write-Protection property in the register description.

When the CPU is halted in debug mode, all write-protection is automatically disabled.

Write-protection does not apply for accesses through an external debugger. Refer to [“PAC – Peripheral Access Control” on page 33](#) for details..

### 37.5.9 Analog Connections

I/O-pins (AINx), as well as the VREFA reference voltage pins are analog inputs to the ADC.

### 37.5.10 Calibration

The BIAS and LINEARITY calibration values from the production test must be loaded from the NVM Software Calibration Area into the ADC Calibration register (CALIB) by software to achieve specified accuracy.

Refer to [“NVM Software Calibration Area Mapping” on page 25](#) for further details.

## 37.6 Functional Description

### 37.6.1 Principle of Operation

By default, the ADC provides results with 12-bit resolution. 8-bit or 10-bit results can be selected in order to reduce the conversion time. The ADC has an oversampling with decimation option that can extend the resolution to 16 bits. The input values can be either internal (e.g., internal temperature sensor) or external (connected I/O pins). The user can also configure whether the conversion should be single-ended or differential.

### 37.6.2 Basic Operation

#### 37.6.2.1 Initialization

The following registers are enable-protected, meaning that they can only be written when the ADC is disabled (CTRLA.ENABLE is zero):

- Control B register (CTRLB)
- Reference Control register (REFCTRL)
- Event Control register (EVCTRL)
- Calibration register (CALIB)

Enable-protection is denoted by the Enable-Protected property in the register description.

#### 37.6.2.2 Enabling, Disabling and Resetting

The ADC is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The ADC is disabled by writing a zero to CTRLA.ENABLE.

The ADC is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the ADC, except DBGCTRL, will be reset to their initial state, and the ADC will be disabled. Refer to [CTRLA](#) for details.

#### 37.6.2.3 Basic Operation

In the most basic configuration, the ADC sample values from the configured internal or external sources (INPUTCTRL register). The rate of the conversion depends on the combination of the GCLK\_ADCx frequency and the clock prescaler.

To convert analog values to digital values, the ADC needs to be initialized first, as described in [“Initialization” on page 815](#). Data conversion can be started either manually, by writing a one to the Start bit in the Software Trigger register (SWTRIG.START), or automatically, by configuring an automatic trigger to initiate the conversions. A free-running mode could be used to continuously convert an input channel. There is no need for a trigger to start the conversion. It will start automatically at the end of previous conversion.

The result of the conversion is stored in the Result register (RESULT) overwriting the result from the previous conversion.

To avoid data loss if more than one channel is enabled, the conversion result must be read as soon as it is available (INTFLAG.RESRDY). Failing to do so will result in an overrun error condition, indicated by the OVERRUN bit in the Interrupt Flag Status and Clear register (INTFLAG.OVERRUN).

To use an interrupt handler, the corresponding bit in the Interrupt Enable Set register (INTENSET) must be written to one.

#### 37.6.2.4 Prescaler Selection

The ADC is clocked by GCLKx\_ADC. There is also a prescaler in the ADC to enable conversion at lower clock rates. Refer to [CTRLB](#) for details on prescaler settings.

**Figure 37-2. ADC Prescaler**

The propagation delay of an ADC measurement is given by:

$$PropagationDelay = \frac{1 + Resolution}{f_{ADC}}$$

#### 37.6.2.5 Reference configuration

The ADC has various reference configuration options. By default, the internal bandgap voltage reference is selected. The REFSEL value in Reference Control register (REFCTRL) determines which reference will be selected. Based on customer application requirements, the external or internal reference can be selected. Two external references are available. The supply accepted on these pins is from 1.0V to VDD<sub>ANA</sub>. Four internal inputs are also available. Refer to [REFCTRL](#) for further details on available selections.

#### 37.6.2.6 ADC Resolution

The ADC supports 8-bit, 10-bit or 12-bit resolution. Resolution can be changed by writing the Resolution bit group in the Control B register (CTRLC.RESSEL). By default, the ADC resolution is set to 12 bits.

#### 37.6.2.7 Differential and Single-Ended Conversions

The ADC has two conversion options: differential and single-ended. If the positive input is always positive, the single-ended conversion should be used in order to have full 12-bit resolution in the conversion. If the positive input may go below the negative input, creating some negative results, the differential mode should be used in order to get correct results. The differential mode is enabled by setting DIFFMODE bit in the Control B register (CTRLC.DIFFMODE). Both conversion types could be run in single mode or in free-running mode. When the free-running mode is selected, an ADC input will continuously sample the input and performs a new conversion. The INTFLAG.RESRDY bit will be set at the end of each conversion.

#### 37.6.2.8 Conversion Timing

[Figure 37-3](#) shows the ADC timing for a single conversion. A conversion starts after the software or event start are synchronized with the GCLK\_ADCx clock. The input channel is sampled in the first half CLK\_ADCx period. The sampling time can be increased by using the Sampling Time Length bit group in the Sampling Time Control register (SAMPCTRL.SAMPLEN). [Figure 37-4](#) shows the timing conversion with increased sampling time

**Figure 37-3. ADC Timing for One Conversion**

**Figure 37-4. ADC Timing for One Conversion with Increased Sampling Time**

**Figure 37-5. ADC Timing for One Conversion with Offset Compensation**

**Figure 37-6. ADC Timing for Free Running**

### 37.6.2.9 Accumulation

The result from multiple consecutive conversions can be accumulated. The number of samples to be accumulated is specified by the Sample Number field in the Average Control register (AVGCTRL.SAMPLENUM) as shown in [Table 37-1](#). When accumulating more than 16 samples, the result will be too large to match the 16-bit RESULT register size. To avoid overflow, the result is shifted right automatically to fit within the available register size. The number of automatic right shifts are specified in [Table 37-1](#). Note that to be able to perform the accumulation of two or more samples, the Conversion Result Resolution field in the Control B register (CTRLC.RESSEL) must be written to one.

**Table 37-1. Accumulation**

| Number of Accumulated Samples | AVGCTRL.SAMPLENUM | Intermediate Result Precision <sup>1</sup> | Number of Automatic Right Shifts | Final Result Precision | Automatic Division Factor |
|-------------------------------|-------------------|--|----------------------------------|------------------------|---------------------------|
| 1                             | 0x0               | 12 bits                                    | 0                                | 12 bits                | 0                         |
| 2                             | 0x1               | 13 bits                                    | 0                                | 13 bits                | 0                         |
| 4                             | 0x2               | 14 bits                                    | 0                                | 14 bits                | 0                         |
| 8                             | 0x3               | 15 bits                                    | 0                                | 15 bits                | 0                         |

| Number of Accumulated Samples | AVGCTRL.SAMPLENUM | Intermediate Result Precision <sup>1</sup> | Number of Automatic Right Shifts | Final Result Precision | Automatic Division Factor |
|-------------------------------|-------------------|--|----------------------------------|------------------------|---------------------------|
| 16                            | 0x4               | 16 bits                                    | 0                                | 16 bits                | 0                         |
| 32                            | 0x5               | 17 bits                                    | 1                                | 16 bits                | 2                         |
| 64                            | 0x6               | 18 bits                                    | 2                                | 16 bits                | 4                         |
| 128                           | 0x7               | 19 bits                                    | 3                                | 16 bits                | 8                         |
| 256                           | 0x8               | 20 bits                                    | 4                                | 16 bits                | 16                        |
| 512                           | 0x9               | 21 bits                                    | 5                                | 16 bits                | 32                        |
| 1024                          | 0xA               | 22 bits                                    | 6                                | 16 bits                | 64                        |
| Reserved                      | 0xB –0xF          | 12 bits                                    |                                  | 12 bits                | 0                         |

Note: 1. this result isn't available for user.

### 37.6.2.10 Averaging

Averaging is a feature that increases the sample accuracy, though at the cost of reduced sample rate. This feature is suitable when operating in noisy conditions. Averaging is done by accumulating  $m$  samples, as described in “Accumulation” on page 817, and divide the result by  $m$ . The averaged result is available in the RESULT register. The number of samples to be accumulated is specified by writing to AVGCTRL.SAMPLENUM as shown in Table 37-2. The division is obtained by a combination of the automatic right shift described above, and an additional right shift that must be specified by writing to the Adjusting Result/Division Coefficient field in AVGCTRL (AVGCTRL.ADJRES) as described in Table 37-2. Note that to be able to perform the averaging of two or more samples, the Conversion Result Resolution field in the Control B register (CTRLC.RESSEL) must be written to one.

Averaging AVGCTRL.SAMPLENUM samples will reduce the effective sample rate by  $\frac{1}{\text{AVGCTRL.SAMPLENUM}}$ .

When the averaged result is available, the INTFLAG.RESRDY bit will be set.

Table 37-2. Averaging

| Number of Accumulated Samples | AVGCTRL.SAMPLENUM | Intermediate Result Precision | Number of Automatic Right Shifts | Division Factor | AVGCTRL.ADJRES | Total Number of Right Shifts | Final Result Precision | Automatic Division Factor |
|-------------------------------|-------------------|-------------------------------|----------------------------------|-----------------|----------------|------------------------------|------------------------|---------------------------|
| 1                             | 0x0               | 12 bits                       | 0                                | 1               | 0x0            |                              | 12 bits                | 0                         |
| 2                             | 0x1               | 13                            | 0                                | 2               | 0x1            | 1                            | 12 bits                | 0                         |
| 4                             | 0x2               | 14                            | 0                                | 4               | 0x2            | 2                            | 12 bits                | 0                         |
| 8                             | 0x3               | 15                            | 0                                | 8               | 0x3            | 3                            | 12 bits                | 0                         |
| 16                            | 0x4               | 16                            | 0                                | 16              | 0x4            | 4                            | 12 bits                | 0                         |
| 32                            | 0x5               | 17                            | 1                                | 16              | 0x4            | 5                            | 12 bits                | 2                         |
| 64                            | 0x6               | 18                            | 2                                | 16              | 0x4            | 6                            | 12 bits                | 4                         |
| 128                           | 0x7               | 19                            | 3                                | 16              | 0x4            | 7                            | 12 bits                | 8                         |
| 256                           | 0x8               | 20                            | 4                                | 16              | 0x4            | 8                            | 12 bits                | 16                        |
| 512                           | 0x9               | 21                            | 5                                | 16              | 0x4            | 9                            | 12 bits                | 32                        |
| 1024                          | 0xA               | 22                            | 6                                | 16              | 0x4            | 10                           | 12 bits                | 64                        |
| Reserved                      | 0xB–0xF           |                               |                                  |                 | 0x0            |                              | 12 bits                | 0                         |

### 37.6.2.11 Oversampling and Decimation

By using oversampling and decimation, the ADC resolution can be increased from 12 bits to up-to 16 bits. To increase the resolution by  $n$  bits,  $4^n$  samples must be accumulated. The result must then be right-shifted by  $n$  bits. This right-shift is a combination of the automatic right-shift and the value written to AVGCTRL.ADJRES. To obtain the correct resolution, the ADJRES must be configured as described in the table below. This method will result in  $n$  bit extra LSB resolution.

Table 37-3. Configuration Required for Oversampling and Decimation

| Result Resolution | Number of Samples to Average | AVGCTRL.SAMPLENUM[3:0] | Number of Automatic Right Shifts | AVGCTRL.ADJRES[2:0] |
|-------------------|------------------------------|------------------------|----------------------------------|---------------------|
| 13 bits           | $4^1 = 4$                    | 0x2                    | 0                                | 0x1                 |
| 14 bits           | $4^2 = 16$                   | 0x4                    | 0                                | 0x2                 |
| 15 bits           | $4^3 = 64$                   | 0x6                    | 2                                | 0x1                 |
| 16 bits           | $4^4 = 256$                  | 0x8                    | 4                                | 0x0                 |

### 37.6.2.12 Automatic Sequences

The ADC has the ability to automatically sequence a series of conversion. This means that each time the ADC receives a start-of-conversion request, it can perform multiple conversions automatically. All of the 32 positive inputs can be included in a sequence, by writing to the Sequence Control register (SEQCTRL). The order of the conversion in a sequence is the lower positive MUX selection to upper positive MUX (AIN0, AIN1, AIN2 ...). In differential mode, the negative inputs selected by MUXNEG field, will be used for the entire sequence.

When a sequence starts, the Sequence Busy status bit in Sequence Status register (SEQSTATUS.SEBUSY) will be set to one. When the sequence is complete, the Sequence Busy status bit will be cleared.

Each time a conversion is completed, the Sequence State status in Sequence Status register (SEQSTATUS.SEQSTATE) will store the input number from which the conversion is done. The result will be stored in RESULT register and the Result Ready Interrupt Flag (INTFLAG.RESRDY) is set.

If additional inputs must be scanned, the ADC will automatically start a new conversion on the next input present in the sequence list.

Note that if SEQCTRL register has no bits set to one, the conversion is done with the selected MUXPOS input.

### 37.6.2.13 Window Monitor

The window monitor feature allows the conversion result in the RESULT register to be compared to predefined threshold values. The window mode is selected by writing the Window Monitor Mode bits in the Window Monitor Control register (CTRLC.WINMODE). Threshold values must be written in the Window Monitor Lower Threshold register (WINLT) and Window Monitor Upper Threshold register (WINUT).

If differential input is selected, the WINLT and WINUT are evaluated as signed values. Otherwise they are evaluated as unsigned values. The significant WINLT and WINUT bits are given by the precision selected in the Conversion Result Resolution bit group in the Control B register (CTRLC.RESSEL). This means that if 8-bit mode is selected, only the eight lower bits will be considered. In addition, in differential mode, the eighth bit will be considered as the sign bit even if the ninth bit is zero.

The INTFLAG.WINMON interrupt flag will be set if the conversion result matches the window monitor condition.

### 37.6.2.14 Offset and Gain Correction

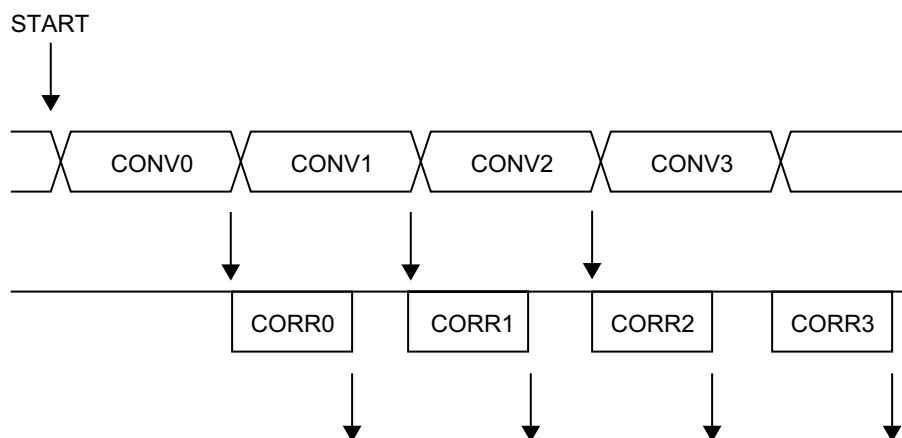

Inherent gain and offset errors affect the absolute accuracy of the ADC. The offset error is defined as the deviation of the actual ADC transfer function from an ideal straight line at zero input voltage. The offset error cancellation is handled by the Offset Correction register (OFFSETCORR). The offset correction value is subtracted from the converted data before writing the Result register (RESULT). The gain error is defined as the deviation of the last output step's midpoint from the ideal straight line, after compensating for offset error. The gain error cancellation is handled by the Gain Correction register (GAINCORR). To correct these two errors, the Digital Correction Logic Enabled bit in the Control B register (CTRLC.CORREN) must be written to one.

Offset and gain error compensation results are both calculated according to:

$$\text{Result} = (\text{Conversion value} - \text{OFFSETCORR}) \cdot \text{GAINCORR}$$

The correction will introduce a latency of 13 GCLK\_ADCx clock cycles. In free running mode this latency is introduced on the first conversion only, since its duration is always less than the propagation delay. In single ended mode this latency is introduced for each conversion.

**Figure 37-7. ADC Timing Correction Enabled**

### 37.6.3 Additional Features

#### 37.6.3.1 Rail-to-Rail Operation

The accuracy of the ADC is highest when the input common mode voltage ( $V_{\text{CMIN}}$ ) is close to  $V_{\text{REF}}/2$ . To enable a full range of common mode voltages (rail-to-rail operation), the Rail-to-Rail bit in the Control C register (CTRLC.R2R) should be written to one. Rail-to-rail operation requires a sampling period of four cycles. This is achieved by enabling offset compensation (SAMPCTRL.OFFCOMP = 1). Rail-to-rail operation should not be used when offset compensation is disabled.

#### 37.6.4 DMA Operation

The ADC generates the following DMA request:

- Result Conversion Ready (RESRDY): the request is set when a conversion result is available and cleared when the RESULT register is read. When the averaging operation is enabled, the DMA request is set when the averaging is completed and result is available.

#### 37.6.5 Interrupts

The ADC has the following interrupt sources:

- Result Conversion Ready: RESRDY
- Window Monitor: WINMON
- Overrun: OVERRUN

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the ADC is reset. See [INTFLAG](#) for details on how to clear interrupt flags. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to “[Nested Vector Interrupt Controller](#)” on page 27 for details.

#### 37.6.6 Events

The ADC can generate the following output events:

- Result Ready (RESRDY): Generated when the conversion is complete and the result is available. Refer to [EVCTRL](#) for details.
- Window Monitor (WINMON): Generated when the window monitor condition match. Refer to [CTRLC](#) for details.

Writing a one to an Event Output bit in the Event Control Register (EVCTRL.xxE0) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to the Event System chapter for details on configuring the event system.

The ADC can take the following actions on an input event:

- Start conversion (START): Start a conversion. Refer to [SWTRIG](#) for details.
- Conversion flush (FLUSH): Flush the conversion. Refer to [SWTRIG](#) for details.

Writing a one to an Event Input bit into the Event Control register (EVCTRL.xxEI) enables the corresponding action on input event. Writing a zero to this bit disables the corresponding action on input event.

The ADC can use any type of events and Event System channel path must be configured accordingly. For further details, refer to “[EVSYS – Event System](#)” on page 467. By default, the ADC will detect a rising edge on the incoming event. If the

ADC action must be performed on the falling edge of the incoming event, the event line must be inverted first, by writing a one to the corresponding Event Invert Enable bit in Event Control register (EVCTRL.xINV).

Note that if several events are connected to the ADC, the enabled action will be taken on any of the incoming events. If FLUSH and START events are available at the same time, the FLUSH event has the highest priority.

### 37.6.7 Sleep Mode Operation

The ONDEMAND and RUNSTDBY bits in the Control A register (CTRLA) control the behavior of the ADC during standby sleep mode, in cases where the ADC is enabled (CTRLA.ENABLE = 1. For further details on available options, refer to [Table 37-4](#). Note that when CTRLA.ONDEMAND is one, the analog block is powered-off when the conversion is complete. When a start request is detected, the system returns from sleep and starts a new conversion after the start-up time delay.

**Table 37-4. ADC Sleep Behavior**

| CTRLA.RUNSTDBY | CTRLA.ONDEMAND | CTRLA.ENABLE | Description  |
|----------------|----------------|--------------|--|
| x              | x              | 0            | Disabled   |
| 0              | 0              | 1            | Run in all sleep modes except STANDBY.             |
| 0              | 1              | 1            | Run in all sleep modes on request, except STANDBY. |
| 1              | 0              | 1            | Run in all sleep modes.                            |
| 1              | 1              | 1            | Run in all sleep modes on request.                 |

### 37.6.8 Synchronization

Due to the asynchronicity between CLK\_ADCx\_APB and GCLK\_ADCx some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding synchronization bit is set in Synchronisation Busy register (SYNCBUSY) and cleared when synchronization is complete.

If an operation that require synchronization is executed while its busy bit is on, the operation is discarded and a bus error is generated.

The following bits need synchronization when written:

- Software Reset bit in Control A register (CTRLA.SWRST)
- Enable bit in Control A register (CTRLA.ENABLE)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

The following registers need synchronization when written:

- Input Control register (INPUTCTRL)
- Control C register (CTRLC)
- Average control register (AVGCTRL)
- Sampling time control register (SAMPCTRL)
- Window Monitor Lower Threshold register (WINLT)
- Window Monitor Upper Threshold register (WINUT)
- Gain correction register (GAINCORR)

- Offset Correction register (OFFSETCORR)
- Software Trigger register (SWTRIG)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

## 37.7 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 814](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 822](#) for details.

Some registers are enable-protected, meaning they can only be written when the ADC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 37.7.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized (ENABLE, SWRST)

| Bit    | 7               | 6               | 5 | 4 | 3 | 2 | 1             | 0            |
|--------|-----------------|-----------------|---|---|---|---|---------------|--------------|
|        | <b>ONDEMAND</b> | <b>RUNSTDBY</b> |   |   |   |   | <b>ENABLE</b> | <b>SWRST</b> |
| Access | R/W             | R/W             | R | R | R | R | R/W           | R/W          |
| Reset  | 0               | 0               | 0 | 0 | 0 | 0 | 0             | 0            |

- **Bit 7 – ONDEMAND: On Demand Control**

The On Demand operation modes allows the ADC to be enabled or disabled, depending on other peripheral request.

In On Demand operation mode, i.e., if the ONDEMAND bit has been previously written to one, the ADC will only be running when requested by a peripheral. If there is no peripheral requesting the ADC will be in a disable state.

If On Demand is disable the ADC will always be running when enabled.

In standby sleep mode, the On Demand operation is still active if the CTRLA.RUNSTDBY bit is one. If CTRLA.RUNSTDBY is zero, the ADC is disabled.

0: The ADC is always on , if enabled.

1: The ADC is enabled, when a peripheral is requesting the ADC conversion. The ADC is disabled if no peripheral is requesting it.

This bit is not synchronized.

- **Bit 6 – RUNSTDBY: Run in Standby**

This bit controls how the ADC behaves during standby sleep mode:

0: The ADC is halted during standby sleep mode.

1: The ADC is not stopped in standby sleep mode. If CTRLA.ONDEMAND is one, the ADC will be running when a peripheral is requesting it. If CTRLA.ONDEMAND is zero, the ADC will always be running in standby sleep mode.

This bit is not synchronized.

- **Bit 54:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

0: The ADC is disabled.

1: The ADC is enabled.

Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the ENABLE bit in the SYNCBUSY register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the ADC, except DBGCTRL, to their initial state, and the ADC will be disabled.

Writing a one to CTRL.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 37.7.2 Control B

**Name:** CTRLB

**Offset:** 0x01

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Enable-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2              | 1   | 0   |
|--------|---|---|---|---|---|----------------|-----|-----|
|        |   |   |   |   |   | PRESCALER[2:0] |     |     |
| Access | R | R | R | R | R | R/W            | R/W | R/W |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0              | 0   | 0   |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:0 – PRESCALER[2:0]: Prescaler Configuration**

This field defines the ADC clock relative to the peripheral clock according [Table 37-5](#).

This field is not synchronized.

**Table 37-5. Prescaler Configuration.**

| Value | Name   | Description                     |
|-------|--------|---------------------------------|
| 0x0   | DIV2   | Peripheral clock divided by 2   |
| 0x1   | DIV4   | Peripheral clock divided by 4   |
| 0x2   | DIV8   | Peripheral clock divided by 8   |
| 0x3   | DIV16  | Peripheral clock divided by 16  |
| 0x4   | DIV32  | Peripheral clock divided by 32  |
| 0x5   | DIV64  | Peripheral clock divided by 64  |
| 0x6   | DIV128 | Peripheral clock divided by 128 |
| 0x7   | DIV256 | Peripheral clock divided by 256 |

### 37.7.3 Reference Control

**Name:** REFCTRL

**Offset:** 0x02

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Enable-Protected

| Bit    | 7       | 6 | 5 | 4 | 3           | 2   | 1   | 0   |
|--------|---------|---|---|---|-------------|-----|-----|-----|
|        | REFCOMP |   |   |   | REFSEL[3:0] |     |     |     |
| Access | R/W     | R | R | R | R/W         | R/W | R/W | R/W |
| Reset  | 0       | 0 | 0 | 0 | 0           | 0   | 0   | 0   |

- Bit 7 – REFCOMP: Reference Buffer Offset Compensation Enable**  
 The gain error can be reduced by enabling the reference buffer offset compensation. This will decrease the input impedance and thus increase the start-up time of the reference.  
 0: Reference buffer offset compensation is disabled.  
 1: Reference buffer offset compensation is enabled.
- Bits 6:4 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 3:0 – REFSEL[3:0]: Reference Selection**  
 These bits select the reference for the ADC according to [Table 37-6](#).

**Table 37-6. Reference Selection.**

| Value     | Name    | Description                         |
|-----------|---------|-------------------------------------|
| 0x0       | INTREF  | Internal bandgap reference          |
| 0x1       | INTVCC0 | 1/1.6 VDDANA                        |
| 0x2       | INTVCC1 | 1/2 VDDANA (only for VDDANA > 4.0V) |
| 0x3       | VREFA   | External reference A                |
| 0x4       |         | Reserved                            |
| 0x5       | INTVCC2 | VDDANA                              |
| 0x6 - 0xF |         | Reserved                            |

### 37.7.4 Event Control

**Name:** EVCTRL

**Offset:** 0x03

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Enable-Protected

| Bit    | 7 | 6 | 5        | 4        | 3        | 2        | 1       | 0       |
|--------|---|---|----------|----------|----------|----------|---------|---------|
|        |   |   | WINMONEO | RESRDYEO | STARTINV | FLUSHINV | STARTEI | FLUSHEI |
| Access | R | R | R/W      | R/W      | R/W      | R/W      | R/W     | R/W     |
| Reset  | 0 | 0 | 0        | 0        | 0        | 0        | 0       | 0       |

- **Bits 7:6 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 5 – WINMONEO: Window Monitor Event Out**  
This bit indicates whether the Window Monitor event output is enabled or not and an output event will be generated when the window monitor detects something.  
0: Window Monitor event output is disabled and an event will not be generated.  
1: Window Monitor event output is enabled and an event will be generated.
- **Bit 4 – RESRDYEO: Result Ready Event Out**  
This bit indicates whether the Result Ready event output is enabled or not and an output event will be generated when the conversion result is available.  
0: Result Ready event output is disabled and an event will not be generated.  
1: Result Ready event output is enabled and an event will be generated.
- **Bit 3 – STARTINV: Start Conversion Event Invert Enable**  
0: Start event input source is not inverted.  
1: Start event input source is inverted.
- **Bit 2 – FLUSHINV: Flush Event Invert Enable**  
0: Flush event input source is not inverted..  
1: Flush event input source is inverted.
- **Bit 1– STARTEI: Start Conversion Event Input Enable**  
0: A new conversion will not be triggered on any incoming event.  
1: A new conversion will be triggered on any incoming event.
- **Bit 0– FLUSHEI: Flush Event Input Enable**  
0: A flush and new conversion will not be triggered on any incoming event.  
1: A flush and new conversion will be triggered on any incoming event.

### 37.7.5 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set (INTENSET) register.

**Name:** INTENCLR

**Offset:** 0x04

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2      | 1       | 0      |
|--------|---|---|---|---|---|--------|---------|--------|
|        |   |   |   |   |   | WINMON | OVERRUN | RESRDY |
| Access | R | R | R | R | R | R/W    | R/W     | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0      | 0       | 0      |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – WINMON: Window Monitor Interrupt Enable**

0: The window monitor interrupt is disabled.

1: The window monitor interrupt is enabled, and an interrupt request will be generated when the Window Monitor interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Window Monitor Interrupt Enable bit, which disables the corresponding interrupt request.

- **Bit 1 – OVERRUN: Overrun Interrupt Enable**

0: The Overrun interrupt is disabled.

1: The Overrun interrupt is enabled, and an interrupt request will be generated when the Overrun interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Overrun Interrupt Enable bit, which disables the corresponding interrupt request.

- **Bit 0 – RESRDY: Result Ready Interrupt Enable**

0: The Result Ready interrupt is disabled.

1: The Result Ready interrupt is enabled, and an interrupt request will be generated when the Result Ready interrupt flag is set.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the Result Ready Interrupt Enable bit, which disables the corresponding interrupt request.

### 37.7.6 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear (INTENCLR) register.

**Name:** INTENSET

**Offset:** 0x05

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2      | 1       | 0      |
|--------|---|---|---|---|---|--------|---------|--------|
|        |   |   |   |   |   | WINMON | OVERRUN | RESRDY |
| Access | R | R | R | R | R | R/W    | R/W     | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0      | 0       | 0      |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 2 – WINMON: Window Monitor Interrupt Enable**

0: The Window Monitor interrupt is disabled.

1: The Window Monitor interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Window Monitor Interrupt bit, which enables the Window Monitor interrupt.

- **Bit 1 – OVERRUN: Overrun Interrupt Enable**

0: The Overrun interrupt is disabled.

1: The Overrun interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Overrun Interrupt bit, which enables the Overrun interrupt.

- **Bit 0 – RESRDY: Result Ready Interrupt Enable**

0: The Result Ready interrupt is disabled.

1: The Result Ready interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Result Ready Interrupt bit, which enables the Result Ready interrupt.

### 37.7.7 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x06  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3 | 2      | 1       | 0      |
|--------|---|---|---|---|---|--------|---------|--------|
|        |   |   |   |   |   | WINMON | OVERRUN | RESRDY |
| Access | R | R | R | R | R | R/W    | R/W     | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0      | 0       | 0      |

- Bits 7:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 2 – WINMON: Window Monitor**  
 This flag is cleared by writing a one to the flag or by reading the RESULT register.  
 This flag is set on the next GCLK\_ADC cycle after a match with the window monitor condition, and an interrupt request will be generated if INTENCLR/SET.WINMON is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Window Monitor interrupt flag.
- Bit 1 – OVERRUN: Overrun**  
 This flag is cleared by writing a one to the flag.  
 This flag is set if RESULT is written before the previous value has been read by CPU, and an interrupt request will be generated if INTENCLR/SET.OVERRUN is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Overrun interrupt flag.
- Bit 0 – RESRDY: Result Ready**  
 This flag is cleared by writing a one to the flag or by reading the RESULT register.  
 This flag is set when the conversion result is available, and an interrupt will be generated if INTENCLR/SET.RESRDY is one.  
 Writing a zero to this bit has no effect.  
 Writing a one to this bit clears the Result Ready interrupt flag.

### 37.7.8 Sequence Status

**Name:** SEQSTATUS

**Offset:** 0x07

**Access:** Read-only

**Reset:** 0x00

**Property:** -

| Bit    | 7       | 6 | 5 | 4             | 3 | 2 | 1 | 0 |
|--------|---------|---|---|---------------|---|---|---|---|
|        | SEQBUSY |   |   | SEQSTATE[4:0] |   |   |   |   |
| Access | R       | R | R | R             | R | R | R | R |
| Reset  | 0       | 0 | 0 | 0             | 0 | 0 | 0 | 0 |

- **Bit 7 – SEQBUSY: Sequence busy**  
This bit is set when the sequence start.  
This bit is clear when the last conversion in a sequence is done.
- **Bits 6:5 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 4:0 – SEQSTATE[4:0]: Sequence State**  
This bit field is the pointer of sequence. This value identifies the last conversion done in the sequence.

### 37.7.9 Input Control

**Name:** INPUTCTRL

**Offset:** 0x08

**Access:** Read/Write

**Reset:** 0x0000

**Property:** Write-Protected, Write-Synchronized

|        |    |    |    |             |     |     |     |     |
|--------|----|----|----|-------------|-----|-----|-----|-----|
| Bit    | 15 | 14 | 13 | 12          | 11  | 10  | 9   | 8   |
|        |    |    |    | MUXNEG[4:0] |     |     |     |     |
| Access | R  | R  | R  | R/W         | R/W | R/W | R/W | R/W |
| Reset  | 0  | 0  | 0  | 0           | 0   | 0   | 0   | 0   |
| Bit    | 7  | 6  | 5  | 4           | 3   | 2   | 1   | 0   |
|        |    |    |    | MUXPOS[4:0] |     |     |     |     |
| Access | R  | R  | R  | R/W         | R/W | R/W | R/W | R/W |
| Reset  | 0  | 0  | 0  | 0           | 0   | 0   | 0   | 0   |

- **Bits 15:13 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 12:8 – MUXNEG[4:0]: Negative Mux Input Selection**

These bits define the Mux selection for the negative ADC input. [Table 37-7](#) shows the possible input selections.

**Table 37-7. Negative Mux Input Selection.**

| Value       | Name | Description     |
|-------------|------|-----------------|
| 0x00        | AIN0 | ADC AIN0 pin    |
| 0x01        | AIN1 | ADC AIN1 pin    |
| 0x02        | AIN2 | ADC AIN2 pin    |
| 0x03        | AIN3 | ADC AIN3 pin    |
| 0x04        | AIN4 | ADC AIN4 pin    |
| 0x05        | AIN5 | ADC AIN5 pin    |
| 0x06 - 0x17 |      | Reserved        |
| 0x18        | GND  | Internal ground |
| 0x19 - 0x1F |      | Reserved        |

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 4:0 – MUXPOS[4:0]: Positive Mux Input Selection**

These bits define the Mux selection for the positive ADC input. Table shows the possible input selections. If the internal bandgap voltage input channel is selected, then the Sampling Time Length bit group in the Sampling Control register must be written with a corresponding value (see electrical characteristics).

**Table 37-8. Positive Mux Input Selection.**

| Value     | Name           | Description            |
|-----------|----------------|------------------------|
| 0x00      | AIN0           | ADC AIN0 pin           |
| 0x01      | AIN1           | ADC AIN1 pin           |
| 0x02      | AIN2           | ADC AIN2 pin           |
| 0x03      | AIN3           | ADC AIN3 pin           |
| 0x04      | AIN4           | ADC AIN4 pin           |
| 0x05      | AIN5           | ADC AIN5 pin           |
| 0x06      | AIN6           | ADC AIN6 pin           |
| 0x07      | AIN7           | ADC AIN7 pin           |
| 0x08      | AIN8           | ADC AIN8 pin           |
| 0x09      | AIN9           | ADC AIN9 pin           |

### 37.7.10 Control C

**Name:** CTRLC  
**Offset:** 0x0A  
**Access:** Read/Write  
**Reset:** 0x0000  
**Property:** Write-Protected, Write-Synchronized

|        |     |    |             |     |        |              |         |          |
|--------|-----|----|-------------|-----|--------|--------------|---------|----------|
| Bit    | 15  | 14 | 13          | 12  | 11     | 10           | 9       | 8        |
|        |     |    |             |     |        | WINMODE[2:0] |         |          |
| Access | R   | R  | R           | R   | R      | R/W          | R/W     | R/W      |
| Reset  | 0   | 0  | 0           | 0   | 0      | 0            | 0       | 0        |
| Bit    | 7   | 6  | 5           | 4   | 3      | 2            | 1       | 0        |
|        | R2R |    | RESSEL[1:0] |     | CORREN | FREERUN      | LEFTADJ | DIFFMODE |
| Access | R/W | R  | R/W         | R/W | R/W    | R/W          | R/W     | R/W      |
| Reset  | 0   | 0  | 0           | 0   | 0      | 0            | 0       | 0        |

- **Bits 15:11 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 10:8 – WINMODE[2:0]: Window Monitor Mode**  
 These bits enable and define the window monitor mode. [Table 37-9](#) shows the mode selections.

**Table 37-9. Window Monitor Mode**

| Value     | Name    | Description              |
|-----------|---------|--------------------------|
| 0x0       | DISABLE | No window mode (default) |
| 0x1       | MODE1   | RESULT > WINLT           |
| 0x2       | MODE2   | RESULT < WINUT           |
| 0x3       | MODE3   | WINLT < RESULT < WINUT   |
| 0x4       | MODE4   | WINUT < RESULT < WINLT   |
| 0x5 - 0x7 |         | Reserved                 |

- **Bit 7 – R2R: Rail-to-Rail Operation**  
 0: Disable rail-to-rail operation.  
 1: Enable rail-to-rail operation to increase the allowable range of the input common mode voltage ( $V_{CMIN}$ ). When R2R is one, a sampling period of four cycles is required. Offset compensation (SAMPCTRL.OFFCOMP) must be written to one when using this period.
- **Bit 6 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 5:4 – RESSEL[1:0]: Conversion Result Resolution**

These bits define whether the ADC completes the conversion 12-, 10- or 8-bit result resolution.

**Table 37-10. Conversion Result Resolution**

| Value | Name  | Description               |
|-------|-------|---------------------------|
| 0x0   | 12BIT | 12-bit result             |
| 0x1   | 16BIT | For averaging mode output |
| 0x2   | 10BIT | 10-bit result             |
| 0x3   | 8BIT  | 8-bit result              |

- **Bit 3 – CORREN: Digital Correction Logic Enabled**

0: Disable the digital result correction.

1: Enable the digital result correction. The ADC conversion result in the RESULT register is then corrected for gain and offset based on the values in the GAINCORR and OFFSETCORR registers. Conversion time will be increased by 13 cycles according to the value in the Offset Correction Value bit group in the Offset Correction register.

- **Bit 2 – FREERUN: Free Running Mode**

0: The ADC run in single conversion mode.

1: The ADC is in free running mode and a new conversion will be initiated when a previous conversion completes.

- **Bit 1 – LEFTADJ: Left-Adjusted Result**

0: The ADC conversion result is right-adjusted in the RESULT register.

1: The ADC conversion result is left-adjusted in the RESULT register. The high byte of the 12-bit result will be present in the upper part of the result register. Writing this bit to zero (default) will right-adjust the value in the RESULT register.

- **Bit 0 – DIFFMODE: Differential Mode**

0: The ADC is running in singled-ended mode.

1: The ADC is running in differential mode. In this mode, the voltage difference between the MUXPOS and MUX-NEG inputs will be converted by the ADC.

### 37.7.11 Average Control

**Name:** AVGCTRL

**Offset:** 0x0C

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

|        |             |     |     |                |     |     |     |     |
|--------|-------------|-----|-----|----------------|-----|-----|-----|-----|
| Bit    | 7           | 6   | 5   | 4              | 3   | 2   | 1   | 0   |
|        | ADJRES[2:0] |     |     | SAMPLENUM[3:0] |     |     |     |     |
| Access | R           | R/W | R/W | R/W            | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0              | 0   | 0   | 0   | 0   |

- Bit 7– Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bits 6:4 – ADJRES[2:0]: Adjusting Result / Division Coefficient**  
 These bits define the division coefficient in  $2^n$  steps.
- Bits 3:0 – SAMPLENUM[3:0]: Number of Samples to be Collected**  
 These bits define how many samples should be added together. The result will be available in the Result register (RESULT). Note: if the result width increases, CTRLC.RESSEL must be changed.

**Table 37-11. Number of Samples to be Collected**

| Value     | Name | Description  |
|-----------|------|--------------|
| 0x0       |      | 1 sample     |
| 0x1       |      | 2 samples    |
| 0x2       |      | 4 samples    |
| 0x3       |      | 8 samples    |
| 0x4       |      | 16 samples   |
| 0x5       |      | 32 samples   |
| 0x6       |      | 64 samples   |
| 0x7       |      | 128 samples  |
| 0x8       |      | 256 samples  |
| 0x9       |      | 512 samples  |
| 0xA       |      | 1024 samples |
| 0xB - 0xF |      | Reserved     |

### 37.7.12 Sampling Time Control

**Name:** SAMPCTRL

**Offset:** 0x0D

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7       | 6 | 5            | 4   | 3   | 2   | 1   | 0   |
|--------|---------|---|--------------|-----|-----|-----|-----|-----|
|        | OFFCOMP |   | SAMPLEN[5:0] |     |     |     |     |     |
| Access | R/W     | R | R/W          | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0       | 0 | 0            | 0   | 0   | 0   | 0   | 0   |

- Bit 7 – OFFCOMP: Comparator Offset Compensation Enable**  
 Writing this bit to one enables the offset compensation for each sampling period to ensure low offset and immunity to temperature or voltage drift. This compensation increases the sampling time by three clock cycles.  
 This bit must be set to zero to validate the SAMPLEN value. It's not possible to cumulate OFFCOMP and SAMPLEN.
- Bit 6 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bits 5:0 – SAMPLEN[5:0]: Sampling Time Length**  
 These bits control the ADC sampling time in number of CLK\_ADC cycles, depending of the prescaler value, thus controlling the ADC input impedance. Sampling time is set according to the equation:

$$\text{Sampling time} = (\text{SAMPLEN} + 1) \cdot (\text{CLK}_{\text{ADC}})$$

### 37.7.13 Window Monitor Lower Threshold

**Name:** WINLT  
**Offset:** 0x0E  
**Access:** Read/Write  
**Reset:** 0x0000  
**Property:** Write-Protected, Write-Synchronized

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | WINLT[15:8] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | WINLT[7:0]  |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:0 – WINLT[15:0]: Window Lower Threshold**  
If the window monitor is enabled, these bits define the lower threshold value.

### 37.7.14 Window Monitor Upper Threshold

**Name:** WINUT  
**Offset:** 0x10  
**Access:** Read/Write  
**Reset:** 0x0000  
**Property:** Write-Protected, Write-Synchronized

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | WINUT[15:8] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | WINUT[7:0]  |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:0 – WINUT[15:0]: Window Upper Threshold**  
If the window monitor is enabled, these bits define the upper threshold value.

### 37.7.15 Gain Correction

**Name:** GAINCORR

**Offset:** 0x12

**Access:** Read/Write

**Reset:** 0x0000

**Property:** Write-Protected, Write-Synchronized

|        |               |     |     |     |                |     |     |     |
|--------|---------------|-----|-----|-----|----------------|-----|-----|-----|
| Bit    | 15            | 14  | 13  | 12  | 11             | 10  | 9   | 8   |
|        |               |     |     |     | GAINCORR[11:8] |     |     |     |
| Access | R             | R   | R   | R   | R/W            | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0              | 0   | 0   | 0   |
| Bit    | 7             | 6   | 5   | 4   | 3              | 2   | 1   | 0   |
|        | GAINCORR[7:0] |     |     |     |                |     |     |     |
| Access | R/W           | R/W | R/W | R/W | R/W            | R/W | R/W | R/W |
| Reset  | 0             | 0   | 0   | 0   | 0              | 0   | 0   | 0   |

- **Bits 15:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:0 – GAINCORR[11:0]: Gain Correction Value**

If the CTRL.CORREN bit is one, these bits define how the ADC conversion result is compensated for gain error before being written to the result register. The gain correction is a fractional value, a 1-bit integer plus an 11-bit fraction, and therefore  $\frac{1}{2} \leq \text{GAINCORR} < 2$ . GAINCORR values range from 0.1000000000 to 1.1111111111.

### 37.7.16 Offset Correction

**Name:** OFFSETCORR

**Offset:** 0x14

**Access:** Read/Write

**Reset:** 0x0000

**Property:** Write-Protected, Write-Synchronized

|        |                 |     |     |     |                  |     |     |     |
|--------|-----------------|-----|-----|-----|------------------|-----|-----|-----|
| Bit    | 15              | 14  | 13  | 12  | 11               | 10  | 9   | 8   |
|        |                 |     |     |     | OFFSETCORR[11:8] |     |     |     |
| Access | R               | R   | R   | R   | R/W              | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0                | 0   | 0   | 0   |
| Bit    | 7               | 6   | 5   | 4   | 3                | 2   | 1   | 0   |
|        | OFFSETCORR[7:0] |     |     |     |                  |     |     |     |
| Access | R/W             | R/W | R/W | R/W | R/W              | R/W | R/W | R/W |
| Reset  | 0               | 0   | 0   | 0   | 0                | 0   | 0   | 0   |

- **Bits 15:12 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 11:0 – OFFSETCORR[11:0]: Offset Correction Value**

If the CTRLC.CORREN bit is one, these bits define how the ADC conversion result is compensated for offset error before being written to the Result register. This OFFSETCORR value is in two's complement format.

### 37.7.17 Software Trigger

**Name:** SWTRIG

**Offset:** 0x18

**Access:** Write-only

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1     | 0     |
|--------|---|---|---|---|---|---|-------|-------|
|        |   |   |   |   |   |   | START | FLUSH |
| Access | R | R | R | R | R | R | W     | W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0     | 0     |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – START: ADC Start Conversion**

Writing a one to this bit will start a conversion or sequence. The bit is cleared by hardware when the conversion has started. Setting this bit when it is already set has no effect.

Writing this bit to zero will have no effect.

- **Bit 0 – FLUSH: ADC Conversion Flush**

Writing a one to this bit will flush the ADC pipeline. A flush will restart the ADC clock on the next peripheral clock edge, and all conversions in progress will be aborted and lost. This bit is cleared until the ADC has been flushed.

After the flush, the ADC will resume where it left off; i.e., if a conversion was pending, the ADC will start a new conversion.

Writing this bit to zero will have no effect.

### 37.7.18 Debug Control

**Name:** DBGCTRL  
**Offset:** 0x1C  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0             |
|--------|---|---|---|---|---|---|---|---------------|
|        |   |   |   |   |   |   |   | <b>DBGRUN</b> |
| Access | R | R | R | R | R | R | R | R/W           |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0             |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGRUN: Debug Run**

This bit is not reset by a software reset.

This bit controls the functionality when the CPU is halted by an external debugger.

0: The ADC is halted when the CPU is halted by an external debugger.

1: The ADC continues normal operation when the CPU is halted by an external debugger.

This bit should be written only while a conversion is not ongoing.

### 37.7.19 Synchronisation Busy

**Name:** SYNCBUSY

**Offset:** 0x20

**Access:** Read-only

**Reset:** 0x0000

**Property:** -

| Bit    | 15    | 14    | 13       | 12      | 11    | 10        | 9          | 8        |
|--------|-------|-------|----------|---------|-------|-----------|------------|----------|
|        |       |       |          |         |       | SWTRIG    | OFFSETCORR | GAINCORR |
| Access | R     | R     | R        | R       | R     | R         | R          | R        |
| Reset  | 0     | 0     | 0        | 0       | 0     | 0         | 0          | 0        |
| Bit    | 7     | 6     | 5        | 4       | 3     | 2         | 1          | 0        |
|        | WINUT | WINLT | SAMPCTRL | AVGCTRL | CTRLC | INPUTCTRL | ENABLE     | SWRST    |
| Access | R     | R     | R        | R       | R     | R         | R          | R        |
| Reset  | 0     | 0     | 0        | 0       | 0     | 0         | 0          | 0        |

- **Bits 15:11 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 10 – SWTRIG: Software Trigger Synchronization Busy**

This bit is cleared when the synchronization of SWTRIG register between the clock domains is complete.

This bit is set when the synchronization of SWTRIG register between clock domains is started.

- **Bit 9 – OFFSETCORR: Offset Correction Synchronization Busy**

This bit is cleared when the synchronization of OFFSETCORR register between the clock domains is complete.

This bit is set when the synchronization of OFFSETCORR register between clock domains is started.

- **Bit 8 – GAINCORR: Gain Correction Synchronization Busy**

This bit is cleared when the synchronization of GAINCORR register between the clock domains is complete.

This bit is set when the synchronization of GAINCORR register between clock domains is started.

- **Bit 7 – WINUT: Window Monitor Lower Threshold Synchronization Busy**

This bit is cleared when the synchronization of WINUT register between the clock domains is complete.

This bit is set when the synchronization of WINUT register between clock domains is started.

- **Bit 6 – WINLT: Window Monitor Upper Threshold Synchronization Busy**

This bit is cleared when the synchronization of WINLT register between the clock domains is complete.

This bit is set when the synchronization of WINLT register between clock domains is started.

- **Bit 5 – SAMPCTRL: Sampling Time Control Synchronization Busy**

This bit is cleared when the synchronization of SAMPCTRL register between the clock domains is complete.

This bit is set when the synchronization of SAMPCTRL register between clock domains is started.

- **Bit 4 – AVGCTRL: Average Control Synchronization Busy**

This bit is cleared when the synchronization of AVGCTRL register between the clock domains is complete.

This bit is set when the synchronization of AVGCTRL register between clock domains is started.

- **Bit 3 – CTRLC: Control C Synchronization Busy**

This bit is cleared when the synchronization of CTRLC register between the clock domains is complete.

This bit is set when the synchronization of CTRLC register between clock domains is started.

- **Bit 2 – INPUTCTRL: Input Control Synchronization Busy**

This bit is cleared when the synchronization of INPUTCTRL register between the clock domains is complete.

This bit is set when the synchronization of INPUTCTRL register between clock domains is started.

- **Bit 1 – ENABLE: ENABLE Synchronization Busy**

This bit is cleared when the synchronization of ENABLE register between the clock domains is complete.

This bit is set when the synchronization of ENABLE register between clock domains is started.

- **Bit 0 – SWRST: SWRST Synchronization Busy**

This bit is cleared when the synchronization of SWRST register between the clock domains is complete.

This bit is set when the synchronization of SWRST register between clock domains is started

### 37.7.20 Result

**Name:** RESULT  
**Offset:** 0x24  
**Access:** Read-only  
**Reset:** 0x0000  
**Property:** -

| Bit    | 15           | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|--------|--------------|----|----|----|----|----|---|---|
|        | RESULT[15:8] |    |    |    |    |    |   |   |
| Access | R            | R  | R  | R  | R  | R  | R | R |
| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0 | 0 |
| Bit    | 7            | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
|        | RESULT[7:0]  |    |    |    |    |    |   |   |

| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0 | 0 |

- Bits 15:0 – RESULT[15:0]: Result Conversion Value**

These bits will hold up to a 16-bit ADC result, depending on the configuration.

In single-ended without averaging mode, the ADC conversion will produce a 12-bit result, which can be left- or right-shifted, depending on the setting of CTRLC.LEFTADJ. If the result is left-adjusted (CTRLC.LEFTADJ), the high byte of the result will be in bit position [15:8], while the remaining 4 bits of the result will be placed in bit locations [7:4]. This can be used only if an 8-bit result is required; i.e., one can read only the high byte of the entire 16-bit register. If the result is not left-adjusted (CTRLC.LEFTADJ) and no oversampling is used, the result will be available in bit locations [11:0], and the result is then 12 bits long. If oversampling is used, the result will be located in bit locations [15:0], depending on the settings of the Average Control register ([AVGCTRL](#)).

### 37.7.21 Sequence Control

**Name:** SEQCTRL

**Offset:** 0x28

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected

- **Bits 31:0 – SEQENx: Enable Positive Input in the Sequence**

0: Disable the positive input mux x selection from the sequence.

1: enable the positive input mux x selection to the sequence.

for further details on available positive mux selection, refer to [Table](#) .

The sequence start from the lowest input, and go to the next enabled input automatically when the conversion is done. If no bits are set the sequence is disabled.

### 37.7.22 Calibration

**Name:** CALIB  
**Offset:** 0x2C  
**Access:** Read/Write  
**Reset:** 0x0000  
**Property:** Write-Protected, Enable-Protected

- Bits 15:11 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 10:8 – BIASREFBUF[2:0]: Bias Reference Buffer Scaling**  
 This value from production test must be loaded from the NVM software calibration row into the CALIB register by software to achieve the specified accuracy.  
 The value must be copied only, and must not be changed.
- Bits 7:3 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 2:0 – BIASCOMP[2:0]: Bias Comparator Scaling**  
 This value from production test must be loaded from the NVM software calibration row into the CALIB register by software to achieve the specified accuracy.  
 The value must be copied only, and must not be changed

## 37.8 Register Summary

| Offset | Name       | Bit pos. |                 |             |              |               |                  |                |            |          |
|--------|------------|----------|-----------------|-------------|--------------|---------------|------------------|----------------|------------|----------|
| 0x00   | CTRLA      | 7:0      | ONDEMAND        | RUNSTDBY    |              |               |                  |                | ENABLE     | SWRST    |

## 38. AC – Analog Comparators

### 38.1 Overview

The Analog Comparator (AC) supports two individual comparators. Each comparator (COMP) compares the voltage levels on two inputs, and provides a digital output based on this comparison. Each comparator may be configured to generate interrupt requests and/or peripheral events upon several different combinations of input change.

Hysteresis and propagation delay are two important properties of the comparators' dynamic behavior. Both parameters may be adjusted to achieve the optimal operation for each application.

The input selection includes four shared analog port pins and several internal signals. Each comparator output state can also be output on a pin for use by external devices.

The comparators are always grouped in pairs on each port. The AC module may implement one pair. These are called Comparator 0 (COMP0) and Comparator 1 (COMP1). They have identical behaviors, but separate control registers. The pair can be set in window mode to compare a signal to a voltage range instead of a single voltage level.

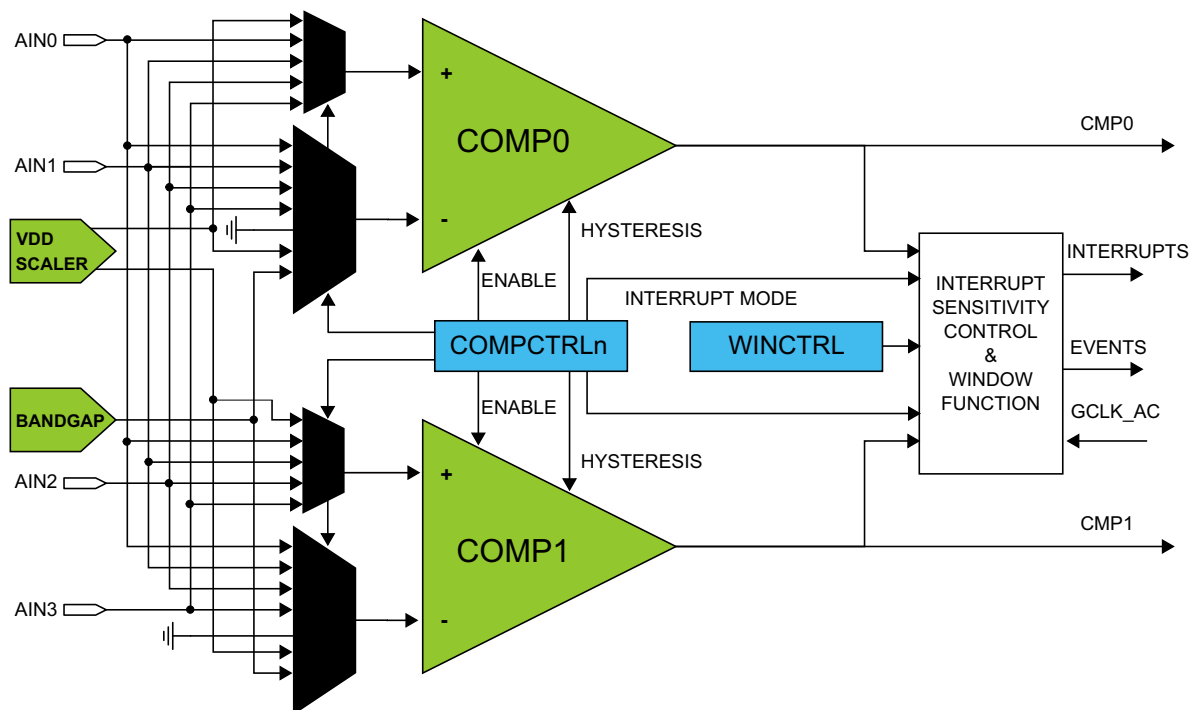

### 38.2 Features

- Two individual comparators
- Selectable propagation delay versus current consumption
- Selectable hysteresis
  - On or Off
- Analog comparator outputs available on pins
  - Asynchronous or synchronous
- Flexible input selection
  - Four pins selectable for positive or negative inputs
  - Ground (for zero crossing)
  - Bandgap reference voltage
  - 64-level programmable VDD scaler per comparator
- Interrupt generation on:
  - Rising or falling edge
  - Toggle
  - End of comparison
- Window function interrupt generation on:
  - Signal above window
  - Signal inside window
  - Signal below window
  - Signal outside window
- Event generation on:
  - Comparator output
  - Window function inside/outside window
- Optional digital filter on comparator output
- Low-power option
  - Single-shot support

## 38.3 Block Diagram

Figure 38-1. Analog Comparator Block Diagram

## 38.4 Signal Description

| Signal    | Description    | Type               |
|-----------|----------------|--------------------|
| AIN[3..0] | Analog input   | Comparator inputs  |
| CMP[1..0] | Digital output | Comparator outputs |

Refer to the Peripheral Multiplexing on I/O Lines section in the Pinout and Block Diagram chapter for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

## 38.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

### 38.5.1 I/O Lines

Using the AC's I/O lines requires the I/O pins to be configured. Refer to the PORT chapter for details.

### 38.5.2 Power Management

The AC will continue to operate in any sleep mode where the selected source clock is running. The AC's interrupts can be used to wake up the device from sleep modes. Events connected to the event system can trigger other operations in the system without exiting sleep modes. Refer to the Power Manager chapter for details on the different sleep modes.

### 38.5.3 Clocks

The AC bus clock (CLK\_AC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_AC\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

A generic clock (GCLK\_AC) is required to clock the AC. This clock must be configured and enabled in the generic clock controller before using the AC. Refer to the Generic Clock Controller chapter for details.

This generic clock is asynchronous to the bus clock (CLK\_AC\_APB). Due to this asynchronicity, writes to certain registers will require synchronization between the clock domains. Refer to [“Synchronization” on page 862](#) for further details.

### 38.5.4 DMA

Not applicable.

### 38.5.5 Interrupts

The interrupt request lines are connected to the interrupt controller. Using the AC interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 38.5.6 Events

The events are connected to the Event System. Refer to [“EVSYS – Event System” on page 467](#) for details on how to configure the Event System.

### 38.5.7 Debug Operation

When the CPU is halted in debug mode the AC will halt normal operation when the on-going comparison is completed. The AC can be forced to continue normal operation during debugging. Refer to [DBGCTRL](#) for details. If the AC is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

### 38.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Control B (CTRLB) register
- Interrupt Flag (INTFLAG) register

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to the Peripheral Access Controller chapter for details.

### 38.5.9 Analog Connections

Each comparator has up to four I/O pins that can be used as analog inputs. Each pair of comparators shares the same four pins. These pins must be configured for analog operation before using them as comparator inputs.

Any internal reference source, such as a bandgap voltage reference, must be configured and enabled prior to its use as a comparator input.

## 38.6 Functional Description

### 38.6.1 Principle of Operation

Each comparator has one positive input and one negative input. Each positive input may be chosen from a selection of analog input pins. Each negative input may be chosen from a selection of analog input pins or internal inputs, such as a

bandgap voltage reference. The digital output from the comparator is one when the difference between the positive and the negative input voltage is positive, and zero otherwise.

The individual comparators can be used independently (normal mode) or grouped in pairs to generate a window comparison (window mode).

## 38.6.2 Basic Operation

### 38.6.2.1 Initialization

The following register is enable-protected:

- Event Control register (EVCTRL)

Enable-protection is denoted by the Enable-Protected property in the register description.

### 38.6.2.2 Enabling, Disabling and Resetting

The AC is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The AC is disabled by writing a zero to CTRLA.ENABLE.

The AC is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the AC, will be reset to their initial state, and the AC will be disabled. Refer to [CTRLA](#) for details.

### 38.6.2.3 Comparator Configuration

Each individual comparator must be configured by its respective Comparator Control register (COMPCTRLx) before that comparator is enabled. These settings cannot be changed while the comparator is enabled.

- Select the desired measurement mode with COMPCTRLx.SINGLE. See [“Starting a Comparison” on page 855](#) for more details
- Select the desired hysteresis with COMPCTRLx.HYSTEN. See [“Input Hysteresis” on page 859](#) for more details
- Select the comparator speed versus power with COMPCTRLx.SPEED. See [“Propagation Delay vs. Power Consumption” on page 859](#) for more details
- Select the interrupt source with COMPCTRLx.INTSEL
- Select the positive and negative input sources with the COMPCTRLx.MUXPOS and COMPCTRLx.MUXNEG bits. See section [“Selecting Comparator Inputs” on page 857](#) for more details
- Select the filtering option with COMPCTRLx.FLEN
- Select standby operation with Run in Standby bit (COMPCTRLx.RUNSTDBY)

The individual comparators are enabled by writing a one to the Enable bit in the Comparator x Control registers (COMPCTRLx.ENABLE). The individual comparators are disabled by writing a zero to COMPCTRLx.ENABLE. Writing a zero to CTRLA.ENABLE will also disable all the comparators, but will not clear their COMPCTRLx.ENABLE bits.

### 38.6.2.4 Starting a Comparison

Each comparator channel can be in one of two different measurement modes, determined by the Single bit in the Comparator x Control register (COMPCTRLx.SINGLE):

- Continuous measurement
- Single-shot

After being enabled, a start-up delay is required before the result of the comparison is ready. This start-up time is measured automatically to account for environmental changes, such as temperature or voltage supply level, and is specified in [“Electrical Characteristics” on page 903](#). During the start-up time, the COMP output is not available.

The comparator can be configured to generate interrupts when the output toggles, when the output changes from zero to one (rising edge), when the output changes from one to zero (falling edge) or at the end of the comparison. An end-of-comparison interrupt can be used with the single-shot mode to chain further events in the system, regardless of the state of the comparator outputs. The interrupt mode is set by the Interrupt Selection bit group in the Comparator Control register (COMPCTRLx.INTSEL). Events are generated using the comparator output state, regardless of whether the interrupt is enabled or not.

## Continuous Measurement

Continuous measurement is selected by writing COMPCTRLx.SINGLE to zero. In continuous mode, the comparator is continuously enabled and performing comparisons. This ensures that the result of the latest comparison is always available in the Current State bit in the Status A register (STATUSA.STATEx). After the start-up time has passed, a comparison is done and STATUSA is updated. The Comparator x Ready bit in the Status B register (STATUSB.READYx) is set, and the appropriate peripheral events and interrupts are also generated. New comparisons are performed continuously until the COMPCTRLx.ENABLE bit is written to zero. The start-up time applies only to the first comparison.

In continuous operation, edge detection of the comparator output for interrupts is done by comparing the current and previous sample. The sampling rate is the GCLK\_AC frequency. An example of continuous measurement is shown in Figure 38-2.

**Figure 38-2. Continuous Measurement Example**

For low-power operation, comparisons can be performed during sleep modes without a clock. The comparator is enabled continuously, and changes in the state of the comparator are detected asynchronously. When a toggle occurs, the Power Manager will start GCLK\_AC to register the appropriate peripheral events and interrupts. The GCLK\_AC clock is then disabled again automatically, unless configured to wake up the system from sleep.

## Single-Shot

Single-shot operation is selected by writing COMPCTRLx.SINGLE to one. During single-shot operation, the comparator is normally idle. The user starts a single comparison by writing a one to the respective Start Comparison bit in the write-only Control B register (CTRLB.STARTx). The comparator is enabled, and after the start-up time has passed, a single comparison is done and STATUSA is updated. Appropriate peripheral events and interrupts are also generated. No new comparisons will be performed.

Writing a one to CTRLB.STARTx also clears the Comparator x Ready bit in the Status B register (STATUSB.READYx). STATUSB.READYx is set automatically by hardware when the single comparison has completed.

A single-shot measurement can also be triggered by the Event System. Writing a one to the Comparator x Event Input bit in the Event Control Register (EVCTRL.COMPEIx) enables triggering on incoming peripheral events. Each comparator can be triggered independently by separate events. Event-triggered operation is similar to user-triggered operation; the difference is that a peripheral event from another hardware module causes the hardware to automatically start the comparison and clear STATUSB.READYx.

To detect an edge of the comparator output in single-shot operation for the purpose of interrupts, the result of the current measurement is compared with the result of the previous measurement (one sampling period earlier). An example of single-shot operation is shown in Figure 38-3.

**Figure 38-3. Single-Shot Example**

For low-power operation, event-triggered measurements can be performed during sleep modes. When the event occurs, the Power Manager will start GCLK\_AC. The comparator is enabled, and after the startup time has passed, a comparison is done and appropriate peripheral events and interrupts are also generated. The comparator and GCLK\_AC are then disabled again automatically, unless configured to wake up the system from sleep.

### 38.6.3 Selecting Comparator Inputs

Each comparator has one positive and one negative input. The positive input is fed from an external input pin (AINx). The negative input can be fed either from an external input pin (AINx) or from one of the several internal reference voltage sources common to all comparators. The user selects the input source as follows:

- The positive input is selected by the Positive Input MUX Select bit group in the Comparator Control register (COMPCTRLx.MUXPOS)
- The negative input is selected by the Negative Input MUX Select bit group in the Comparator Control register (COMPCTRLx.MUXNEG)

In the case of using an external I/O pin, the selected pin must be configured for analog usage in the PORT Controller by disabling the digital input and output. The switching of the analog input multiplexors is controlled to minimize crosstalk between the channels. The input selection must be changed only while the individual comparator is disabled.

### 38.6.4 Window Operation

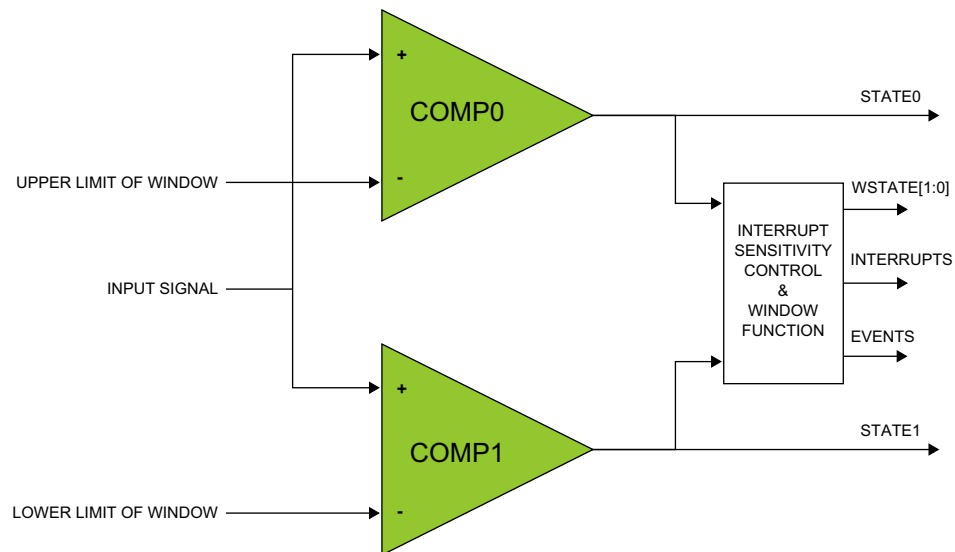

Each comparator pair can be configured to work together in window mode. In this mode, a voltage range is defined, and the comparators give information about whether an input signal is within this range or not. Window mode is enabled by the Window Enable x bit in the Window Control register (WINCTRL.WENx). Both comparators in a pair must have the same measurement mode setting in their respective Comparator Control Registers (COMPCTRLx.SINGLE).

To physically configure the pair of comparators for window mode, the same I/O pin should be chosen for each comparator's positive input to create the shared input signal. The negative inputs define the range for the window. In [Figure 38-4](#), COMP0 defines the upper limit and COMP1 defines the lower limit of the window, as shown but the window will also work in the opposite configuration with COMP0 lower and COMP1 higher. The current state of the window function is available in the Window x State bit group of the Status register (STATUS.WSTATEx).

Window mode can be configured to generate interrupts when the input voltage changes to below the window, when the input voltage changes to above the window, when the input voltage changes into the window or when the input voltage changes outside the window. The interrupt selections are set by the Window Interrupt Selection bit group in the Window Control register (WINCTRL.WINTSELx[1:0]). Events are generated using the inside/outside state of the window, regardless of whether the interrupt is enabled or not. Note that the individual comparator outputs, interrupts and events continue to function normally during window mode.

When the comparators are configured for window mode and single-shot mode, measurements are performed simultaneously on both comparators. Writing a one to either Start Comparison bit in the Control B register (CTRLB.STARTx) starts a measurement. Likewise either peripheral event can start a measurement.

**Figure 38-4. Comparators in Window Mode**

### 38.6.5 VDD Scaler

The VDD scaler generates a reference voltage that is a fraction of the device's supply voltage, with 64 levels. One independent voltage channel is dedicated for each comparator. The scaler is enabled when a comparator's Negative Input Mux bit group in its Comparator Control register (COMPCTRLx.MUXNEG) is set to five and the comparator is enabled. The voltage of each channel is selected by the Value bit group in the Scaler x registers (SCALERx.VALUE[5:0]).

**Figure 38-5. VDD Scaler**

### 38.6.6 Input Hysteresis

Application software can selectively enable/disable hysteresis for the comparison. Applying hysteresis will help prevent constant toggling of the output, which can be caused by noise when the input signals are close to each other. Hysteresis is enabled for each comparator individually by the Hysteresis Enable bit in the Comparator x Control register (COMPCTRLx.HYSTEN). Hysteresis is available only in continuous mode (COMPCTRLx.SINGLE=0).

### 38.6.7 Propagation Delay vs. Power Consumption

It is possible to trade off comparison speed for power efficiency to get the shortest possible propagation delay or the lowest power consumption. The speed setting is configured for each comparator individually by the Speed bit group in the Comparator x Control register (COMPCTRLx.SPEED). The Speed bits select the amount of bias current provided to the comparator, and as such will also affect the start-up time.

### 38.6.8 Filtering

The output of the comparators can be digitally filtered to reduce noise using a simple digital filter. The filtering is determined by the Filter Length bits in the Comparator Control x register (COMPCTRLx.FLEN), and is independent for each comparator. Filtering is selectable from none, 3-bit majority (N=3) or 5-bit majority (N=5) functions. Any change in the comparator output is considered valid only if N/2+1 out of the last N samples agree. The filter sampling rate is the GCLK\_AC frequency.

Note that filtering creates an additional delay of N-1 sampling cycles from when a comparison is started until the comparator output is validated. For continuous mode, the first valid output will occur when the required number of filter samples is taken. Subsequent outputs will be generated every cycle based on the current sample plus the previous N-1 samples, as shown in Figure 38-6. For single-shot mode, the comparison completes after the Nth filter sample, as shown in Figure 38-7.

**Figure 38-6. Continuous Mode Filtering**

**Figure 38-7. Single-Shot Filtering**

During sleep modes, filtering is supported only for single-shot measurements. Filtering must be disabled if continuous measurements will be done during sleep modes, or the resulting interrupt/event may be generated incorrectly.

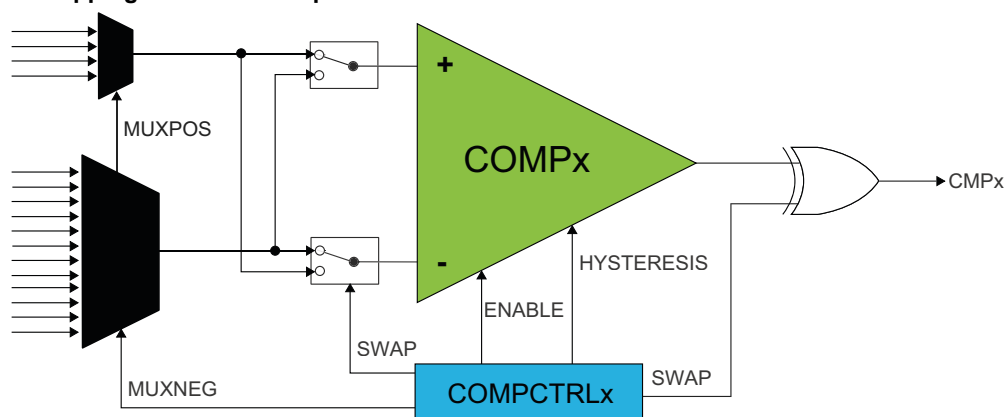

### 38.6.9 Comparator Output

The output of each comparator can be routed to an I/O pin by setting the Output bit group in the Comparator Control x register (COMPCTRLx.OUT). This allows the comparator to be used by external circuitry. Either the raw, non-synchronized output of the comparator or the CLK\_AC-synchronized version, including filtering, can be used as the I/O signal source. The output appears on the corresponding CMP[x] pin.

### 38.6.10 Offset Compensation

The Swap bit in the Comparator Control registers (COMPCTRLx.SWAP) controls switching of the input signals to a comparator's positive and negative terminals. When the comparator terminals are swapped, the output signal from the comparator is also inverted, as shown in Figure 38-8. This allows the user to measure or compensate for the comparator input offset voltage. As part of the input selection, COMPCTRLx.SWAP can be changed only while the comparator is disabled.

Figure 38-8. Input Swapping for Offset Compensation

### 38.6.11 DMA Operation

Not applicable.

### 38.6.12 Interrupts

The AC has the following interrupt sources:

- Comparator (COMP0, COMP1): Indicates a change in comparator status.
- Window (WIN0): Indicates a change in the window status.

Comparator interrupts are generated based on the conditions selected by the Interrupt Selection bit group in the Comparator Control registers (COMPCTRLx.INTSEL). Window interrupts are generated based on the conditions selected by the Window Interrupt Selection bit group in the Window Control register (WINCTRL.WINTSEL[1:0]).

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is cleared, the interrupt is disabled, or the AC is reset. See [INTFLAG](#) for details on how to clear interrupt flags. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

### 38.6.13 Events

The AC can generate the following output events:

- Comparator (COMP0, COMP1): Generated as a copy of the comparator status
- Window (WIN0): Generated as a copy of the window inside/outside status

Writing a one to an Event Output bit in the Event Control Register (EVCTRL.xxEO) enables the corresponding output event. Writing a zero to this bit disables the corresponding output event. Refer to the Event System chapter for details on configuring the event system.

The AC can take the following action on an input event:

- Start comparison (START0, START1): Start a comparison.

Writing a one to an Event Input bit into the Event Control register (EVCTRL.COMPxEI) enables the corresponding action on input event. Writing a zero to this bit disables the corresponding action on input event. Note that if several events are connected to the AC, the enabled action will be taken on any of the incoming events. Refer to the Event System chapter for details on configuring the event system.

When EVCTRL.COMPEIx is one, the event will start a comparison on COMPx after the start-up time delay. In normal mode, each comparator responds to its corresponding input event independently. For a pair of comparators in window mode, either comparator event will trigger a comparison on both comparators simultaneously.

### 38.6.14 Sleep Mode Operation

The Run in Standby bits in the Comparator x Control registers (COMPCTRLx.RUNSTDBY) control the behavior of the AC during standby sleep mode. Each RUNSTDBY bit controls one comparator. When the bit is zero, the comparator is disabled during sleep, but maintains its current configuration. When the bit is one, the comparator continues to operate during sleep. Note that when RUNSTDBY is zero, the analog blocks are powered off for the lowest power consumption. This necessitates a start-up time delay when the system returns from sleep.

For Window Mode operation, both comparators in a pair must have the same RUNSTDBY configuration.

When RUNSTDBY is one, any enabled AC interrupt source can wake up the CPU. The AC can also be used during sleep modes where the clock used by the AC is disabled, provided that the AC is still powered (not in shutdown). In this case, the behavior is slightly different and depends on the measurement mode, as listed in [Table 38-1](#).

**Table 38-1. Sleep Mode Operation**

| COMPCTRLx.MODE  | RUNSTDBY=0     | RUNSTDBY=1   |
|-----------------|----------------|--|
| 0 (Continuous)  | COMPx disabled | GCLK_AC stopped, COMPx enabled                                       |
| 1 (Single-shot) | COMPx disabled | GCLK_AC stopped, COMPx enabled only when triggered by an input event |

#### 38.6.14.1 Continuous Measurement during Sleep

When a comparator is enabled in continuous measurement mode and GCLK\_AC is disabled during sleep, the comparator will remain continuously enabled and will function asynchronously. The current state of the comparator is asynchronously monitored for changes. If an edge matching the interrupt condition is found, GCLK\_AC is started to register the interrupt condition and generate events. If the interrupt is enabled in the Interrupt Enable registers (INTENCLR/SET), the AC can wake up the device; otherwise GCLK\_AC is disabled until the next edge detection. Filtering is not possible with this configuration.

**Figure 38-9. Continuous Mode SleepWalking**

#### 38.6.14.2 Single-Shot Measurement during Sleep

For low-power operation, event-triggered measurements can be performed during sleep modes. When the event occurs, the Power Manager will start GCLK\_AC. The comparator is enabled, and after the start-up time has passed, a comparison is done, with filtering if desired, and the appropriate peripheral events and interrupts are also generated, as shown in Figure 38-10. The comparator and GCLK\_AC are then disabled again automatically, unless configured to wake the system from sleep. Filtering is allowed with this configuration.

**Figure 38-10. Single-Shot SleepWalking**

#### 38.6.15 Synchronization

Due to the asynchronicity between CLK\_AC\_APB and GCLK\_AC some registers must be synchronized when accessed. A register can require:

- Synchronization when written
- Synchronization when read
- Synchronization when written and read
- No synchronization

When executing an operation that requires synchronization, the corresponding status bit in the Synchronization Busy register (SYNCBUSY) will be set immediately, and cleared when synchronization is complete.

If an operation that requires synchronization is executed while its busy bit is one, the operation is discarded and an error is generated.

The following bits need synchronization when written:

- Software Reset bit in control register ([CTRLA.SWRST](#))
- Enable bit in control register ([CTRLA.ENABLE](#))
- Enable bit in Comparator Control register ([COMPCTRLn.ENABLE](#))

The following register needs synchronization when written:

- Window Control register ([WINCTRL](#))

Write-synchronization is denoted by the Write-Synchronized property in the register description.

Refer to the Synchronization chapter for further details.

## 38.7 Register Summary

| Offset | Name      | Bit Pos. |      |             |              |             |           |               |            |         |
|--------|-----------|----------|------|-------------|--------------|-------------|-----------|---------------|------------|---------|
| 0x00   | CTRLA     | 7:0      |      |             |              |             |           |               | ENABLE     | SWRST   |
| 0x01   | CTRLB     | 7:0      |      |             |              |             |           |               | START1     | START0  |

## 38.8 Register Description

Registers can be 8, 16 or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Refer to [“Register Access Protection” on page 854](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Refer to [“Synchronization” on page 862](#) for details.

Some registers are enable-protected, meaning they can be written only when the AC is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 38.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0     |
|--------|---|---|---|---|---|---|--------|-------|
|        |   |   |   |   |   |   | ENABLE | SWRST |
| Access | R | R | R | R | R | R | R/W    | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0      | 0     |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

0: The AC is disabled.

1: The AC is enabled. Each comparator must also be enabled individually by the Enable bit in the Comparator Control register (COMPCTRLn.ENABLE).

Due to synchronization, there is delay from updating the register until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately after being written. SYNCBUSY.ENABLE is set. SYNCBUSY.ENABLE is cleared when the peripheral is enabled/disabled.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the AC to their initial state, and the AC will be disabled.

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

Due to synchronization, there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

### 38.8.2 Control B

**Name:** CTRLB  
**Offset:** 0x01  
**Access:** Write-only  
**Reset:** 0x00  
**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3   | 2   | 1      | 0      |
|--------|---|---|---|---|-----|-----|--------|--------|
|        |   |   |   |   |     |     | START1 | START0 |
| Access | R | R | R | R | R/W | R/W | R/W    | R/W    |
| Reset  | 0 | 0 | 0 | 0 | 0   | 0   | 0      | 0      |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – STARTx: Comparator x Start Comparison**

Writing a zero to this field has no effect.

Writing a one to STARTx starts a single-shot comparison on COMPx if both the Single-Shot and Enable bits in the Comparator x Control Register are one (COMPCTRLx.SINGLE and COMPCTRLx.ENABLE). If comparator x is not implemented, or if it is not enabled in single-shot mode, writing a one has no effect.

This bit always reads as zero.

### 38.8.3 Event Control

**Name:** EVCTRL

**Offset:** 0x02

**Access:** Read/Write

**Reset:** 0x0000

**Property:** Write-Protected, Enable-Protected

|        |     |     |        |        |     |     |         |         |
|--------|-----|-----|--------|--------|-----|-----|---------|---------|
| Bit    | 15  | 14  | 13     | 12     | 11  | 10  | 9       | 8       |
|        |     |     | INVEI1 | INVEI0 |     |     | COMPEI1 | COMPEI0 |
| Access | R/W | R/W | R/W    | R/W    | R/W | R/W | R/W     | R/W     |
| Reset  | 0   | 0   | 0      | 0      | 0   | 0   | 0       | 0       |
| Bit    | 7   | 6   | 5      | 4      | 3   | 2   | 1       | 0       |
|        |     |     |        | WINEO0 |     |     | COMPEO1 | COMPEO0 |
| Access | R   | R   | R/W    | R/W    | R/W | R/W | R/W     | R/W     |
| Reset  | 0   | 0   | 0      | 0      | 0   | 0   | 0       | 0       |

- Bits 15:14 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 13:12 – INVEIx: Inverted Event Input Enable x**  
 0: Incoming event is not inverted for comparator x.  
 1: Incoming event is inverted for comparator x.
- Bits 9:8 – COMPEIx: Comparator x Event Input**  
 Note that several actions can be enabled for incoming events. If several events are connected to the peripheral, the enabled action will be taken for any of the incoming events. There is no way to tell which of the incoming events caused the action.  
 These bits indicate whether a comparison will start or not on any incoming event.  
 0: Comparison will not start on any incoming event.  
 1: Comparison will start on any incoming event.
- Bits 7:5 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 4 – WINEO0: Window 0 Event Output Enable**  
 This bit indicates whether the window 0 function can generate a peripheral event or not.  
 0: Window 0 event is disabled.  
 1: Window 0 event is enabled.
- Bits 3:2 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bits 1:0 – COMPEOx: Comparator x Event Output Enable**  
 These bits indicate whether the comparator x output can generate a peripheral event or not.

0: COMPx event generation is disabled.  
1: COMPx event generation is enabled.

### 38.8.4 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set register (INTENSET).

**Name:** INTENCLR

**Offset:** 0x04

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5   | 4           | 3   | 2   | 1            | 0            |
|--------|---|---|-----|-------------|-----|-----|--------------|--------------|
|        |   |   |     | <b>WIN0</b> |     |     | <b>COMP1</b> | <b>COMP0</b> |
| Access | R | R | R/W | R/W         | R/W | R/W | R/W          | R/W          |
| Reset  | 0 | 0 | 0   | 0           | 0   | 0   | 0            | 0            |

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 – WIN0: Window 0 Interrupt Enable**

Reading this bit returns the state of the Window 0 interrupt enable.

0: The Window 0 interrupt is disabled.

1: The Window 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit disables the Window 0 interrupt.

- **Bits 3:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – COMPx: Comparator x Interrupt Enable**

Reading this bit returns the state of the Comparator x interrupt enable.

0: The Comparator x interrupt is disabled.

1: The Comparator x interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit disables the Comparator x interrupt.

### 38.8.5 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear register (INTENCLR).

**Name:** INTENSET

**Offset:** 0x05

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5   | 4           | 3   | 2   | 1            | 0            |
|--------|---|---|-----|-------------|-----|-----|--------------|--------------|
|        |   |   |     | <b>WIN0</b> |     |     | <b>COMP1</b> | <b>COMP0</b> |
| Access | R | R | R/W | R/W         | R/W | R/W | R/W          | R/W          |
| Reset  | 0 | 0 | 0   | 0           | 0   | 0   | 0            | 0            |

- **Bits 7:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 4 – WIN0: Window 0 Interrupt Enable**

Reading this bit returns the state of the Window 0 interrupt enable.

0: The Window 0 interrupt is disabled.

1: The Window 0 interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit enables the Window 0 interrupt.

- **Bits 3:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – COMPx: Comparator x Interrupt Enable**

Reading this bit returns the state of the Comparator x interrupt enable.

0: The Comparator x interrupt is disabled.

1: The Comparator x interrupt is enabled.

Writing a zero to this bit has no effect.

Writing a one to this bit will set the Ready interrupt bit and enable the Ready interrupt.

### 38.8.6 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x06  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** –

| Bit    | 7 | 6 | 5   | 4           | 3   | 2   | 1            | 0            |
|--------|---|---|-----|-------------|-----|-----|--------------|--------------|
|        |   |   |     | <b>WIN0</b> |     |     | <b>COMP1</b> | <b>COMP0</b> |
| Access | R | R | R/W | R/W         | R/W | R/W | R/W          | R/W          |
| Reset  | 0 | 0 | 0   | 0           | 0   | 0   | 0            | 0            |

- **Bits 7:5 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 4 – WIN0: Window 0**  
This flag is set according to the Window 0 Interrupt Selection bit group in the [WINCTRL](#) register (WINCTRL.WINTSEL0) and will generate an interrupt if INTENCLR/SET.WIN0 is also one.  
Writing a zero to this bit has no effect.  
Writing a one to this bit clears the Window 0 interrupt flag.
- **Bits 3:2 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bits 1:0 – COMPx: Comparator x**  
Reading this bit returns the status of the Comparator x interrupt flag. If comparator x is not implemented, COMPx always reads as zero.  
This flag is set according to the Interrupt Selection bit group in the Comparator x Control register (COMPCTRLx.INTSEL) and will generate an interrupt if INTENCLR/SET.COMPx is also one.  
Writing a zero to this bit has no effect.  
Writing a one to this bit clears the Comparator x interrupt flag.

### 38.8.7 Status A

**Name:** STATUSA

**Offset:** 0x07

**Access:** Read-only

**Reset:** 0x00

**Property:** –

| Bit    | 7 | 6 | 5            | 4 | 3 | 2 | 1      | 0      |
|--------|---|---|--------------|---|---|---|--------|--------|
|        |   |   | WSTATE0[1:0] |   |   |   | STATE1 | STATE0 |
| Access | R | R | R            | R | R | R | R      | R      |
| Reset  | 0 | 0 | 0            | 0 | 0 | 0 | 0      | 0      |

- **Bits 7:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:4 – WSTATE0[1:0]: Window 0 Current State**

These bits show the current state of the signal if the window 0 mode is enabled, according to [Table 38-2](#).

**Table 38-2. Window Mode Current State**

| Value | Name   | Description             |
|-------|--------|-------------------------|
| 0x0   | ABOVE  | Signal is above window  |
| 0x1   | INSIDE | Signal is inside window |
| 0x2   | BELOW  | Signal is below window  |
| 0x3   | –      | Reserved                |

- **Bits 3:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – STATEx: Comparator x Current State**

This bit shows the current state of the output signal from COMPx. STATEx is valid only when STATUSB.READYx is one.

### 38.8.8 Status B

**Name:** STATUSB

**Offset:** 0x08

**Access:** Read-only

**Reset:** 0x00

**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0      |
|--------|---|---|---|---|---|---|--------|--------|
|        |   |   |   |   |   |   | READY1 | READY0 |
| Access | R | R | R | R | R | R | R      | R      |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0      | 0      |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 1:0 – READYx: Comparator x Ready**

This bit is cleared when the comparator x output is not ready.

This bit is set when the comparator x output is ready.

### 38.8.9 Debug Control

**Name:** DBGCTRL

**Offset:** 0x09

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0             |
|--------|---|---|---|---|---|---|---|---------------|
|        |   |   |   |   |   |   |   | <b>DBGRUN</b> |
| Access | R | R | R | R | R | R | R | R/W           |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0             |

- **Bits 7:1 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 0 – DBGRUN: Debug Run**

This bit is not reset by a software reset.

This bit controls the functionality when the CPU is halted by an external debugger.

0: The AC is halted when the CPU is halted by an external debugger. Any on-going comparison will complete.

1: The AC continues normal operation when the CPU is halted by an external debugger.

### 38.8.10 Window Control

**Name:** WINCTRL

**Offset:** 0x0A

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Synchronized, Write-Protected

| Bit    | 7 | 6   | 5   | 4   | 3 | 2             | 1   | 0    |
|--------|---|-----|-----|-----|---|---------------|-----|------|
|        |   |     |     |     |   | WINTSEL0[1:0] |     | WEN0 |
| Access | R | R/W | R/W | R/W | R | R/W           | R/W | R/W  |
| Reset  | 0 | 0   | 0   | 0   | 0 | 0             | 0   | 0    |

- **Bits 7:3 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 2:1 – WINTSEL0: Window 0 Interrupt Selection**

These bits configure the interrupt mode for the comparator window 0 mode, as shown in [Table 38-3](#):

**Table 38-3. Window 0 Interrupt Selection**

| Value | Name    | Description                        |
|-------|---------|------------------------------------|
| 0x0   | ABOVE   | Interrupt on signal above window   |
| 0x1   | INSIDE  | Interrupt on signal inside window  |
| 0x2   | BELOW   | Interrupt on signal below window   |
| 0x3   | OUTSIDE | Interrupt on signal outside window |

- **Bit 0 – WEN0: Window 0 Mode Enable**

0: Window mode is disabled for comparators 0 and 1.

1: Window mode is enabled for comparators 0 and 1.

### 38.8.11 Scaler n

**Name:** SCALERn  
**Offset:** 0x0C+n\*0x1 [n=0..1]  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5          | 4   | 3   | 2   | 1   | 0   |
|--------|---|---|------------|-----|-----|-----|-----|-----|
|        |   |   | VALUE[5:0] |     |     |     |     |     |
| Access | R | R | R/W        | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0 | 0 | 0          | 0   | 0   | 0   | 0   | 0   |

- **Bits 7:6 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 5:0 – VALUE[5:0]: Scaler Value**

These bits define the scaling factor for channel n of the  $V_{DD}$  voltage scaler. The output voltage,  $V_{SCALE}$ , is:

$$V_{SCALE} = \frac{V_{DD} \cdot (VALUE + 1)}{64}$$

### 38.8.12 Comparator Control n

The configuration of comparator n is protected while comparator n is enabled (COMPCTRLn.ENABLE = 1). Changes to the other bits in COMPCTRLn can only occur when COMPCTRLn.ENABLE is zero.

**Name:** COMPCTRLn

**Offset:** 0x10+n\*0x4 [n=0..1]

**Access:** Read/Write

**Reset:** 0x00000000

**Property:** Write-Protected, Write-Synchronized

|        |      |             |          |             |        |             |            |     |
|--------|------|-------------|----------|-------------|--------|-------------|------------|-----|
| Bit    | 31   | 30          | 29       | 28          | 27     | 26          | 25         | 24  |
|        |      |             | OUT[1:0] |             |        | FLEN[2:0]   |            |     |
| Access | R    | R           | R/W      | R/W         | R      | R/W         | R/W        | R/W |
| Reset  | 0    | 0           | 0        | 0           | 0      | 0           | 0          | 0   |
| Bit    | 23   | 22          | 21       | 20          | 19     | 18          | 17         | 16  |
|        |      |             |          |             | HYSTEN |             | SPEED[1:0] |     |
| Access | R    | R           | R        | R           | R/W    | R           | R/W        | R/W |
| Reset  | 0    | 0           | 0        | 0           | 0      | 0           | 0          | 0   |
| Bit    | 15   | 14          | 13       | 12          | 11     | 10          | 9          | 8   |
|        | SWAP | MUXPOS[2:0] |          |             |        | MUXNEG[2:0] |            |     |
| Access | R/W  | R/W         | R/W      | R/W         | R      | R/W         | R/W        | R/W |
| Reset  | 0    | 0           | 0        | 0           | 0      | 0           | 0          | 0   |
| Bit    | 7    | 6           | 5        | 4           | 3      | 2           | 1          | 0   |
|        |      | RUNSTDBY    |          | INTSEL[1:0] |        | SINGLE      | ENABLE     |     |
| Access | R    | R/W         | R        | R/W         | R/W    | R/W         | R/W        | R   |
| Reset  | 0    | 0           | 0        | 0           | 0      | 0           | 0          | 0   |

- **Bits 31:30 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 29:28 – OUT[1:0]: Output**

These bits configure the output selection for comparator n, as shown in [Table 38-4](#). COMPCTRLn.OUT can be written only while COMPCTRLn.ENABLE is zero.

These bits are not synchronized.

**Table 38-4. Output Selection**

| Value | Name   | Description   |
|-------|--------|---|
| 0x0   | OFF    | The output of COMPn is not routed to the COMPn I/O port                               |
| 0x1   | ASYNCR | The asynchronous output of COMPn is routed to the COMPn I/O port                      |
| 0x2   | SYNC   | The synchronous output (including filtering) of COMPn is routed to the COMPn I/O port |
| 0x3   | N/A    | Reserved  |

- Bit 27 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bits 26:24 – FLEN[2:0]: Filter Length**  
 These bits configure the filtering for comparator n, as shown in [Table 38-5](#). COMPCTRLn.FLEN can only be written while COMPCTRLn.ENABLE is zero.  
 These bits are not synchronized.

**Table 38-5. Filter Length**

| Value   | Name | Description                      |
|---------|------|----------------------------------|
| 0x0     | OFF  | No filtering                     |
| 0x1     | MAJ3 | 3-bit majority function (2 of 3) |
| 0x2     | MAJ5 | 5-bit majority function (3 of 5) |
| 0x3-0x7 | N/A  | Reserved                         |

- Bits 23:20 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 19 – HYSTEN: Hysteresis Enable**  
 This bit indicates the hysteresis mode of comparator n. Hysteresis is available only for continuous mode (COMPCTRLn.SINGLE=0). COMPCTRLn.HYST can be written only while COMPCTRLn.ENABLE is zero.  
 0: Hysteresis is disabled.  
 1: Hysteresis is enabled.  
 This bit is not synchronized.
- Bit 18 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bits 17:16 – SPEED[1:0]: Speed Selection**  
 This bit indicates the speed/propagation delay mode of comparator n, as shown in [Table 38-6](#). COMPCTRLn.SPEED can be written only while COMPCTRLn.ENABLE is zero.  
 These bits are not synchronized.

**Table 38-6. Speed Selection**

| Value   | Name | Description |
|---------|------|-------------|
| 0x0     | LOW  | Low speed   |
| 0x1-0x2 | –    | Reserved    |
| 0x3     | HIGH | High speed  |

- **Bit 15 – SWAP: Swap Inputs and Invert**

This bit swaps the positive and negative inputs to COMPn and inverts the output. This function can be used for offset cancellation. COMPCTRLn.SWAP can be written only while COMPCTRLn.ENABLE is zero.

0: The output of MUXPOS connects to the positive input, and the output of MUXNEG connects to the negative input.

1: The output of MUXNEG connects to the positive input, and the output of MUXPOS connects to the negative input.

These bits are not synchronized.

- **Bits 14:12 – MUXPOS[2:0]: Positive Input Mux Selection**

These bits select which input will be connected to the positive input of comparator n, as shown in [Table 38-7](#).

COMPCTRLn.MUXPOS can be written only while COMPCTRLn.ENABLE is zero.

These bits are not synchronized.

**Table 38-7. Positive Input Mux Selection**

| Value   | Name   | Description |
|---------|--------|-------------|
| 0x0     | PIN0   | I/O pin 0   |
| 0x1     | PIN1   | I/O pin 1   |
| 0x2     | PIN2   | I/O pin 2   |
| 0x3     | PIN3   | I/O pin 3   |
| 0x4     | VSCALE | VDD scaler  |
| 0x5–0x7 | –      | Reserved    |

- **Bit 11 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

- **Bits 10:8 – MUXNEG[2:0]: Negative Input Mux Selection**

These bits select which input will be connected to the negative input of comparator n, as shown in [Table 38-8](#).

COMPCTRLn.MUXNEG can only be written while COMPCTRLn.ENABLE is zero.

These bits are not synchronized.

**Table 38-8. Negative Input Mux Selection**

| Value | Name | Description |
|-------|------|-------------|
| 0x0   | PIN0 | I/O pin 0   |
| 0x1   | PIN1 | I/O pin 1   |
| 0x2   | PIN2 | I/O pin 2   |

| Value | Name    | Description              |
|-------|---------|--------------------------|
| 0x3   | PIN3    | I/O pin 3                |
| 0x4   | GND     | Ground                   |
| 0x5   | VSCALE  | VDD scaler               |
| 0x6   | BANDGAP | Internal bandgap voltage |
| 0x7   |         | Reserved                 |

- Bit 7 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bit 6 – RUNSTDBY: Run in Standby**  
 This bit controls the behavior of the comparator during standby sleep mode.  
 0: The comparator is disabled during sleep.  
 1: The comparator continues to operate during sleep.  
 This bit is not synchronized
- Bit 5 – Reserved**  
 This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.
- Bits 4:3 – INTSEL[1:0]: Interrupt Selection**  
 These bits select the condition for comparator n to generate an interrupt or event, as shown in [Table 38-9](#). COMPCTRLn.INTSEL can be written only while COMPCTRLn.ENABLE is zero.  
 These bits are not synchronized.

**Table 38-9. Interrupt Selection**

| Value | Name    | Description  |
|-------|---------|--|
| 0x0   | TOGGLE  | Interrupt on comparator output toggle                  |
| 0x1   | RISING  | Interrupt on comparator output rising                  |
| 0x2   | FALLING | Interrupt on comparator output falling                 |
| 0x3   | EOC     | Interrupt on end of comparison (single-shot mode only) |

- Bit 2 – SINGLE: Single-Shot Mode**  
 This bit determines the operation of comparator n. COMPCTRLn.SINGLE can be written only while COMPCTRLn.ENABLE is zero.  
 0: Comparator n operates in continuous measurement mode.  
 1: Comparator n operates in single-shot mode.  
 These bits are not synchronized.
- Bit 1 – ENABLE: Enable**  
 Writing a zero to this bit disables comparator n.  
 Writing a one to this bit enables comparator n.  
 Due to synchronization, there is delay from updating the register until the comparator is enabled/disabled. The value written to COMPCTRLn.ENABLE will read back immediately after being written. SYNCBUSY.COMPCTRLn is set. SYNCBUSY.COMPCTRLn is cleared when the peripheral is enabled/disabled.

Writing a one to COMPCTRLn.ENABLE will prevent further changes to the other bits in COMPCTRLn. These bits remain protected until COMPCTRLn.ENABLE is written to zero and the write is synchronized.

- **Bit 0 – Reserved**

This bit is unused and reserved for future use. For compatibility with future devices, always write this bit to zero when this register is written. This bit will always return zero when read.

### 38.8.13 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x20

**Access:** Read-only

**Reset:** 0x00000000

**Property:** –

|        |    |    |    |           |           |         |        |       |
|--------|----|----|----|-----------|-----------|---------|--------|-------|
| Bit    | 31 | 30 | 29 | 28        | 27        | 26      | 25     | 24    |
|        |    |    |    |           |           |         |        |       |
| Access | R  | R  | R  | R         | R         | R       | R      | R     |
| Reset  | 0  | 0  | 0  | 0         | 0         | 0       | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20        | 19        | 18      | 17     | 16    |
|        |    |    |    |           |           |         |        |       |
| Access | R  | R  | R  | R         | R         | R       | R      | R     |
| Reset  | 0  | 0  | 0  | 0         | 0         | 0       | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12        | 11        | 10      | 9      | 8     |
|        |    |    |    |           |           |         |        |       |
| Access | R  | R  | R  | R         | R         | R       | R      | R     |
| Reset  | 0  | 0  | 0  | 0         | 0         | 0       | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4         | 3         | 2       | 1      | 0     |
|        |    |    |    | COMPCTRL1 | COMPCTRL0 | WINCTRL | ENABLE | SWRST |
| Access | R  | R  | R  | R         | R         | R       | R      | R     |
| Reset  | 0  | 0  | 0  | 0         | 0         | 0       | 0      | 0     |

- **Bits 31:5 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 4:2 – COMPCTRLx: COMPCTRLx Synchronization Busy**

This bit is cleared when the synchronization of the COMPCTRLx register between the clock domains is complete. This bit is set when the synchronization of the COMPCTRLx register between clock domains is started.

- **Bit 2 – WINCTRL: WINCTRL Synchronization Busy**

This bit is cleared when the synchronization of the WINCTRL register between the clock domains is complete. This bit is set when the synchronization of the WINCTRL register between clock domains is started.

- **Bit 1 – ENABLE: Enable Synchronization Busy**

This bit is cleared when the synchronization of the CTRLA.ENABLE bit between the clock domains is complete. This bit is set when the synchronization of the CTRLA.ENABLE bit between clock domains is started.

- **Bit 0 – SWRST: Software Reset Synchronization Busy**

This bit is cleared when the synchronization of the CTRLA.SWRST bit between the clock domains is complete.

This bit is set when the synchronization of the CTRLA.SWRST bit between clock domains is started.

## 39. PTC - Peripheral Touch Controller

### 39.1 Overview

The purpose of PTC is to acquire signals to detect touch on capacitive sensors. The external capacitive touch sensor is typically formed on a PCB, and the sensor electrodes are connected to the analog front end of the PTC through the I/O pins in the device. The PTC supports both self- and mutual-capacitance sensors.

In mutual-capacitance mode, sensing is done using capacitive touch matrices in various X-Y configurations, including indium tin oxide (ITO) sensor grids. The PTC requires one pin per X-line and one pin per Y-line.

In self-capacitance mode, the PTC requires only one pin (Y-line or X-line) for each touch sensor.

### 39.2 Features

- Low-power, high-sensitivity, environmentally robust capacitive touch buttons, sliders, wheels and proximity sensing
- Supports mutual capacitance and self-capacitance sensing
  - 16/22/32 buttons in self-capacitance mode, for 32-/48-/64- pins respectively
    - 6/10/16 buttons in self-capacitance mode using Y-lines, for 32-/48-/64- pins respectively
    - 10/12/16 buttons in self-capacitance mode using X-lines, for 32-/48-/64- pins respectively
  - 60/120/256 buttons in mutual-capacitance mode, for 32-/48-/64- pins respectively
  - Mix-and-match mutual-and self-capacitance sensors
- One pin per electrode – no external components
- Load compensating charge sensing
  - Parasitic capacitance compensation and adjustable gain for superior sensitivity
- Zero drift over the temperature and  $V_{DD}$  range
  - Auto calibration and re-calibration of sensors
- Single-shot and free-running charge measurement
- Hardware noise filtering and noise signal de-synchronization for high conducted immunity
- Selectable channel change delay
  - Allows choosing the settling time on a new channel, as required
- Acquisition-start triggered by command or interrupt event
- Low CPU utilization through interrupt on acquisition-complete
  - 5% CPU utilization scanning 10 channels at 50ms scan rate
- Supported by the Atmel® QTouch® Composer development tool, which comprises QTouch Library project builder and QTouch analyzer

### 39.3 Block Diagram

Figure 39-1. PTC Block Diagram Mutual-capacitance

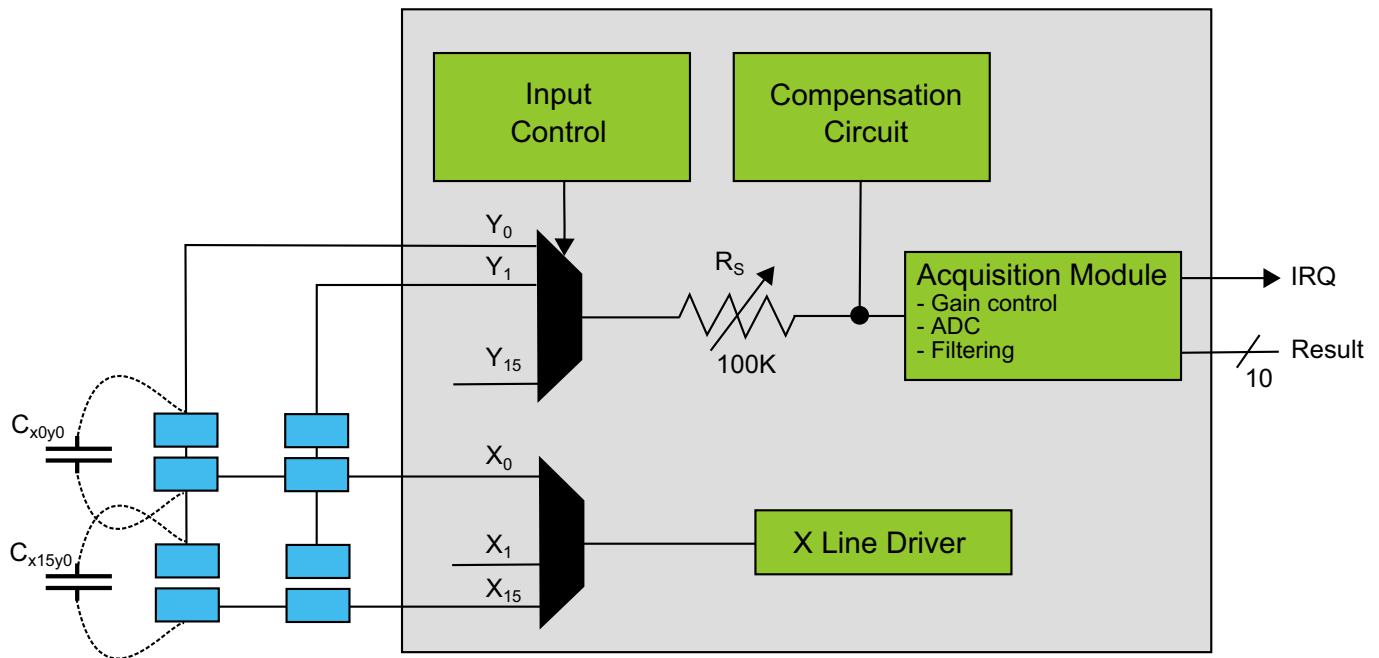

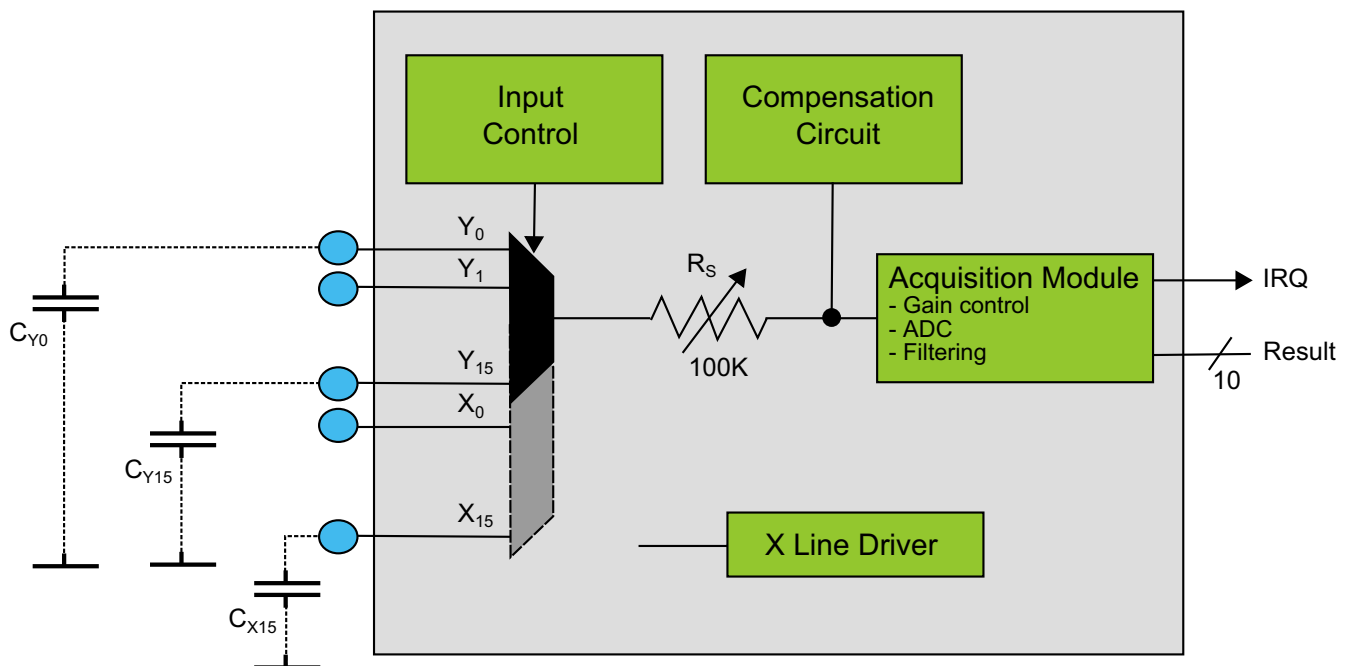

Figure 39-2. PTC Block Diagram Self-capacitance

39.4 Signal Description

| Name   | Type           | Description           |
|--------|----------------|-----------------------|
| X[n:0] | Digital/Analog | X-line (Input/Output) |
| Y[m:0] | Analog         | Y-line (Input/Output) |

Note: 1. The number of X and Y lines are device dependent. Refer to “Configuration Summary” on page 3 for details. Refer to “I/O Multiplexing and Considerations” on page 13 for details on the pin mapping for this peripheral. One signal can be mapped on several pins.

39.5 Product Dependencies

In order to use this Peripheral, configure the other components of the system as described in the following sections.

39.5.1 I/O Lines

The I/O lines used for analog X-lines and Y-lines must be connected to external capacitive touch sensor electrodes. External components are not required for normal operation. However, to improve the EMC performance, a series resistor of 1 KΩ can be used on X-lines and Y-lines.

Mutual-capacitance Sensor Arrangement

A mutual-capacitance sensor is formed between two I/O lines - an X electrode for transmitting and Y electrode for receiving. The mutual capacitance between the X and Y electrode is measured by the Peripheral Touch Controller.

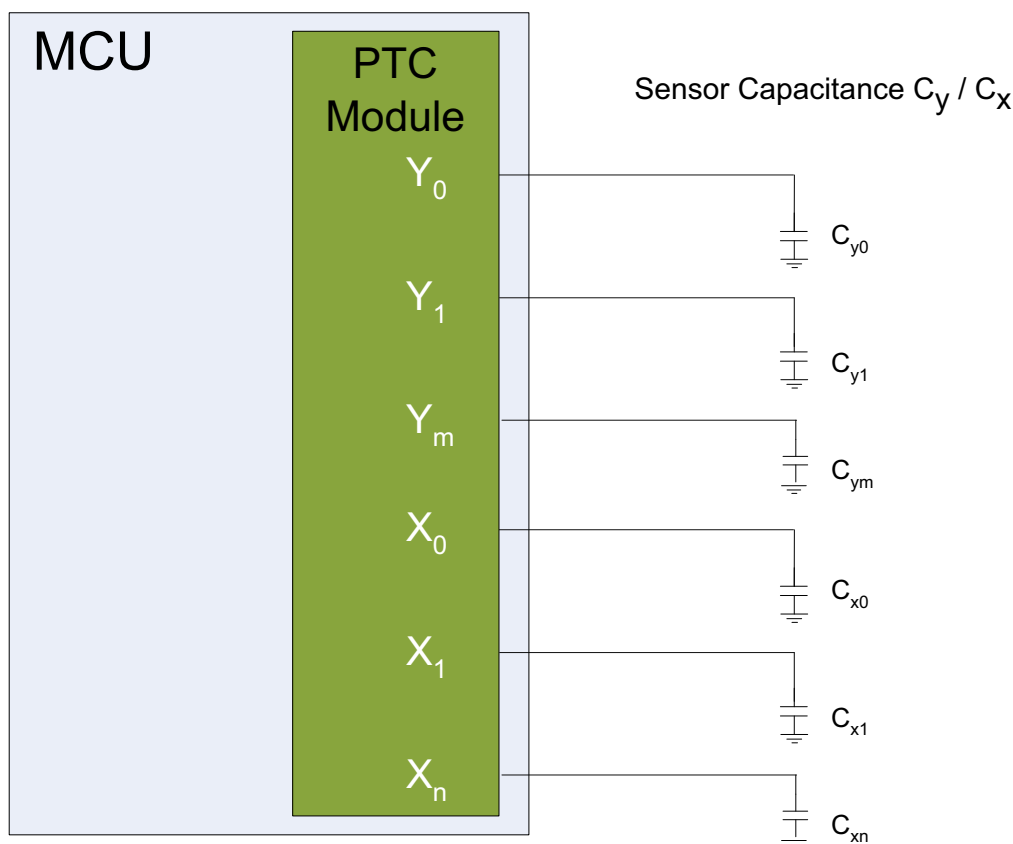

Figure 39-3. Mutual Capacitance Sensor Arrangement

## Self-capacitance Sensor Arrangement

The self-capacitance sensor is connected to a single pin on the Peripheral Touch Controller through the X or Y electrode for receiving the signal. The sense electrode capacitance is measured by the Peripheral Touch Controller.

Figure 39-4. Self-capacitance Sensor Arrangement

For more information about designing the touch sensor, refer to Buttons, Sliders and Wheels Touch Sensor Design Guide on <http://www.atmel.com>.

### 39.5.2 Clocks

The PTC is clocked by the GCLK\_PTC clock. The PTC operates from an asynchronous clock source and the operation is independent of the main system clock and its derivative clocks, such as the peripheral bus clock (CLK\_APB). A number of clock sources can be selected as the source for the asynchronous GCLK\_PTC. The clock source is selected by configuring the Generic Clock Selection ID in the Generic Clock Control register. For more information about selecting the clock sources, refer to “GCLK – Generic Clock Controller” on page 109. The frequency range of GCLK\_PTC is 400kHz to 4MHz.

The PTC bus clock (CLK\_PTC\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_PTC\_APB can be found in the Peripheral Clock Masking section in the Table 17-1.

## 39.6 Functional Description

In order to access the PTC, the user must use the QTouch Composer tool to configure and link the QTouch Library firmware with the application code. QTouch Library can be used to implement buttons, sliders, wheels and proximity sensor in a variety of combinations on a single interface.

For more information about QTouch library, refer to the [Atmel QTouch Library Peripheral Touch Controller User Guide](#).

**Figure 39-5. QTouch Library Usage**

## 40. FREQM – Frequency Meter

### 40.1 Overview

The Frequency Meter (FREQM) can be used to accurately measure the frequency of a clock by comparing it to a known reference clock.

### 40.2 Features

- Accurately measures a clock frequency
- A selectable reference clock from GCLK\_FREQM\_REF sources
- A selectable clock from GCLK\_FREQM\_MSR sources can be measured
- Ratio can be measured with 24-bit accuracy

### 40.3 Block Diagram

Figure 40-1. FREQM Block Diagram.

### 40.4 Signal Description

Not applicable.

### 40.5 Product Dependencies

In order to use this peripheral, other parts of the system must be configured correctly, as described below.

#### 40.5.1 I/O Lines

Not applicable.

## 40.5.2 Power Management

The FREQM will continue to operate in idle sleep mode where the selected source clock is running. The FREQM's interrupts can be used to wake up the device from sleep modes. Refer to the Power Manager chapter for details on the different sleep modes.

## 40.5.3 Clocks

The FREQM bus clock (CLK\_FREQM\_APB) can be enabled and disabled in the Main Clock module, and the default state of CLK\_FREQM\_APB can be found in the Peripheral Clock Masking section in the [Table 17-1](#).

Two generic clocks are used by the FREQM (GCLK\_FREQM\_REF and GCLK\_FREQM\_MSR). The reference clock (GCLK\_FREQM\_REF) is required to clock the internal reference timer while operating as a frequency reference, while the measurement clock (GCLK\_FREQM\_MSR) is required to clock a ripple counter for frequency measurement. These clocks must be configured and enabled in the generic clock controller before using the FREQM. Refer to the Generic Clock Controller chapter for details.

## 40.5.4 DMA

Not applicable.

## 40.5.5 Interrupts

The interrupt request lines are connected to the interrupt controller. Using the FREQM interrupts requires the interrupt controller to be configured first. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

## 40.5.6 Events

Not applicable

## 40.5.7 Debug Operation

When the CPU is halted in debug mode the FREQM continues normal operation. If the FREQM is configured in a way that requires it to be periodically serviced by the CPU through interrupts or similar, improper operation or data loss may result during debugging.

## 40.5.8 Register Access Protection

All registers with write-access are optionally write-protected by the peripheral access controller (PAC), except the following registers:

- Control B (CTRLB) register
- Interrupt Flag Status and Clear (INTFLAG) register
- Status (STATUS) register

Write-protection is denoted by the Write-Protected property in the register description.

Write-protection does not apply to accesses through an external debugger. Refer to the Peripheral Access Controller chapter for details.

# 40.6 Functional Description

## 40.6.1 Principle of Operation

The FREQM accurately measures the frequency of a clock by comparing the frequency to a known frequency:

$$f_{\text{CLK\_MSR}} = \left( \frac{\text{VALUE}}{\text{REFNUM}} \right) f_{\text{CLK\_REF}}$$

## 40.6.2 Basic Operation

### 40.6.2.1 Initialization

Each of the generic clocks (GCLK\_FREQM\_REF and GCLK\_FREQM\_MSR) should be configured and enabled. Please refer to Generic Clock Controller chapter for details. Note that the reference clock should be slower than the measurement clock.

The following register is enable-protected, meaning that they can only be written when the FREQM is disabled (CTRLA.ENABLE is zero):

- Configuration A (CFGA)

Enable-protection is denoted by the Enable-Protected property in the register description.

### 40.6.2.2 Enabling, Disabling and Resetting

The FREQM is enabled by writing a one to the Enable bit in the Control A register (CTRLA.ENABLE). The MODULE is disabled by writing a zero to CTRLA.ENABLE.

The FREQM is reset by writing a one to the Software Reset bit in the Control A register (CTRLA.SWRST). All registers in the FREQM will be reset to their initial state, and the FREQM will be disabled. Refer to [Control A](#) for details.

### 40.6.2.3 Measurement

In the Configuration A, the Number of Reference Clock Cycles (CFGA.REFNUM) field selects the duration of the measurement. The measurement is given in number of GCLK\_FREQM\_REF periods. Note this field must be written before the FREQM is enabled.

After the FREQM is enabled, writing a one to the START bit in Control B register (CTRLB.START) starts the measurement. The BUSY bit in Status register (STATUS.BUSY) is cleared when the measurement is done. There is also an interrupt request for measurement done. When Measurement Done bit in Interrupt Enable Set register (INTENSET.DONE) is one and a measurement is finished, Measurement Done bit in Interrupt Flag Status and Clear register (INTFLAG.DONE) will become one and an interrupt request is generated.

The result of the measurement can be read from the Value register (VALUE.VALUE). The frequency of the measured clock GCLK\_FREQM\_MSR is then:

$$f_{\text{CLK\_MSR}} = \left( \frac{\text{VALUE}}{\text{REFNUM}} \right) f_{\text{CLK\_REF}}$$

Note that overflow status (STATUS.OVF) should be checked in order to make sure the measurement result (VALUE.VALUE) is valid. In case an overflow condition occurred, the CFGA.REFNUM needs to be made smaller or a faster reference clock should be selected. Once the configuration is adjusted, clear the overflow status by writing a one to STATUS.OVF. Then write one to CTRLB.START to start another measurement.

### 40.6.3 DMA Operation

Not applicable.

### 40.6.4 Interrupts

The FREQM has one interrupt source:

- DONE: A frequency measurement is done

Each interrupt source has an interrupt flag associated with it. The interrupt flag in the Interrupt Flag Status and Clear (INTFLAG) register is set when the interrupt condition occurs. Each interrupt can be individually enabled by writing a one to the corresponding bit in the Interrupt Enable Set (INTENSET) register, and disabled by writing a one to the corresponding bit in the Interrupt Enable Clear (INTENCLR) register. An interrupt request is generated when the interrupt flag is set and the corresponding interrupt is enabled. The interrupt request remains active until the interrupt flag is

cleared, the interrupt is disabled, or the FREQM is reset. See [Interrupt Flag Status and Clear](#) for details on how to clear interrupt flags. All interrupt requests from the peripheral are ORed together on system level to generate one combined interrupt request to the NVIC. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details. The user must read the INTFLAG register to determine which interrupt condition is present.

Note that interrupts must be globally enabled for interrupt requests to be generated. Refer to [“Nested Vector Interrupt Controller” on page 27](#) for details.

#### 40.6.5 Events

Not applicable.

#### 40.6.6 Sleep Mode Operation

The FREQM will continue to operate in idle sleep mode where the selected source clock is running. The FREQM's interrupts can be used to wake up the device from sleep modes. Refer to the Power Manager chapter for details on the different sleep modes.

For lowest chip power consumption in sleep modes, FREQM should be disabled before entering a sleep mode.

#### 40.6.7 Synchronization

Due to the asynchronicity between the main clock domain (CLK\_FREQM\_APB) and the peripheral clock domain (GCLK\_FREQM) some registers are synchronized when written. When a write-synchronized register is written, the corresponding bit in the Synchronization Busy register (SYNCBUSY) is set immediately. When the write-synchronization is complete, this bit is cleared. Reading a write-synchronized register while the synchronization is ongoing will return the value written, and not the current value in the peripheral clock domain. To read the current value in the peripheral clock domain after writing a register, the user must wait for the corresponding SYNCBUSY bit to be cleared before reading the value.

If a register is written while the corresponding bit in SYNCBUSY is one, the write is discarded and an error is generated.

The following bits and registers are write-synchronized:

- Software Reset bit in Control A register (CTRLA.SWRST)
- Enable bit in Control A register (CTRLA.ENABLE)

Write-synchronization is denoted by the Write-Synchronized property in the register description.

Refer to the Synchronization chapter for further details.

## 40.7 Register Summary

| Offset | Name     | Bit pos. |              |  |  |  |  |  |        |       |
|--------|----------|----------|--------------|--|--|--|--|--|--------|-------|
| 0x00   | CTRLA    | 7:0      |              |  |  |  |  |  | ENABLE | SWRST |
| 0x01   | CTRLB    | 7:0      |              |  |  |  |  |  |        | START |
| 0x02   | CFGA     | 7:0      | REFNUM[7:0]  |  |  |  |  |  |        |       |
| 0x03   |          | 15:8     |              |  |  |  |  |  |        |       |
| 0x04   | Reserved | 31:0     |              |  |  |  |  |  |        |       |
| 0x08   | INTENCLR | 7:0      |              |  |  |  |  |  |        | DONE  |
| 0x09   | INTENSET | 7:0      |              |  |  |  |  |  |        | DONE  |
| 0x0A   | INTFLAG  | 7:0      |              |  |  |  |  |  |        | DONE  |
| 0x0B   | STATUS   | 7:0      |              |  |  |  |  |  | OVF    | BUSY  |
| 0x0C   | SYNCBUSY | 7:0      |              |  |  |  |  |  | ENABLE | SWRST |
| 0x0D   |          | 15:8     |              |  |  |  |  |  |        |       |
| 0x0E   |          | 23:16    |              |  |  |  |  |  |        |       |
| 0x0F   |          | 31:24    |              |  |  |  |  |  |        |       |
| 0x10   | VALUE    | 7:0      | VALUE[7:0]   |  |  |  |  |  |        |       |
| 0x11   |          | 15:8     | VALUE[15:8]  |  |  |  |  |  |        |       |
| 0x12   |          | 23:16    | VALUE[23:16] |  |  |  |  |  |        |       |
| 0x13   |          | 31:24    |              |  |  |  |  |  |        |       |

## 40.8 Register Description

Registers can be 8, 16, or 32 bits wide. Atomic 8-, 16- and 32-bit accesses are supported. In addition, the 8-bit quarters and 16-bit halves of a 32-bit register, and the 8-bit halves of a 16-bit register can be accessed directly.

Some registers are optionally write-protected by the Peripheral Access Controller (PAC). Write-protection is denoted by the Write-Protected property in each individual register description. Please refer to [“Register Access Protection” on page 889](#) for details.

Some registers require synchronization when read and/or written. Synchronization is denoted by the Write-Synchronized or the Read-Synchronized property in each individual register description. Please refer to [“Synchronization” on page 891](#) for details.

Some registers are enable-protected, meaning they can only be written when the FREQM is disabled. Enable-protection is denoted by the Enable-Protected property in each individual register description.

### 40.8.1 Control A

**Name:** CTRLA

**Offset:** 0x00

**Access:** Read/Write

**Reset:** 0x00

**Property:** Write-Protected, Write-Synchronized (ENABLE, SWRST), Read-Synchronized

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0     |
|--------|---|---|---|---|---|---|--------|-------|
|        |   |   |   |   |   |   | ENABLE | SWRST |
| Access | R | R | R | R | R | R | R/W    | R/W   |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0      | 0     |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

0: The peripheral is disabled.

1: The peripheral is enabled.

Due to synchronization there is delay from writing CTRLA.ENABLE until the peripheral is enabled/disabled. The value written to CTRLA.ENABLE will read back immediately and the ENABLE bit in the Synchronization Busy register (SYNCBUSY.ENABLE) will be set. SYNCBUSY.ENABLE will be cleared when the operation is complete.

This bit is not enable-protected.

- **Bit 0 – SWRST: Software Reset**

0: There is no reset operation ongoing.

1: The reset operation is ongoing.

Writing a zero to this bit has no effect.

Writing a one to this bit resets all registers in the FREQM to their initial state, and the FREQM will be disabled.

For all modules:

Writing a one to CTRLA.SWRST will always take precedence, meaning that all other writes in the same write-operation will be discarded.

Due to synchronization there is a delay from writing CTRLA.SWRST until the reset is complete. CTRLA.SWRST and SYNCBUSY.SWRST will both be cleared when the reset is complete.

This bit is not enable-protected.

40.8.2 Control B

**Name:** CTRLB  
**Offset:** 0x01  
**Access:** Write Only  
**Reset:** 0x00  
**Property:** –

|        |   |   |   |   |   |   |   |       |
|--------|---|---|---|---|---|---|---|-------|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|        |   |   |   |   |   |   |   | START |
| Access | R | R | R | R | R | R | R | W     |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0     |

- Bits 7:1 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 – START: Start Measurement**  
0: Writing a zero to this bit has no effect.  
1: Writing a one to this bit starts a measurement

### 40.8.3 Configuration A

**Name:** CFGA

**Offset:** 0x02

**Access:** Read/Write

**Reset:** 0x0000

**Property:** Write-Protected, Enable-protected

| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
|        |             |     |     |     |     |     |     |     |
| Access | R           | R   | R   | R   | R   | R   | R   | R   |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | REFNUM[7:0] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

- **Bits 15:8 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bits 7:0 – REFNUM[7:0]: Number of Reference Clock Cycles**

Selects the duration of a measurement, given number of CLK\_FREQM\_REF cycles. This must be a non-zero value.

40.8.4 Interrupt Enable Clear

This register allows the user to disable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Set (INTENSET) register.

**Name:** INTENCLR  
**Offset:** 0x08  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** Write-Protected

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0    |
|--------|---|---|---|---|---|---|---|------|
|        |   |   |   |   |   |   |   | DONE |
| Access | R | R | R | R | R | R | R | R/W  |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0    |

- Bits 7:1 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 – DONE: Measurement Done Interrupt Enable**  
0: The Measurement Done interrupt is disabled.  
1: The Measurement Done interrupt is enabled.  
Writing a zero to this bit has no effect.  
Writing a one to this bit will clear the Measurement Done Interrupt Enable bit, which disables the Measurement Done interrupt.

40.8.5 Interrupt Enable Set

This register allows the user to enable an interrupt without doing a read-modify-write operation. Changes in this register will also be reflected in the Interrupt Enable Clear (INTENCLR) register.

**Name:** INTENSET  
**Offset:** 0x09  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** Write-Protected

|        |   |   |   |   |   |   |   |      |
|--------|---|---|---|---|---|---|---|------|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0    |
|        |   |   |   |   |   |   |   | DONE |
| Access | R | R | R | R | R | R | R | R/W  |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0    |

- Bits 7:1 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 – DONE: Measurement Done Interrupt Enable**  
0: The Measurement Done interrupt is disabled.  
1: The Measurement Done interrupt is enabled.  
Writing a zero to this bit has no effect.  
Writing a one to this bit will set the Measurement Done Interrupt Enable bit, which enables the Measurement Done interrupt.

40.8.6 Interrupt Flag Status and Clear

**Name:** INTFLAG  
**Offset:** 0x0A  
**Access:** Read/Write  
**Reset:** 0x00  
**Property:** –

|        |   |   |   |   |   |   |   |      |
|--------|---|---|---|---|---|---|---|------|
| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0    |
|        |   |   |   |   |   |   |   | DONE |
| Access | R | R | R | R | R | R | R | R/W  |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0    |

- Bits 7:1 – Reserved**  
These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- Bit 0 – DONE: Mesurement Done**  
This flag is cleared by writing a one to it.  
This flag is set when the STATUS.BUSY bit has a one to zero transition.  
Writing a zero to this bit has no effect.  
Writing a one to this bit will clear the DONE interrupt flag.

#### 40.8.7 Status

**Name:** STATUS

**Offset:** 0x0B

**Access:** Refer to table below

**Reset:** 0x00

**Property:** –

| Bit    | 7 | 6 | 5 | 4 | 3 | 2 | 1          | 0           |
|--------|---|---|---|---|---|---|------------|-------------|
|        |   |   |   |   |   |   | <b>OVF</b> | <b>BUSY</b> |
| Access | R | R | R | R | R | R | R/W        | R           |
| Reset  | 0 | 0 | 0 | 0 | 0 | 0 | 0          | 0           |

- **Bits 7:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – OVF: Sticky Count Value Overflow**

This bit is cleared by writing a one to it.

This bit is set when an overflow condition occurs to the value counter.

Writing a zero to this bit has no effect.

Writing a one to this bit will clear the OVF status.

- **Bit 0 – BUSY: FREQM Status**

0: The FREQM module is idle.

1: Frequency measurement is on-going.

#### 40.8.8 Synchronization Busy

**Name:** SYNCBUSY

**Offset:** 0x0C

**Access:** Read Only

**Reset:** 0x00000000

**Property:** –

|        |    |    |    |    |    |    |        |       |
|--------|----|----|----|----|----|----|--------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25     | 24    |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18 | 17     | 16    |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10 | 9      | 8     |
|        |    |    |    |    |    |    |        |       |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2  | 1      | 0     |
|        |    |    |    |    |    |    | ENABLE | SWRST |
| Access | R  | R  | R  | R  | R  | R  | R      | R     |
| Reset  | 0  | 0  | 0  | 0  | 0  | 0  | 0      | 0     |

- **Bits 31:2 – Reserved**

These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.

- **Bit 1 – ENABLE: Enable**

This bit is cleared when the synchronization of CTRLA.ENABLE is complete.

This bit is set when the synchronization of CTRLA.ENABLE is started.

- **Bit 0 – SWRST: Synchronization Busy**

This bit is cleared when the synchronization of CTRLA.SWRST is complete.

This bit is set when the synchronization of CTRLA.SWRST is started.

#### 40.8.9 Value

**Name:** VALUE  
**Offset:** 0x10  
**Access:** Read Only  
**Reset:** 0x00000000  
**Property:** –

- **Bits 31:24 – Reserved**  
 These bits are unused and reserved for future use. For compatibility with future devices, always write these bits to zero when this register is written. These bits will always return zero when read.
- **Bit 23:0 – VALUE: Measurement Value**  
 Result from measurement.

## 41. Electrical Characteristics

### 41.1 Disclaimer

All values in this chapter are preliminary and subject to change without further notice.

All typical values are measured at  $T = 25^{\circ}\text{C}$  unless otherwise specified. All minimum and maximum values are valid across operating temperature and voltage unless otherwise specified.

### 41.2 Absolute Maximum Ratings

Stresses beyond those listed in [Table 41-1](#) may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Table 41-1. Absolute maximum ratings**

| Symbol        | Parameter                                    | Condition | Min.     | Max.                   | Units              |
|---------------|--|-----------|----------|------------------------|--------------------|
| $V_{DD}$      | Power supply voltage                         |           | 0        | 5.5                    | V                  |
| $I_{VDD}$     | Current into a $V_{DD}$ pin                  |           | –        | 92                     | mA                 |
| $I_{GND}$     | Current out of a GND pin                     |           | –        | 130                    | mA                 |
| $V_{PIN}$     | Pin voltage with respect to GND and $V_{DD}$ |           | GND-0.3V | $V_{DD} + 0.3\text{V}$ | V                  |
| $T_{STORAGE}$ | Storage temperature                          |           | -60      | 150                    | $^{\circ}\text{C}$ |

### 41.3 General Operating Ratings

The device must operate within the ratings listed in [Table 41-3](#) in order for all other electrical characteristics and typical characteristics of the device to be valid.

**Table 41-3. General operating conditions**

| Symbol      | Parameter             | Condition | Min.               | Typ. | Max. | Units |
|-------------|-----------------------|-----------|--------------------|------|------|-------|
| $V_{DDIN}$  | Power supply voltage  |           | 2.7 <sup>(1)</sup> | 5.0  | 5.5  | V     |
| $V_{DDANA}$ | Analog supply voltage |           | 2.7 <sup>(1)</sup> | 5.0  | 5.5  | V     |
| $V_{DDIO}$  | IO supply voltage     |           | 2.7 <sup>(1)</sup> | 5.0  | 5.5  | V     |
| $T_A$       | Temperature range     |           | -40                | 25   | 105  | °C    |
| $T_J$       | Junction temperature  |           | –                  | –    | 125  | °C    |

Note: 1. With BODVDD disabled. If the BODVDD is enabled, check [Table 41-14](#)

## 41.4 Supply Characteristics

The following characteristics are applicable to the operating temperature range:  $T_A = -40^{\circ}\text{C}$  to  $105^{\circ}\text{C}$ , unless otherwise specified and are valid for a junction temperature up to  $T_J = 125^{\circ}\text{C}$ . Refer to [“Power Supply and Start-Up Considerations” on page 17](#).

**Table 41-4. Supply Characteristics**

| Symbol                                  | Conditions         | Voltage |      |       |
|---|--------------------|---------|------|-------|
|   |                    | Min.    | Max. | Units |
| $V_{DDIO}$<br>$V_{DDIN}$<br>$V_{DDANA}$ | Full Voltage Range | 2.7     | 5.5  | V     |

**Table 41-5. Supply Rise Rates**

| Symbol      | Parameter   | Rise Rate | Units            |
|-------------|---|-----------|------------------|
|             |   | Max.      |                  |
| $V_{DDIO}$  | DC supply peripheral I/Os, internal regulator and analog supply | 0.1       | V/ $\mu\text{s}$ |
| $V_{DDIN}$  |   | 0.1       |                  |
| $V_{DDANA}$ |   | 0.1       |                  |

## 41.5 Maximum Clock Frequencies

**Table 41-6. Maximum GCLK Generator Output Frequencies**

| Symbol                          | Condition | Max. | Units |
|---------------------------------|-----------|------|-------|
| $f_{GCLKGEN0} / f_{GCLK\_MAIN}$ | Undivided | 96   | MHz   |
| $f_{GCLKGEN1}$                  |           |      |       |
| $f_{GCLKGEN2}$                  |           |      |       |
| $f_{GCLKGEN3}$                  | Divided   | 66   | MHz   |
| $f_{GCLKGEN4}$                  |           |      |       |
| $f_{GCLKGEN5}$                  |           |      |       |
| $f_{GCLKGEN6}$                  |           |      |       |
| $f_{GCLKGEN7}$                  |           |      |       |
| $f_{GCLKGEN8}$                  |           |      |       |

**Table 41-7. Maximum Peripheral Clock Frequencies**

| Symbol                               | Description                              | Max. | Units |
|--------------------------------------|--|------|-------|
| $f_{\text{CPU}}$                     | CPU clock frequency                      | 48   | MHz   |
| $f_{\text{AHB}}$                     | AHB clock frequency                      | 48   | MHz   |
| $f_{\text{APBA}}$                    | APBA clock frequency                     | 48   | MHz   |
| $f_{\text{APBB}}$                    | APBB clock frequency                     | 48   | MHz   |
| $f_{\text{APBC}}$                    | APBC clock frequency                     | 48   | MHz   |
| $f_{\text{GCLK\_DPLL}}$              | FDPLL96M Reference clock frequency       | 2    | MHz   |
| $f_{\text{GCLK\_DPLL\_32K}}$         | FDPLL96M 32k Reference clock frequency   | 32   | kHz   |
| $f_{\text{GCLK\_EIC}}$               | EIC input clock frequency                | 48   | MHz   |
| $f_{\text{GCLK\_FREQM\_MSR}}$        | FREQM Measure                            | 48   | MHz   |

| $f_{\text{GCLK\_EVSYS\_CHANNEL\_0}}$ | EVSYS channel 0 input clock frequency    | 48   | MHz   |
| $f_{\text{GCLK\_EVSYS\_CHANNEL\_1}}$ | EVSYS channel 1 input clock frequency    | 48   | MHz   |
| $f_{\text{GCLK\_EVSYS\_CHANNEL\_2}}$ | EVSYS channel 2 input clock frequency    | 48   | MHz   |
| $f_{\text{GCLK\_EVSYS\_CHANNEL\_3}}$ | EVSYS channel 3 input clock frequency    | 48   | MHz   |
| $f_{\text{GCLK\_EVSYS\_CHANNEL\_4}}$ | EVSYS channel 4 input clock frequency    | 48   | MHz   |
| $f_{\text{GCLK\_EVSYS\_CHANNEL\_5}}$ | EVSYS channel 5 input clock frequency    | 48   | MHz   |
| $f_{\text{GCLK\_SERCOMx\_SLOW}}$     | Common SERCOM slow input clock frequency | 5    | MHz   |
| $f_{\text{GCLK\_SERCOM0\_CORE}}$     | SERCOM0 input clock frequency            | 48   | MHz   |
| $f_{\text{GCLK\_SERCOM1\_CORE}}$     | SERCOM1 input clock frequency            | 48   | MHz   |
| $f_{\text{GCLK\_SERCOM2\_CORE}}$     | SERCOM2 input clock frequency            | 48   | MHz   |
| $f_{\text{GCLK\_SERCOM3\_CORE}}$     | SERCOM3 input clock frequency            | 48   | MHz   |
| $f_{\text{GCLK\_TCC0}}$              | TCC0 input clock frequency               | 96   | MHz   |
| $f_{\text{GCLK\_TCn}}$               | TCn input clock frequency                | 48   | MHz   |
| $f_{\text{GCLK\_ADCn}}$              | ADCn input clock frequency               | 48   | MHz   |
| $f_{\text{GCLK\_PTC}}$               | PTC input clock frequency                | 48   | MHz   |
| $f_{\text{GCLK\_CCL}}$               | CCL input clock frequency                | 48   | MHz   |
| $f_{\text{GCLK\_AC}}$                | AC digital input clock frequency         | 48   | MHz   |

## 41.6 Power Consumption

The values in [Table 41-8](#) are measured values of power consumption under the following conditions, except where noted:

- Operating conditions
  - $V_{DDIN} = 3.3V, 5.0V$
- Wake up time from sleep mode is measured from the edge of the wakeup signal to the first instruction fetched in flash.
- Oscillators
  - XOSC (crystal oscillator) stopped
  - XOSC32K (32kHz crystal oscillator) running with external 32kHz crystal
  - FDPLL using XOSC32K as reference and running at 48MHz
- Clocks
  - FDPLL used as main clock source, except otherwise specified
  - CPU, AHB clocks undivided
  - APBA clock divided by 4
  - APBB and APBC bridges off
  - The AHB module clocks are running
    - NVMCTRL, APBA bridge
    - All other AHB clocks are stopped
  - The following peripheral clocks are running
    - PM, SYSCTRL, RTC
    - All other peripheral clocks are stopped
- I/Os are inactive with internal pull-up
- CPU is running on flash with 1 wait state
- NVMCTRL cache enabled
- BODVDD disabled

**Table 41-8. Current Consumption**

| Mode   | Condition   | T <sub>A</sub> | V <sub>CC</sub> | Typ. | Max. | Units                    |
|--------|---|----------------|-----------------|------|------|--------------------------|
| ACTIVE | CPU running a While 1 algorithm                                   | 25°C           | 5.0V            | 3.4  |      | mA                       |

## 41.8.2 Brown Out Detectors Characteristics

### 41.8.2.1 BODVDD

Table 41-14. BOD LEVEL Values<sup>(1)(2)</sup>

| BODVDD.LEVEL | Condition                             | Min. | Typ. | Max. | Units |
|--------------|---------------------------------------|------|------|------|-------|
| All levels   | Hysteresis ON                         | 2.45 |      | 5.5  | V     |
| 4            |                                       |      | 2.7  |      |       |
| 42           |                                       |      | 4.5  |      |       |
| All levels   | Hysteresis ON<br>or<br>Hysteresis OFF | 2.4  |      | 5.4  |       |
| 4            |                                       |      | 2.6  |      |       |
| 42           |                                       |      | 4.5  |      |       |

Notes: 1. See chapter Memories table “NVM User Row Mapping” on page 24 for the BODVDD default value settings.

2. These values are based on simulation. These values are not covered by test limits in production or characterization.

**Figure 41-2. BODVDD Hysteresis OFF**

**Figure 41-3. BODVDD Hysteresis ON**

**Table 41-15. BODVDD Characteristics<sup>(1)</sup>**

| Symbol        | Parameter   | Conditions   | Min. | Typ. | Max. | Units   |
|---------------|---|--|------|------|------|---------|
|               | Step size, between adjacent values in BODVDDLEVEL |  |      | 47   |      | mV      |
| $V_{HYST}$    | $VBOD+ - VBOD-$                                   | Hysteresis ON  | 44   |      | 96   | mV      |
| $t_{DET}$     | Detection time                                    | Time with $V_{DDIN} < V_{TH}$ necessary to generate a reset signal |      | TBD  |      | $\mu s$ |
| $I_{BOD33}$   | Current consumption                               | Continuous mode  |      | TBD  |      | $\mu A$ |
|               |   | Sampling mode  |      | TBD  |      | $\mu A$ |
| $t_{STARTUP}$ | Startup time                                      |  |      |      | 3.1  | $\mu s$ |

Note: 1. These values are based on simulation. These values are not covered by test limits in production or characterization.

### 41.8.3 LDO Regulator Characteristics

**Table 41-16. LDO Regulator Characteristics**

| Symbol  | Parameter                    | Min. | Typ. | Max. | Units |
|---------|------------------------------|------|------|------|-------|
| VDDIN   | Input voltage range          | 2.7  |      | 5.5  | V     |
| VDDCORE | DC calibrated output voltage |      | 1.23 |      | V     |

**Table 41-17. Decoupling Requirements**

| Symbol | Parameter                  | Conditions         | Min. | Typ. | Max. | Units |
|--------|----------------------------|--------------------|------|------|------|-------|
| Cin    | Input regulator capacitor  | tantalum           | -    | 1    | -    | μF    |
|        |                            | ceramic dielectric | -    | 100  | -    | nF    |
| Cout   | Output regulator capacitor | tantalum           | -    | 1    | -    | μF    |
|        |                            | ceramic dielectric | -    | 100  | -    | nF    |

#### 41.8.4 Analog-to-Digital (ADC) Characteristics

**Table 41-18. Operation Conditions<sup>(1)</sup>**

| Symbol              | Parameter                  | Condition          | Min.       | Typ.  | Max.       | Units |
|---------------------|----------------------------|--------------------|------------|-------|------------|-------|
| Res                 | Resolution                 |                    |            | -     | 12         | bits  |
|                     | Conversion speed           |                    | 10         | -     | 1000       | ksps  |

|                      |                              | Enable to ready delay<br>Low power mode                      |      | 6    |        | μs    |

## 41.8.6 Bandgap Reference Characteristics

**Table 41-22. Internal Voltage Reference Characteristics**

| Symbol  | Parameter                         | Conditions  | Min. | Typ.  | Max. | Units |
|---------|-----------------------------------|---|------|-------|------|-------|
| ADC Ref | ADC0, ADC1, AC Internal reference | After calibration at T= 25°C, over [-40, +85]°C. VREF.SEL = 0 |      | 1.024 |      | V     |
|         |                                   | After calibration at T= 25°C, over [-40, +85]°C. VREF.SEL = 2 |      | 2.048 |      |       |
|         |                                   | After calibration at T= 25°C, over [-40, +85]°C. VREF.SEL = 3 |      | 4.096 |      |       |
|         |                                   | Over voltage at 25°C  |      | TBD   |      |       |

## 41.9 NVM Characteristics

Table 41-23. Maximum Operation Frequency<sup>(1)</sup>

| VDD Range    | NVM Wait States | Maximum Operating Frequency | Units |
|--------------|-----------------|-----------------------------|-------|
| 2.7V to 5.5V | 0               | 16                          | MHz   |
|              | 1               | 32                          |       |
|              | 2               | 48                          |       |
|              | 3               | 48                          |       |

Note: 1. Based on simulation.

Note that on this flash technology, a max number of 8 consecutive write is allowed per row. Once this number is reached, a row erase is mandatory.

## 41.10 Oscillator Characteristics

### 41.10.1 Crystal Oscillator (XOSC) Characteristics

#### 41.10.1.1 Digital Clock Characteristics

The following table describes the characteristics for the oscillator when a digital clock is applied on XIN.

**Table 41-24. Digital Clock Characteristics**

| Symbol             | Parameter            | Condition    | Min | Typ | Max | Units |
|--------------------|----------------------|--------------|-----|-----|-----|-------|
| f <sub>CPXIN</sub> | XIN clock frequency  | Digital mode | -   | -   | 48  | MHz   |
| DC <sub>XIN</sub>  | XIN clock duty cycle | Digital mode | 40  | 50  | 60  | %     |

#### 41.10.1.2 Crystal Oscillator Characteristics

The following table describes the characteristics for the oscillator when a crystal is connected between XIN and XOUT as shown in [Figure 41-4](#). The user must choose a crystal oscillator where the crystal load capacitance C<sub>L</sub> is within the range given in the table. The exact value of C<sub>L</sub> can be found in the crystal datasheet. The capacitance of the external capacitors (C<sub>LEXT</sub>) can then be computed as follows:

$$C_{LEXT} = 2(C_L - C_{STRAY} - C_{SHUNT})$$

where C<sub>STRAY</sub> is the capacitance of the pins and PCB, C<sub>SHUNT</sub> is the shunt capacitance of the crystal.

**Table 41-25. Crystal Oscillator Characteristics**

| Symbol | Parameter                                     | Conditions                                 | Min. | Typ. | Max.               | Units |
|--------|---|--|------|------|--------------------|-------|
| Fout   | Crystal oscillator frequency                  |  | 0.4  | -    | 32                 | MHz   |
| ESR    | Crystal Equivalent Series Resistance - SF = 3 | f = 0.455 MHz, CL = 100pF<br>XOSC.GAIN = 0 | -    | -    | 663 <sup>(1)</sup> | Ω     |

Note: 1. These values are based on simulation. These values are not covered by test limits in production or characterization.

**Figure 41-4. Oscillator Connection**

## 41.10.2 External 32kHz Crystal Oscillator (XOSC32K) Characteristics

### 41.10.2.1 Digital Clock Characteristics

The following table describes the characteristics for the oscillator when a digital clock is applied on XIN32 pin.

**Table 41-26. Digital Clock Characteristics**

| Symbol        | Parameter              | Condition    | Min | Typ    | Max | Units |
|---------------|------------------------|--------------|-----|--------|-----|-------|
| $f_{CPXIN32}$ | XIN32 clock frequency  | Digital mode |     | 32.768 |     | MHz   |
| $DC_{XIN32}$  | XIN32 clock duty cycle | Digital mode |     | 50     |     | %     |

### 41.10.2.2 Crystal Oscillator Characteristics

Figure 41-4 and the equation above also applies to the 32kHz oscillator connection. The user must choose a crystal oscillator where the crystal load capacitance  $C_L$  is within the range given in the table. The exact value of  $C_L$  can then be found in the crystal datasheet.

**Table 41-27. 32kHz Crystal Oscillator Characteristics**

| Symbol        | Parameter   | Condition                           | Min | Typ   | Max  | Units      |
|---------------|---|-------------------------------------|-----|-------|------|------------|
| $f_{OUT}$     | Crystal oscillator frequency  |                                     |     | 32768 |      | Hz         |
| $t_{STARTUP}$ | Startup time  | $R_m = 100k\Omega$ , $C_L = 12.5pF$ |     | 28K   |      | cycles     |
| $C_L$         | Crystal load capacitance  |                                     |     |       | 12.5 | pF         |
| $C_{SHUNT}$   | Crystal shunt capacitance   |                                     |     | 0.1   |      |            |
| $C_{XIN32}$   | Parasitic capacitor load  | TQFP64:48 package                   |     | 3.1   |      |            |
| $C_{XOUT32}$  | Parasitic capacitor load  |                                     |     | 3.3   |      |            |
| $I_{OSC32K}$  | Current consumption   |                                     |     | 1.5   |      | nA         |
| ESR           | Crystal equivalent series resistance $f=32.768kHz$<br>Safety Factor = 3 | $C_L=12.5pF$                        |     | 290   |      | k $\Omega$ |

### 41.10.3 Digital Phase Locked Loop (DPLL) Characteristics

**Table 41-28. Fractional Digital Phase Locked Loop Characteristics**

| Symbol        | Parameter           | Conditions  | Min. | Typ.               | Max. | Units   |
|---------------|---------------------|---|------|--------------------|------|---------|

**Table 41-31. Internal 48MHz RC Oscillator Characteristics**

| Symbol   | Parameter                                  | Conditions  | Min. | Typ. | Max. | Units |
|----------|--|-------------|------|------|------|-------|
| Fout     | Output frequency                           |             |      | 48   |      | MHz   |
| TempCo   | Freq vs temperature drift                  |             |      |      |      | %     |
| SupplyCo | Freq vs supply drift                       |             |      |      |      |       |
| Iosc48m  | Current consumption                        |             |      | 200  |      | uA    |
| Twup     | Wake up time - 1st clock edge after enable |             |      |      | 7    | us    |
| Tstart   | Startup time                               | 95% of Fout |      |      | 15   | us    |
| Duty     | Duty Cycle                                 |             |      | 50   |      | %     |

## 41.11 Timing Characteristics

Note: 1.

### 41.11.1 External Reset

Table 41-32. External Reset Characteristics

| Symbol    | Parameter                 | Min. | Typ. | Max. | Units |
|-----------|---------------------------|------|------|------|-------|
| $t_{EXT}$ | Minimum reset pulse width | 10   |      |      | ns    |

## 42. Packaging Information

### 42.1 Thermal Considerations

#### 42.1.1 Thermal Resistance Data

Table 6-1 on page 13 summarizes the thermal resistance data depending on the package.

Table 42-1. Thermal Resistance Data

| Package Type | $\theta_{JA}$ | $\theta_{JC}$ |
|--------------|---------------|---------------|
| 32-pin TQFP  | 68 °C/W       | 25.8 °C/W     |
| 48-pin TQFP  | 78.8 °C/W     | 12.3 °C/W     |
| 64-pin TQFP  | 66.7 °C/W     | 11.9 °C/W     |
| 32-pin QFN   | 37.2 °C/W     | 3.1 °C/W      |
| 48-pin QFN   | 33 °C/W       | 11.4 °C/W     |
| 64-pin QFN   | 33.5 °C/W     | 11.2 °C/W     |

#### 42.1.2 Junction Temperature

The average chip-junction temperature,  $T_J$ , in °C can be obtained from the following:

1.  $T_D = T_A + (P_D \times \theta_{JA})$
2.  $T_D = T_A + (P_D \times (\theta_{HEATSINK} + \theta_{JC}))$

where:

- $\theta_{JA}$  = package thermal resistance, Junction-to-ambient (°C/W), provided in Table 6-1 on page 13.
- $\theta_{JC}$  = package thermal resistance, Junction-to-case thermal resistance (°C/W), provided in Table 6-1 on page 13.
- $\theta_{HEATSINK}$  = cooling device thermal resistance (°C/W), provided in the device datasheet.
- $P_D$  = device power consumption (W).
- $T_A$  = ambient temperature (°C).

From the first equation, the user can derive the estimated lifetime of the chip and decide if a cooling device is necessary or not. If a cooling device is to be fitted on the chip, the second equation should be used to compute the resulting average chip-junction temperature  $T_J$  in °C.

## 42.3 Soldering Profile

The following table gives the recommended soldering profile from J-STD-20.

| Profile Feature                            | Green Package |
|--|---------------|
| Average Ramp-up Rate (217°C to peak)       | 3°C/s max     |
| Preheat Temperature 175°C +/-25°C          | 150-200°C     |
| Time Maintained Above 217°C                | 60-150s       |
| Time within 5°C of Actual Peak Temperature | 30s           |
| Peak Temperature Range                     | 260°C         |
| Ramp-down Rate                             | 6°C/s max     |
| Time 25°C to Peak Temperature              | 8 minutes max |

A maximum of three reflow passes is allowed per component.

## 43. Schematic Checklist

### 43.1 Introduction

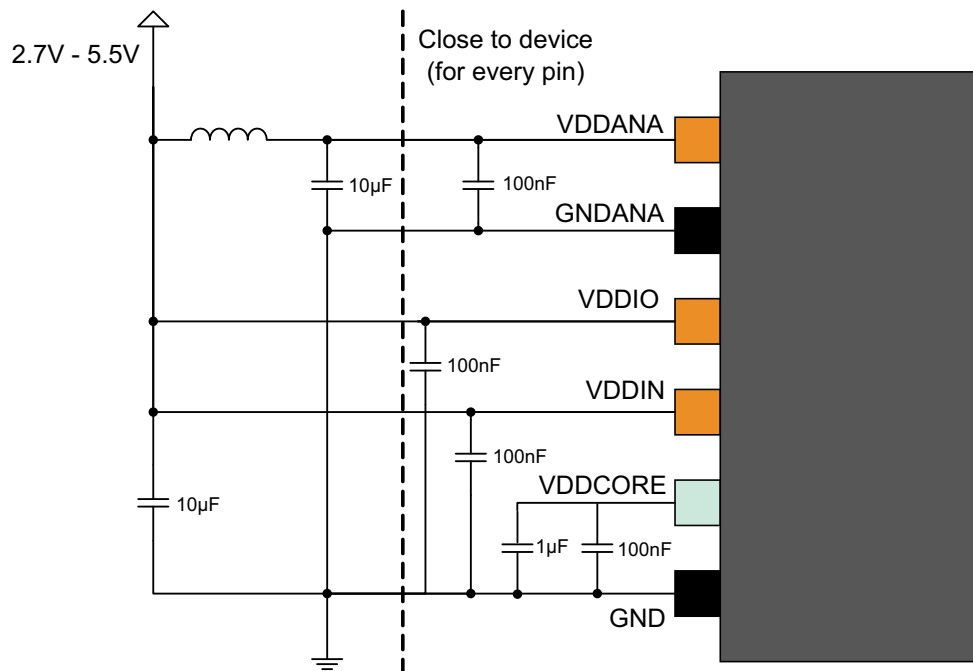

This chapter describes a common checklist which should be used when starting and reviewing the schematics for a SAM C20 design. This chapter illustrates a recommended power supply connection, how to connect external analog references, programmer, debugger, oscillator and crystal.

### 43.2 Power Supply

The SAM C20 supports a single power supply or dual power supplies from 2.7 to 5.5V.

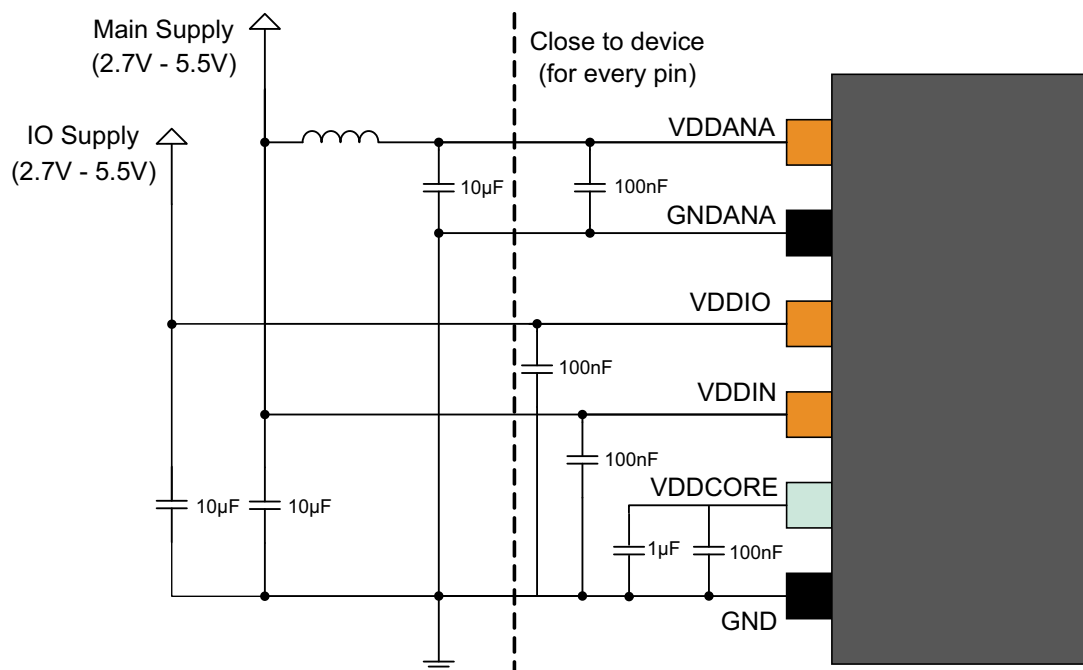

#### 43.2.1 Power Supply Connections

Figure 43-1. Single Power Supply Schematic

**Figure 43-2. Dual Power Supply Schematic**

**Table 43-1. Power Supply Connections,  $V_{DDCORE}$  From Internal Regulator**

| Signal Name  | Recommended Pin Connection   | Description                                   |
|--------------|--|---|
| $V_{DDIN}$   | 2.7V to 5.5V<br>Decoupling/filtering capacitors 100nF <sup>(1)(2)</sup> and 10µF <sup>(1)</sup><br>Decoupling/filtering inductor 10µH <sup>(1)(3)</sup>                                | Digital supply voltage                        |
| $V_{DDIO}$   | 2.7V to 5.5V<br>Decoupling/filtering capacitors 100nF <sup>(1)(2)</sup> and 10µF <sup>(1)</sup><br>Decoupling/filtering inductor 10µH <sup>(1)(3)</sup>                                | IO supply voltage                             |
| $V_{DDANA}$  | 2.7V to 5.5V<br>Decoupling/filtering capacitors 100nF <sup>(1)(2)</sup> and 10µF <sup>(1)</sup><br>Ferrite bead <sup>(4)</sup> prevents the $V_{DD}$ noise interfering the $V_{DDANA}$ | Analog supply voltage                         |
| $V_{DDCORE}$ | 1.1V to 1.3V<br>Decoupling/filtering capacitor 100nF <sup>(1)(2)</sup>   | Core supply voltage / external decoupling pin |
| GND          |  | Ground  |
| $GND_{ANA}$  |  | Ground for the analog power domain            |

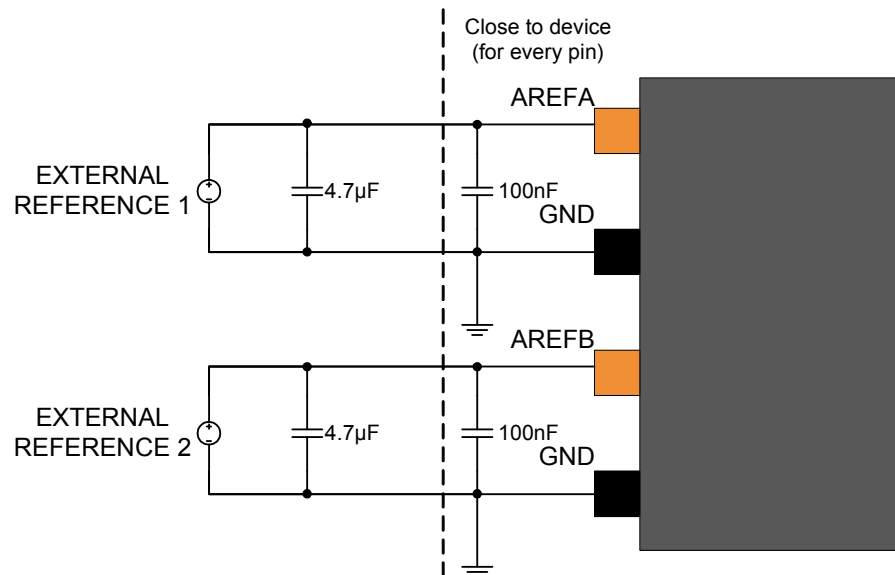

- Notes:
1. These values are only given as typical examples.
  2. Decoupling capacitor should be placed close to the device for each supply pin pair in the signal group, low ESR caps should be used for better decoupling.
  3. An inductor should be added between the external power and the  $V_{DD}$  for power filtering.
  4. Ferrite bead has better filtering performance than the common inductor at high frequencies. It can be added between  $V_{DD}$  and  $V_{DDANA}$  for preventing digital noise from entering the analog power domain. The bead should provide enough impedance (e.g. 50Ω at 20MHz and 220Ω at 100MHz) for separating the digital

power from the analog power domain. Make sure to select a ferrite bead designed for filtering applications with a low DC resistance to avoid a large voltage drop across the ferrite bead.

### 43.3 External Analog Reference Connections

The following schematic checklist is only necessary if the application is using one or more of the external analog references. If the internal references are used instead, the following circuits in [Figure 43-3](#) and [Figure 43-4](#) are not necessary.

**Figure 43-3. External Analog Reference Schematic With Two References**

**Figure 43-4. External Analog Reference Schematic With One Reference**

**Table 43-2. External Analog Reference Connections**

| Signal Name | Recommended Pin Connection  | Description  |
|-------------|---|--|
| VREFA       | 1.0V to $V_{DDANA} - 0.6V$ for ADC<br>Decoupling/filtering capacitors<br>100nF <sup>(1)(2)</sup> and 4.7µF <sup>(1)</sup> | External reference from VREFA pin on the analog port |
| GND         |   | Ground   |

- Notes:
1. These values are given as a typical example.
  2. Decoupling capacitor should be placed close to the device for each supply pin pair in the signal group.

### 43.4 External Reset Circuit

The external reset circuit is connected to the  $\overline{\text{RESET}}$  pin when the external reset function is used. If the external reset function has been disabled, the circuit is not necessary. The reset switch can also be removed, if the manual reset is not necessary. The  $\overline{\text{RESET}}$  pin itself has an internal pull-up resistor, hence it is optional to also add an external pull-up resistor.

Figure 43-5. External Reset Circuit Example Schematic

A pull-up resistor makes sure that the reset does not go low unintended causing a device reset. An additional resistor has been added in series with the switch to safely discharge the filtering capacitor, i.e. preventing a current surge when shorting the filtering capacitor which again causes a noise spike that can have a negative effect on the system.

Table 43-3. Reset Circuit Connections

| Signal Name               | Recommended Pin Connection  | Description |
|---------------------------|---|-------------|
| $\overline{\text{RESET}}$ | Reset low level threshold voltage<br>$V_{DDIO} = 1.68V - 2.0V$ : Below $0.33 * V_{DDIO}$<br>$V_{DDIO} = 2.7V - 3.6V$ : Below $0.36 * V_{DDIO}$<br>Decoupling/filter capacitor 100nF <sup>(1)</sup><br>Pull-up resistor 10kΩ <sup>(1)(2)</sup><br>Resistor in series with the switch 330Ω <sup>(1)</sup> | Reset pin   |

- Notes:
1. These values are given as a typical example.
  2. The SAM C20 features an internal pull-up resistor on the  $\overline{\text{RESET}}$  pin, hence an external pull-up is optional.

### 43.5 Unused or Unconnected Pins

Unused or unconnected pins (unless marked as NC where applicable) should not be left unconnected and floating. Floating pins will add to the overall power consumption of the device. To prevent this one should always draw the pin voltage towards a given level, either  $V_{DD}$  or GND, through a pull up/down resistor. External or internal pull up/down

resistors can be used, e.g. the pins can be configured in pull-up or pull-down mode eliminating the need for external components, for more information see “[PORT – IO Pin Controller](#)” on [page 437](#) for details. There are no obvious benefit in choosing external vs. internal pull resistors.

### 43.6 Clocks and Crystal Oscillators

The SAM C20 can be run from internal or external clock sources, or a mix of internal and external sources. An example of usage will be to use the internal 8MHz oscillator as source for the system clock, and an external 32.768kHz watch crystal as clock source for the Real-Time Counter (RTC).

#### 43.6.1 External Clock Source

Figure 43-6. External Clock Source Example Schematic

Table 43-4. External Clock Source Connections

| Signal Name | Recommended Pin Connection                        | Description                        |
|-------------|---|------------------------------------|
| XIN         | XIN is used as input for an external clock signal | Input for inverting oscillator pin |
| XOUT/GPIO   | Can be left unconnected or used as normal GPIO    |                                    |

#### 43.6.2 Crystal Oscillator

Figure 43-7. Crystal Oscillator Example Schematic

The crystal should be located as close to the device as possible. Long signal lines may cause too high load to operate the crystal, and cause crosstalk to other parts of the system.

Table 43-5. Crystal Oscillator Checklist

| Signal Name | Recommended Pin Connection            | Description                           |
|-------------|---------------------------------------|---------------------------------------|
| XIN         | Load capacitor 15pF <sup>(1)(2)</sup> | External crystal between 0.4 to 30MHz |
| XOUT        | Load capacitor 15pF <sup>(1)(2)</sup> |                                       |

- Notes:
- 1. These values are given only as typical example.
  - 2. Decoupling capacitor should be placed close to the device for each supply pin pair in the signal group.

43.6.3 External Real Time Oscillator

The low frequency crystal oscillator is optimized for use with a 32.768kHz watch crystal. When selecting crystals, load capacitance and crystal's Equivalent Series Resistance (ESR) must be taken into consideration. Both values are specified by the crystal vendor.

SAM C20 oscillator is optimized for very low power consumption, hence close attention should be made when selecting crystals, see [Table 43-6](#) for maximum ESR recommendations on 9pF and 12.5pF crystals.

The Low-frequency Crystal Oscillator provides an internal load capacitance of typical values available in [Table 1-38, "32kHz Crystal Oscillator Characteristics," on page 31](#). This internal load capacitance and PCB capacitance can allow to use a Crystal inferior to 12.5pF load capacitance without external capacitors as shown in [Figure 43-8](#).

Table 43-6. Maximum ESR Recommendation for 32.768kHz Crystal

| Crystal C <sub>L</sub> (pF) | Max ESR [kΩ] |
|-----------------------------|--------------|
| 12.5                        | 313          |

Note: Maximum ESR is typical value based on characterization. These values are not covered by test limits in production.

Figure 43-8. External Real Time Oscillator without Load Capacitor

However, to improve Crystal accuracy and Safety Factor, it can be recommended by crystal datasheet to add external capacitors as shown in [Figure 43-9](#).

To find suitable load capacitance for a 32.768kHz crystal, consult the crystal datasheet.

Figure 43-9. External Real Time Oscillator with Load Capacitor

Table 43-7. External Real Time Oscillator Checklist

| Signal Name | Recommended Pin Connection            | Description             |
|-------------|---------------------------------------|-------------------------|
| XIN32       | Load capacitor 22pF <sup>(1)(2)</sup> | Timer oscillator input  |
| XOUT32      | Load capacitor 22pF <sup>(1)(2)</sup> | Timer oscillator output |

Notes:

- 1. These values are given only as typical examples.

- Decoupling capacitor should be placed close to the device for each supply pin pair in the signal group.

#### 43.6.4 Calculating the Correct Crystal Decoupling Capacitor

In order to calculate correct load capacitor for a given crystal one can use the model shown in [Figure 43-10](#) which includes internal capacitors  $C_{L1}$ , external parasitic capacitance  $C_{EL1}$  and external load capacitance  $C_{P1}$ .

**Figure 43-10. Crystal Circuit With Internal, External and Parasitic Capacitance**

Using this model the total capacitive load for the crystal can be calculated as shown in the equation below:

$$\sum C_{tot} = \frac{(C_{L1} + C_{P1} + C_{EL1})(C_{L2} + C_{P2} + C_{EL2})}{C_{L1} + C_{P1} + C_{EL1} + C_{L2} + C_{P2} + C_{EL2}}$$

where  $C_{tot}$  is the total load capacitance seen by the crystal, this value should be equal to the load capacitance value found in the crystal manufacturer datasheet.

The parasitic capacitance  $C_{ELn}$  can in most applications be disregarded as these are usually very small. If accounted for the value is dependent on the PCB material and PCB layout.

For some crystal the internal capacitive load provided by the device itself can be enough. To calculate the total load capacitance in this case.  $C_{ELn}$  and  $C_{Pn}$  are both zero,  $C_{L1} = C_{L2} = C_L$ , and the equation reduces to the following:

$$\sum C_{tot} = \frac{C_L}{2}$$

[Table 43-8](#) shows the device equivalent internal pin capacitance.

Table 43-8. Equivalent Internal Pin Capacitance

| Symbol              | Value  | Description                         |
|---------------------|--------|-------------------------------------|
| C <sub>XIN32</sub>  | 3.05pF | Equivalent internal pin capacitance |
| C <sub>XOUT32</sub> | 3.29pF | Equivalent internal pin capacitance |

43.7 Programming and Debug Ports

For programming and/or debugging the SAM C20 the device should be connected using the Serial Wire Debug, SWD, interface. Currently the SWD interface is supported by several Atmel and third party programmers and debuggers, like the SAM-ICE, JTAGICE3 or SAM C21 Xplained Pro (SAM C21 evaluation kit) Embedded Debugger.

Refer to the SAM-ICE, JTAGICE3 or SAM C21 Xplained Pro user guides for details on debugging and programming connections and options. For connecting to any other programming or debugging tool, refer to that specific programmer or debugger’s user guide.

The SAM C21 Xplained Pro evaluation board for the SAM C21 supports programming and debugging through the onboard embedded debugger so no external programmer or debugger is needed.

43.7.1 Cortex Debug Connector (10-pin)

For debuggers and/or programmers that support the Cortex Debug Connector (10-pin) interface the signals should be connected as shown in Figure 43-11 with details described in Table 43-9.

Figure 43-11.Cortex Debug Connector (10-pin)

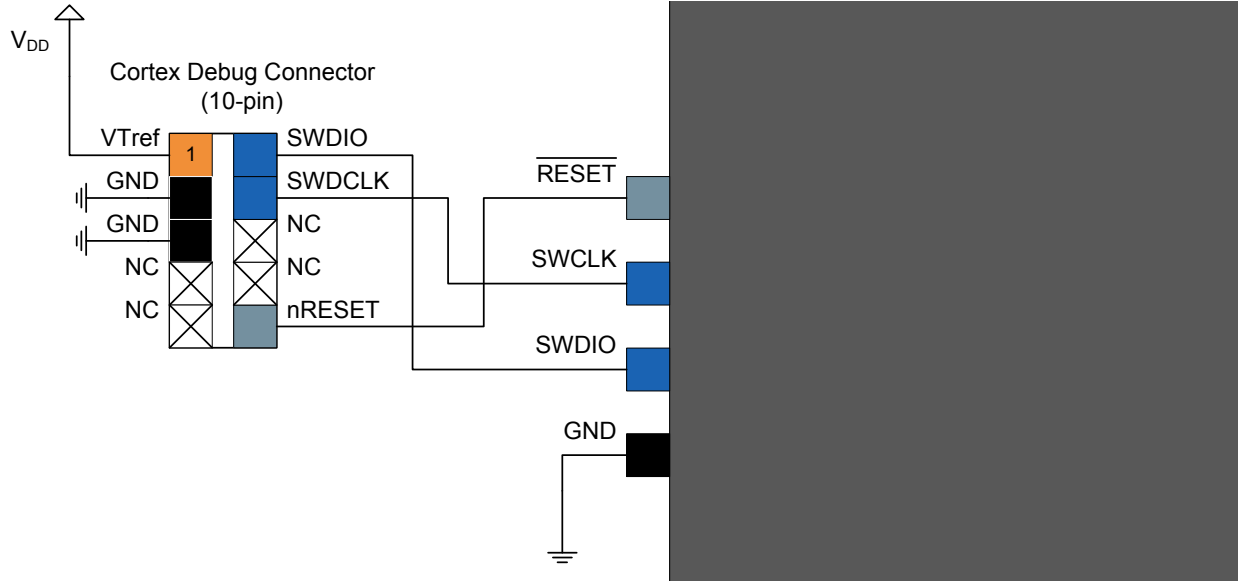

Table 43-9. Cortex Debug Connector (10-pin)

| Header Signal Name | Description                        |
|--------------------|------------------------------------|
| SWDCLK             | Serial wire clock pin              |
| SWDIO              | Serial wire bidirectional data pin |

| Header Signal Name        | Description  |
|---------------------------|--|
| $\overline{\text{RESET}}$ | Target device reset pin, active low                              |
| VTref                     | Target voltage sense, should be connected to the device $V_{DD}$ |
| GND                       | Ground   |

43.7.2 10-pin JTAGICE3 Compatible Serial Wire Debug Interface

The JTAGICE3 debugger and programmer does not support the Cortex Debug Connector (10-pin) directly, hence a special pinout is needed to directly connect the SAM C20 to the JTAGICE3, alternatively one can use the JTAGICE3 squid cable and manually match the signals between the JTAGICE3 and SAM C20. Figure 43-12 describes how to connect a 10-pin header that support connecting the JTAGICE3 directly to the SAM C20 without the need for a squid cable.

To connect the JTAGICE3 programmer and debugger to the SAM C20, one can either use the JTAGICE3 squid cable, or use a 10-pin connector as shown in Figure 43-12 with details given in Table 43-10 to connect to the target using the JTAGICE3 50 mil cable directly.

Figure 43-12.10-pin JTAGICE3 Compatible Serial Wire Debug Interface

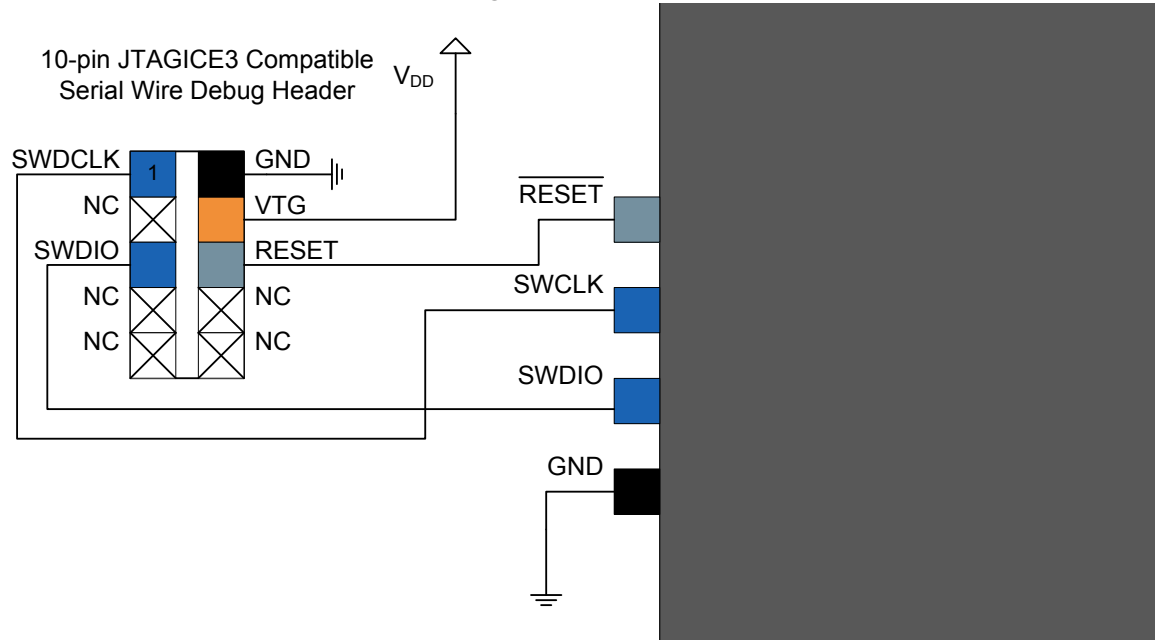

Table 43-10. 10-pin JTAGICE3 Compatible Serial Wire Debug Interface

| Header Signal Name | Description  |
|--------------------|--|
| SWDCLK             | Serial wire clock pin  |
| SWDIO              | Serial wire bidirectional data pin                               |
| RESET              | Target device reset pin, active low                              |
| VTG                | Target voltage sense, should be connected to the device $V_{DD}$ |
| GND                | Ground   |

43.7.3 20-pin IDC JTAG Connector

For debuggers and/or programmers that support the 20-pin IDC JTAG Connector, e.g. the SAM-ICE, the signals should be connected as shown in Figure 43-13 with details described in Table 43-11.

Figure 43-13.20-pin IDC JTAG Connector

Table 43-11. 20-pin IDC JTAG Connector

| Header Signal Name | Description  |
|--------------------|--|
| SWDCLK             | Serial wire clock pin  |
| SWDIO              | Serial wire bidirectional data pin   |
| nRESET             | Target device reset pin, active low  |
| VCC                | Target voltage sense, should be connected to the device V <sub>DD</sub>  |
| GND                | Ground   |
| GND*               | These pins are reserved for firmware extension purposes. They can be left open or connected to GND in normal debug environment. They are not essential for SWD in general. |

## 44. Errata

### 44.1 Revision A

Not sampled

### 44.2 Revision B

#### 44.2.1 DMAC

**1 - If data is written to CRCDATAIN in two consecutive instructions, the CRC computation may be incorrect. Errata reference: 13507**

**Fix/Workaround:**

Add a NOP instruction between each write to CRCDATAIN register.

#### 44.2.2 PORT

**1 - When the PORT is defined as EVSYS.USER in a synch/resynch path, the first event is transmitted to the PORT but the acknowledgement coming from the PORT is not released. So next coming events are treated as overrun by EVSYS. Errata reference: 14317**

**Fix/Workaround:**

None.

Do not use the synch/resynch path, only use asynchronous path.

#### 44.2.3 OSC48M

**1 - When a System Reset is applied, the OSC48MDIV register is reset, but the value is not synchronized. This may result in the system clock running too fast. Errata reference: 14497**

**Fix/Workaround:**

Do not write OSC48MDIV to lower than 0xB. Do not run the device faster than 4MHz when running from external oscillators

#### 44.2.4 OSC32KCTRL

**1 - At start-up and in case of clock failure detection(CFD), the auto switch by the CFD does not work if the XOSC32K is requested by the GCLK. Errata reference: 14039**

**Errata/Workaround**

Manually change clock from XOSC32K to another 32K source.

#### 44.2.5 TC

**1 - A capture overflow can occur without INTFLAG.ERR being set if a new capture occurs within 3 APB clock periods + 3 generic clock periods after a previous capture. Errata reference: 13367**

**Fix/Workaround:**

The delay between two capture events must be longer than 3 APB clock periods + 3 generic clock periods.

**2 - The input capture on IO pins does not work. Errata reference: 14024**

**Fix/Workaround:**

Use the input capture through TC event and use the EIC or CCL as event generators.

#### 44.2.6 FDPLL

**1 - When entering standby mode, the FDPLL is still running even if not requested by any module causing extra consumption. Errata reference: 12244**

**Fix/Workaround:**

FDPLL must be disabled before entering in standby mode and re-enabled after wake-up

#### 44.2.7 TCC

**1 - FCTRLX.CAPTURE[CAPTMARK] does not work as described in the datasheet. CAPTMARK cannot be used to identify captured values triggered by fault inputs source A or B on the same channel. Errata reference: 13316**

**Fix/Workaround:**

Use two different channels to timestamp FaultA and FaultB.

**2 - A capture overflow can occur without INTFLAG.ERR being set if a new capture occurs within 3 APB clocks + 3 generic Clock periods from a previous capture. Errata reference: 13366**

**Fix/Workaround:**

The delay between two capture events must be longer than 3 APB clock periods + 3 generic clock periods.

**3 - When the circular buffer is enabled, an APB clock is requested to update the corresponding APB register. If all masters in the system (CPU, DMA) are disabled, the APB clock is never provided to the TCC, making the circular buffer feature not functional in standby sleep mode. Errata reference: 12269**

**Fix/Workaround:**

Keep a master enabled in the system (enable DMA, or do not enable standby sleep mode when circular buffer is enabled).

**4 - In RAMP 2 mode with Fault keep, qualified and restart: Errata reference: 13262**

If a fault occurred at the end of the period during the qualified state, the switch to the next ramp can have two restarts.

**Fix/Workaround:**

Avoid faults few cycles before the end or the beginning of a ramp.

#### 44.2.8 RTC

**1 - COUNTSYNC bit has no effect in RTL.CTRLA register. Read synchronization of COUNT/CLOCK register is always enabled. Errata reference: 13714**

**Fix/Workaround:**

None

#### 44.2.9 Device

**1 - VREGSMOD bits have no effect in PM.STDBYCFG register. The power domain controller always operates in automatic regulator mode. Errata reference: 14498**

**Fix/Workaround:**

None

**2 - SYSTICK calibration value is wrong. Errata reference: 14156**

**Fix/Workaround:**

right SYSTICK calibration value is 0x1000000.

**3 - In IDLE sleep mode, the APB and AHB clocks are not stopped if the FDPLL is running as a GCLK clock source. Errata reference: 13401**

**Fix/Workaround:**

Disable the FDPLL before entering IDLE sleep mode.

**4 - The Analog Comparators and ADC1 use the same generic clock configuration. GCLK\_ADC1 must be used to configure the clock for AC as GCLK\_AC is not functional. Errata reference: 13404**

**Fix/Workaround:**

None

**5 - Increased power consumption in standby sleep mode. Errata reference: 14100**

**Fix/Workaround:**

None

**6 - In I2C Slave mode, writing the CTRLB register when in the AMATCH or DRDY interrupt service routines can cause the state machine to reset. Errata reference: 13574**

**Fix/Workaround:**

Write CTRLB.ACKACT to 0 using the following sequence:

```
// If higher priority interrupts exist, then disable so that the
// following two writes are atomic.
SERCOM - STATUS.reg = 0;
SERCOM - CTRLB.reg = 0;
// Re-enable interrupts if applicable.
```

Write CTRLB.ACKACT to 1 using the following sequence:

```
// If higher priority interrupts exist, then disable so that the
// following two writes are atomic.
SERCOM - STATUS.reg = 0;
SERCOM - CTRLB.reg = SERCOM_I2CS_CTRLB_ACKACT;
// Re-enable interrupts if applicable.
```

Otherwise, only write to CTRLB in the AMATCH or DRDY interrupts if it is to close out a transaction.

When not closing a transaction, clear the AMATCH interrupt by writing a 1 to its bit position instead of using CTRLB.CMD. The DRDY interrupt is automatically cleared by reading/writing to the DATA register in smart mode. If not in smart mode, DRDY should be cleared by writing a 1 to its bit position.

Code replacements examples:

Current:

```
SERCOM - CTRLB.reg |= SERCOM_I2CS_CTRLB_ACKACT;
```

Change to:

```
// If higher priority interrupts exist, then disable so that the
// following two writes are atomic.
SERCOM - STATUS.reg = 0;
SERCOM - CTRLB.reg = SERCOM_I2CS_CTRLB_ACKACT;
// Re-enable interrupts if applicable.
```

Current:

```
SERCOM - CTRLB.reg &= ~SERCOM_I2CS_CTRLB_ACKACT;
```

Change to:

```
// If higher priority interrupts exist, then disable so that the
// following two writes are atomic.
SERCOM - STATUS.reg = 0;
SERCOM - CTRLB.reg = 0;
// Re-enable interrupts if applicable.
```

Current:

```
/* ACK or NACK address */
SERCOM - CTRLB.reg |= SERCOM_I2CS_CTRLB_CMD(0x3);
```

Change to:

```
// CMD=0x3 clears all interrupts, so to keep the result similar,
// PREC is cleared if it was set.
if (SERCOM - INTFLAG.bit.PREC) SERCOM - INTFLAG.reg =
SERCOM_I2CS_INTFLAG_PREC;
SERCOM - INTFLAG.reg = SERCOM_I2CS_INTFLAG_AMATCH;
```

**7 - The default TC selection as CCL input is not TC0, but TC4. Thus the TC selection for the CCL is TC4/TC0/TC1/TC2 instead of TC0/TC1/TC2/TC3. The TC alternate selection is TC0/TC1/TC2/TC3 instead of TC1/TC2/TC3/TC4. Errata reference: 13449**

**Fix/Workaround:**

Use the TC input mapping described above.

#### 44.2.10 EIC

**1 - The EIC ASYNCH register is not write protected. Errata reference: 13848**

**Fix/Workaround:**

None

**2 - If the NMI pin PORT config is INPUT+PULL-UP enabled and the NMI is configured to trigger on rising edge (or both edges), the NMI exception is triggered as soon as the NMI config is written. Errata reference: 13074**

**Fix/Workaround:**

Set the NMI pin PORT config, enable EIC in edge detection mode then disable EIC. Clear INTFLAG, then write NMI configuration.

#### 44.2.11 CCL

**1 - The reset of the RS latch is not functional. The latch can only be cleared by disabling the LUT. Errata reference: 14043**

**Fix/Workaround:**

None

#### 44.2.12 PTC

**1 - The PTC generic clock is always requested during standby when RUNSTDBY is set to one. Power consumption will be higher if the PTC is enabled during standby sleep mode even if no conversion is on-going. Errata reference: 14370**

**Fix/workaround**

Disable PTC in standby mode to reduce power consumption

#### 44.2.13 SERCOM

**1 - In USART autobaud mode, missing stop bits are not recognized as inconsistent sync (ISF) or framing (FERR) errors. Errata reference: 13852**

**Fix/Workaround:**

None

**2 - If the SERCOM is enabled in SPI mode with SSL detection enabled (CTRLB.SSDE) and CTRLB.RXEN=1, an erroneous slave select low interrupt (INTFLAG.SSL) can be generated. Errata reference: 13369**

**Fix/Workaround:**

Enable the SERCOM first with CTRLB.RXEN=0. In a subsequent write, set CTRLB.RXEN=1.

#### 44.2.14 ADC

**1 - Once set, the ADC.SWTRIG.START will not be cleared until the Microcontroller is reset. Errata reference: 14094**

**Fix/Workaround:**

None

**2 - When window monitor is enabled and its output is 0, the ADC GCLK is kept running. Power consumption will be higher than expected in sleep modes Errata reference: 14449**

**Fix/Workaround:**

None

**3 - The LSB bit of ADC result is stuck at zero, in unipolar mode for 8-bit and 10-bit resolution. Errata reference: 14431**

**Fix/Workaround:**

None

#### 44.2.15 AC

**1 - Hysteresis is only present for a falling (1->0) transition of the comparator output. Errata reference: 13712**

**Fix/Workaround:**

None

## 45. About This Document

### 45.1 Conventions

#### 45.1.1 Numerical Notation

**Table 45-1.** Numerical notation

|        |   |
|--------|---|
| 165    | Decimal number  |
| 0101b  | Binary number (example 0b0101 = 5 decimal)                                |
| 0101   | Binary numbers are given without suffix if unambiguous                    |
| 0x3B24 | Hexadecimal number  |
| X      | Represents an unknown or don't care value                                 |
| Z      | Represents a high-impedance (floating) state for either a signal or a bus |

#### 45.1.2 Memory Size and Type

**Table 45-2.** Memory Size and Bit Rate

| Symbol   | Description  |
|----------|--|
| kB/kbyte | kilobyte ( $2^{10} = 1024$ )                         |
| MB/Mbyte | megabyte ( $2^{20} = 1024 \times 1024$ )             |
| GB/Gbyte | gigabyte ( $2^{30} = 1024 \times 1024 \times 1024$ ) |
| b        | bit (binary 0 or 1)                                  |
| B        | byte (8 bits)  |
| 1kbit/s  | 1,000 bit/s rate (not 1,024 bit/s)                   |
| 1Mbit/s  | 1,000,000 bit/s rate                                 |
| 1Gbit/s  | 1,000,000,000 bit/s rate                             |

#### 45.1.3 Frequency and Time

**Table 45-3.** Frequency and Time

| Symbol | Description                |
|--------|----------------------------|
| kHz    | 1kHz = $10^3$ Hz = 1,000Hz |
| MHz    | $10^6 = 1,000,000$ Hz      |
| GHz    | $10^9 = 1,000,000,000$ Hz  |
| s      | second                     |
| ms     | millisecond                |
| μs     | microsecond                |
| ns     | nanosecond                 |

## 45.1.4 Registers and Bits

**Table 45-4.** Register and bit mnemonics

|                     |   |
|---------------------|---|
| R/W                 | Read/Write accessible register bit. The user can read from and write to this bit.   |
| R                   | Read-only accessible register bit. The user can only read this bit. Writes will be ignored.   |
| W                   | Write-only accessible register bit. The user can only write this bit. Reading this bit will return an undefined value.  |
| BIT                 | Bit names are shown in uppercase. (Example PINA1)   |
| BITS[n:m]           | A set of bits from bit n down to m. (Example: PINA3..0 = {PINA3, PINA2, PINA1, PINA0})  |
| Reserved            | Reserved bits are unused and reserved for future use. For compatibility with future devices, always write reserved bits to zero when the register is written. Reserved bits will always return zero when read.  |
| PERIPHERAL <i>i</i> | If several instances of a peripheral exist, the peripheral name is followed by a number to indicate the number of the instance in the range 0-n. PERIPHERAL <i>i</i> denotes one specific instance.   |
| Reset               |   |
| SET/CLR             | Registers with SET/CLR suffix allows the user to clear and set bits in a register without doing a read-modify-write operation. These registers always come in pairs. Writing a one to a bit in the CLR register will clear the corresponding bit in both registers, while writing a one to a bit in the SET register will set the corresponding bit in both registers. Both registers will return the same value when read. If both registers are written simultaneously, the write to the CLR register will take precedence. |

## 45.2 Acronyms and Abbreviations

[Table](#) contains acronyms and abbreviations used in this document.

**Table 45-5.** Acronyms and Abbreviations

| Abbreviation     | Description                        |
|------------------|------------------------------------|
| AC               | Analog Comparator                  |
| ADC              | Analog-to-Digital Converter        |
| ADDR             | Address                            |
| AHB              | AMBA Advanced High-performance Bus |
| APB              | AMBA Advanced Peripheral Bus       |
| AREF             | Analog reference voltage           |
| AV <sub>DD</sub> | Analog supply voltage              |
| BLB              | Boot Lock Bit                      |
| BOD              | Brown-out detector                 |
| CAL              | Calibration                        |
| CC               | Compare/capture                    |
| CLK              | Clock                              |
| CRC              | Cyclic Redundancy Check            |
| CTRL             | Control                            |

**Table 45-5. Acronyms and Abbreviations (Continued)**

|                  |   |
|------------------|---|
| DAC              | Digital to Analog converter                         |
| DFLL             | Digital Frequency Locked Loop                       |
| DSU              | Device service unit                                 |
| EEPROM           | Electrically Erasable Programmable Read-Only Memory |
| EIC              | External interrupt controller                       |
| EVSYS            | Event System  |
| GCLK             | Generic clock                                       |
| GND              | Ground  |
| GPIO             | General Purpose Input/Output                        |
| I <sup>2</sup> C | Inter-integrated circuit                            |
| IF               | Interrupt Flag                                      |
| INT              | Interrupt   |
| IOBUS            | I/O Bus   |
| NMI              | Non-Maskable Interrupt                              |
| NVIC             | Nested vector interrupt controller                  |
| NVMCTRL          | Non-Volatile Memory controller                      |
| OSC              | Oscillator  |
| PAC              | Peripheral access controller                        |
| PC               | Program counter                                     |
| PER              | Period  |
| PM               | Power manager                                       |
| POR              | Power-on reset                                      |
| PTC              | Peripheral touch controller                         |
| PWM              | Pulse Width Modulation                              |
| RAM              | Random-access memory                                |
| REF              | Reference   |
| RMW              | Read-modify-write                                   |
| RTC              | Real-time counter                                   |
| RX               | Receiver  |
| SERCOM           | Serial communication interface                      |
| SMBus            | System Management Bus                               |

## Table of Contents

---

|   |    |
|---|----|
| Description . . . . .                                 | 1  |
| Features . . . . .                                    | 2  |
| 1. Configuration Summary . . . . .                    | 3  |
| 2. Ordering Information . . . . .                     | 5  |
| 2.1 SAM C20E . . . . .                                | 5  |
| 2.2 SAM C20G . . . . .                                | 5  |
| 2.3 SAM C20J . . . . .                                | 6  |
| 3. Block Diagram . . . . .                            | 7  |
| 4. Pinout . . . . .                                   | 8  |
| 4.1 SAM C20J . . . . .                                | 8  |
| 4.2 SAM C20G . . . . .                                | 9  |
| 4.3 SAM C20E . . . . .                                | 10 |
| 5. Signal Descriptions List . . . . .                 | 11 |
| 6. I/O Multiplexing and Considerations . . . . .      | 13 |
| 6.1 Multiplexed Signals . . . . .                     | 13 |
| 6.2 Other Functions . . . . .                         | 16 |
| 7. Power Supply and Start-Up Considerations . . . . . | 17 |
| 7.1 Power Domain Overview . . . . .                   | 17 |
| 7.2 Power Supply Considerations . . . . .             | 17 |
| 7.3 Power-Up . . . . .                                | 19 |
| 7.4 Power-On Reset and Brown-Out Detector . . . . .   | 20 |
| 8. Product Mapping . . . . .                          | 21 |
| 9. Memories . . . . .                                 | 23 |
| 9.1 Embedded Memories . . . . .                       | 23 |
| 9.2 Physical Memory Map . . . . .                     | 23 |
| 9.3 NVM User Row Mapping . . . . .                    | 24 |
| 9.4 NVM Software Calibration Area Mapping . . . . .   | 25 |
| 9.5 Serial Number . . . . .                           | 25 |
| 10. Processor And Architecture . . . . .              | 26 |
| 10.1 Cortex M0+ Processor . . . . .                   | 26 |
| 10.2 Nested Vector Interrupt Controller . . . . .     | 27 |
| 10.3 Micro Trace Buffer . . . . .                     | 29 |
| 10.4 High-Speed Bus System . . . . .                  | 30 |
| 11. PAC – Peripheral Access Control . . . . .         | 33 |
| 11.1 Overview . . . . .                               | 33 |
| 11.2 Features . . . . .                               | 33 |
| 11.3 Block Diagram . . . . .                          | 33 |
| 11.4 Product Dependencies . . . . .                   | 33 |
| 11.5 Functional Description . . . . .                 | 34 |
| 11.6 Register Summary . . . . .                       | 37 |
