11.5.3.1 Revision (ESW\_REV)

Address: 400E\_8000h base + 0h offset = 400E\_8000h

- \* Notes:
- See ESW chip-configuration information for revision number.

ESW\_REV field descriptions

Field	Description
REVISION	Revision number

11.5.3.2 Scratch register (ESW\_SCR)

The scratch register provides a memory location to test register access. It returns all data written to it in inverted form.

Address: 400E\_8000h base + 4h offset = 400E\_8004h

ESW\_SCR field descriptions

Field	Description
SCRATCH	Scratch register

### 11.5.3.3 Port enable register (ESW\_PER)

The port enable register independently enables the transmit and receive direction for each port.

Address: 400E\_8000h base + 8h offset = 400E\_8008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved													RE2	RE1	RE0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved													TE2	TE1	TE0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_PER field descriptions

Field	Description
31–19 Reserved	This field is reserved. This field must be 0.
18 RE2	Enable receive on port 2.  0 Disable. The input is ignored and never selected for frame reception. 1 Enable. The port is selected and a frame is accepted if it indicates data available.
17 RE1	Enable receive on port 1.  0 Disable. The input is ignored and never selected for frame reception. 1 Enable. The port is selected and a frame is accepted if it indicates data available.
16 RE0	Enable receive on port 0.  0 Disable. The input is ignored and never selected for frame reception. 1 Enable. The port is selected and a frame is accepted if it indicates data available.
15–3 Reserved	This field is reserved. This field must be 0.
2 TE2	Enable transmit on port 2.  0 Disable. All frames forwarded to the port are discarded. 1 Enable. A frame can be forwarded to the port.
1 TE1	Enable transmit on port 1.  0 Disable. All frames forwarded to the port are discarded. 1 Enable. A frame can be forwarded to the port.
0 TE0	Enable transmit on port 0.  0 Disable. All frames forwarded to the port are discarded. 1 Enable. A frame can be forwarded to the port.

### 11.5.3.4 VLAN verify (ESW\_VLANV)

#### NOTE

The DUV<sub>n</sub>, DU<sub>n</sub>, and DUT<sub>n</sub> fields are relevant only if the port's VV field is enabled.

Address: 400E\_8000h base + 10h offset = 400E\_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved													DU2	DU1	DU0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved													VV2	VV1	VV0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_VLANV field descriptions

Field	Description
31–19 Reserved	This field is reserved. This field must be cleared.
18 DU2	Discard unknown on port 2.  0 Received frames with unknown VLAN IDs are not discarded 1 Received frames with an unknown VLAN ID or no VLAN tag are discarded and not forwarded (that is, the default bcast is ignored)
17 DU1	Discard unknown on port 1.  0 Received frames with unknown VLAN IDs are not discarded 1 Received frames with an unknown VLAN ID or no VLAN tag are discarded and not forwarded (that is, the default bcast is ignored)
16 DU0	Discard unknown on port 0.  0 Received frames with unknown VLAN IDs are not discarded 1 Received frames with an unknown VLAN ID or no VLAN tag are discarded and not forwarded (that is, the default bcast is ignored)
15–3 Reserved	This field is reserved. This field must be 0.
2 VV2	Verify VLAN domain on port 2.  0 Frames are routed to the output port 2 without VLAN domain checking 1 A frame is accepted from the port 2 as valid only when the input and output ports are members of the VLAN domain of the frame.
1 VV1	Verify VLAN domain on port 1.  0 Frames are routed to the output port 1 without VLAN domain checking 1 A frame is accepted from the port 1 as valid only when the input and output ports are members of the VLAN domain of the frame.

Table continues on the next page...

**ESW\_VLANV field descriptions (continued)**

Field	Description
0 VV0	Verify VLAN domain on port 0.  0 Frames are routed to the output port 0 without VLAN domain checking 1 A frame is accepted from the port 0 as valid only when the input and output ports are members of the VLAN domain of the frame.

**11.5.3.5 Default broadcast resolution (ESW\_DBCR)**

The default output port list used for flooding resolution of broadcast frames (see [Broadcast/Multicast/VLAN Domain Resolution](#)).

Address: 400E\_8000h base + 14h offset = 400E\_8014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	Reserved													P2	P1	P0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ESW\_DBCR field descriptions**

Field	Description
31–3 Reserved	This field is reserved. This field must be 0.
2 P2	Default broadcast resolution  0 A frame with the corresponding VLAN ID is not switched to that port 1 Indicates that each port is a member of the VLAN and frames with the corresponding VLAN ID can be switched to the port
1 P1	Default broadcast resolution  0 A frame with the corresponding VLAN ID is not switched to that port 1 Indicates that each port is a member of the VLAN and frames with the corresponding VLAN ID can be switched to the port
0 P0	Default broadcast resolution  0 A frame with the corresponding VLAN ID is not switched to that port 1 Indicates that each port is a member of the VLAN and frames with the corresponding VLAN ID can be switched to the port

### 11.5.3.6 Default multicast resolution (ESW\_DMCR)

The default output port list used for flooding resolution of multicast frames (see [Broadcast/Multicast/VLAN Domain Resolution](#)).

Address: 400E\_8000h base + 18h offset = 400E\_8018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved													P2	P1	P0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_DMCR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This field must be 0.
2 P2	Default multicast resolution. When the received frame carries a multicast address, the default output port list used instead of ESW_DBCR.
1 P1	Default multicast resolution. When the received frame carries a multicast address, the default output port list used instead of ESW_DBCR.
0 P0	Default multicast resolution. When the received frame carries a multicast address, the default output port list used instead of ESW_DBCR.

### 11.5.3.7 Blocking and learning enable (ESW\_BKLR)

ESW\_BKLR independently defines the blocking and learning states for each port.

Address: 400E\_8000h base + 1Ch offset = 400E\_801Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved													LD2	LD1	LD0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved													BE2	BE1	BE0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ESW\_BKLR field descriptions**

<b>Field</b>	<b>Description</b>
31–19 Reserved	This field is reserved.
18 LD2	Disable learning on port 2.  0 Enable. 1 Disable. Only bridge protocol data unit frames are learned. Other frames are ignored for learning.
17 LD1	Disable learning on port 1.  0 Enable. 1 Disable. Only bridge protocol data unit frames are learned. Other frames are ignored for learning.
16 LD0	Disable learning on port 0.  0 Enable. 1 Disable. Only bridge protocol data unit frames are learned. Other frames are ignored for learning.
15–3 Reserved	This field is reserved. This field must be 0.
2 BE2	Enable blocking on port 2.  0 Disable. 1 Enable. Only bridge protocol data units are accepted on that input, all other frames are discarded.
1 BE1	Enable blocking on port 1.  0 Disable. 1 Enable. Only bridge protocol data units are accepted on that input, all other frames are discarded.
0 BE0	Enable blocking on port 0.  0 Disable. 1 Enable. Only bridge protocol data units are accepted on that input, all other frames are discarded.

### 11.5.3.8 Bridge management port configuration (ESW\_BMPC)

ESW\_BMPC enables and defines the management port that receives bridge protocol frames.

Address: 400E\_8000h base + 20h offset = 400E\_8020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved													PORTMASK		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	PRIORITY			Reserved					DIS	EN	MSGTX	Reserved	PORT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_BMPC field descriptions

Field	Description
31–19 Reserved	This field is reserved. Reserved, must be 0.
18–16 PORTMASK	Portmask for transmission of BPDU frames as defined in Section 32.5.9.5.4, "Management Frame Forwarding". When the management port transmits a BPDU frame to the switch, it is forwarded to all ports in this portmask (bit16=port0, bit17=port1, bit 18=port2).
15–13 PRIORITY	Priority to use for transmitted management frames. Used to e.g. put a management frame in a high-priority output queue for fast delivery.
12–8 Reserved	This field is reserved. Reserved, must be 0.
7 DIS	If set, BPDU frames are discarded always. Setting has no effect, when the enable bit is set.
6 EN	If set, all BPDU frames are forwarded exclusively to the management port specified in bits 3:0. If 0, BPDU frames are forwarded as any other frame, or discarded if the discard bit is set.
5 MSGTX	Set (latched) when a BPDU frame as defined in Section 32.5.9.5.4, "Management Frame Forwarding" was transmitted from the management port to any output port. Bit is reset by writing into the register.
4 Reserved	This field is reserved. Reserved, must be 0.
PORT	The Port number of the port that should act as a management port. Relevant to all functions that forward frames to the management port (i.e. BPDU processing, snooping). Note: It must be set 0 in this switch configuration (Port 0 to DMA0 is the management port).

### 11.5.3.9 Mode configuration (ESW\_MODE)

ESW\_MODE defines several global configuration settings.

Address: 400E\_8000h base + 24h offset = 400E\_8024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STATRST	Reserved														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved							P0CT	CRCTRAN	STOP	Reserved				SWEN	SWRST
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_MODE field descriptions

Field	Description
31 STATRST	Reset Statistics Counters Command. When set during a write, all statistics counters are cleared. When set, all other bits are ignored and do not influence the currently stored value in the register (i.e. it is not necessary to read/preserve the register contents prior to writing this bit).
30–10 Reserved	This field is reserved. This field must be 0.
9 P0CT	Enable Port0 input buffer cut-through mode. When cleared (0, default) the input buffer operates in store&forward mode, which is the recommended mode of operation.
8 CRCTRAN	When enabled (1) the MAC ports are expected to process frames to/from the switch including CRC.
7 STOP	Controls toplevel output pin stop_en. No internal function.
6–2 Reserved	This field is reserved. This field must be 0.
1 SWEN	Enables Switch IP block  0 Switching logic is disabled and bypassed. All associated DMA registers are cleared. Ethernet MACs are directly connected internally. 1 Switching logic is enabled and may be configured and used.
0 SWRST	Software reset. Bit must be cleared by software after being set.  0 When switch is enabled (SWEN=1), setting SWRST to 1 will soft reset the UDMA as well as MAC0 and MAC1. 1 Software reset not requested.

11.5.3.10 VLAN input manipulation select (ESW\_VIMSEL)

ESW\_VIMSEL defines behavior of the VLAN input manipulation function, if such a function is present on an input port. ESW\_VIMSEL has effect only if enabled by the corresponding port bit in ESW\_VIMEN.

Address: 400E\_8000h base + 28h offset = 400E\_8028h

ESW\_VIMSEL field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved, must be 0.
5–4 IM2	Input manipulation select for port 2.  00 Mode 1, single tag passthrough 01 Mode 2, single tag overwrite 10 Mode 3, double tag passthrough 11 Mode 4, double tag overwrite
3–2 IM1	Input manipulation select for port 1.  00 Mode 1, single tag passthrough 01 Mode 2, single tag overwrite 10 Mode 3, double tag passthrough 11 Mode 4, double tag overwrite
IM0	Input manipulation select for port 0.  00 Mode 1, single tag passthrough 01 Mode 2, single tag overwrite 10 Mode 3, double tag passthrough 11 Mode 4, double tag overwrite

### 11.5.3.11 VLAN output manipulation select (ESW\_VOMSEL)

ESW\_VOMSEL defines behavior of the VLAN output manipulation function, if such a function is present on an output port.

Address: 400E\_8000h base + 2Ch offset = 400E\_802Ch

ESW\_VOMSEL field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved, must be 0.
5–4 OM2	Output manipulation select for port 2.  00 No output manipulation 01 Mode 1, strip mode 10 Mode 2, tag through 11 Mode 3, transparent
3–2 OM1	Output manipulation select for port 1.  00 No output manipulation 01 Mode 1, strip mode 10 Mode 2, tag through 11 Mode 3, transparent
OM0	Output manipulation select for port 0.  00 No output manipulation 01 Mode 1, strip mode 10 Mode 2, tag through 11 Mode 3, transparent

### 11.5.3.12 VLAN input manipulation enable (ESW\_VIMEN)

ESW\_VIMEN enables the input processing according to the ESW\_VIMSEL for a port.

Address: 400E\_8000h base + 30h offset = 400E\_8030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												EN2		EN1	EN0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_VIMEN field descriptions

Field	Description
31–3 Reserved	This field is reserved. Reserved, must be 0.
2 EN2	Input manipulation enable for port 2.  0 Disable. ESW_VIMSEL has no effect and the frames are processed unmodified. 1 Enable
1 EN1	Input manipulation enable for port 1.  0 Disable. ESW_VIMSEL has no effect and the frames are processed unmodified. 1 Enable
0 EN0	Input manipulation enable for port 0.  0 Disable. ESW_VIMSEL has no effect and the frames are processed unmodified. 1 Enable

### 11.5.3.13 VLAN tag ID (ESW\_VID)

The VLAN type field value to expect to identify a VLAN-tagged frame. A valid 802.1Q VLAN-tagged frame must use the value 0x8100.

Address: 400E\_8000h base + 34h offset = 400E\_8034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### ESW\_VID field descriptions

Field	Description
TAG	ID to identify a VLAN-tagged frame. A valid 802.1Q VLAN-tagged frame must use the value 0x8100.

#### 11.5.3.14 Mirror control register (ESW\_MCR)

The mirror control register defines port mirroring and filtering conditions.

Address: 400E\_8000h base + 40h offset = 400E\_8040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ESW\_MCR field descriptions

Field	Description
31–11 Reserved	This field is reserved. Reserved, must be 0.
10 EGDA	If set, only frames transmitted on an egress port with a destination address matching the value in ESW_EGDA{L,H} are mirrored. Other frames are not mirrored.  <b>NOTE:</b> If the egress map is not enabled (EGMAP = 0) then any frame with a matching destination address is mirrored.
9 EGSA	If set, only frames transmitted on an egress port with a source address matching the value in ESW_EGSA{L,H} are mirrored. Other frames are not mirrored.  <b>NOTE:</b> If the egress map is not enabled (EGMAP = 0) then any frame with a matching source address is mirrored.
8 INGDA	If set, only frames received on an ingress port with a destination address matching the value in ESW_INGDA{L,H} are mirrored. Other frames are not mirrored.  <b>NOTE:</b> If the ingress map is not enabled (INGMAP = 0) then any frame with a matching destination address is mirrored.
7 INGSA	If set, only frames received on an ingress port with a source address matching the value in ESW_INGSA{L,H} are mirrored. Other frames are not mirrored.

Table continues on the next page...

**ESW\_MCR field descriptions (continued)**

Field	Description
	<b>NOTE:</b> If the ingress map is not enabled (INGMAP = 0) then any frame with a matching source address is mirrored.
6 EGMAP	Egress map enable.  0 Egress port map has no effect 1 Egress map is enabled. A frame forwarded to an output port that has a bit set in the egress map is mirrored.
5 INGMAP	Ingress map enable.  0 Ingress port map has no effect 1 Ingress map is enabled. A frame received on an ingress port that has a bit set in the ingress map is mirrored.
4 MEN	Mirroring enable.  0 Disabled 1 Enabled
PORT	The port number that should act as the mirror port and receive all mirrored frames.

**11.5.3.15 Egress port definitions (ESW\_EGMAP)**

Address: 400E\_8000h base + 44h offset = 400E\_8044h

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_MCVAL field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved, must be 0.
COUNT	Count value for mirror filtering. Every $n^{\text{th}}$ frame is forwarded to the mirror port, if enabled. 0x00 Every frame forwarded 0x01 Every frame forwarded 0x02 Every second frame forwarded ... 0xFF Every 255 <sup>th</sup> frame forwarded

### 11.5.3.26 Memory manager status (ESW\_MMSR)

All latched bits are cleared upon a write with any content to the register.

Address: 400E\_8000h base + 80h offset = 400E\_8080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								CELLS_AVAIL							
W																
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								DQGRNT	Reserved			MFLATCH	MEMFULL	NOCELL	BUSY
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0

#### ESW\_MMSR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This field must be 0.
23–16 CELLS_AVAIL	Real-time indication of currently available cells in memory.
15–7 Reserved	This field is reserved. This field must be 0.
6 DQGRNT	Indication of if currently inputs are de-queued. Should be set always and is cleared when the memory becomes full (see the MEMFULL bit).  <b>NOTE:</b> The bit is cleared upon reset. However, set shortly after when the memory manager completes initialization.
5–4 Reserved	This field is reserved. This field must be 0.
3 MFLATCH	Latched version of MEMFULL. Is kept set even when MEMFULL is cleared again. The bit is cleared when the register is written.
2 MEMFULL	Current memory full indication. The memory is full when less than the programmed minimum cell threshold is available in memory. This is not an error and the memory controller is working fine. It just indicates that the switch does no longer serve its input ports to avoid memory overrun (NOCELL error).
1 NOCELL	Set, when memory has exceeded the maximum available number of cells. The event is latched and the bit stays set if the event is no longer active. This is a fatal error and must never happen during operation. The minimum cells threshold must be increased if it happens. The bit is always set after reset (during initialization) and must be cleared when the busy initialization (see bit 0) indication is cleared.  <b>NOTE:</b> When this bit is set any time during operation (after initialization completed) the switch is in an inoperable state and must be reset completely to restore correct operation. If such an event

Table continues on the next page...

**ESW\_MMSR field descriptions (continued)**

Field	Description
	happens the ESW_LMT setting must be increased during initialization to avoid such situation. The bit is cleared when the register is written.
0 BUSY	When set (1), Memory controller is initializing. The initialization is only preparing the internal data structures within the controller, it does not initialize the shared memory used for frame storage as this is not required. It is asserted after reset and stays set until the memory controller is ready to store frames. The switch must not be enabled before initialization of the memory controller has been completed.

**11.5.3.27 Low memory threshold (ESW\_LMT)**

If the number of cells available in memory is less than ESW\_LMT, the switch discards frames. Choose a value for at least two full-sized frames. A memory overflow due to a too low threshold is a fatal error and may require a device reset.

Address: 400E\_8000h base + 84h offset = 400E\_8084h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	0 Not ready 1 Ready
0 OR0	Output ready to accept data for port 0.  0 Not ready 1 Ready

#### 11.5.3.31 Queue weights (ESW\_QWT)

ESW\_QWT defines the weight for the corresponding queue for all ports. Setting all weights to zero implements a strict priority scheme.

Address: 400E\_8000h base + 94h offset = 400E\_8094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
R	Reserved								Q3WT				Reserved				Q2WT				Reserved				Q1WT				Reserved				Q0WT			
W	Reserved								Q3WT				Reserved				Q2WT				Reserved				Q1WT				Reserved				Q0WT			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0				

### ESW\_QWT field descriptions

Field	Description
31–29 Reserved	This field is reserved. Reserved, must be cleared
28–24 Q3WT	Queue 3 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Queue 3 is the highest priority queue. Valid values are 0-30.
23–21 Reserved	This field is reserved. Reserved, must be cleared
20–16 Q2WT	Queue 2 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Valid values are 0-30.
15–13 Reserved	This field is reserved. Reserved, must be cleared
12–8 Q1WT	Queue 1 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Valid values are 0-30.
7–5 Reserved	This field is reserved. Reserved, must be cleared
Q0WT	Queue 0 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Valid values are 0-30.

### 11.5.3.32 Port 0 Backpressure Congestion Threshold (ESW\_P0BCT)

ESW\_P0BCT defines the congestion threshold for port 0 backpressure. If the total output queues' shared memory (see [Output Frame Queuing](#)) has less than this number of free cells available, the switch stops serving the port 0 input buffer. This eventually fills the input buffer .

Address: 400E\_8000h base + 9Ch offset = 400E\_809Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																THRESH															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1

ESW\_P0BCT field descriptions

Field	Description
31–8 Reserved	This field is reserved. This field must be 0.
THRESH	Defines the congestion threshold for port 0 backpressure. Clearing this field disables the function (no backpressure).  <b>NOTE:</b> THRESH must be greater than the memory full threshold, ESW_LMT, to stop the DMA0 before a memory full situation.  The recommended value for THRESH is 0x40, which will eliminate or minimize the number of frames discarded in the ESW due to congestion.

### 11.5.3.33 Port 0 forced forwarding enable (ESW\_FFEN)

ESW\_FFEN forces forwarding for port 0 frames (i.e. frames transmitted from the DMA0 to the port 0 of the switch).

Address: 400E\_8000h base + BCh offset = 400E\_80BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												FD		Reserved	FEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_FFEN field descriptions

Field	Description
31–4 Reserved	This field is reserved. This field must be 0.
3–2 FD	When FEN is set, this field defines if the port 0 frame should be forwarded to the MAC at ports 1 and 2.  <b>NOTE:</b> It is possible to forward to one or both MAC ports. If neither bit is set, FEN is ignored and the frame is processed normally. This can be used to implement a handshake, as FEN is still reset but no further action occurs.  00 Do not forward. Frame is processed normally. 01 Forward to port 1 only 10 Forward to port 2 only 11 Forward to both ports
1 Reserved	This field is reserved. This field must be 0.
0 FEN	When set, the next frame received from port 0 (the local DMA port) is forwarded to the ports defined in FD. The bit resets to zero automatically when one frame from port 0 has been processed by the switch (i.e. has been read from the port 0 input buffer; see Figure 32-1). Therefore, the bit must be set again as necessary. See also Section 32.5.8.2, "Forced Forwarding" for a description.

### 11.5.3.34 Port snooping registers (ESW\_PSNP1)

ESW\_PSNP1 defines the TCP/UDP port number snooping function configuration.

Address: 400E\_8000h base + C0h offset = 400E\_80C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PORT_COMPARE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												CS	CD	MODE	EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_PSNP1 field descriptions

Field	Description
31–16 PORT_COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. This field must be 0.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value.  <b>NOTE:</b> The management port is defined in ESW_BMPC register.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

### 11.5.3.35 Port snooping registers (ESW\_PSNP2)

ESW\_PSNP2 defines the TCP/UDP port number snooping function configuration.

Address: 400E\_8000h base + C4h offset = 400E\_80C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PORT_COMPARE															
W

R	Reserved												CS	CD	MODE	EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_PSNP2 field descriptions

Field	Description
31–16 PORT_COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. This field must be 0.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value.  <b>NOTE:</b> The management port is defined in ESW_BMPC register.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

### 11.5.3.36 Port snooping registers (ESW\_PSNP3)

ESW\_PSNP3 defines the TCP/UDP port number snooping function configuration.

Address: 400E\_8000h base + C8h offset = 400E\_80C8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PORT_COMPARE

#### ESW\_PSNP3 field descriptions

Field	Description
31–16 PORT_COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. This field must be 0.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value.  <b>NOTE:</b> The management port is defined in ESW_BMPC register.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

### 11.5.3.37 Port snooping registers (ESW\_PSNP4)

ESW\_PSNP4 defines the TCP/UDP port number snooping function configuration.

Address: 400E\_8000h base + CCh offset = 400E\_80CCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### ESW\_PSNP4 field descriptions

Field	Description
31–16 PORT_COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. This field must be 0.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value.  <b>NOTE:</b> The management port is defined in ESW_BMPC register.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

### 11.5.3.38 Port snooping registers (ESW\_PSNP5)

ESW\_PSNP5 defines the TCP/UDP port number snooping function configuration.

Address: 400E\_8000h base + D0h offset = 400E\_80D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	PROTOCOL								Reserved					MODE		EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_IPSNP2 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This field must be 0.
15–8 PROTOCOL	The 8-bit protocol value to match with the incoming frame's IP header protocol field.
7–3 Reserved	This field is reserved. This field must be 0.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value (see the PROTOCOL bits).  <b>NOTE:</b> The management port is defined in register ESW_BMPC.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the protocol value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the IP snooping function only if the enable bit is set. Otherwise the settings are ignored. Defaults to 0 upon reset.

### 11.5.3.44 IP snooping registers (ESW\_IPSNP3)

ESW\_IPSNP3 defines the IP snooping function configuration.

Address: 400E\_8000h base + E8h offset = 400E\_80E8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	PROTOCOL								Reserved					MODE		EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_IPSNP3 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This field must be 0.
15–8 PROTOCOL	The 8-bit protocol value to match with the incoming frame's IP header protocol field.
7–3 Reserved	This field is reserved. This field must be 0.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value (see the PROTOCOL bits).  <b>NOTE:</b> The management port is defined in register ESW_BMPC.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the protocol value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the IP snooping function only if the enable bit is set. Otherwise the settings are ignored. Defaults to 0 upon reset.

### 11.5.3.45 IP snooping registers (ESW\_IPSNP4)

ESW\_IPSNP4 defines the IP snooping function configuration.

Address: 400E\_8000h base + ECh offset = 400E\_80ECh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PROTOCOL								Reserved					MODE		EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_IPSNP8 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This field must be 0.
15–8 PROTOCOL	The 8-bit protocol value to match with the incoming frame's IP header protocol field.
7–3 Reserved	This field is reserved. This field must be 0.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value (see the PROTOCOL bits).  <b>NOTE:</b> The management port is defined in register ESW_BMPC.  00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the protocol value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the IP snooping function only if the enable bit is set. Otherwise the settings are ignored. Defaults to 0 upon reset.

### 11.5.3.50 Port 0 VLAN priority resolution map (ESW\_P0VRES)

The ESW\_P0VRES register implements a 3-bit to 3-bit VLAN priority mapping capability. The current frame's 3-bit VLAN priority field is used as an index and the corresponding priority is taken from the respective position of the register giving the final classification for the frame.

Address: 400E\_8000h base + 100h offset = 400E\_8100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
R									PRI7				PRI6				PRI5				PRI4				PRI3				PRI2				PRI1				PRI0			
W																																								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0								

#### ESW\_P0VRES field descriptions

Field	Description
31–24 Reserved	This field is reserved. This field must be 0.
23–21 PRI7	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI7 field to give the final priority classification for the frame.
20–18 PRI6	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI6 field to give the final priority classification for the frame.
17–15 PRI5	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI5 field to give the final priority classification for the frame.
14–12 PRI4	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI4 field to give the final priority classification for the frame.
11–9 PRI3	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI3 field to give the final priority classification for the frame.
8–6 PRI2	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI2 field to give the final priority classification for the frame.
5–3 PRI1	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI1 field to give the final priority classification for the frame.
PRI0	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI0 field to give the final priority classification for the frame.

### 11.5.3.51 Port 1 VLAN priority resolution map (ESW\_P1VRES)

The ESW\_P1VRES register implements a 3-bit to 3-bit VLAN priority mapping capability. The current frame's 3-bit VLAN priority field is used as an index and the corresponding priority is taken from the respective position of the register giving the final classification for the frame.

Address: 400E\_8000h base + 104h offset = 400E\_8104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
R	Reserved								PRI7				PRI6				PRI5				PRI4				PRI3				PRI2				PRI1				PRI0			
W																																								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0								

#### ESW\_P1VRES field descriptions

Field	Description
31–24 Reserved	This field is reserved. This field must be 0.
23–21 PRI7	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI7 field to give the final priority classification for the frame.
20–18 PRI6	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI6 field to give the final priority classification for the frame.
17–15 PRI5	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI5 field to give the final priority classification for the frame.
14–12 PRI4	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI4 field to give the final priority classification for the frame.
11–9 PRI3	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI3 field to give the final priority classification for the frame.
8–6 PRI2	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI2 field to give the final priority classification for the frame.
5–3 PRI1	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI1 field to give the final priority classification for the frame.
PRI0	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI0 field to give the final priority classification for the frame.

### 11.5.3.52 Port 2 VLAN priority resolution map (ESW\_P2VRES)

The ESW\_P2VRES register implements a 3-bit to 3-bit VLAN priority mapping capability. The current frame's 3-bit VLAN priority field is used as an index and the corresponding priority is taken from the respective position of the register giving the final classification for the frame.

Address: 400E\_8000h base + 108h offset = 400E\_8108h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ESW\_P2VRES field descriptions

Field	Description
31–24 Reserved	This field is reserved. This field must be 0.
23–21 PRI7	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI7 field to give the final priority classification for the frame.
20–18 PRI6	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI6 field to give the final priority classification for the frame.
17–15 PRI5	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI5 field to give the final priority classification for the frame.
14–12 PRI4	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI4 field to give the final priority classification for the frame.
11–9 PRI3	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI3 field to give the final priority classification for the frame.
8–6 PRI2	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI2 field to give the final priority classification for the frame.
5–3 PRI1	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI1 field to give the final priority classification for the frame.
PRI0	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI0 field to give the final priority classification for the frame.

### 11.5.3.53 IPv4/v6 priority resolution table (ESW\_IPRES)

Address: 400E\_8000h base + 140h offset = 400E\_8140h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	READ	Reserved														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved	PRI2		PRI1		PRI0		IPV4SEL	ADDRESS							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_IPRES field descriptions

Field	Description
31 READ	Must be cleared to write values in the tables. When set during register writes, the IPv6 select and address bits are stored in the register only and the priority bits are ignored and not written into the addressed table. When the register is read, the priority bits represent the value read from the table always.
30–15 Reserved	This field is reserved. This field must be 0.
14–13 PRI2	The priority information to write into the addressed table entry. These 2 bits represent the output priority selected when the frame is received on port 2. When reading from the register, the bits show the value from the addressed table entry (address from last write operation).
12–11 PRI1	The priority information to write into the addressed table entry. These 2 bits represent the output priority selected when the frame is received on port 1. When reading from the register, the bits show the value from the addressed table entry (address from last write operation).
10–9 PRI0	The priority information to write into the addressed table entry. These 2 bits represent the output priority selected when the frame is received on port 0. 00=priority 0 (will be forwarded to output queue 0) 01=priority 1 (output queue 1) 10=priority 2 (output queue 2) 11=priority 3 (output queue 3) When reading from the register, the bits show the value from the addressed table entry (address from last write operation).
8 IPV4SEL	If set during a write, the IPv4 table is accessed. Valid address values range from 0 to 63. If cleared, the IPv6 table is accessed. Valid address values range from 0 to 255.
ADDRESS	The address of the priority entry to read or write for a frame received on port n. The IPv4 priority table has 64 entries. The IPv6 table has 256 entries. See also Section 32.5.5.2.1, "Classification Table Programming Model" for a description of the mapping table.

11.5.3.54 Port 0 priority resolution configuration (ESW\_P0RES)

ESW\_P0RES defines which priority information should be used for priority resolution.

Address: 400E\_8000h base + 180h offset = 400E\_8180h

ESW\_P0RES field descriptions

Field	Description
31–7 Reserved	This field is reserved. This field must be 0.
6–4 DFLT_PRI	The default priority of a frame received on port n, if none of the priority resolutions could define a priority of the frame. Up to 3 bits can be implemented.
3 Reserved	This field is reserved. This field must be 0.
2 MAC	Enable MAC based priority resolution for frame received on port n. If set, the priority information found within the MAC address table is used.
1 IP	Enable IP priority resolution for frame received on port n. If set, the IP DiffServ/COS field is used and priority is resolved according to the ESW_IPRES setting for the port. If cleared, IP Diffserv/COS fields are ignored.
0 VLAN	Enable VLAN priority resolution for frame received on port n. If set, the VLAN tag field of a frame is inspected and priority is resolved according to the setting programmed in ESW_P n VRES for the port on which the frame was received. If cleared, VLAN priority is ignored.

### 11.5.3.55 Port 1 priority resolution configuration (ESW\_P1RES)

ESW\_P1RES defines which priority information should be used for priority resolution.

Address: 400E\_8000h base + 184h offset = 400E\_8184h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								DFLT_PRI				Reserved	MAC	IP	VLAN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ESW\_P1RES field descriptions

Field	Description
31–7 Reserved	This field is reserved. This field must be 0.
6–4 DFLT_PRI	The default priority of a frame received on port n, if none of the priority resolutions could define a priority of the frame. Up to 3 bits can be implemented.
3 Reserved	This field is reserved. This field must be 0.
2 MAC	Enable MAC based priority resolution for frame received on port n. If set, the priority information found within the MAC address table is used.
1 IP	Enable IP priority resolution for frame received on port n. If set, the IP DiffServ/COS field is used and priority is resolved according to the ESW_IPRES setting for the port. If cleared, IP Diffserv/COS fields are ignored.
0 VLAN	Enable VLAN priority resolution for frame received on port n. If set, the VLAN tag field of a frame is inspected and priority is resolved according to the setting programmed in ESW_P n VRES for the port on which the frame was received. If cleared, VLAN priority is ignored.

11.5.3.56 Port 2 priority resolution configuration (ESW\_P2RES)

ESW\_P2RES defines which priority information should be used for priority resolution.

Address: 400E\_8000h base + 188h offset = 400E\_8188h

ESW\_P2RES field descriptions

Field	Description
31–7 Reserved	This field is reserved. This field must be 0.
6–4 DFLT_PRI	The default priority of a frame received on port n, if none of the priority resolutions could define a priority of the frame. Up to 3 bits can be implemented.
3 Reserved	This field is reserved. This field must be 0.
2 MAC	Enable MAC based priority resolution for frame received on port n. If set, the priority information found within the MAC address table is used.
1 IP	Enable IP priority resolution for frame received on port n. If set, the IP DiffServ/COS field is used and priority is resolved according to the ESW_IPRES setting for the port. If cleared, IP Diffserv/COS fields are ignored.
0 VLAN	Enable VLAN priority resolution for frame received on port n. If set, the VLAN tag field of a frame is inspected and priority is resolved according to the setting programmed in ESW_P n VRES for the port on which the frame was received. If cleared, VLAN priority is ignored.

### 11.5.3.57 Port 0 VLAN ID (ESW\_P0ID)

ESW\_P0ID defines the VLAN ID field for VLAN input manipulation function of a port (if it exists).

Address: 400E\_8000h base + 200h offset = 400E\_8200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ESW\_VRES19 field descriptions

Field	Description
31–15 Reserved	This field is reserved. This field must be 0.
14–3 VLANID	VLAN identifier
2 P2	One bit per port that is member of the VLAN identified with the 12-bit VLAN ID of the entry.
1 P1	One bit per port that is member of the VLAN identified with the 12-bit VLAN ID of the entry.
0 P0	One bit per port that is member of the VLAN identified with the 12-bit VLAN ID of the entry.

### 11.5.3.80 VLAN domain resolution entry 20 (ESW\_VRES20)

#### NOTE

The VLAN table is always searched completely. Therefore, the table entries do not need to be written in any order.

Address: 400E\_8000h base + 2D0h offset = 400E\_82D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**ESW\_NDISCN field descriptions**

Field	Description
COUNT	Total number of incoming frames processed and not discarded

### 11.5.3.95 Bytes of non-discarded frames (ESW\_NDISCB)

Sum of bytes of frames counted in ESW\_NDISCN

Address: 400E\_8000h base + 30Ch offset = 400E\_830Ch

#### ESW\_NDISCB field descriptions

Field	Description
COUNT	Sum of bytes of frames counted in ESW_NDISCN

### 11.5.3.96 Port 0 output queue congestion (ESW\_P0OQC)

Port 0 outgoing frames discarded due to output queue congestion

Address: 400E\_8000h base + 310h offset = 400E\_8310h

#### ESW\_P0OQC field descriptions

Field	Description
COUNT	Number of outgoing frames discarded due to output queue congestion

11.5.3.97 Port 0 mismatching VLAN ID (ESW\_P0MVID)

Port 0 incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled. See ESW\_VLANV.

Address: 400E\_8000h base + 314h offset = 400E\_8314h

ESW\_P0MVID field descriptions

Field	Description
COUNT	Number of incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled

11.5.3.98 Port 0 missing VLAN tag (ESW\_P0MVTAG)

Port 0 incoming frames discarded due to missing VLAN tag. See ESW\_VLANV.

Address: 400E\_8000h base + 318h offset = 400E\_8318h

ESW\_P0MVTAG field descriptions

Field	Description
COUNT	Number of incoming frames discarded due to missing VLAN tag

### 11.5.3.99 Port 0 blocked (ESW\_P0BL)

Port 0 incoming frames discarded (after learning) as port is configured in blocking mode

Address: 400E\_8000h base + 31Ch offset = 400E\_831Ch

#### ESW\_P0BL field descriptions

Field	Description
COUNT	Number of incoming frames discarded (after learning) as port is configured in blocking mode

### 11.5.3.100 Port 1 output queue congestion (ESW\_P1OQC)

Port 1 outgoing frames discarded due to output queue congestion

Address: 400E\_8000h base + 320h offset = 400E\_8320h

#### ESW\_P1OQC field descriptions

Field	Description
COUNT	Number of outgoing frames discarded due to output queue congestion

11.5.3.101 Port 1 mismatching VLAN ID (ESW\_P1MVID)

Port 1 incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled. See ESW\_VLANV.

Address: 400E\_8000h base + 324h offset = 400E\_8324h

ESW\_P1MVID field descriptions

Field	Description
COUNT	Number of incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled

11.5.3.102 Port 1 missing VLAN tag (ESW\_P1MVTAG)

Port 1 incoming frames discarded due to missing VLAN tag. See ESW\_VLANV.

Address: 400E\_8000h base + 328h offset = 400E\_8328h

ESW\_P1MVTAG field descriptions

Field	Description
COUNT	Number of incoming frames discarded due to missing VLAN tag

### 11.5.3.103 Port 1 blocked (ESW\_P1BL)

Port 1 incoming frames discarded (after learning) as port is configured in blocking mode

Address: 400E\_8000h base + 32Ch offset = 400E\_832Ch

#### ESW\_P1BL field descriptions

Field	Description
COUNT	Number of incoming frames discarded (after learning) as port is configured in blocking mode

### 11.5.3.104 Port 2 output queue congestion (ESW\_P2OQC)

Port 2 outgoing frames discarded due to output queue congestion

Address: 400E\_8000h base + 330h offset = 400E\_8330h

#### ESW\_P2OQC field descriptions

Field	Description
COUNT	Number of outgoing frames discarded due to output queue congestion

11.5.3.105 Port 2 mismatching VLAN ID (ESW\_P2MVID)

Port 2 incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled. See ESW\_VLANV.

Address: 400E\_8000h base + 334h offset = 400E\_8334h

ESW\_P2MVID field descriptions

Field	Description
COUNT	Number of incoming frames discarded due to mismatching or missing VLAN ID while VLAN verification was enabled

11.5.3.106 Port 2 missing VLAN tag (ESW\_P2MVTAG)

Port 2 incoming frames discarded due to missing VLAN tag. See ESW\_VLANV.

Address: 400E\_8000h base + 338h offset = 400E\_8338h

ESW\_P2MVTAG field descriptions

Field	Description
COUNT	Number of incoming frames discarded due to missing VLAN tag

### 11.5.3.107 Port 2 blocked (ESW\_P2BL)

Port 2 incoming frames discarded (after learning) as port is configured in blocking mode

Address: 400E\_8000h base + 33Ch offset = 400E\_833Ch

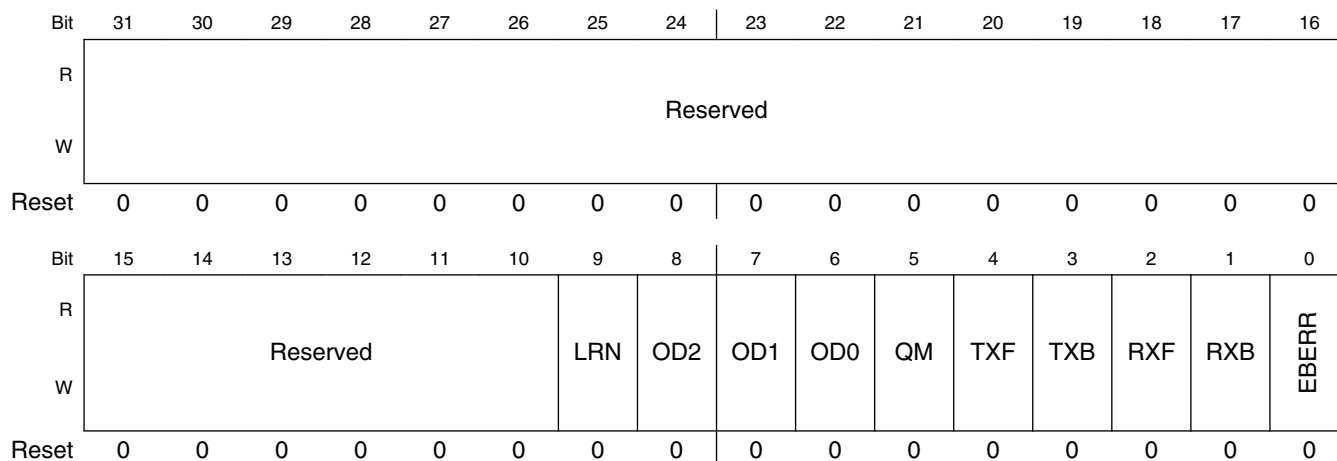

**ESW\_P2BL field descriptions**

Field	Description
COUNT	Number of incoming frames discarded (after learning) as port is configured in blocking mode

### 11.5.3.108 Interrupt status register (ESW\_ISR)

ESW\_ISR indicates the interrupt status. To clear a bit write a one to it. The bit stays set if the event condition persists.

Address: 400E\_8000h base + 400h offset = 400E\_8400h

**ESW\_ISR field descriptions**

Field	Description
31–10 Reserved	This field is reserved. This field must be 0.

*Table continues on the next page...*

## ESW\_ISR field descriptions (continued)

Field	Description
9 LRN	Learning Record available in registers LNR_REC_0 and LNR_REC_1 . Note: this interrupt can be very frequent on a heavy loaded network. It is not recommended to use this interrupt source as interrupt but rather implement a slow background task polling the bit to perform learning.
8 OD2	Outgoing frames discarded due to output Queue congestion on Port 2 or port is disabled (ESW_PER).
7 OD1	Outgoing frames discarded due to output Queue congestion on Port 1 or port is disabled (ESW_PER).
6 OD0	Outgoing frames discarded due to output Queue congestion on Port 0 or port is disabled (ESW_PER).
5 QM	Low Memory Threshold. Asserted if the memory became congested and number of free cells dropped below threshold ESW_LMT .  <b>NOTE:</b> This field will become asserted after reset immediately due to memory initialization.
4 TXF	Transmit frame interrupt. This bit indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated .
3 TXB	Transmit buffer interrupt. This bit indicates a transmit buffer descriptor has been updated .
2 RXF	Receive frame interrupt. This bit indicates a frame has been received and the last corresponding buffer descriptor has been updated .
1 RXB	Receive buffer interrupt. This bit indicates a receive buffer descriptor not the last in the frame has been updated .
0 EBERR	Ethernet bus error. This bit indicates a system bus error occurs when a DMA transaction is underway .

## 11.5.3.109 Interrupt mask register (ESW\_IMR)

Address: 400E\_8000h base + 404h offset = 400E\_8404h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W								EBERR								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ESW\_IMR field descriptions**

<b>Field</b>	<b>Description</b>
31–10 Reserved	This field is reserved. This field must be 0.
9 LRN	This field corresponds to the ESW_ISR[LRN] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[LRN] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
8 OD2	This field corresponds to the ESW_ISR[OD2] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[OD2] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
7 OD1	This field corresponds to the ESW_ISR[OD1] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[OD1] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
6 OD0	This field corresponds to the ESW_ISR[OD0] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[OD0] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
5 QM	This field corresponds to the ESW_ISR[QM] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[QM] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
4 TXF	This field corresponds to the ESW_ISR[TXF] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[TXF] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
3 TXB	This field corresponds to the ESW_ISR[TXB] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[TXB] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
2 RXF	This field corresponds to the ESW_ISR[RXF] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[RXF] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .

*Table continues on the next page...*

**ESW\_IMR field descriptions (continued)**

Field	Description
1 RXB	This field corresponds to the ESW_ISR[RXB] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[RXB] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
0 EBERR	This field corresponds to the ESW_ISR[EBERR] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[EBERR] reflects the state of the interrupt signal even if this field is masked.  0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .

**11.5.3.110 Receive descriptor ring pointer (ESW\_RDSR)**

This register points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

**NOTE**

- This register is undefined at reset and must be initialized by the user.
- When the switch is enabled, i.e., in switch mode, this register overrides the ENET\_RDSR register.

Address: 400E\_8000h base + 408h offset = 400E\_8408h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**ESW\_RDSR field descriptions**

Field	Description
31–3 ADDRESS	Pointer to start of receive buffer descriptor queue.
2 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.5.3.111 Transmit descriptor ring pointer (ESW\_TDSR)

This register provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16. The least two significant bits should be written to zero. The hardware ignores non-zero values in these two bit positions.

#### NOTE

- This register is undefined at reset and must be initialized by the user.
- When the switch is enabled, i.e., in switch mode, this register overrides the ENET\_TDSR register.

Address: 400E\_8000h base + 40Ch offset = 400E\_840Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### ESW\_TDSR field descriptions

Field	Description
31–3 ADDRESS	Pointer to start of transmit buffer descriptor queue.
2 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.5.3.112 Maximum receive buffer size (ESW\_MRBR)

This register dictates the maximum size of all receive buffers. The SIZE field is concatenated with the four least-significant bits of this register to produce the maximum receive buffer size. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, ESW\_MRBR must be set to ENET<sub>n</sub>\_RCR[MAX\_FL] or larger. To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, the lower four bits are set to zero by the device.

To minimize bus utilization (descriptor fetches), it is recommended that ESW\_MRBR be greater than or equal to 256 bytes.

ESW\_MRBR clears to 0 when ESW\_MODE\_CONFIG[SWITCH\_E] = 0.

NOTE

- This register is undefined at reset and must be initialized by the user.
- When the switch is enabled, i.e., in switch mode, this register overrides the ENET\_MRBR register.

Address: 400E\_8000h base + 410h offset = 400E\_8410h

ESW\_MRBR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–4 SIZE	Maximum size of receive buffer. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size in bytes.  To minimize bus utilization (descriptor fetches), it is recommended that the buffer size be greater than or equal to 256 bytes, that is, that SIZE be greater than or equal to 16.
Reserved	The four least-significant bits of the maximum receive buffer size.  This field is reserved. This read-only field is reserved and always has the value 0.

11.5.3.113 Receive descriptor active (ESW\_RDAR)

This command register, written by the user, indicates the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (provided ENET n\_ECR[ETHER\_EN] is also set). After the MAC polls a receive descriptor whose empty bit is not set, the MAC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

Class0 clears to 0 when ESW\_MODE\_CONFIG[SWITCH\_E] = 0. The ESW\_RDAR register is cleared at reset and when ENET n\_ECR[ETHER\_EN] is cleared.

**NOTE**

When the switch is enabled, i.e., in switch mode, this register overrides the ENET\_RDAR register.

Address: 400E\_8000h base + 414h offset = 400E\_8414h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved							RDAR	Reserved							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ESW\_RDAR field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This field must be 0.
24 RDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC device when no additional empty descriptors remain in the receive ring. Also cleared when ENET <i>n</i> _ECR[ETHER_EN] is cleared.
Reserved	This field is reserved. This field must be 0.

**11.5.3.114 Transmit descriptor active (ESW\_TDAR)**

This command register, written by the user, indicates the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR bit is set. This value is independent of the data actually written by the user. When set, the MAC polls the transmit descriptor ring and processes transmit frames (provided ENET $n$ \_ECR[ETHER\_EN] is also set). After the MAC polls a transmit descriptor that is a ready bit not set, MAC clears TDAR and ceases transmit descriptor ring polling until you set the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

Class0 clears to 0 when ESW\_MODE\_CONFIG[SWITCH\_E] = 0. The ENET $n$ \_TDAR registers are cleared at reset, when ENET $n$ \_ECR[ETHER\_EN] is cleared, or when ENET $n$ \_ECR[RESET] is set.

**NOTE**

When the switch is enabled, i.e., in switch mode, this register overrides the ENET\_TDAR register.

Address: 400E\_8000h base + 418h offset = 400E\_8418h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0 DA	Indicates if the learning record is valid and can be read.  0    Learning record invalid 1    Learning record valid

11.5.4 MAC address lookup table

The MAC Address Lookup Table contains 2048 MAC address lookup entries. Each entry is 64 bits. The table is implemented as 32-bit registers, so each 64-bit entry is split into two 32-bit words. The low address (ADDRL) represents the lower 32 bits (31:0). The high address (ADDRH) represents the higher 32 bits (63:32) of an entry. See [Address Memory](#) for the structure of a 64-bit entry.

Each entry must be written or read with the low address accessed first followed by the high address. The table should be initialized by software during system startup.

11.5.5 Functional Description

The switch implements the following main functions:

- Input/output VLAN processing
- IP snooping
- Input frame parsing and priority extraction
- Input port selection
- Output port(s) resolution
- Frame queuing
- Output queue scheduling

### 11.5.5.1 VLAN Input Processing Function

The VLAN input processing function is used on each switch input port to inspect and manipulate the VLAN tag of frames entering the switch. It performs the following functions:

- Input frame parsing
- VLAN tag insertion or manipulation

Based on the information of the input processing function the frame can be switched to the corresponding output port or is discarded.

#### NOTE

When the input processing function inserts a VLAN tag into the frame, the further switch forwarding decisions treat the frame as a tagged frame and no longer as untagged.

#### 11.5.5.1.1 Terms and Definitions

- VLAN information — The 16-bit field following the VLAN type field within a frame
- VLAN ID — The lower 12 bits of the VLAN information field
- VLAN priority — The upper 3 bits of the VLAN information field that prioritizes incoming frames. A value of 0 represents lowest priority; a value of 7 represents highest priority.

#### 11.5.5.1.2 Configuration Information

The switch management provides the following information to configure and control the operation of the function:

- [ESW\\_PnID\[VLANID\]](#) — The VLAN information field (VLAN-ID and priority) used for tag insertion and optionally tag overwrite operations.
- Mode of operation — There are different modes of operation, which define how incoming frames must be processed for a port. The function can be enabled and configured individually per port. See the `ESW_VIMEN` and `ESW_VIMSEL` registers.

### Note

If the VLAN input processing function is not enabled (ESW\_VIMEN = 0) the mode setting has no effect.

#### 11.5.5.1.3 Modes of Operation

##### 11.5.5.1.3.1 Frame Processing

The VLAN input processing function modifies the frames before they enter the switching engine. If a VLAN tag is inserted, the switch only acts on the inserted VLAN tag (e.g. priority). Any original tag that was found in the frame before the modification, if any, has no effect within the switch.

In addition, if VLAN verification is enabled for a port (see the ESW\_VLANV register), the VLAN ID used for insertion/overwrite (ESW\_PnID) must also be configured in the global VLAN resolution table (see the ESW\_VRES $n$  register). This ensures the switch accepts frames, which contain the inserted/overwritten tag.

When a tag is inserted in any of the modes, it is always inserted as the first tag (outer) and its information field is set as programmed in the ESW\_PnID register for the port  $n$  where the frame is received.

##### 11.5.5.1.3.2 Mode 1 — Single Tagging with Passthrough

Mode 1 inserts a tag only if the frame is untagged. If the frame is already tagged, the frame is unmodified.

### NOTE

The mode does not check for double tagged. That is, double tagged is treated the same as single tagged and hence will be left unmodified.

##### 11.5.5.1.3.3 Mode 2 — Single Tagging with Replace

If untagged, add the tag. If single tagged, overwrite it.

The overwrite value can be different from the inserted tag value when enabled in ESW\_VIMEN.

**NOTE**

The mode does not check for double tagged. That is, double tagged is treated same as single tagged and hence will have its outer tag overwritten.

**11.5.5.1.3.4 Mode 3 — Double Tagging with Passthrough**

Insert a tag on untagged and tagged frames. This results in a single-tagged frame when an untagged is received, and a double-tagged frame, when a single-tagged frame is received. When a double-tagged frame is received, the frame is unmodified.

**11.5.5.1.3.5 Mode 4 — Double Tagging with Replace**

Insert tag on untagged and single-tagged frames. If a double-tagged frame is received, overwrite the outer tag.

The overwrite value can be different from the inserted tag value when enabled in ESW\_VIMEN.

**11.5.5.2 IP Snooping**

The switch supports programmable snooping for up to eight programmable IP protocols. If the protocol field of an IPv4 or IPv6 frame matches one of the programmed values and snooping is enabled for that entry, the frame can be processed as follows:

- Forward to designated management port only
- Copy to management port and normal forward/flood
- Discard on match

The management port is identified by the port number set in the ESW\_BMPC register. The function is configured using ESW\_IPSNP1–8.

The snooping function can be enabled/disabled individually for each of the entries. If no protocol matches, a match occurs but snooping is disabled, or the frame is coming from the management port itself, the frame is processed normally.

**Note**

Snooping respects any optional VLAN tags (i.e. extracts next after last VLAN tag).

### 11.5.5.3 TCP/UDP Port Number Snooping

Programmable snooping for up to eight programmable TCP or UDP port numbers. If the source or destination port number field within an TCP/IP or UDP/IP frame (IPv4 and IPv6) matches the compare value and snooping is enabled for that entry, the frame can be processed as follows:

- Forward to designated management port only
- Copy to management port and normal forward/flood
- Discard on match

The management port is identified by the port number set in the ESW\_BMPC register. The function is configured using ESW\_IPSNP1–8.

The snooping function can be enabled/disabled individually for each of the entries. If no entry matches, a match occurs but snooping is disabled, or the frame is coming from the management port itself, the frame is processed normally.

#### Note

Port number snooping is possible only if the IP header ends up to ten words (40 bytes) after the MAC header. If the IP header ends later (e.g. IPv6 + VLAN or IPv4 + >20 byte options) the port numbers cannot be parsed any more and the port number snooping is ignored (protocol-based snooping is not affected by this limit).

For IPv6 frames the port number can only be compared if the UDP or TCP header is the very next header to the IPv6 header (i.e. it does not detect such headers if any extension headers are present in an IPv6 frame before the TCP or UDP header).

### 11.5.5.4 VLAN Output Processing Function

The VLAN output processing function is used on a switch output port to manipulate the VLAN tag of the outgoing frames that leave the switch. Frames are processed based on the output processing mode and the number of tags in the frame.

#### 11.5.5.4.1 Configuration Information

The switch management provides the information on operating mode to configure and control the operation of the function using the ESW\_VOMSEL register of a port. There are three different modes of operation, which define how the outgoing frames should be processed.

Additionally, you can use the VLAN resolution table, which allows VID-specific tag removal.

##### 11.5.5.4.1.1 Mode 0 — Disabled

No frame manipulation occurs.

##### 11.5.5.4.1.2 Mode 1 — Strip Mode

In strip mode, all the tags (single or double) are removed from incoming frame.

##### 11.5.5.4.1.3 Mode 2 — Tag Through Mode

In tag through mode, the inner tag is passed through while the outer tag is removed for a double-tagged frame. The following rules apply:

- When a single-tagged frame is received, strip the tag from the frame.
- When a double-tagged frame is received, strip the outer tag from the frame.

##### 11.5.5.4.1.4 Mode 3 — Transparent Mode

In transparent mode, a single-tagged frame is unchanged. The following rules apply:

- When a single-tagged frame is received, frame is unchanged.
- When a double-tagged frame is received, strip the outer tag from the frame.

#### 11.5.5.5 Frame Classification and Priority Resolution

When a frame is received on an input port, several pieces are extracted from the frame (Ethernet MAC address, VLAN tag, and IP headers) to determine the frame type and perform the relevant classification actions.

In addition, the MAC address table can provide a priority indication for the destination MAC address if the switch management has programmed the address table accordingly (static entry).

The frame is classified in up to four priority levels (0 = lowest, 3 = highest) and is eventually queued in the corresponding priority queue at the output port.

#### 11.5.5.5.1 VLAN Priority Look-Up

An eight-entry programmable priority table is implemented on each port. The ESW\_PnVRES registers contain the priority mapping for port  $n$ .

The switch uses 3-bit priority field from the VLAN tag information to extract the corresponding bits from the table, which indicates which priority the frame is finally classified.

The index in the mapping table is the three bits of the first octet of the VLAN tag data (bit 5 (prio0) is the lsb and bit 7 (prio2) is the msb).

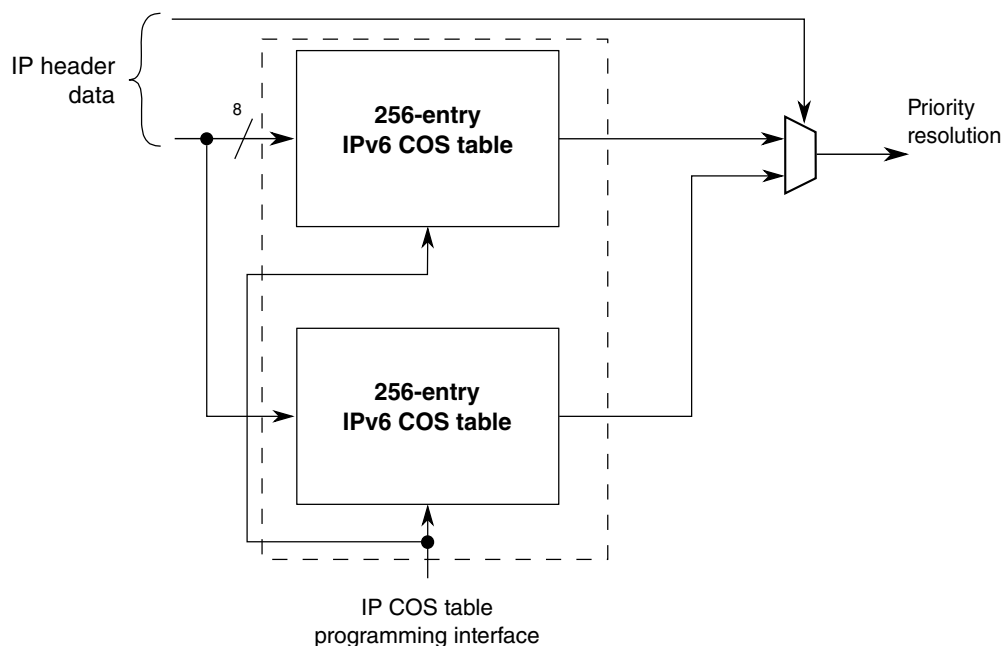

**Figure 11-66. VLAN Table Overview**

#### 11.5.5.5.2 IPv4 and IPv6 Priority Look Up

The switch can classify IPv4 and IPv6 frames:

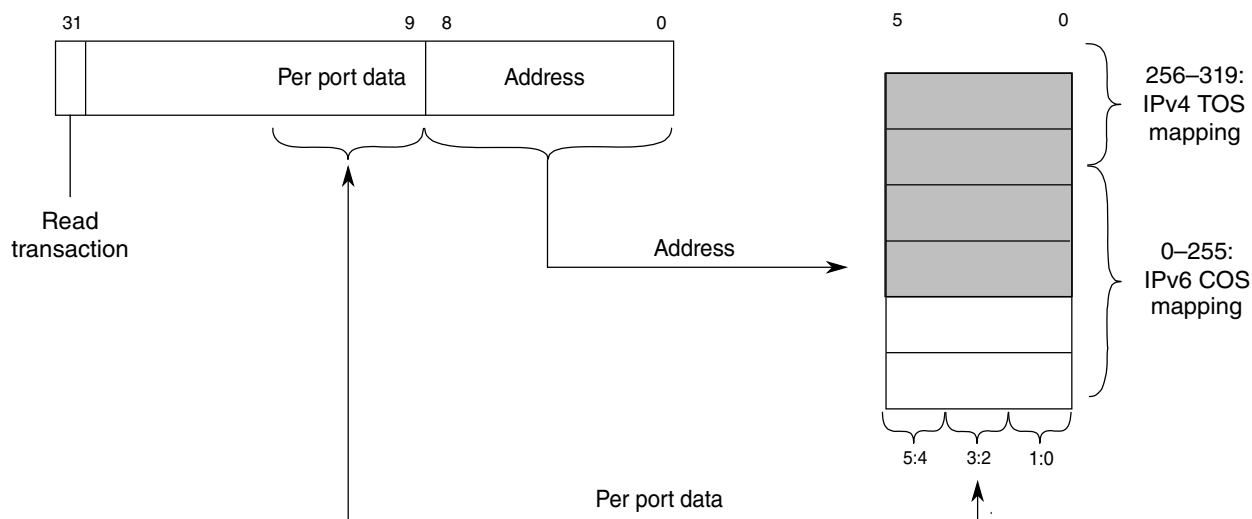

- A 64-entry table is implemented per port to classify the IPv4 frames
  - The frame's six-bit DiffServ field is provided and the table returns the 3-bit priority information
- A 256-entry table is implemented per port to classify IPv6 Frames (IP COS tables)
  - The eight-bit class of service field is provided and the table returns the 3-bit priority information

**Figure 11-67. IP COS Tables Overview**

#### 11.5.5.5.2.1 Classification Table Programming Model

An indirect addressing scheme is implemented to program the mapping tables using a single register (ESW\_IPRES).

**Figure 11-68. ESW\_IPRES Mapping Table Programming Model**

The table is implemented in a single 320-deep table used for IPv4 6-bit TOS and IPv6 8-bit COS mappings.

- The first 256 entries represent the IPv6 COS field mapping. The received COS field of a frame is used to address a row from 0–255. The value stored is read and used as priority for the frame.
- The last 64 entries represent the IPv4 DiffServ field mapping. The received DiffServ (upper 6-bits of TOS) value of a frame is used to address a row from 256–319.
- Each entry of the table provides the priority mapping in bits 1:0 for port 0 (00 = queue0, 01 = queue1, 10 = queue2, 11 = queue3), bits 3:2 for port 1, and bits 5:4 for port 2.

To write a table row into the table the address is provided in bits 8:0 and the data in bits 13:9, where bit 9 represents bit 0 of the data and bit 13 represents bit 5 of the data.

To read a table row, the read bit must be set when writing into the ESW\_IPRES register. This triggers a read transaction to the address provided in bits 8:0 of the register. After this, reading the register provides the data returned from the table for this address.

When writing an entry into the table, software can only write the mapping for all ports in one write transaction. Therefore software must implement a read-modify-write scheme, to:

1. Read the current table contents
2. Modify the priority bits for the port of interest without modifying the other ports bits
3. Write back the complete data word into the table

### **11.5.5.5.3 Priority Resolution**

The priority resolution function is independently programmable on each port through the ESW\_PnRES registers by enabling or disabling VLAN, IP, or MAC address-based classification (see [Port 0 priority resolution configuration \(ESW\\_P0RES\)](#)).

The priority resolution follows the following rule set depending on which classifications are enabled (ESW\_PnRES) and which fields are found within the frame:

- If IP classification is enabled and an IP header found, map the priority according to the ESW\_IPRES table
- Else, if VLAN classification is enabled and a VLAN tag is found, map the priority according to the ESW\_PnVRES table

- Else, if MAC classification is enabled and MAC address found, take the priority from address table, if it is a static entry
- Else, use default priority as specified in ESW\_PnRES

#### 11.5.5.5.4 Bridge Control Protocol Identification

To allow for implementation of bridge control protocols like the spanning tree protocol, all control frames (bridge protocol data units, BPDU) are marked when they enter the switch. The mark then can be used by the input port blocking function to drop the frame after the address learning (see [Protocol Snooping](#)).

In addition, the function can be configured to pass all frames or to pass only control frames (e.g. covering spanning tree port states blocking, listening, and learning) and discard all other frames.

#### 11.5.5.6 Input Port Selection

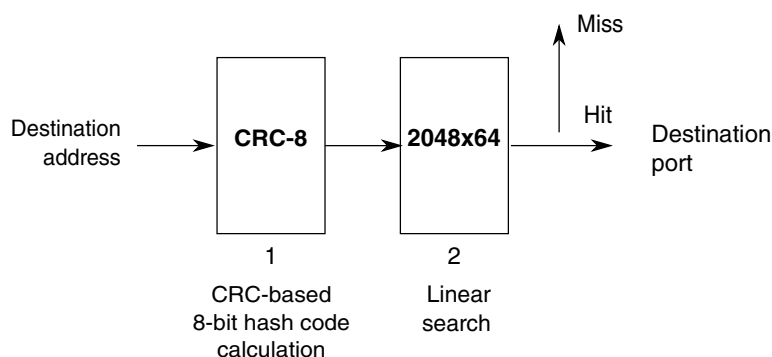

The port selection constantly polls all input ports for available data. If any data is available, the port is selected and frame data is read from the input. After one frame is read, another port is selected, even if more data is available on the current port.

This means for the application on a port atlantic input interface, that it is not allowed to perform back-to-back frame transfers to the switch. Instead the application must wait for a new selection after one frame has been transferred.

#### 11.5.5.7 Layer 2 Look-Up Engine

An eight-bit hash code is calculated using the frame destination's MAC address. It is used as an index to the MAC address lookup table which contains MAC addresses with destination port number and validity information.

As one hash code value can represent more than one MAC address, the memory implements for each pointer, up to eight MAC address entries, which are searched linearly.

**Figure 11-69. Port Look-Up Overview**

### 11.5.5.7.1 Hash Code

For a MAC address table up to 2048 entries, an 8-bit hash value is calculated from the 48-bit destination MAC address. The hash code uses a CRC-8:

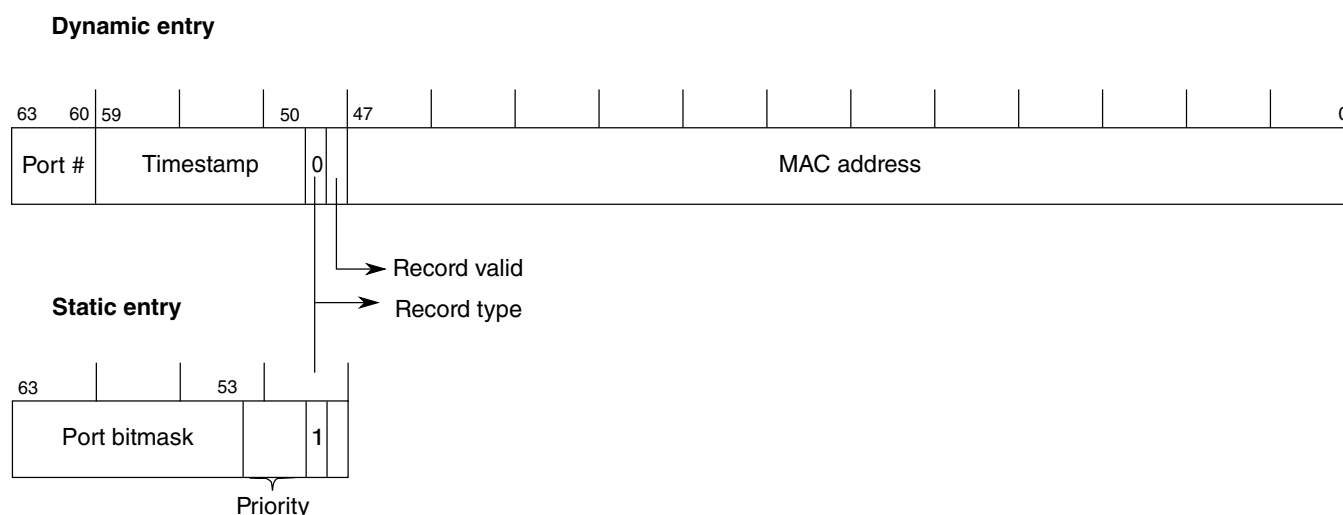

$$x^8 + x^2 + x + 1 \text{ (0x07)}$$

### 11.5.5.7.2 Address Memory

The address memory is divided into blocks. Each block contains eight records, which contain 64 bits of information each. Each record contains the 48-bit MAC address and provides the necessary forwarding information, and priority or timestamp information.

Two types of records are defined:

- **Dynamic record** — The dynamic entry provides the MAC address together with a 10-bit timestamp and destination port number. These entries are created by the learning function based on received frames to enable forwarding of frames to dedicated ports. Dynamic entries are deleted by the aging function if not updated.
- **Static multiport/priority record** — Switch management can also write static entries in the table, which can include priority information and multiple destination ports for forwarding. The MAC address can be unicast or multicast. These records can be used to specify the ports to participate in a specific multicast domain or to assign a MAC address based priority to a frame. The aging and learning functions ignore static records.

**Figure 11-70. Address Memory Record Types**

The record's bit 49 decides which type of record is found in the table:

- If 0, a dynamic entry is available. The 10-bit timestamp and 4-bit port number are given in the upper bits of the record.
- If 1, a static entry is available with a 3-bit priority field followed by a 3-bit port bit mask. The record bit 53 represents port 0, bit 54 port 1, and bit 55 port 2. The frame is forwarded to all ports whose port bitmask is set. The source port is removed dynamically from the bitmask during forwarding (a frame is never forwarded to the port where it came from).

The 48-bit MAC address is stored with the first octet in bits 7:0 and the sixth octet in 47:40 of the record.

## 11.5.5.8 Layer 2 Lookup Tasks Overview

### 11.5.5.8.1 MAC Address Lookup

The 48-bit destination MAC address of each frame received by the switch, on any of its interfaces, is extracted by the hardware and provided to the look-up engine together with the physical interface number. If the frame carries a VLAN tag, the tag information is also extracted and provided to the look-up engine.

If the received frame is a unicast or multicast frame, a two-stage lookup process is implemented. The look-up engine first calculates the hash value from the MAC address. The hash code is used as an index to the MAC address lookup table. The look-up function can provide three results with three different associated actions performed by the switch hardware:

1. The address is in the table and associated with a correct port number:

The switch forwards the frame only to the looked up port.

2. The address is in the table but is associated with the port on which it was received:

The switch discards the frame and does not forward it to any port.

3. The address is not found in the table:

The switch engine sends the received frame to all ports except the port on which it was received (flooding).

If a broadcast frame is received, the switch hardware sends the received frame to all output ports, except the one from which it was received (flooding).

### **Note**

Flooding and additional frame filtering can be controlled (for example, to avoid the duplication of critical information to unwanted destinations) with the mechanism described in [Broadcast/Multicast/VLAN Domain Resolution](#).

#### **11.5.5.8.2 Forced Forwarding**

The MAC address lookup result can be overwritten using the forced forwarding configuration available in the ESW\_FFEN register. This feature is available only for frames coming from the local port (port 0).

When forced forwarding is enabled for a frame, the frame is forwarded to the forced destination ports, ignoring any results from the MAC destination address lookup. Forced forwarding only replaces the MAC lookup function, all other filtering functions (e.g. VLAN verification) act as normal.

#### **11.5.5.8.3 Learning**

The switch hardware extracts the source MAC address of each frame received on each of the switch ports and provides it (via the ESW\_LREC0 and ESW\_LREC1 registers) to the switch which implements the learning task. The ESW\_LSR register indicates availability of learning data.

##### **11.5.5.8.3.1 Learning Interface**

The interface implements a FIFO buffer that stores up to 32 words of 32-bit each.

Figure 11-71. Learning Interface Overview

For each frame processed by the switch engine, two 32-bit records (record A0 and record B1) are written in the information FIFO. Record A is written first.

The MAC address available in records A0 and B1 is the source MAC address of the frame. Record A holds the first four bytes of the frame source address, and record B contains the last two bytes.

The hash code in record B is calculated with the source MAC address and the same hash polynomial used for look-up, as defined in [Hash Code](#).

The 4-bit port number defines the port/MAC address association.

Table 11-127. Frame Information Records — 8-Bit Hash Values

	3 3 2 2	2 2 2 2	2 2 2 2	1 1 1 1	1 1 1 1	1 1		
	1 0 9 8	7 6 5 4	3 2 1 0	9 8 7 6	5 4 3 2	1 0 9 8	7 6 5 4	3 2 1 0
Frame record A	MAC address							
Frame record B	Reserved	Port #	Hash code	MAC address (cont'd)				

When information for at least one frame (two records) is available, the status indication in ESW\_LSR register is set. To read the frame records, read the ESW\_LREC0 register (record A) first followed by the ESW\_LREC1 register (record B).

Note

Reading ESW\_LREC1 triggers the retrieval of the next record pair from the FIFO, if any.

The learning task (software) uses this information and then executes as follows:

1. For every frame received, the source address with port and timestamp information is stored in the address lookup table. The following information is stored for each entry:

- MAC address
  - Time stamp: a 10-bit value, determines the age of an entry
  - Port number: a 4-bit value, indicates the port the frame was received
2. If the MAC address table is full, a new entry replaces the oldest entry with an identical matching hash value.

#### **11.5.5.8.4 Migration**

When the switch receives a MAC address, which is already in the switch table but is associated to a different physical port number, the current entry is overwritten with the new information and the timestamp is set to the current time.

#### **11.5.5.8.5 Aging**

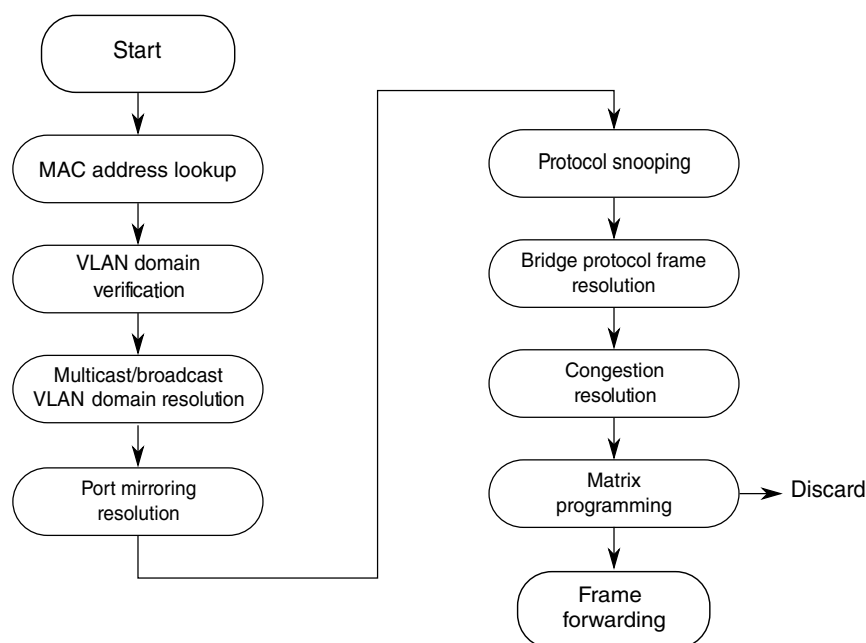

Aging refers to deleting old entries within the table. It proceeds as follows:

1. The 10-bit timestamp is stored with all the entries and is updated each time the source address appears.
2. If a record is not updated for a longer period of time, it is removed from the table if it is a dynamic entry.
3. Static entries are not affected by the aging process and are always kept.

This process runs continuously. The aging period is software-controlled and programmable, defaulting to four seconds per step. This gives a range of 4 seconds to 68 minutes.

### **11.5.5.9 Frame-Forwarding Tasks**

When an input port is selected the frame is forwarded to its corresponding output port. Output port resolution and switching is based on the information from the two-stage MAC address look-up (see [Layer 2 Lookup Tasks Overview](#)) followed by additional resolution functions to allow frame duplication and flooding control. These are described in the following sections.

**Figure 11-72. Frame Forwarding Tasks Overview**

#### 11.5.5.9.1 VLAN Domain Verification

When the L2 MAC address lookup is successful and identifies a dedicated output port for the frame, the output and input port can be verified to be in the correct VLAN domain if VLAN verification is enabled for the port and the frame contains a VLAN tag. The VLAN resolution table (see [VLAN Resolution Table](#)) is used as follows:

- If the frame's VLAN ID is in the table but the output port number is not a member of the VLAN domain, or the input port is not a member of the VLAN domain, the frame is marked invalid and is eventually discarded.
- If the frame's VLAN ID is in the table and the output and input ports are members of the VLAN domain, the frame is forwarded normally.
- If the frame's VLAN ID is not found in the VLAN table or the frame has no VLAN tag, the frame is forwarded normally (default broadcast domain), or if the discard bit for the port is set (also in register ESW\_VLANV) it is discarded.

#### 11.5.5.9.2 Broadcast/Multicast/VLAN Domain Resolution

To ensure that traffic within VLAN channels are always routed to the correct ports, for example to avoid the duplication of critical information through a network, the switch implements a resolution mechanism that, for any frame that is switched to multiple ports, checks the VLAN ID provided with the current frame.

The VLAN resolution mechanism searches the VLAN resolution table (see ESW\_VRES<sub>n</sub> registers), which stores up to 32 unique VLAN IDs, each associated to a port bit mask. The resolution mechanism is used for the following conditions:

- Unicast frames with a destination MAC address that are not in the table of the layer 2 engine
- Multicast frames with a destination MAC address that are not in the table of the layer 2 engine
- Any broadcast frame

11.5.5.9.2.1 VLAN Resolution Table

The VLAN resolution table (ESW\_VRES<sub>n</sub>) provides a unique VLAN ID/port bit mask association for up to 32 VLANs. A default entry (ESW\_DBCR) provides an additional port bit mask. The port bit mask implements one bit for each port.

Each port bit indicates, if set, that it is member of the VLAN and frames with the corresponding VLAN ID can be switched to the port. If the port bit is cleared, a frame with the corresponding VLAN ID is not switched to that port. If no VLAN ID matches, the default mask is applied.

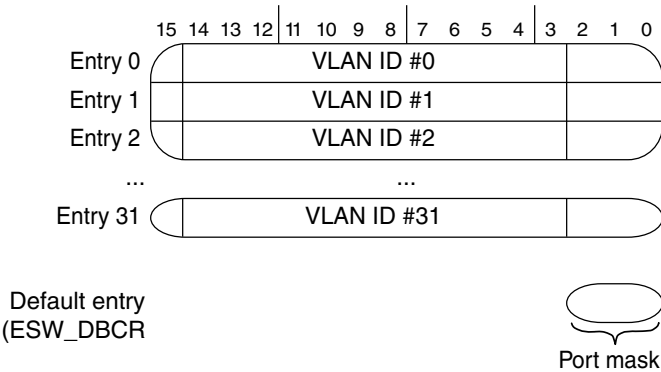

Figure 11-73. VLAN Resolution Table Overview

11.5.5.9.2.2 VLAN Switching / Resolution Mechanism

The VLAN table is used for VLAN domain verification (see [VLAN Domain Verification](#)) and VLAN resolution. Once the frame has passed any VLAN domain verification (i.e. will not be discarded by the verification function already) the forwarding resolution applies.

- If the destination MAC address (Unicast or Multicast) is found in the MAC address table and
  - the frame carries a VLAN tag that is found in the VLAN table, the frame can be forwarded only to the ports within the VLAN domain and will be discarded if the destination port is not member of the VLAN domain.
  - else if the frame carries a VLAN tag that is not found in the VLAN table, or does not contain a VLAN tag, it is forwarded as indicated by the lookup table (note that VLAN domain verification can be configured to discard the frame in this case if enabled).
- If the destination MAC address (Unicast or Multicast) is not found in the MAC address table, or if the destination address is the Broadcast address, the frame is forwarded according to the following rules:
  - If the frame carries a VLAN tag, the VLAN resolution table is searched for a matching VLAN ID and the frame is sent to all ports that are associated with the VLAN ID.
  - If the frame carries a VLAN tag and the VLAN ID does not match any entry in the VLAN Resolution Table, the frame is forwarded to all ports that are enabled to receive broadcast frames by the default entry.
  - If the frame does not carry a VLAN tag the frame is forwarded to all ports that are enabled to receive broadcast frames by the default entry.
  - The frame is discarded if it cannot be associated with any VLAN group and if the default (broadcast) group has been set to all zero.

To disable the VLAN resolution set all VLAN IDs to 0xFFFF or (0x000 if that ID is not used) and all port mask bits to 1. If the VLAN resolution is disabled, normal port flooding is implemented as described in [Frame Classification and Priority Resolution](#). The default entry can still be used to restrict broadcast to only dedicated ports, if not programmed to all 1s.

### 11.5.5.9.3 Port Mirroring

The function allows duplicating traffic to a dedicated mirror port. Any one of the ports can be assigned to act as a mirror port (register ESW\_MCR).

The mirror port then is always added to the list of output ports and therefore receives a copy of the frame, if any of the following rules matches with the currently processed frame:

- Ingress Port Number Match

When a frame is received on port N and the corresponding bit in the register ESW\_INGMAP is set to 1, the frame is mirrored.

- Egress Port Number Match

When a frame is forwarded to port N and the corresponding bit in the register ESW\_EGMAP is set to 1, the frame will be mirrored.

- MAC Ingress SA Match

When the Ingress Port Number match succeeded (see above) and the MAC source address matches the ESW\_INGSA{L,H}, the frame will be mirrored.

- MAC Ingress DA Match

When the Ingress Port Number match succeeded (see above) and the MAC destination address matches the ESW\_INGDA{L,H}, the frame will be mirrored.

- MAC Egress SA Match

When the Egress Port Number match succeeded (see above) and the MAC source address matches the ESW\_EGSA{L,H}, the frame will be mirrored.

- MAC Egress DA Match

When the Egress Port Number match succeeded (see above) and the MAC destination address matches the ESW\_EGDA{L,H}, the frame will be mirrored.

In addition, a counter is implemented (Register MIRROR\_COUNT) that allows specifying that only every Nth frame that matches any of the above criteria is mirrored. If the counter is set to 1 or 0, every frame is mirrored that matches any of the above criteria.

#### **11.5.5.9.4 Protocol Snooping**

The incoming frames are parsed for IPv4 and IPv6 headers and UDP/TCP if available. The snooping function can be programmed to redirect specific protocols exclusively to the management port. See [IP Snooping](#) and [TCP/UDP Port Number Snooping](#) for a description of the snooping options.

The snooping is active only for frames received from the external ports. When a frame is transmitted from the management port itself, snooping does not apply and the frames are forwarded normally (MAC lookup).

#### **11.5.5.9.5 Bridge Protocol Frame Resolution**

To implement bridge control protocols like the Spanning Tree protocol, the following control functions are performed by the Protocol Frame Resolution function:

#### 11.5.5.9.5.1 Input Port Blocking

The input port blocking function is used to avoid forwarding of frames after address learning. The software can program the ESW\_BKLR register and if a frame is received on port  $n$  that should be blocked ( $BE_n = 1$ ) and the frame is not a bridge protocol frame (see below), the frame is marked for discard and is not forwarded to any output port.

#### 11.5.5.9.5.2 Input Port Learning Disable

To reduce processing load, a port can be configured for exclusion from learning (see the ESW\_BKLR register).

When learning is disabled on a port no source address extraction happens for incoming frames, with the exception of incoming BPDU frames. BPDU frame source addresses are always extracted and forwarded to the learning interface.

#### 11.5.5.9.5.3 Management Port Forwarding

If enabled, bridge protocol frames are always forwarded to the dedicated management port (see the ESW\_BMPC register) independent of any address lookup or other resolution functions.

Bridge protocol frames are identified by its destination address being any of the following:

- 01-80-C2-00-00-00 to 01-80-C2-00-00-0F (Spanning Tree, IEEE 802.1d, Table 7-9)
- 01-80-C2-00-00-10 (Bridge Management Address, 802.1d, Table 7-10)
- 01-80-C2-00-00-20 to 01-80-C2-00-00-2F (Generic Attribute Registration Protocol, 802.1d, Table 12-1)

#### 11.5.5.9.5.4 Management Frame Forwarding

If the management port transmits frames, they are forwarded according to the port mask defined in the configuration register ESW\_BMPC on a frame-by-frame basis.

#### NOTE

VLAN domain verification/discard (see the ESW\_VLANV register) should be switched off for the management port to avoid that the switch discards management frames.

### 11.5.5.9.6 Congestion Resolution

The congestion resolution function is used whenever an output port is not available and data needs to be sent to that port. An output port is defined to be available if the port is enabled (bit in ESW\_PER set 1) and the output buffer (shared memory) is not congested. If, for a port, one of these conditions is not valid, the port is not available and frames cannot be switched to that port.

The congestion resolution function determines whether the frame should be processed further or discarded according to the following rules:

#### 11.5.5.9.6.1 Unique Destination (one input to one output)

If the output port is enabled and can accept a frame the frame will be forwarded normally.

In any other case the frame will be discarded. If a frame switched to port N, the counter ESW\_PnOQC is incremented.

#### 11.5.5.9.6.2 Multiple Destinations (Flooding)

After broadcast / flooding resolution a frame needs to be switched to multiple output ports.

- Output disabled: All disabled ports are removed from the list of outputs.
- Output congestion: If any of the outputs cannot accept a frame (As indicated by the output queue management for the port, implementation specific) it is also removed from the list of outputs.

If no output port is left in the list of outputs, the frame is discarded.

If a frame switched to port N, the counter ESW\_PnOQC is incremented.

### 11.5.5.9.7 Switching

After the output port(s) have been determined, the switch control enables the corresponding path through the Switch Matrix and the frame is forwarded to the output queue(s).

In a similar fashion, if a Frame should be switched to multiple ports (e.g. Broadcast), the switch control enables the corresponding paths through the Switch Matrix and the frame is forwarded to all the destination output ports.

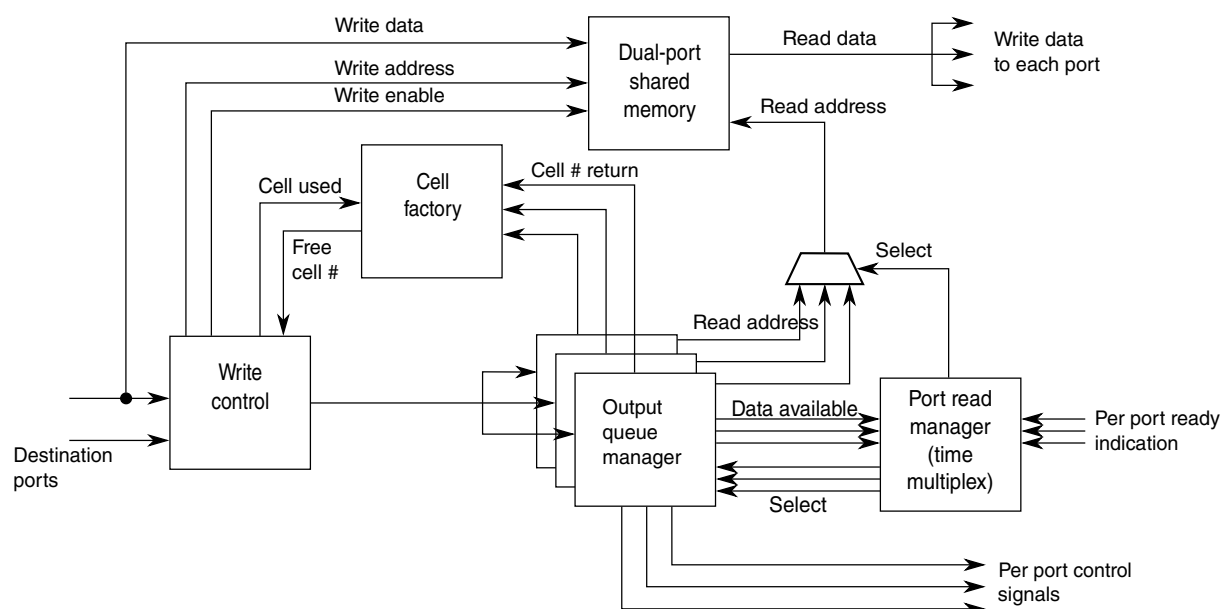

### 11.5.5.10 Output Frame Queuing

The memory controller implements a shared memory architecture to store Frames of arbitrary size for multiple destination ports.

Each destination port implements 4 priority queues. The memory controller implements a single write input port and three output ports with the capability to perform virtual frame duplication on the output ports (Multiple reads on multiple ports of a single frame stored in the buffer).

A single large memory, partitioned in 256 byte cells, is implemented to efficiently share the available space for small and large frames without leaving large unused spaces when storing small frames.

**Figure 11-74. Memory Controller Overview**

#### 11.5.5.10.1 Cell and Queue Concept

The shared memory is partitioned in 256 byte cells using a 32-bit datapath implementation. This results in a cell holding 64 32-bit words.

Incoming frames are stored, partitioned in cells, in the shared memory and only the cell numbers are managed by the individual port queues.

Due to the arbitrary length of incoming frames, the last cell may not be fully utilized. A frame can spread from one to any number of cells. The number of bytes used in the last cell is also stored in the queue FIFO together with the individual cell numbers.

Cells can be stored anywhere in the shared memory. A single frame must not necessarily be stored in consecutive cells but instead can be scattered over the complete memory at arbitrary positions. The start of a cell is fixed to a 64-word boundary (i.e. the memory start address of a cell is simply the cell # multiplied by 64).

Per port, a queue FIFO is implemented that stores the cell numbers for the frames. The number of bytes used in the last cell is also stored in the queue FIFO together with the individual cell numbers.

Figure 11-75. Cell storage concept

The example in the figure above shows the storage of three frames with one frame duplicated and stored in two queues.

11.5.5.10.2 Write Control Module

The Write Control Module receives frames from the Switch engine, partitions and stores the frames in the shared memory. The cell numbers used to store the frame are forwarded to the port output managers.

### 11.5.5.10.3 Cell Factory Module

The Cell Factory implements the cell management, it always provides a free cell number to the write control module so the write control module can immediately start writing into memory to avoid any write latency.

### 11.5.5.10.4 Output Queue Manager

The Output Queue Manager implements, per port, the individual queue FIFOs (One queue FIFO per priority). The queue FIFOs are addressed by the priority information extracted by the Switch classification engine. Per port, eight prioritized queues are implemented.

When more than one queue has data available, the read logic selects one of the queues with a Weighted Fair Queuing scheduling algorithm.

#### 11.5.5.10.4.1 Weighted Fair Queuing Scheduling Algorithm

The weight of each queue, common for all ports, can be configured between 0 and 30 with the register ESW\_QWT. A Queue with a higher weight is served more often than a queue with lower weight.

Queue 0 represents the lowest priority, Queue 3 the highest priority queue.

The scheduler first serves the queue with the highest weight. Each time the scheduler serves a queue, the weight of the other queues is increased and the weight of the selected queue is reset (decreased) to its programmed weight value. This guarantees that all queues are served eventually.

When multiple queues have the same weight the queue with the higher number is served first.

If all weights are programmed to 0 (default) a strict priority scheme is active where the higher priority queues are served as long as they are not empty.

### 11.5.5.10.5 Congestion Management

The Write control logic is protected against memory overflow. When data is written is the cell factory has no more free cells (Number of available cells less than value programmed in register ESW\_LMT), the frame is discarded or terminated with an error (i.e. forwarded to the output queue manager with the end-of-packet and error indication).

If the congestion persists, the switch resolves the congestion as specifies in [Congestion Resolution](#).

## 11.5.5.11 Reset and stop functions

### 11.5.5.11.1 Stop Controls

See [Mode configuration \(ESW\\_MODE\)](#) for information on these control fields.

- STOP: no internal function.
- SWEN: controls the bypass of the switch. When de-asserted, all DMA registers are cleared.
- SWRST: used as a soft reset to the switch if the switch is enabled.

### 11.5.5.11.2 Port Disable

If the ESW\_PER port 0 transmit and receive enable fields are cleared, the input buffer and output buffer at the port 0 DMA interface are reset.

- The ready output to DMA0 will be asserted allowing the application to continue writing data at the interface, which will be ignored (application flush). No further transmitted frame status will be given (i.e. for any currently stored if any, as well as the currently ignored).
- If the transmit enable is cleared while the interface is currently transferring a frame to the DMA, the frame is aborted (output buffer reset). The eop is not produced. Therefore the connected DMA module must be reset to ensure proper restart after re-enabling the port.

If any port's transmit enable bit is cleared, the shared memory will continue delivering the frames stored currently for a port as normal (i.e. flushing the memory). New frames will be discarded before they are written into the shared memory. That is, no invalid frame will appear on the MAC interfaces after disabling or re-enabling a port.

If any port's receive enable bit is cleared while a frame is transferred, this frame will be aborted with an error internally. The port's ready indication will stay asserted to flush any application data. Reenabling the port at any time will ignore any input data until a sop starts a new frame.

### 11.5.5.11.3 Port 0 Input Protection

The port 0 input buffer is protected for application errors that abort a frame without writing a proper eop to the interface. The next frame then written to the port 0 transmit interface will be concatenated with whatever data was already written before, but the frame will be marked with an error and hence will be forwarded and transmitted with an error indication (MII tx error).

If the port0 input buffer is reset (by deasserting ESW\_PER receive enable bit) while a frame is transferred to the switch internally, the frame transfer will be aborted in a clean way (producing an eop with error indication) to avoid blocking the switch.

### 11.5.5.11.4 Port 1/2 Input Protection

Ports 1 and 2 are protected for a 2nd SOP in case the MAC is reset in the middle of a receive transaction to the switch hence did not produce a proper EOP to the switch. The next frame will be concatenated with whatever was provided to the switch before and marked with an error.

If the MAC is stopped in the middle of a transaction, the switch is blocked, waiting for the EOP, not serving any of the other ports. Clearing the ESW\_PER receive enable bit in this situation will terminate the frame with an error internally to the switch hence remove the blocking condition.

### 11.5.5.11.5 DMA Bus Error

When the DMA bus error asserts, the DMA registers are all cleared. A bus error interrupt request will be flagged to the device interrupt controller. See the device interrupt controller chapter for related vector.

# Chapter 12

## Low Speed Communications and Interconnects

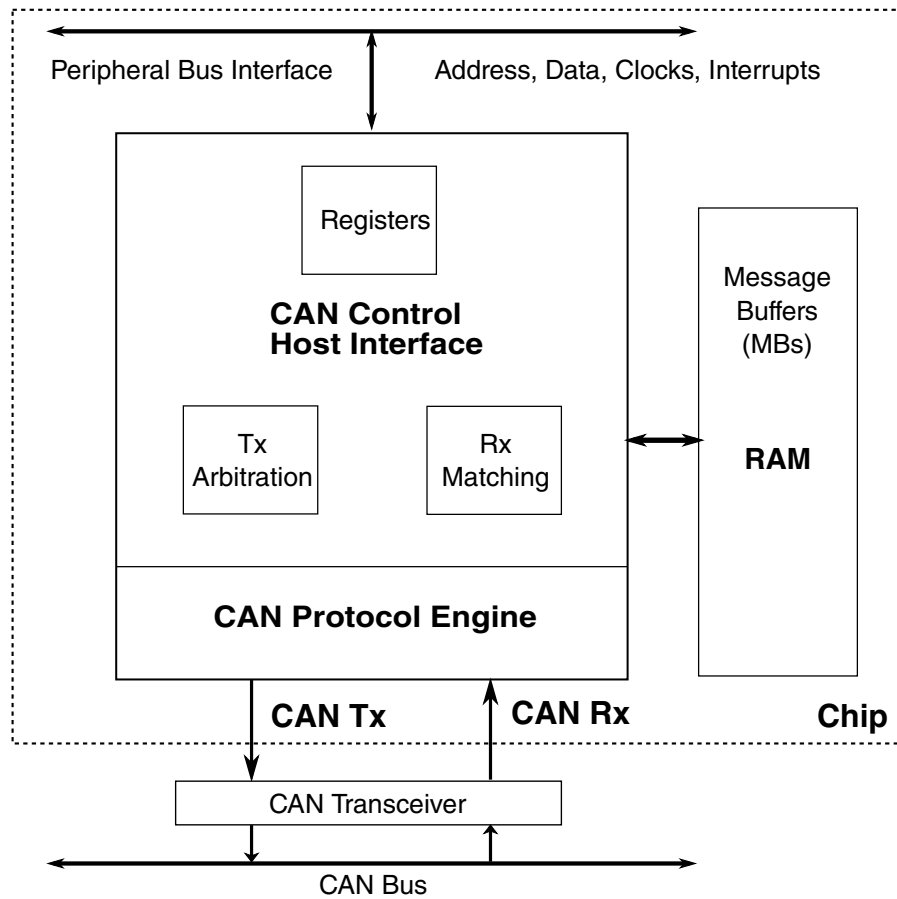

### 12.1 Flexible Controller Area Network (FlexCAN)

#### 12.1.1 Introduction

##### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0 B protocol specification. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive (Rx) Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

**Figure 12-1. FlexCAN block diagram**

### 12.1.1.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The CAN Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames

- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

### 12.1.1.2 FlexCAN module features

The FlexCAN module includes these distinctive legacy features:

- Full implementation of the CAN protocol specification, Version 2.0 B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused structures space can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation

- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes

New major features are also provided:

- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors).

### **12.1.1.3 Modes of operation**

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ\_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See [Stop mode](#) for more information.

## 12.1.2 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 12-1. FlexCAN signal descriptions**

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

### 12.1.2.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 12.1.2.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 12.1.3 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

### 12.1.3.1 FlexCAN memory mapping

The complete memory map for a FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of [Table 12-2](#).

**Table 12-2. Register access and reset information**

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 register (CTRL1)	S/U	Yes	No
Free Running Timer register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control Register (MECR)	S/U	Yes	Yes
Error Injection Address Register (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern Register (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern Register (ERRIPPR)	S/U	Yes	Yes
Error Report Address Register (RERRAR)	S/U	Yes	Yes
Error Report Data Register (RERRDR)	S/U	Yes	Yes
Error Report Syndrome Register (RERRSYNR)	S/U	Yes	Yes
Error Status Register (ERRSR)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

This module's memory map includes sixty-four 128-bit message buffers (MBs) that occupy the range from offset 0x80 to 0x47F .

### 12.1.3.2 Module Configuration Register (CANx\_MCR)

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

**CANx\_MCR field descriptions**

Field	Description
31 MDIS	<p>Module Disable</p> <p>This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This is the only bit within this register not affected by soft reset.</p> <p>0 Enable the FlexCAN module. 1 Disable the FlexCAN module.</p>
30 FRZ	<p>Freeze Enable</p> <p>The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR Register is set or when Debug mode is requested at chip level . When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.</p>

*Table continues on the next page...*

**CANx\_MCR field descriptions (continued)**

Field	Description
	0 Not enabled to enter Freeze mode. 1 Enabled to enter Freeze mode.
29 RFEN	<b>Rx FIFO Enable</b>  This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in section "Arbitration and Matching Timing"). This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  0 Rx FIFO not enabled. 1 Rx FIFO enabled.
28 HALT	<b>Halt FlexCAN</b>  Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode.  0 No Freeze mode request. 1 Enters Freeze mode if the FRZ bit is asserted.
27 NOTRDY	<b>FlexCAN Not Ready</b>  This read-only bit indicates that FlexCAN is either in Disable mode , Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes.  0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode. 1 FlexCAN module is either in Disable mode , Stop mode or Freeze mode.
26 Reserved	This field is reserved. Always write 0 to this field.
25 SOFTTRST	<b>Soft Reset</b>  When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER , ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, all RXIMR registers, RXMGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR, all Message Buffers .  The SOFTTRST bit can be asserted directly by the CPU when it writes to the MCR Register, but it is also asserted when global soft reset is requested at chip level . Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.  Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied.  0 No reset request. 1 Resets the registers affected by soft reset.
24 FRZACK	<b>Freeze Mode Acknowledge</b>  This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished.

*Table continues on the next page...*

**CANx\_MCR field descriptions (continued)**

Field	Description
	<p>Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode".</p> <p><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN not in Freeze mode, prescaler running. 1 FlexCAN in Freeze mode, prescaler stopped.</p>
23 SUPV	<p>Supervisor Mode</p> <p>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.</p>
22 Reserved	<p>This field is reserved. Always write 0 to this field.</p>
21 WRNEN	<p>Warning Interrupt Enable</p> <p>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.</p>
20 LPMACK	<p>Low-Power Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode.</p> <p><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN is not in a low-power mode. 1 FlexCAN is in a low-power mode.</p>
19 Reserved	<p>This field is reserved. Always write 0 to this field.</p>
18 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
17 SRXDIS	<p>Self Reception Disable</p> <p>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to</p>

*Table continues on the next page...*

**CANx\_MCR field descriptions (continued)**

Field	Description
	the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  0 Self reception enabled. 1 Self reception disabled.
16 IRMQ	Individual Rx Masking And Queue Enable  This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 Individual Rx masking and queue feature are enabled.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LPRIEN	Local Priority Enable  This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  0 Local Priority disabled. 1 Local Priority enabled.
12 AEN	Abort Enable  This bit is supplied for backwards compatibility with legacy applications. When asserted, it enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  <b>NOTE:</b> When MCR[AEN] is asserted, only the abort mechanism (see Section "Transmission Abort Mechanism") must be used for updating Mailboxes configured for transmission.  <b>CAUTION:</b> Writing the Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted.  0 Abort disabled. 1 Abort enabled.
11–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 IDAM	ID Acceptance Mode  This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes.  00 Format A: One full ID (standard and extended) per ID Filter Table element.

*Table continues on the next page...*

**CANx\_MCR field descriptions (continued)**

Field	Description
	01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element. 10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element. 11 Format D: All frames rejected.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MAXMB	Number Of The Last Message Buffer  This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  Number of the last MB = MAXMB  <b>NOTE:</b> MAXMB must be programmed with a value smaller than the parameter NUMBER_OF_MB, otherwise the number of the last effective Message Buffer will be: (NUMBER_OF_MB - 1)  Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in Section "Arbitration and Matching Timing").

**12.1.3.3 Control 1 register (CANx\_CTRL1)**

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: Base address + 4h offset

**CANx\_CTRL1 field descriptions**

Field	Description
31–24 PRES DIV	<p>Prescaler Division Factor</p> <p>This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclck) frequency. The Sclck period defines the time quantum of the CAN protocol. For the reset value, the Sclck frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclck frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Sclck frequency} = \text{PE clock frequency} / (\text{PRES DIV} + 1)</math></p>
23–22 RJW	<p>Resync Jump Width</p> <p>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclck period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Resync Jump Width} = \text{RJW} + 1.</math></p>
21–19 PSEG1	<p>Phase Segment 1</p> <p>This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Phase Buffer Segment 1} = (\text{PSEG1} + 1) \times \text{Time-Quanta}.</math></p>
18–16 PSEG2	<p>Phase Segment 2</p> <p>This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Phase Buffer Segment 2} = (\text{PSEG2} + 1) \times \text{Time-Quanta}.</math></p>
15 BOFFMSK	<p>Bus Off Mask</p> <p>This bit provides a mask for the Bus Off Interrupt.</p> <p>0 Bus Off interrupt disabled. 1 Bus Off interrupt enabled.</p>
14 ERRMSK	<p>Error Mask</p> <p>This bit provides a mask for the Error Interrupt.</p> <p>0 Error interrupt disabled. 1 Error interrupt enabled.</p>
13 CLKSRC	<p>CAN Engine Clock Source</p> <p>This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock (driven by the PLL) or the crystal oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclck). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Section "Protocol Timing".</p> <p>0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock. 1 The CAN engine clock source is the peripheral clock.</p>
12 LPB	<p>Loop Back Mode</p> <p>This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back</p>

*Table continues on the next page...*

## CANx\_CTRL1 field descriptions (continued)

Field	Description
	<p>internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> In this mode, the MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message.</p> <p>0 Loop Back disabled. 1 Loop Back enabled.</p>
11 TWRNMSK	<p>Tx Warning Interrupt Mask</p> <p>This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.</p> <p>0 Tx Warning Interrupt disabled. 1 Tx Warning Interrupt enabled.</p>
10 RWRNMSK	<p>Rx Warning Interrupt Mask</p> <p>This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.</p> <p>0 Rx Warning Interrupt disabled. 1 Rx Warning Interrupt enabled.</p>
9–8 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
7 SMP	<p>CAN Bit Sampling</p> <p>This bit defines the sampling mode of CAN bits at the Rx input. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Just one sample is used to determine the bit value. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.</p>
6 BOFFREC	<p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p>0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B. 1 Automatic recovering from Bus Off state disabled.</p>

Table continues on the next page...

**CANx\_CTRL1 field descriptions (continued)**

Field	Description
5 TSYN	<p>Timer Sync</p> <p>This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in MCR is set (Rx FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Timer Sync feature disabled 1 Timer Sync feature enabled</p>
4 LBUF	<p>Lowest Buffer Transmitted First</p> <p>This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIEN bit does not affect the priority arbitration. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Buffer with highest priority is transmitted first. 1 Lowest number buffer is transmitted first.</p>
3 LOM	<p>Listen-Only Mode</p> <p>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the REC, as if it was trying to acknowledge the message.</p> <p>Listen-Only mode acknowledgement can be obtained by the state of ESR1[FLTCNF] field which is Passive Error when Listen-Only mode is entered. There can be some delay between the Listen-Only mode request and acknowledge.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Listen-Only mode is deactivated. 1 FlexCAN module operates in Listen-Only mode.</p>
PROPSEG	<p>Propagation Segment</p> <p>This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Propagation Segment Time = (PROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.</p>

**12.1.3.4 Free Running Timer (CANx\_TIMER)**

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure; see Section "Mailbox Lock Mechanism".

TIMER	Timer Value  Contains the free-running counter value.

### 12.1.3.5 Rx Mailboxes Global Mask Register (CANx\_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the MCR[IRMQ] bit is negated, RXMGMASK is always in effect.
- When the MCR[IRMQ] bit is asserted, RXMGMASK has no effect.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0    The corresponding bit in the filter is "don't care."																																															
1    The corresponding bit in the filter is checked.																																															

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).

2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.

3. If the CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

### 12.1.3.6 Rx 14 Mask register (CANx\_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RX15M[31:0]	<p>Rx Buffer 15 Mask Bits</p> <p>Each mask bit masks the corresponding Mailbox 15 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register.</p> <p>0 The corresponding bit in the filter is "don't care."  1 The corresponding bit in the filter is checked.</p>

### 12.1.3.8 Error Counter (CANx\_ECR)

This register has two 8-bit fields reflecting the value of two FlexCAN error counters: Transmit Error Counter (TXERRCNT field) and Receive Error Counter (RXERRCNT field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read-only except in Freeze mode, where they can be written by the CPU.

FlexCAN responds to any bus state as described in the protocol, for example, transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in Bus Off state.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FlexCAN state is 'Error Passive', and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in 'Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–8 RXERRCNT	Receive Error Counter
TXERRCNT	Transmit Error Counter

**12.1.3.9 Error and Status 1 register (CANx\_ESR1)**

This register reflects various error conditions and some general status of the device. It is also the source of interrupts to the CPU.

A CPU read operation clears the following fields to 0, so these fields report error conditions that occurred after the last time the CPU read this register: BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, and STFERR. TXWRN, RXWRN, IDLE, TX, FLTCONF, and RX provide status information.

The following table shows the FlexCAN state variables and their meanings. Combinations not shown in the table are reserved.

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

### CANx\_ESR1 field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SYNCH	CAN Synchronization Status  This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description.  0 FlexCAN is not synchronized to the CAN bus. 1 FlexCAN is synchronized to the CAN bus.
17 TWRNINT	Tx Warning Interrupt Flag  If the WRNEN bit in MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will

Table continues on the next page...

**CANx\_ESR1 field descriptions (continued)**

Field	Description
	<p>be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode.</p> <p>0 No such occurrence. 1 The Tx error counter transitioned from less than 96 to greater than or equal to 96.</p>
16 RWRNINT	<p>Rx Warning Interrupt Flag</p> <p>If the WRNEN bit in MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode.</p> <p>0 No such occurrence. 1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.</p>
15 BIT1ERR	<p>Bit1 Error</p> <p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.</p> <p><b>NOTE:</b> This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.</p> <p>0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.</p>
14 BIT0ERR	<p>Bit0 Error</p> <p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.</p> <p>0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.</p>
13 ACKERR	<p>Acknowledge Error</p> <p>This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT.</p> <p>0 No such occurrence. 1 An ACK error occurred since last read of this register.</p>
12 CRCERR	<p>Cyclic Redundancy Check Error</p> <p>This bit indicates that a CRC Error has been detected by the receiver node, that is, the calculated CRC is different from the received.</p> <p>0 No such occurrence. 1 A CRC error occurred since last read of this register.</p>
11 FRMERR	<p>Form Error</p> <p>This bit indicates that a Form Error has been detected by the receiver node, that is, a fixed-form bit field contains at least one illegal bit.</p> <p>0 No such occurrence. 1 A Form Error occurred since last read of this register.</p>

*Table continues on the next page...*

**CANx\_ESR1 field descriptions (continued)**

Field	Description
10 STFERR	<p>Stuffing Error</p> <p>This bit indicates that a Stuffing Error has been detected.</p> <p>0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.</p>
9 TXWRN	<p>TX Error Warning</p> <p>This bit indicates when repetitive errors are occurring during message transmission. This bit is not updated during Freeze mode.</p> <p>0 No such occurrence. 1 TXERRCNT is greater than or equal to 96.</p>
8 RXWRN	<p>Rx Error Warning</p> <p>This bit indicates when repetitive errors are occurring during message reception. This bit is not updated during Freeze mode.</p> <p>0 No such occurrence. 1 RXERRCNT is greater than or equal to 96.</p>
7 IDLE	<p>This bit indicates when CAN bus is in IDLE state. See the table in the overall CAN_ESR1 register description.</p> <p>0 No such occurrence. 1 CAN bus is now IDLE.</p>
6 TX	<p>FlexCAN In Transmission</p> <p>This bit indicates if FlexCAN is transmitting a message. See the table in the overall CAN_ESR1 register description.</p> <p>0 FlexCAN is not transmitting a message. 1 FlexCAN is transmitting a message.</p>
5–4 FLTCONF	<p>Fault Confinement State</p> <p>This 2-bit field indicates the Confinement State of the FlexCAN module.</p> <p>If the LOM bit in the Control Register is asserted, after some delay that depends on the CAN bit timing the FLTCONF field will indicate “Error Passive”. The very same delay affects the way how FLTCONF reflects an update to ECR register by the CPU. It may be necessary up to one CAN bit time to get them coherent again.</p> <p>Because the Control Register is not affected by soft reset, the FLTCONF field will not be affected by soft reset if the LOM bit is asserted.</p> <p>00 Error Active 01 Error Passive 1x Bus Off</p>
3 RX	<p>FlexCAN In Reception</p> <p>This bit indicates if FlexCAN is receiving a message. See the table in the overall CAN_ESR1 register description.</p> <p>0 FlexCAN is not receiving a message. 1 FlexCAN is receiving a message.</p>

*Table continues on the next page...*

**CANx\_ESR1 field descriptions (continued)**

Field	Description
2 BOFFINT	<p>Bus Off Interrupt</p> <p>This bit is set when FlexCAN enters 'Bus Off' state. If the corresponding mask bit in the Control Register (BOFFMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0 No such occurrence. 1 FlexCAN module entered Bus Off state.</p>
1 ERRINT	<p>Error Interrupt</p> <p>This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0 No such occurrence. 1 Indicates setting of any Error Bit in the Error and Status Register.</p>
0 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

**12.1.3.10 Interrupt Masks 2 register (CANx\_IMASK2)**

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

Address: Base address + 24h offset

**CANx\_IMASK2 field descriptions**

Field	Description
BUFHM	<p>Buffer MB<sub>i</sub> Mask</p> <p>Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB63 to MB32.</p> <p><b>NOTE:</b> Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set.</p> <p>0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.</p>

12.1.3.11 Interrupt Masks 1 register (CANx\_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

Address: Base address + 28h offset

CANx\_IMASK1 field descriptions

Field	Description
BUFLM	<div>Buffer MB<sub>i</sub> Mask</div> <div>Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0.</div> <div><b>NOTE:</b> Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set.</div> <div>0 The corresponding buffer Interrupt is disabled.</div> <div>1 The corresponding buffer Interrupt is enabled.</div>

12.1.3.12 Interrupt Flags 2 register (CANx\_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG2 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: Base address + 2Ch offset

**CANx\_IFLAG2 field descriptions**

Field	Description
BUFHI	<p>Buffer MB<sub>i</sub> Interrupt</p> <p>Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB63 to MB32.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception.</p> <p>1 The corresponding buffer has successfully completed transmission or reception.</p>

**12.1.3.13 Interrupt Flags 1 register (CANx\_IFLAG1)**

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit MCR[RFEN] is set, the function of the 8 least significant interrupt flags BUF[7:0]I changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, and the BUF4TO0I field is reserved.

Before enabling the RFEN, the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when an RFFN value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

Before updating MCR[MAXMB] field, CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

## CANx\_IFLAG1 field descriptions

Field	Description
31–8 BUF31TO8I	<p>Buffer MB<sub>i</sub> Interrupt</p> <p>Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.</p>
7 BUF7I	<p>Buffer MB7 Interrupt Or "Rx FIFO Overflow"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF7I flag represents "Rx FIFO Overflow" when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox.</p> <p>0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1</p>
6 BUF6I	<p>Buffer MB6 Interrupt Or "Rx FIFO Warning"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF6I flag represents "Rx FIFO Warning" when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4.</p> <p>0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1</p>
5 BUF5I	<p>Buffer MB5 Interrupt Or "Frames available in Rx FIFO"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF5I flag represents "Frames available in Rx FIFO" when MCR[RFEN] is set. In this case, the flag indicates that at least one frame is available to be read from the Rx FIFO.</p>

Table continues on the next page...

**CANx\_IFLAG1 field descriptions (continued)**

Field	Description
	<p>0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1</p> <p>1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1</p>
4–1 BUF4TO1I	<p>Buffer MB<sub>i</sub> Interrupt Or "reserved"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1.</p> <p><b>NOTE:</b> These flags are cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when MCR[RFEN] is set.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.</p> <p>1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p>
0 BUF0I	<p>Buffer MB0 Interrupt Or "reserved"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF0I flag is reserved when MCR[RFEN] is set.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.</p> <p>1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p>

**12.1.3.14 Control 2 register (CANx\_CTRL2)**

This register contains control bits for CAN errors, FIFO features, and mode selection.

Address: Base address + 34h offset

## CANx\_CTRL2 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 ECRWRE	Error-correction Configuration Register Write Enable  Enable that the MECR register is updated. This bit is automatically set to 0 if the protocol described in the "Detection and Correction of Memory Errors" section is not followed.  0   Disable update. 1   Enable update.
28 WRMFRZ	Write-Access To Memory In Freeze Mode  Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode.  0   Maintain the write access restrictions. 1   Enable unrestricted write access to FlexCAN memory.
27–24 RFFN	Number Of Rx FIFO Filters  This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by MCR[MAXMB].  <b>NOTE:</b> Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available.  Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows:  $(\text{SETUP\_MB} - 6) \times 4$  where SETUP_MB is the least between NUMBER_OF_MB and MAXMB.  The number of remaining Mailboxes available will be:  $(\text{SETUP\_MB} - 8) - (\text{RFFN} \times 2)$  If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional.

RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes <sup>1</sup>	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask <sup>2</sup>
0x0	8	MB 0-7	MB 8-63	Elements 0-7	none

23–19 TASD	<p>Tx Arbitration Start Delay</p> <p>This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency.</p> <p>The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa.</p> <p>If TASD is 0 then the arbitration start is not delayed, thus the CPU has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. On the other hand, if TASD is 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration.</p> <p>If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is not the best to be transmitted.</p> <p>The optimal configuration for TASD can be calculated as:</p> $\text{TASD} = 25 - \left\{ f_{\text{CANCLK}} \times [\text{MAXMB} + 3 - (\text{RFEN} \times 8) - (\text{RFEN} \times \text{RFFN} \times 2)] \times 2 \right\} / \left\{ f_{\text{SYS}} \times [1 + (\text{PSEG1} + 1) + (\text{PSEG2} + 1) + (\text{PROPSEG} + 1)] \times (\text{PRES DIV} + 1) \right\}$ <p>where:</p> <ul style="list-style-type: none"> <li><math>f_{\text{CANCLK}}</math> is the Protocol Engine (PE) Clock (see section "Protocol Timing"), in Hz</li> <li><math>f_{\text{SYS}}</math> is the peripheral clock, in Hz</li> <li>MAXMB is the value in CTRL1[MAXMB] field</li> <li>RFEN is the value in CTRL1[RFEN] bit</li> </ul>					

Table continues on the next page...

**CANx\_CTRL2 field descriptions (continued)**

Field	Description
	<ul style="list-style-type: none"> <li>• RFFN is the value in CTRL2[RFFN] field</li> <li>• PSEG1 is the value in CTRL1[PSEG1] field</li> <li>• PSEG2 is the value in CTRL1[PSEG2] field</li> <li>• PROPSEG is the value in CTRL1[PROPSEG] field</li> <li>• PRESDIV is the value in CTRL1[PRES DIV] field</li> </ul> <p>See Section "Arbitration process" and Section "Protocol Timing" for more details.</p>
18 MRP	<p>Mailboxes Reception Priority</p> <p>If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Matching starts from Rx FIFO and continues on Mailboxes. 1 Matching starts from Mailboxes and continues on Rx FIFO.</p>
17 RRS	<p>Remote Request Storing</p> <p>If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated.</p> <p>If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Remote Response Frame is generated. 1 Remote Request Frame is stored.</p>
16 EACEN	<p>Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes</p> <p>This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.</p>
Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER\_OF\_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

### 12.1.3.15 Error and Status 2 register (CANx\_ESR2)

This register reflects various interrupt flags and some general status.

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0									LPTM						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	VPS	IMB	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### CANx\_ESR2 field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 LPTM	Lowest Priority Tx Mailbox  If ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 VPS	Valid Priority Status  This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox.  <b>NOTE:</b> ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.  0 Contents of IMB and LPTM are invalid. 1 Contents of IMB and LPTM are valid.
13 IMB	Inactive Mailbox  If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases:

*Table continues on the next page...*

**CANx\_ESR2 field descriptions (continued)**

Field	Description
	<ul style="list-style-type: none"> <li>During arbitration, if an LPTM is found and it is inactive.</li> <li>If IMB is not asserted and a frame is transmitted successfully.</li> </ul> <p>This bit is cleared in all start of arbitration (see Section "Arbitration process").</p> <p><b>NOTE:</b> LPTM mechanism have the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive Mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM].</p> <p>0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox.  1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.</p>
Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

**12.1.3.16 CRC Register (CANx\_CRCR)**

This register provides information about the CRC of transmitted messages.

Address: Base address + 44h offset

Field	Description
31–23 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
22–16 MBCRC	<p>CRC Mailbox</p> <p>This field indicates the number of the Mailbox corresponding to the value in TXCRC field.</p>
15 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
TXCRC	<p>CRC Transmitted</p> <p>This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted.</p>

### 12.1.3.17 Rx FIFO Global Mask register (CANx\_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 48h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### CANx\_RXFGMASK field descriptions

Field	Description					
FGM[31:0]	Rx FIFO Global Mask Bits					
	These bits mask the ID Filter Table elements bits in a perfect alignment.					
	The following table shows how the FGM bits correspond to each IDAF field.					
	Rx FIFO ID Filter Table Elements Format (MCR[IDAM])	Identifier Acceptance Filter Fields				
		RTR	IDE	RXIDA	RXIDB <sup>1</sup>	RXIDC <sup>2</sup>
						Reserved
	A	FGM[31]	FGM[30]	FGM[29:1]	-	FGM[0]
	B	FGM[31], FGM[15]	FGM[30], FGM[14]	-	FGM[29:16], FGM[13:0]	-
	C	-	-	-	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	-
	0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.					

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

12.1.3.18 Rx FIFO Information Register (CANx\_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: Base address + 4Ch offset

- \* Notes:
- x = Undefined at reset.

CANx\_RXFIR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
IDHIT	Identifier Acceptance Filter Hit Indicator  This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted.

12.1.3.19 Rx Individual Mask Registers (CANx\_RXIMRn)

These registers are located in RAM.

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on the setting of CTRL2[RFFN].

RXIMR can only be written by the CPU while the module is in Freeze mode; otherwise, they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: Base address + 880h offset + (4d × i), where i=0d to 63d

### CANx\_RXIMRn field descriptions

Field	Description
MI[31:0]	<p>Individual Mask Bits</p> <p>Each Individual Mask Bit masks the corresponding bit in both the Mailbox filter and Rx FIFO ID Filter Table element in distinct ways.</p> <p>For Mailbox filters, see the RXMGMASK register description.</p> <p>For Rx FIFO ID Filter Table elements, see the RXFGMASK register description.</p> <p>0 The corresponding bit in the filter is "don't care."</p> <p>1 The corresponding bit in the filter is checked.</p>

### 12.1.3.20 Memory Error Control Register (CANx\_MECR)

This register contains control bits for memory error detection and correction (ECC).

#### NOTE

When bit CTRL2[ECRWRE] is 0, this register is read-only and writes to this register result in bus transfer errors.

Address: Base address + AE0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	ECRWRDIS	0												HANCEL_MSK	FANCEL_MSK	0	CEI_MSK

**CANx\_MECR field descriptions**

Field	Description
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register.  0 Write is enabled. 1 Write is disabled.
30–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 HANCEI_MSK	Host Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the host (CPU).  0 Interrupt is disabled. 1 Interrupt is enabled.
18 FANCEI_MSK	FlexCAN Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the FlexCAN internal processes.  0 Interrupt is disabled. 1 Interrupt is enabled.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt in case of correctable errors detected in memory reads issued by the host or FlexCAN internal processes.  0 Interrupt is disabled. 1 Interrupt is enabled.
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU).  0 Injection is disabled. 1 Injection is enabled.
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes.  0 Injection is disabled. 1 Injection is enabled.
13 EXERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern Register (FCERRIDPR) and Error Injection Parity Pattern Register (FCERRIPPR)  0 Error injection is applied only to the 32-bit word. 1 Error injection is applied to the 64-bit word.

*Table continues on the next page...*

**CANx\_MECR field descriptions (continued)**

Field	Description
12–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 RERRDIS	<p>Error Report Disable</p> <p>Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active.</p> <p><b>NOTE:</b> When reading the report registers, this bit must be cleared to assure coherence on the consecutive register reads.</p> <p>0 Enable updates of the error report registers. 1 Disable updates of the error report registers.</p>
8 ECCDIS	<p>Error Correction Disable</p> <p>Disables completely the memory error detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions.</p> <p>0 Enable memory error correction. 1 Disable memory error correction.</p>
7 NCEFAFRZ	<p>Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode</p> <p>Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes.</p> <p>0 Keep normal operation. 1 Put FlexCAN in Freeze mode (according to the "Freeze mode" section).</p>
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**12.1.3.21 Error Injection Address Register (CANx\_ERRIAR)**

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM:

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	-
MBs	0x0000	0x0080
Reserved	-	0x0480
RXIMRs	0x0400	0x0880
Reserved	-	0x0980
RXFIR_0	0x0500	0x0A80
RXFIR_1	0x0504	0x0A84

*Table continues on the next page...*

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**CANx\_ERRIPPR field descriptions**

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 PFLIP3	Parity Flip Pattern For Byte 3 (most significant)
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 PFLIP2	Parity Flip Pattern For Byte 2
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 PFLIP1	Parity Flip Pattern For Byte 1
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

**12.1.3.24 Error Report Address Register (CANx\_RERRAR)**

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word in which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Address: Base address + AF0h offset

**CANx\_RERRDR field descriptions**

Field	Description
RDATA	Raw data word read from memory with error

**12.1.3.26 Error Report Syndrome Register (CANx\_RERRSYNR)**

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND<sub>n</sub> field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

**Table 12-4. Syndrome Definition**

SYND <sub>n</sub> (hex)	Type	Bit affected
00	-	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
All others	-	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

Address: Base address + AF8h offset

CANx\_ERRSR field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 HANCEIF	Host Access With Non-Correctable Error Interrupt Flag  Indicates that a non-correctable error was detected in a memory access initiated by Host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] is set, the interrupt is asserted.  0 No non-correctable errors were detected in Host accesses so far. 1 A non-correctable error was detected in a Host access.
18 FANCEIF	FlexCAN Access With Non-Correctable Error Interrupt Flag

Table continues on the next page...

**CANx\_ERRSR field descriptions (continued)**

Field	Description
	Indicates that a non-correctable error was detected in a memory access initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] is set, the interrupt is asserted.  0 No non-correctable errors were detected in FlexCAN accesses so far. 1 A non-correctable error was detected in a FlexCAN access.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CEIF	Correctable Error Interrupt Flag  Indicates that a correctable error was detected in a memory access. If MECR[CEI_MSK] is set, the interrupt is asserted.  0 No correctable errors were detected so far. 1 A correctable error was detected.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag  Indicates that a non-correctable error was detected in a memory access initiated by Host when HANCEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.)  0 No overrun on non-correctable errors in Host access 1 Overrun on non-correctable errors in Host access
2 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag  Indicates that a non-correctable error was detected in a memory access initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.)  0 No overrun on non-correctable errors in FlexCAN access 1 Overrun on non-correctable errors in FlexCAN access
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CEIOF	Correctable Error Interrupt Overrun Flag  Indicates that a correctable error was detected in a memory access when CEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.)  0 No overrun on correctable errors 1 Overrun on correctable errors

**12.1.3.80 Message buffer structure**

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x47F is used by the mailboxes.

**Table 12-5. Message buffer structure**

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0	
0x0					CODE			SRR	IDE	RTR	DLC				TIME STAMP

0xC	Data Byte 4					Data Byte 5					Data Byte 6				Data Byte 7				
					= Unimplemented or Reserved														

**CODE** — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 12-6](#) and [Table 12-7](#). See [Functional description](#) for additional information.

**Table 12-6. Message buffer code for Rx buffers**

CODE description	Rx code BEFORE receive new frame	SRV <sup>1</sup>	Rx code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
0b0000: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0b0100: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the <a href="#">Move-in</a> process), the CODE field is automatically updated to FULL.
0b0010: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See <a href="#">Matching process</a> for matching details related to FULL code.

Table continues on the next page...

**Table 12-6. Message buffer code for Rx buffers (continued)**

CODE description	Rx code BEFORE receive new frame	SRV <sup>1</sup>	Rx code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.
0b0110: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.
0b1010: RANSWER <sup>4</sup> — A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.	RANSWER	—	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See <a href="#">Matching process</a> for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote

Table continues on the next page...

**Table 12-6. Message buffer code for Rx buffers (continued)**

CODE description	Rx code BEFORE receive new frame	SRV <sup>1</sup>	Rx code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
					request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See <a href="#">Matching process</a> for details.
CODE[0]=1b1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY <sup>5</sup>	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.
3. Remote Request Stored bit from CTRL2 register. See section "Control 2 Register (CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 12-7. Message buffer code for Tx buffers**

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.
0b1001: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
0b1100: DATA — MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE — MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER — MB is a Tx Response	TANSWER	—	RANSWER	This is an intermediate code that is

**Table 12-7. Message buffer code for Tx buffers**

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
Frame from an incoming Remote Request Frame				automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details.

**SRR** — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

**IDE** — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

**RTR** — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 12-6](#), [Table 12-7](#), and the description of the RRS bit in Control 2 Register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

### **DLC** — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see the [Table 12-5](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 12-8](#)).

### **TIME STAMP** — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

### **PRI0** — Local priority

This 3-bit field is used only when LPRIO\_EN bit is set in MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

### **ID** — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

### **DATA BYTE 0–7** — Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

**Table 12-8. DATA BYTEs validity**

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0–1
3	DATA BYTE 0–2
4	DATA BYTE 0–3
5	DATA BYTE 0–4
6	DATA BYTE 0–5
7	DATA BYTE 0–6
8	DATA BYTE 0–7

### 12.1.3.81 Rx FIFO structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 12-9. Rx FIFO structure**

	31	28	24	23	22	21	20	19	18	17	16	15	8	7	0
0x80					SRR	IDE	RTR	DLC				TIME STAMP			
0x84		ID standard								ID extended					
0x88	Data byte 0			Data byte 1								Data byte 2		Data byte 3	
0x8C	Data byte 4			Data byte 5								Data byte 6		Data byte 7	
0x90	Reserved														
to															
0xDC															

*Table continues on the next page...*

Table 12-9. Rx FIFO structure (continued)

0xE0	ID filter table element 0
0xE4	ID filter table element 1
0xE8 to 0x2D4	ID filter table elements 2 to 125
0x2D8	ID filter table element 126
0x2DC	ID filter table element 127
	= Unimplemented or reserved

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

Table 12-10. ID table structure

Format	31	30	29	24	23	16	15	14	13	8	7	1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)										
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)				RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)				
C	RXIDC_0 (std/ext = 31–24)				RXIDC_1 (std/ext = 23–16)				RXIDC_2 (std/ext = 15–8)				RXIDC_3 (std/ext = 7–0)
	= Unimplemented or Reserved												

**RTR** — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

- 1 = Remote Frames can be accepted and data frames are rejected
- 0 = Remote Frames are rejected and data frames can be accepted

**IDE** — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

- 1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

### **RXIDA** — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

### **RXIDB\_0, RXIDB\_1** — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

### **RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

## **12.1.4 Functional description**

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 12-6](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 12-7](#)).

### 12.1.4.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)). If backwards compatibility is desired (MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 12-6](#) and [Table 12-7](#) in [Message buffer structure](#)).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

### 12.1.4.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIOEN] bits settings.

#### 12.1.4.2.1 Lowest-number Mailbox first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIOEN] bit has no effect when CTRL1[LBUF] is asserted.

#### 12.1.4.2.2 Highest-priority Mailbox first

If CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN] bit setting.

#### 12.1.4.2.2.1 Local Priority disabled

If MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

**Table 12-11. Composition of the arbitration value when Local Priority is disabled**

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

#### 12.1.4.2.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 12-12. Composition of the arbitration value when Local Priority is enabled**

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 12.1.4.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the Data Length Code (DLC) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. T ASD value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX\_ERR\_CNT=124 to 128. T ASD value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
  - If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process

- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 12.1.4.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most) is stored.
2. The received Identifier field is stored.

3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 12-6](#) and [Table 12-7](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 12-6](#) . If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

### CAUTION

*In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRXDIS] bit is not asserted. If the

MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the IFLAG[BUF5I] "Frames available in Rx FIFO" bit in the IMASK1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional – needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional – needed only if a mask was used)
3. Read the Data field
4. Read the RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory – releases the MB and allows the CPU to read the next Rx FIFO entry)

#### 12.1.4.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

**Table 12-13. Matching architecture**

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EAC EN]	MB[IDE]	MB[RTR]	MB[ID <sup>1</sup> ]	MB[CODE]
Mailbox	0	-	0	cmp <sup>2</sup>	no_cmp <sup>3</sup>	cmp_msk <sup>4</sup>	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO <sup>5</sup>	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no\_cmp: The SMB contents are not compared with the MB contents
4. cmp\_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))

- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - If MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox
  - If MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

**Table 12-14. Matching possibilities and resulting reception structures**

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						

*Table continues on the next page...*

**Table 12-14. Matching possibilities and resulting reception structures (continued)**

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
0	0	X <sup>1</sup>	None <sup>2</sup>	- <sup>3</sup>	None	Frame lost by no match
0	0	X	Free <sup>4</sup>	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
<b>FIFO enabled, no match in FIFO is as if FIFO does not exist</b>						
1	0	X	None	None <sup>5</sup>	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
<b>FIFO enabled, Queue disabled</b>						
1	0	0	X	NotFull <sup>6</sup>	FIFO	
1	0	0	None	Full <sup>7</sup>	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMb	Overrun
<b>FIFO enabled, Queue enabled</b>						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.

2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).

3. This is a forbidden condition.

4. Matched in MB “Free” means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO “None” means that the frame has not matched any filter in FIFO. It is as if the FIFO didn’t exist (CTRL2[RFEN]=0).
6. Matched in FIFO “NotFull” means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO “Full” means that the frame has matched a FIFO filter but couldn’t store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not “free-to-receive”, so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are “free-to-receive”, so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Refer to the description of the Rx Individual Mask Registers (RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is “don't care”. Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXGMASK, RX14MASK, RX15MASK and RXFGMASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

### 12.1.4.5 Move process

There are two types of move process: move-in and move-out.

#### 12.1.4.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

#### 12.1.4.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

#### 12.1.4.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

##### 12.1.4.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters in BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.
- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.

- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

#### 12.1.4.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instruction on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can lead to undesirable results:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without notice

In order to eliminate such risk and perform a *safe inactivation* the CPU must use the following mechanism along with the inactivation itself:

- For Tx Mailboxes, the Transmission Abort (see [Transmission abort mechanism](#))

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

#### NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

### 12.1.4.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking is done to prevent a new frame to be written into the MB while the CPU is reading it.

#### NOTE

The locking mechanism applies only to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

#### Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)) and it will take place only when the module resumes to Normal or Freeze modes.

#### 12.1.4.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

### Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the IRMQ bit is negated, then the FIFO filter table is affected by RXFGMASK.

## 12.1.4.8 CAN protocol related features

This section describes the CAN protocol related features.

### 12.1.4.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

### 12.1.4.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission

- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

#### 12.1.4.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in the description of the Control 1 Register (CTRL1).

#### 12.1.4.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (bit MDIS set in the Module Configuration Register).

**Figure 12-2. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The oscillator clock has better jitter performance.

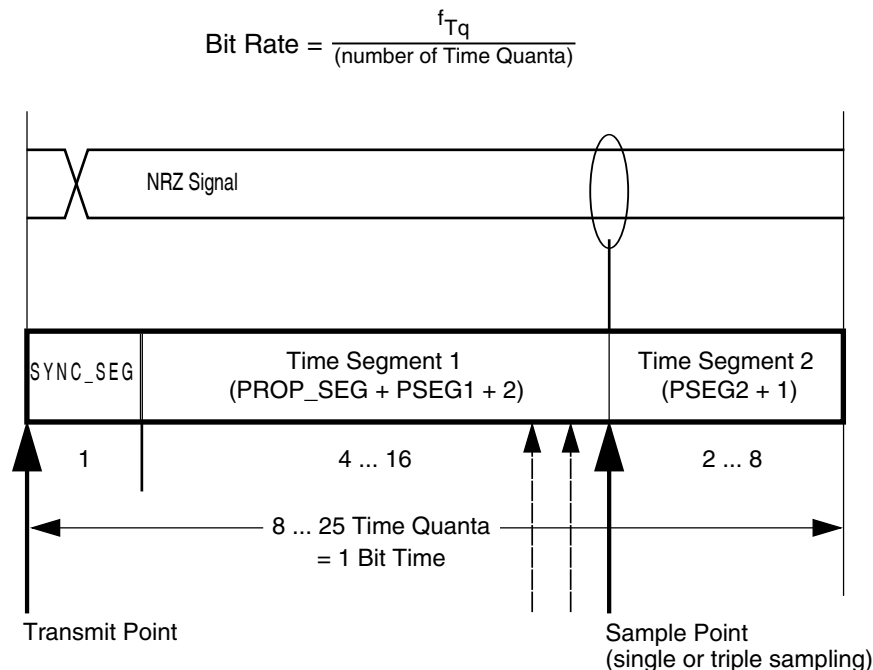

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRES DIV, PROPSEG, PSEG1, PSEG2 and RJW. See the description of the Control 1 Register (CTRL1).

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler Value})}$$

A bit time is subdivided into three segments<sup>1</sup> (see [Figure 12-3](#) and [Table 12-15](#)):

- **SYNC\_SEG:** This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- **Time Segment 1:** This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- **Time Segment 2:** This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL1 Register (plus 1) to be 2 to 8 time quanta long

**Figure 12-3. Segments within the bit time**

1. For further explanation of the underlying concepts, see ISO/DIS 11519-1, Section 10.3. See also the CAN 2.0A/B protocol specification for bit timing.

Whenever CAN bit is used as a measure of duration (for example, MCR[FRZACK] and MCR[LPMACK]), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRES DIV + 1)}{f_{CANCLK}}$$

where:

- NCCP is the number of peripheral clocks in one CAN bit;
- $f_{CANCLK}$  is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- $f_{SYS}$  is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CTRL1[PSEG1] field;
- PSEG2 is the value in CTRL1[PSEG2] field;
- PROPSEG is the value in CTRL1[PROPSEG] field;
- PRES DIV is the value in CTRL1[PRES DIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

**Table 12-15. Time segment syntax**

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives an overview of the CAN compliant segment settings and the related parameter values.

**Table 12-16. Bosch CAN 2.0B standard compliant bit time segment settings**

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1). For bit time calculations, use an IPT (Information Processing Time) of 2, which is the value implemented in the FlexCAN module.

12.1.4.8.5 Arbitration and matching timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

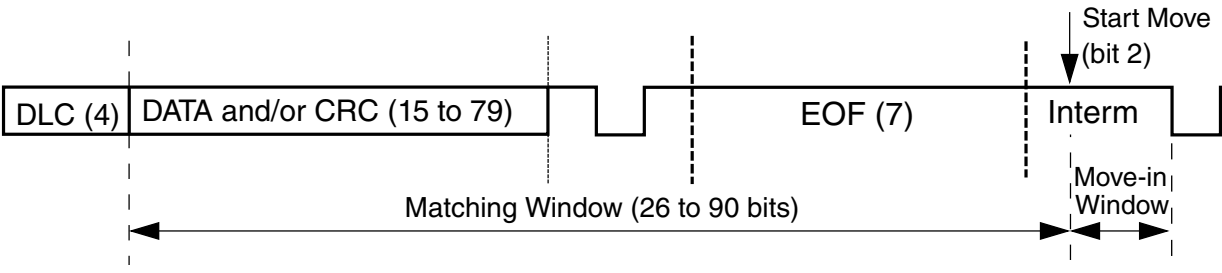

Figure 12-4. Matching and move-in time windows

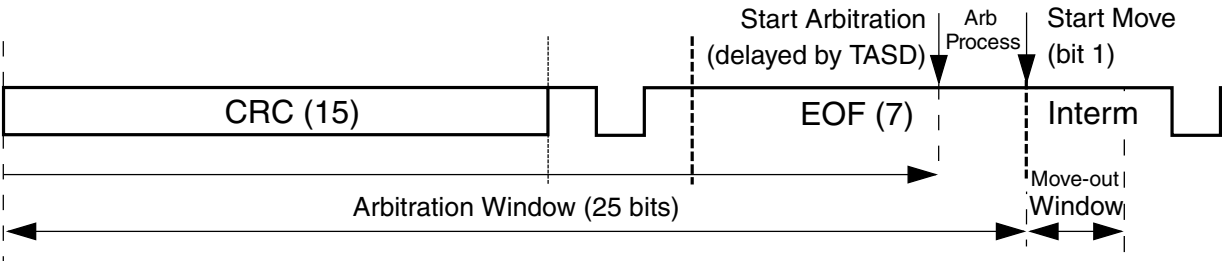

Figure 12-5. Arbitration and move-out time windows

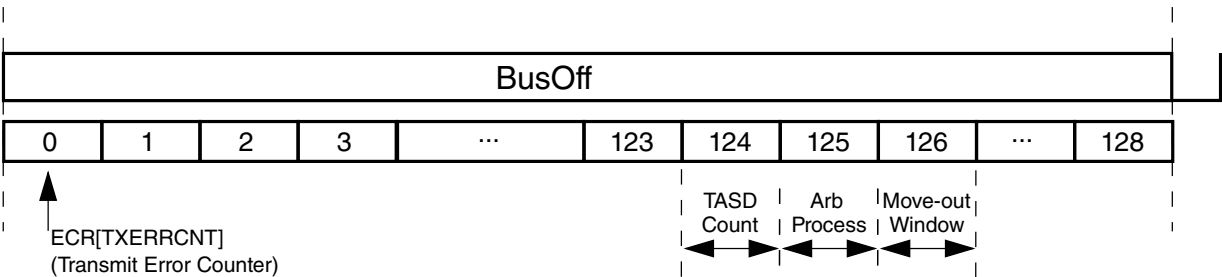

Figure 12-6. Arbitration at the end of bus off and move-out time windows

NOTE

The matching and arbitration timing shown in the preceding figures do not take into account the delay caused by the

concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in [Table 12-16](#)
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, see [Clock domains and restrictions](#)
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table:

**Table 12-17. Minimum ratio between peripheral clock frequency and CAN bit rate**

Number of Message Buffers	RFEN	Minimum number of peripheral clocks per CAN bit
16 and 32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, therefore the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in the preceding table can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRES DIV, PROPSEG, PSEG1, PSEG2) contained in the Control 1 Register (CTRL1).

In case of synchronous operation (when the peripheral clock frequency is equal to the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by selecting an adequate value for PRES DIV in order to meet the requirement in the preceding table. In case of asynchronous operation (the peripheral clock frequency greater than the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by both PRES DIV and/or the frequency ratio.

As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRES DIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

### 12.1.4.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator domain clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

#### NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

### 12.1.4.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

#### CAUTION

“Permanent Dominant” failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a “Permanent Dominant”, the corresponding acknowledge can never be asserted.

#### 12.1.4.10.1 Freeze mode

This mode is requested by the CPU through the assertion of the HALT bit in the MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in a low-power mode.

The acknowledgement is obtained through the assertion by the FlexCAN of FRZ\_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT\_RDY and FRZ\_ACK bits in MCR

After requesting Freeze mode, the user must wait for the FRZ\_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK\_SRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ\_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

#### 12.1.4.10.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM\_ACK bit in the same register. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM\_ACK bit and negates the FRZ\_ACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPM\_ACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

#### 12.1.4.10.3 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive

- Sets the NOTRDY and LPMACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

### 12.1.4.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, ECC Host Access Non-correctable Error, ECC FlexCAN Access Non-correctable Error, ECC Correctable Error, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

#### Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (MCR[RFEN] = 1), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag," and bits 4-0 are unused. See the description of IFLAG1 for more information.

For a combined interrupt where multiple MB interrupt sources are ORed together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Tx Warning, and Rx Warning generate interrupts like the MB interrupt sources, and they can be read from ESR1 and ESR2. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in CTRL1.

The interrupt sources for ECC errors—Host Access with Non-correctable Interrupt Flag, FlexCAN Access with Non-correctable Interrupt Flag, and Correctable Error Interrupt Flag—can be read in ERRSR and the corresponding interrupts masks bits are located in MECCR.

### 12.1.4.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN is configured with 16 MBs, RFFN is 0x0, and MAXMB is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF.

From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

### 12.1.4.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors). Errors in more than 2 bits may not be detected. When read, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

Memory errors are indicated to Host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by ECCDIS bit in Memory Error Control Register (MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations. It assures that memory has consistent parity bits associated to data.

#### NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CTRL2) grants write access to all memory positions from 0x080 to 0xADF.

To avoid that critical error correction configuration be accidentally changed, this protocol must be followed to enable the update of the Memory Error Control Register (MECR):

1. By default, ECRWRE bit in Control 2 Register (CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CTRL2).
3. Clear ECRWRDIS bit.
4. All writes to Memory Error Control Register (MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (MECR) by either setting ECRWRDIS or clearing ECRWRE.

### 12.1.4.13.1 Sources of the Memory Access

The FlexCAN memory can be accessed by 2 major sources (or requestors):

- by Host (CPU): largest word accessed is 32-bit wide
- by FlexCAN internals processes (Match, Arbitration, RxMove on reception, TxMove on transmission): largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

### 12.1.4.13.2 Error Indication

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separately than the ones detected in requests by FlexCAN internal processes. Corrected errors indication makes no distinction of the source of the access. There are 3 independent flags for these 3 cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both non-corrected and corrected errors are found in different bytes in the same read operation both flags are set.

The non-corrected error detected in Host accesses are also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit HANCEIF is not masked, the same non-corrected error will raise a bus transfer error and an interrupt request.

Each indication flag has one Overrun flag in Error Status Register (ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the Interrupt flag
4. If the Overrun flag is active:
  - a. Alert application that at least one error could not be handled
  - b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

### 12.1.4.13.3 Error Reporting

Report registers Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in the “Error Indication” section. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules.

1. If any of the 2 non-corrected error flags is currently set, does not update the registers (preserve the old non-corrected error reporting)
2. Else (no error flag is currently set or only the corrected error flag is currently set), update the report registers according to the new error; or according to the most severe of new errors if non-corrected and corrected errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the semantic described in the “Error Indication” section and in the Error Report Address Register (RERRAR) description.

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. How the reported addresses correspond to locations in the module memory map is shown in the Error Injection Address Register (ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the element accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by clearing the MECCR[RERRDIS] bit before reading the report registers.

### 12.1.4.13.4 Response to Errors

Correctable errors have no consequence on FlexCAN operation, once the corrected data is used by Host or FlexCAN internal processes. For host-initiated reads, a non-corrected error detected does not affect FlexCAN operation.

Non-corrected errors detected on memory reads requested by FlexCAN do not stop the FlexCAN processing and this may result in incorrect operation.

If a non-corrected error occurs during a reception process (Match or RxMove), an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If a non-corrected error occurs during either an Arbitration or a TxMove process, either a non-highest priority frame may be mistakenly selected to be transmitted or no frame may be transmitted at all, when  $\text{MECR}[\text{NCEFAFRZ}] = 1$ .

The error report registers can provide information to the application for a customized handling of these situations. If the delay of this handling is not accepted and  $\text{MECR}[\text{NCEFAFRZ}] = 1$ , the FlexCAN stops operation automatically and enters Freeze mode when these errors are detected. See the Memory Error Control Register (MECR) description for more details.

#### 12.1.4.13.5 Error Injection

The error injection registers  $\text{ERRIAR}$ ,  $\text{ERRIDPR}$ , and  $\text{ERRIPPR}$  are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. How the error injection addresses correspond to locations in the module memory map is shown in the  $\text{ERRIAR}$  description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in  $\text{ERRIDPR}$  and  $\text{ERRIPPR}$ . Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the  $\text{EXTERRIE}$  bit in Memory Error Control Register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

#### NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the  $\text{HAERRIE}$  and  $\text{FAERRIE}$  bits in Memory Error Control Register (MECR) must be cleared while configuring the memory injection registers.

### 12.1.5 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

### 12.1.5.1 FlexCAN initialization sequence

The FlexCAN module may be reset as follows:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See [Table 12-2](#) to see what registers are affected by soft reset.
- Chip level soft reset, which has the same effect as the SOFTRST bit in MCR

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLKSRC bit) should be selected while the module is in Disable mode. After the clock source is selected and the module is enabled (MDIS bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is unsynchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode; see [Freeze mode](#). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control Register

- Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
- Determine the bit rate by programming the PRES DIV field
- Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- When ECC is enabled, follow the initialization note in [Detection and Correction of Memory Errors](#)
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts) and in CTRL Register (for Bus Off and Error interrupts)
- Negate the HALT bit in MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

## 12.2 Inter-Integrated Circuit (I2C)

### 12.2.1 Overview

This chapter describes the Inter-Integrated Circuit (I<sup>2</sup>C) bus module implemented on this chip and presents the following topics:

- [Introduction to I<sup>2</sup>C](#)
- [External signal descriptions](#)
- [Memory map and register definition](#)
- [Functional description](#)
- [Initialization/application information](#)

## 12.2.2 Introduction to I<sup>2</sup>C

This section presents the following topics:

- [Definition: I<sup>2</sup>C module](#)
- [Advantages of the I<sup>2</sup>C bus](#)
- [Module block diagram](#)
- [Features](#)
- [Modes of operation](#)
- [Definition: I<sup>2</sup>C conditions](#)

### 12.2.2.1 Definition: I<sup>2</sup>C module

The I<sup>2</sup>C module is a functional unit that provides a two-wire— serial data (SDA) and serial clock (SCL) — bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

### 12.2.2.2 Advantages of the I<sup>2</sup>C bus

The synchronous, multiple-master two-wire I<sup>2</sup>C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

### 12.2.2.3 Module block diagram

The following figure shows a block diagram of the I<sup>2</sup>C module.

Figure 12-7. I<sup>2</sup>C block diagram

### 12.2.2.4 Features

The I<sup>2</sup>C module has the following key features:

- Compatible with I<sup>2</sup>C bus standard<sup>3</sup>
- Operating speeds
  - Up to 100 kbps in Standard Mode
  - Up to 400 kbps in Fast Mode

3. Compliant with I<sup>2</sup>C 2.0 standard with the exception that HS (high speed) mode is not supported

- Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
- Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

### 12.2.2.5 Modes of operation

The I<sup>2</sup>C module supports the chip modes described in the following table.

**Table 12-18. Chip modes supported by the I<sup>2</sup>C module**

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I <sup>2</sup> C module	The I <sup>2</sup> C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. See <a href="#">STOP mode</a> .
DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See <a href="#">DEBUG mode</a> .

In addition to chip modes, the I<sup>2</sup>C module has several module-specific modes. These are described in the following table.

Table 12-19. Module-specific modes supported by the I<sup>2</sup>C module

Module mode	Description	Important notes
Master mode	The I <sup>2</sup> C module is the driver of the SDA line.	<ul style="list-style-type: none"><li>Do not use the I<sup>2</sup>C module's slave address as a calling address.</li><li>The I<sup>2</sup>C module cannot be a master and a slave simultaneously.</li></ul>
Slave mode	The I <sup>2</sup> C module is not the driver of the SDA line.	<ul style="list-style-type: none"><li>Enable the I<sup>2</sup>C module before a START condition from a non-I<sup>2</sup>C master is detected.</li><li>By default the I<sup>2</sup>C module performs as a slave receiver.</li></ul>

12.2.2.6 Definition: I<sup>2</sup>C conditions

The following table shows the I<sup>2</sup>C-specific conditions defined for the I<sup>2</sup>C module.

Table 12-20. I<sup>2</sup>C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in the following figure.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in the following figure.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

Figure 12-8. START and STOP conditions

### 12.2.3 External signal descriptions

This section presents the following topics:

- [Signal overview](#)
- [Detailed external signal descriptions](#)

#### 12.2.3.1 Signal overview

The I<sup>2</sup>C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

#### 12.2.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in the following table.

**Table 12-21. External signal descriptions**

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I <sup>2</sup> C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I <sup>2</sup> C bus specification

### 12.2.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I<sup>2</sup>C module. It presents the following topics:

- [Register accessibility](#)
- [Register figure conventions](#)
- [I2C Bus Address Register \(I2C\\_IBAD\)](#)

- I2C Bus Frequency Divider Register (I2C\_IBFD)
- I2C Bus Control Register (I2C\_IBCR)
- I2C Bus Status Register (I2C\_IBSR)
- I2C Bus Data I/O Register (I2C\_IBDR)
- I2C Bus Interrupt Config Register (I2C\_IBIC)
- I2C Bus Debug Register (I2C\_IBDBG)

#### 12.2.4.1 Register accessibility

Address location 0x0007 is a reserved location, but access to this location will not generate any bus error.

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

#### 12.2.4.2 Register figure conventions

The register figures show the field structure using the conventions in the following figure.

Figure 12-9. Register figure convention

The memory map for the I<sup>2</sup>C module is given below. The total address for each register is the sum of the base address for the I<sup>2</sup>C module and the address offset for each register.

I<sup>2</sup>C memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4006_6000	I2C Bus Address Register (I2C0_IBAD)	8	R/W	00h	<a href="#">12.2.4.3/2604</a>
4006_6001	I2C Bus Frequency Divider Register (I2C0_IBFD)	8	R/W	00h	<a href="#">12.2.4.4/2605</a>
4006_6002	I2C Bus Control Register (I2C0_IBCR)	8	R/W	80h	<a href="#">12.2.4.5/2605</a>

**12.2.4.3 I2C Bus Address Register (I2Cx\_IBAD)**

This register contains the address the I<sup>2</sup>C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: Base address + 0h offset

Bit	7	6	5	4	3	2	1	0
Read	ADR							0
Write								
Reset	0	0	0	0	0	0	0	0

**I2Cx\_IBAD field descriptions**

Field	Description
7–1 ADR	Slave Address. Specific slave address to be used by the I <sup>2</sup> C Bus module. <b>NOTE:</b> The default mode of I <sup>2</sup> C Bus is slave mode for an address match on the bus.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**12.2.4.4 I2C Bus Frequency Divider Register (I2Cx\_IBFD)**

**Access:** Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

**Address:** Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read	IBC							
Write								
Reset	0	0	0	0	0	0	0	0

**I2Cx\_IBFD field descriptions**

Field	Description
IBC	I-Bus Clock Rate. This field is used to prescale the bus clock for bit rate selection. See <a href="#">Clock rate and IBFD settings</a> .

**12.2.4.5 I2C Bus Control Register (I2Cx\_IBCR)**

**Access:** Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

**Address:** Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	Reserved
Write						RSTA		
Reset	1	0	0	0	0	0	0	0

**I2Cx\_IBCR field descriptions**

Field	Description
7 MDIS	Module disable. This bit controls the software reset of the entire I <sup>2</sup> C Bus module.

*Table continues on the next page...*

**I2Cx\_IBCR field descriptions (continued)**

Field	Description
	<p><b>NOTE:</b> If the I<sup>2</sup>C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I<sup>2</sup>C Bus module losing arbitration, after which, bus operation would return to normal.</p> <p>0 The I<sup>2</sup>C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect</p> <p>1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled.</p>
6 IBIE	<p>I-Bus Interrupt Enable.</p> <p>0 Interrupts from the I<sup>2</sup>C Bus module are disabled. This does not clear any currently pending interrupt condition.</p> <p>1 Interrupts from the I<sup>2</sup>C Bus module are enabled. An I<sup>2</sup>C Bus interrupt occurs provided the IBIF bit in the status register is also set.</p>
5 MSSL	<p>Master/Slave mode select. When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration.</p> <p>0 Slave Mode</p> <p>1 Master Mode</p>
4 TXRX	<p>Transmit/Receive mode select. This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high.</p> <p>0 Receive</p> <p>1 Transmit</p>
3 NOACK	<p>Data Acknowledge disable. This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I<sup>2</sup>C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK.</p> <p><b>NOTE:</b> Values written to this bit are only used when the I<sup>2</sup>C Bus is a receiver, not a transmitter.</p> <p>0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data</p> <p>1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)</p>
2 RSTA	<p>Repeat Start. Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration.</p> <p>0 No effect</p> <p>1 Generate repeat start cycle</p>
1 DMAEN	<p>DMA Enable. When this bit is set, the DMA Tx and Rx lines will be asserted when the I<sup>2</sup>C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I<sup>2</sup>C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See the DMA Application Information section for more details.</p>

*Table continues on the next page...*

**I2Cx\_IBCR field descriptions (continued)**

Field	Description
	0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals
0 Reserved	This field is reserved. Although this bit supports read/write access, writing to this bit is not recommended, and can produce unexpected results.

**12.2.4.6 I2C Bus Status Register (I2Cx\_IBSR)**

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0
Read	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
Write				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

**I2Cx\_IBSR field descriptions**

Field	Description
7 TCF	Transfer complete.  While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer.  <b>NOTE:</b> This bit is only valid during or immediately following a transfer to the I <sup>2</sup> C module or from the I <sup>2</sup> C module.  0 Transfer in progress 1 Transfer complete
6 IAAS	Addressed as a slave.  When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit.  0 Not addressed 1 Addressed as a slave
5 IBB	Bus busy.  This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state.  0 Bus is Idle 1 Bus is busy

Table continues on the next page...

**I2Cx\_IBSR field descriptions (continued)**

Field	Description
4 IBAL	<p>Arbitration Lost.</p> <p>The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances:</p> <ul style="list-style-type: none"> <li>• SDA is sampled low when the master drives a high during an address or data transmit cycle.</li> <li>• SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle.</li> <li>• A start cycle is attempted when the bus is busy.</li> <li>• A repeated start cycle is requested in slave mode.</li> <li>• A stop condition is detected when the master did not request it.</li> </ul> <p>This bit must be cleared by software, by writing a one to it. A write of zero has no effect.</p>
3 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
2 SRW	<p>Slave Read/Write. When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master.</p> <p>0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave</p>
1 IBIF	<p>I-Bus Interrupt Flag. The IBIF bit is set when one of the following conditions occurs:</p> <ul style="list-style-type: none"> <li>• Arbitration lost (IBAL bit set)</li> <li>• Byte transfer complete (TCF bit set and DMAEN bit not set)</li> <li>• Addressed as slave (IAAS bit set)</li> <li>• NoAck from Slave (MS &amp; Tx bits set)</li> <li>• I<sup>2</sup>C Bus going idle (IBB high-low transition and enabled by BIIE)</li> </ul> <p>A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.</p>
0 RXAK	<p>Received Acknowledge. This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete.</p> <p>0 Acknowledge received 1 No acknowledge received</p>

**12.2.4.7 I2C Bus Data I/O Register (I2Cx\_IBDR)**

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

**NOTE**

The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I<sup>2</sup>C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I<sup>2</sup>C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I<sup>2</sup>C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/  $\overline{W}$  bit (in position D0).

**NOTE**

When the I<sup>2</sup>C is configured in master mode and receiving data from a slave that is transmitting data bytes on an irregular basis, the master cannot know whether the data received in the IBDR is the old latched data or the new data received from the slave. To avoid this, 2 consecutive intermittent data bytes from slave should be different.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: Base address + 4h offset

Bit	7	6	5	4	3	2	1	0
Read	DATA							
Write								
Reset	0	0	0	0	0	0	0	0

**I2Cx\_IBDR field descriptions**

Field	Description
DATA	Data transmitted or received

**12.2.4.8 I2C Bus Interrupt Config Register (I2Cx\_IBIC)**

To program BIIE = 1, you must ensure that IBCR[MDIS] = 0.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

## Inter-Integrated Circuit (I2C)

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	BIIE	BYTERXIE	0					
Write								
Reset	0	0	0	0	0	0	0	0

### I2Cx\_IBIC field descriptions

Field	Description
7 BIIE	Bus Idle Interrupt Enable bit. This config bit can be used to enable the generation of an interrupt once the I <sup>2</sup> C bus becomes idle. Once this bit is set, an IBB high-low transition will set the IBIF bit. This feature can be used to signal to the CPU the completion of a STOP on the I <sup>2</sup> C bus.  0 Bus Idle Interrupts disabled 1 Bus Idle Interrupts enabled
6 BYTERXIE	Byte receive interrupt enable  This field is used to generate an interrupt every time the I <sup>2</sup> C master/slave receives a new byte. This feature can be useful when an I <sup>2</sup> C master is receiving data from a slave that is transmitting on an irregular basis.  BYTERXIE is updated only when the I <sup>2</sup> C is enabled (IBCR[MDIS]=0).
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 12.2.4.9 I2C Bus Debug Register (I2Cx\_IBDBG)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: Base address + 6h offset

Bit	7	6	5	4
Read	0			
Write				
Reset	0	0	0	0

Bit	3	2	1	0
Read	0		IPG_DEBUG_HALTED	IPG_DEBUG_EN
Write				
Reset	0	0	0	0

### I2Cx\_IBDBG field descriptions

Field	Description
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

**I2Cx\_IBDBG field descriptions (continued)**

Field	Description
1 IPG_DEBUG_HALTED	<p>Debug Halted Bit: This is a status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not.</p> <p>0 IP is still executing a transaction 1 IP has entered the debug mode</p>
0 IPG_DEBUG_EN	<p>Debug enable bit. This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU.</p> <p><b>NOTE:</b> If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited.</p> <p>0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode</p>

**12.2.5 Functional description**

This section presents the following topics:

- [Notes about module operation](#)
- [Transactions](#)
- [Arbitration procedure](#)
- [Clock behavior](#)
- [Interrupts](#)
- [DEBUG mode](#)
- [DMA interface](#)

**12.2.5.1 Notes about module operation**

- The I<sup>2</sup>C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I<sup>2</sup>C module is acting as a master, it must not try to call its own slave address.

## 12.2.5.2 Transactions

This section presents the following topics:

- [Protocol overview](#)
- [Transaction protocol definitions](#)
- [High-level protocol steps](#)
- [START condition](#)
- [Slave address transmission](#)
- [Data transmission](#)
- [STOP condition](#)
- [Repeated START condition](#)

### 12.2.5.2.1 Protocol overview

The following figure shows the behavior of SCL and SDA during a typical I<sup>2</sup>C transaction.

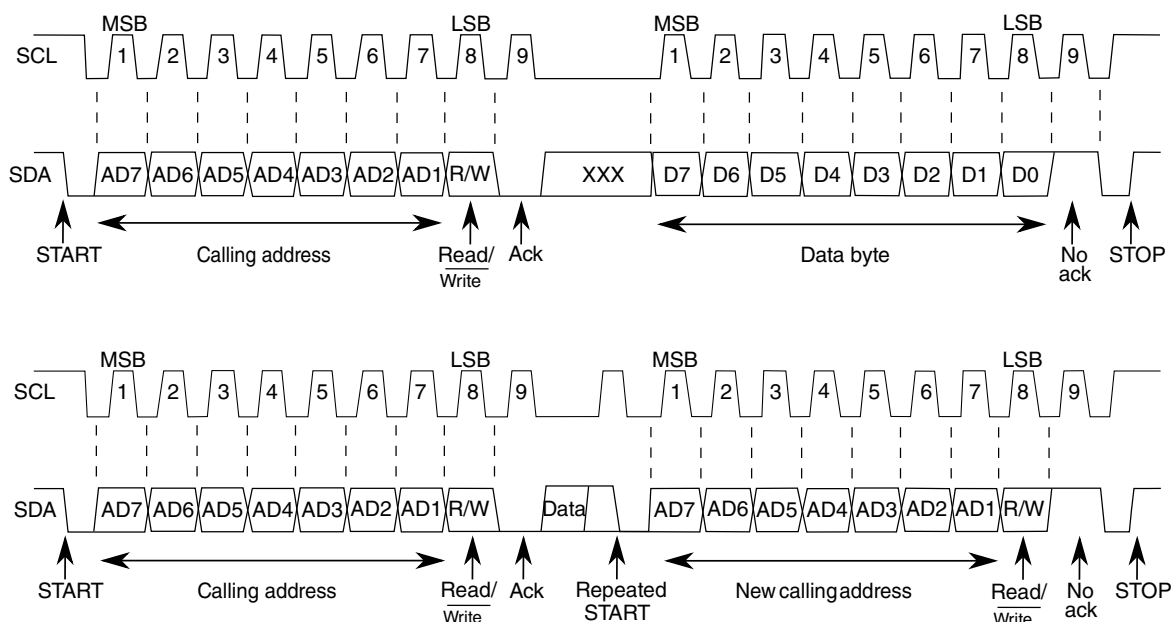

Figure 12-10. I<sup>2</sup>C transaction protocol

### 12.2.5.2.2 Transaction protocol definitions

This section defines several important terms presented in [Figure 12-10](#).

**Table 12-22. I<sup>2</sup>C definitions**

Term	Definition
START	A START condition, as defined in <a href="#">Section 1.2.6, Definition: I<sup>2</sup>C conditions</a> "
STOP	A STOP condition, as defined in <a href="#">Section 1.2.6, Definition: I<sup>2</sup>C conditions</a> "
Calling (slave) address	A seven-bit address used to identify a slave on the I <sup>2</sup> C bus. The requirements for specifying this address are presented in <a href="#">Section 1.5.2.3, I<sup>2</sup>C calling address requirements</a> ."
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: <ul style="list-style-type: none"> <li>• 0=The data is being transferred from the master to the slave ("write")</li> <li>• 1=The data is being transferred from the slave to the master ("read")</li> </ul>
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

### 12.2.5.2.3 I<sup>2</sup>C calling address requirements

The calling addresses of the devices used on an I<sup>2</sup>C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

### 12.2.5.2.4 High-level protocol steps

The I<sup>2</sup>C protocol conceptually supports two types of transfers, which are illustrated in [Figure 12-10](#). The significant steps in these transfers are presented in the following table. Details of each of these steps are presented in subsequent sections.

**Table 12-23. I<sup>2</sup>C high-level protocol steps**

Standard Transfer	Repeated START Transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Acknowledgment from slave	3. Acknowledgment from slave
4. Data transfer	4. Data transfer
5. STOP condition	5. Repeated START condition
6. (repeat Steps 1–4)	6. (repeat Steps 2–4 as needed)
	7. STOP condition.
	8. (repeat Steps 1–7)

### 12.2.5.2.5 START condition

When the bus is free, that is, no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (see [Definition: I<sup>2</sup>C conditions](#)). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

See [Clock rate and IBFD settings](#) and [I2C Bus Frequency Divider Register \(I2C\\_IBFD\)](#) for the associated timing requirements.

### 12.2.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (see [START condition](#)). The process of slave address transmission is presented in the following table.

**Table 12-24. Slave address transmission process**

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: <ul style="list-style-type: none"> <li>• The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition.</li> <li>• The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.</li> </ul>

### 12.2.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.

- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

#### 12.2.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see [Definition: I<sup>2</sup>C conditions](#)). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see [Repeated START condition](#).

See [Clock rate and IBFD settings](#) and [I2C Bus Frequency Divider Register \(I2C\\_IBFD\)](#) for the associated timing requirements.

#### 12.2.5.2.9 Repeated START condition

The I<sup>2</sup>C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of [Figure 12-10](#).

### 12.2.5.3 Arbitration procedure

The I<sup>2</sup>C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to

the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic "1" while another master transmits logic "0". The losing masters immediately switch over to slave mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

#### 12.2.5.4 Clock behavior

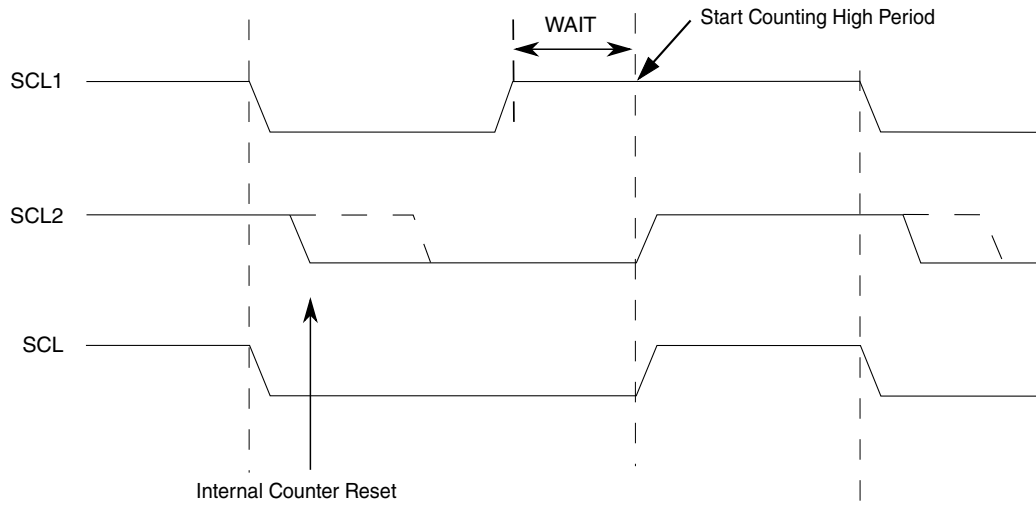

This section presents the following topics:

- [Clock synchronization](#)
- [Clock stretching](#)
- [Handshaking](#)
- [Clock rate and IBFD settings](#)

##### 12.2.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached.

However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see the following figure). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

**Figure 12-11. I²C bus clock synchronization**

#### 12.2.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

#### 12.2.5.4.3 Handshaking

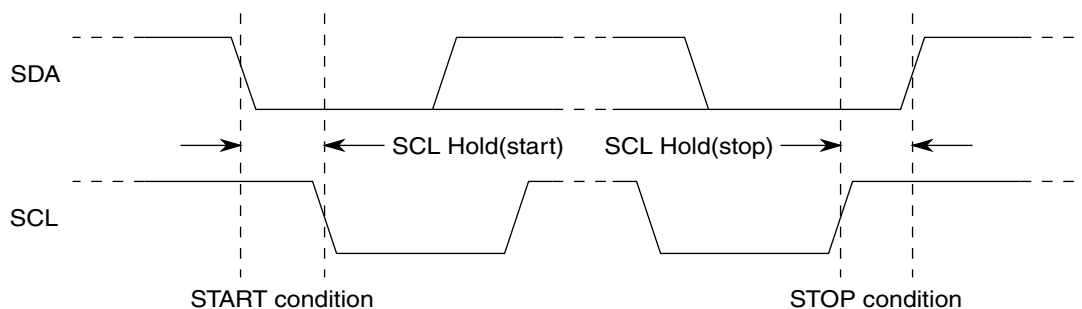

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

#### 12.2.5.4.4 Clock rate and IBFD settings

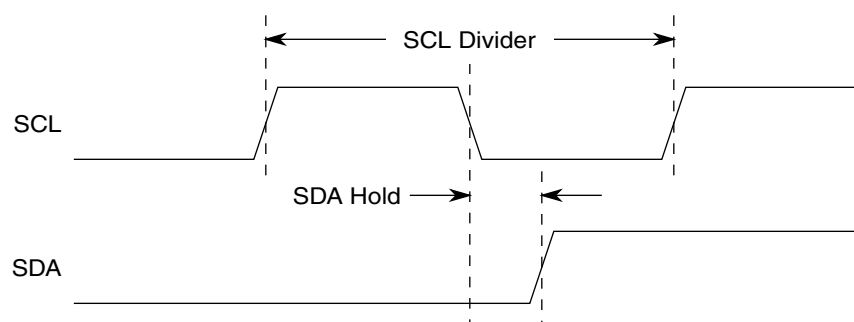

##### 12.2.5.4.4.1 Timing definitions

**Table 12-25. Timing definitions relevant to clock rate and IBFD settings**

Term	Definition
SCL Divider	The factor used to prescale the CPU clock for bit rate selection (see <a href="#">Figure 12-12</a> and <a href="#">Table 12-26</a> )
SCL period	(CPU clock period) × (SCL Divider)
SCL Hold	The required number of CPU clocks to generate a START or STOP condition (see <a href="#">Figure 12-12</a> and <a href="#">Table 12-26</a> )
SDA Hold	See <a href="#">Figure 12-13</a> and <a href="#">Table 12-26</a>

**Figure 12-12. SCL Divider and SDA Hold**

**Figure 12-13. SDA Hold time**

#### 12.2.5.4.4.2 Divider and hold values

**Table 12-26. I<sup>2</sup>C divider and hold values**

	IBC (hex)	SCL Divider (clocks)	SDA Hold (clocks)	SCL Hold (start)	SCL Hold (stop)

### 12.2.5.5 Interrupts

This section presents the following topics:

- [Interrupt vector](#)
- [Interrupt description](#)

#### 12.2.5.5.1 Interrupt vector

The I<sup>2</sup>C module uses only one interrupt vector.

**Table 12-27. Interrupt summary**

Interrupt	Offset	Vector	Priority	Source	Description
I <sup>2</sup> C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

### 12.2.5.5.2 Interrupt description

There are five types of internal interrupts in the I<sup>2</sup>C. The interrupt service routine can determine the interrupt type by reading the Status register.

I<sup>2</sup>C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I<sup>2</sup>C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIIE] bit.

### 12.2.5.6 STOP mode

This mode allows the software to put the I<sup>2</sup>C module in power-down state. Once the STOP request is asserted, the I<sup>2</sup>C module comes to a graceful halt after completing all the ongoing transactions.

As soon as the I<sup>2</sup>C module enters STOP mode:

- The I<sup>2</sup>C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I<sup>2</sup>C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. See the figure below for more details.

**Figure 12-14. I<sup>2</sup>C stop mode behavior when master is receiving and slave is transmitting**

### 12.2.5.7 DEBUG mode

This mode allows CPU to debug the I<sup>2</sup>C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG\_DEBUG\_EN] bit, I<sup>2</sup>C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG\_DEBUG\_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I<sup>2</sup>C module enters DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I<sup>2</sup>C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. See the simulation result in [Figure 12-15](#) for more details.

**Figure 12-15. Simulation result of IPG Debug Halted in case of frame transmission**

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I<sup>2</sup>C module enters DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits DEBUG mode, transmission or reception of the remaining bytes resumes. Please see the simulation snapshot shown in [Figure 12-16](#) for details where the I<sup>2</sup>C is transmitting 8 bytes using DMA and DEBUG mode is requested while a second byte is being transmitted. DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

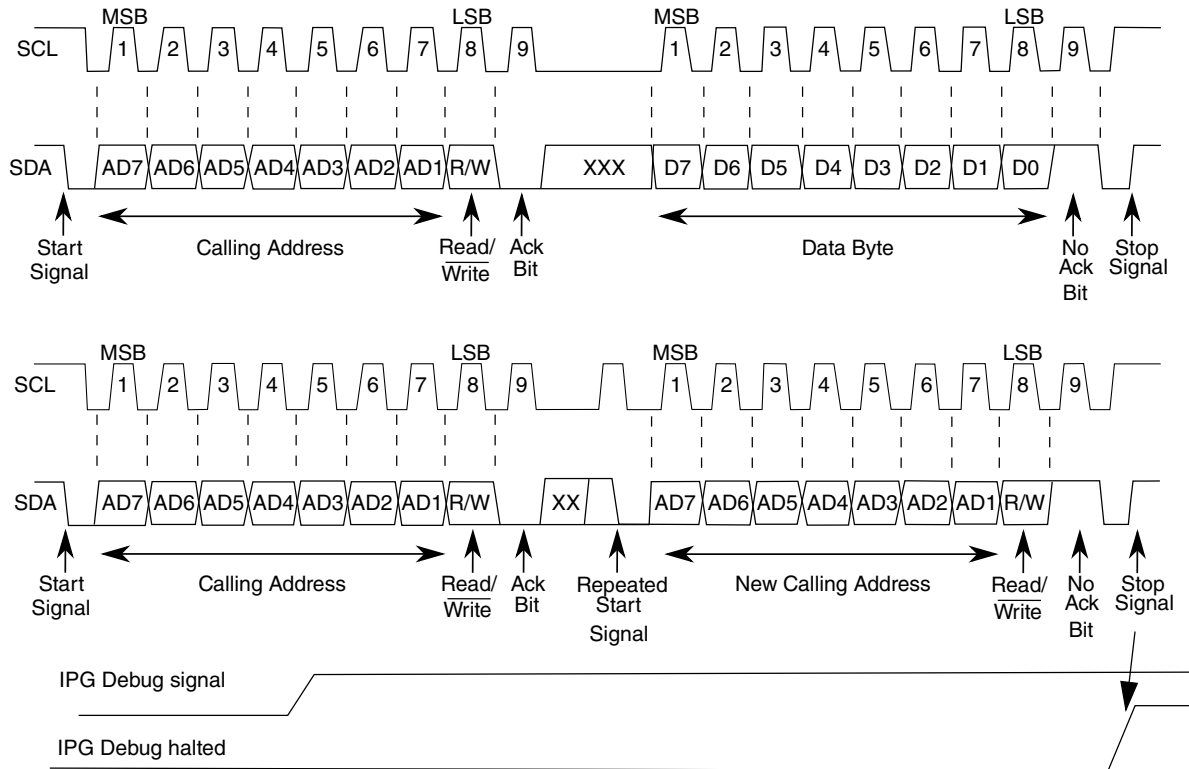

**Figure 12-16. Simulation result of IPG Debug Halted in case of frame transmission using DMA**

No more transaction can take place until the debug signal is de-asserted after which the I<sup>2</sup>C module starts functioning normally. There is a status halted signal IBDBG[IPG\_DEBUG\_HALTED] to indicate to the user that the I<sup>2</sup>C module has entered the DEBUG mode. See the following figure for more details.

**Figure 12-17. DEBUG mode**

The following figure shows a case of DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I<sup>2</sup>C module enters DEBUG mode.

**Figure 12-18. DEBUG mode with repeated start**

### 12.2.5.8 DMA interface

A simple DMA interface is implemented so that the I<sup>2</sup>C can request data transfers with minimal support from the CPU (see [DMA application information](#)). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I<sup>2</sup>C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I<sup>2</sup>C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the [Initialization/application information](#), of this document.

## 12.2.6 Initialization/application information

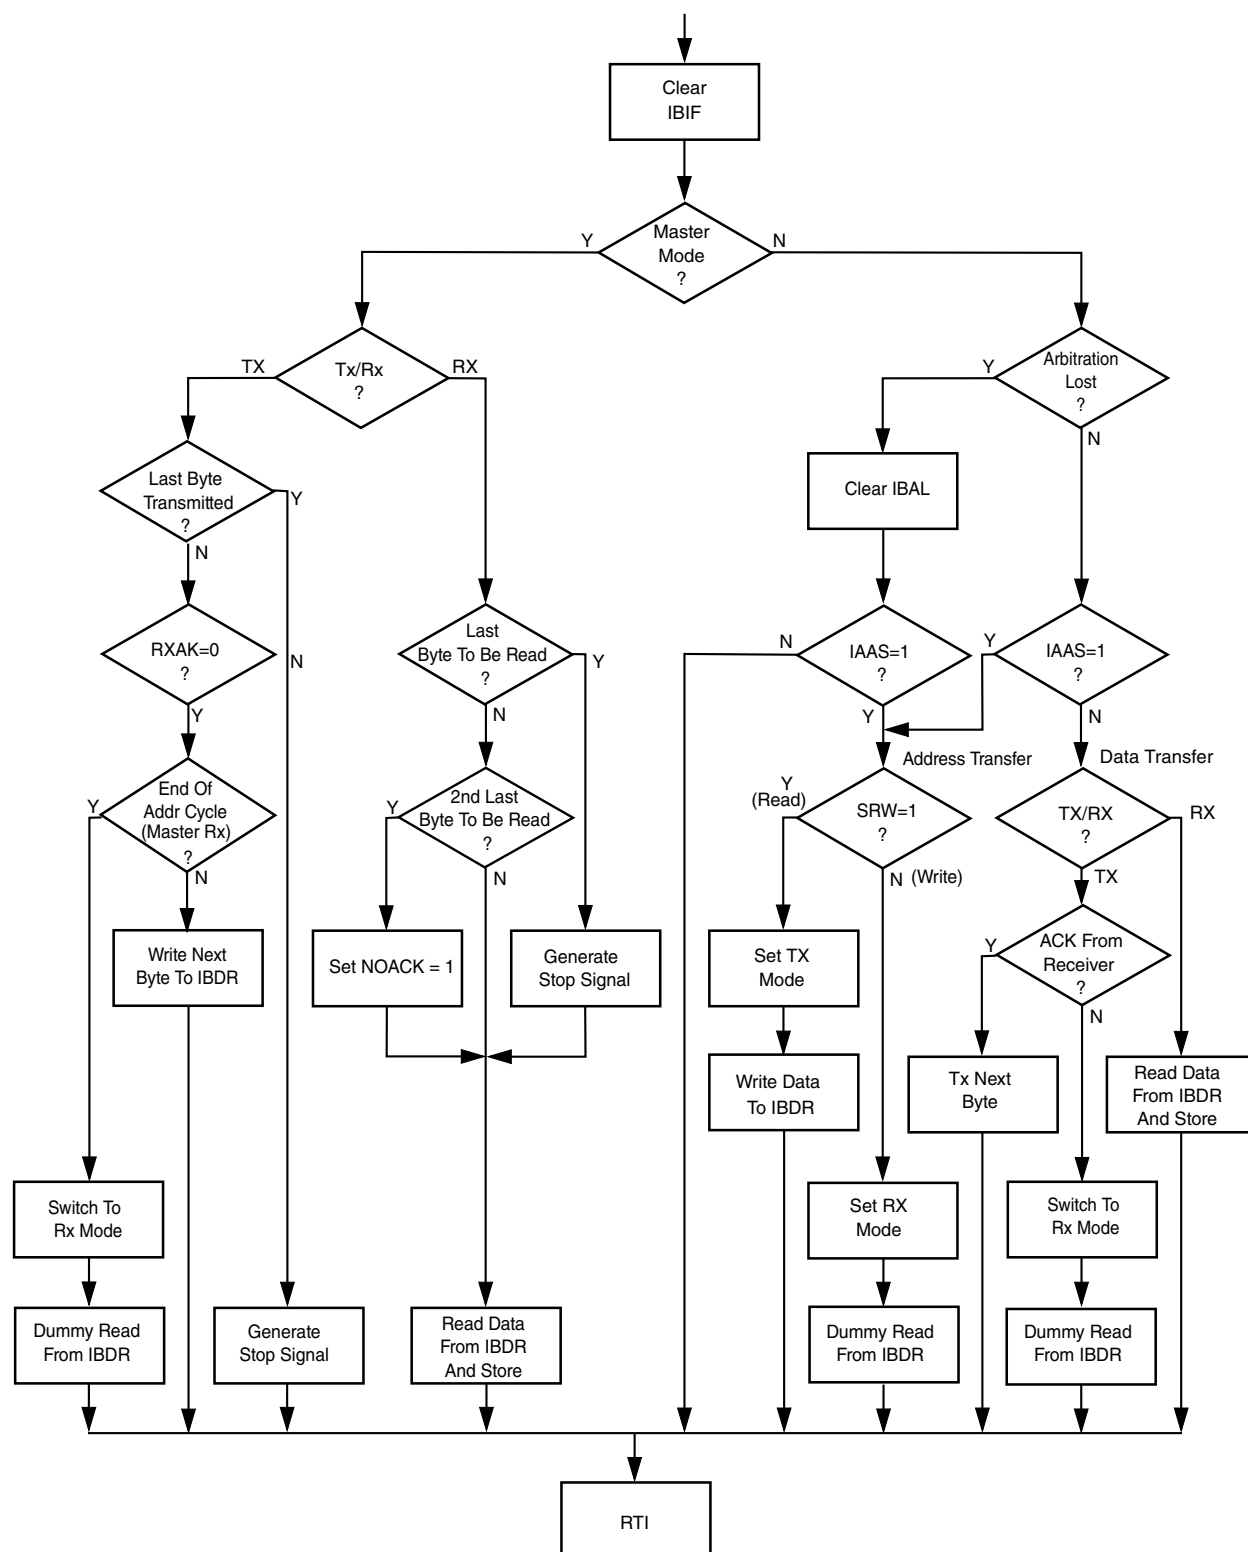

This section presents the following topics:

- [Recommended interrupt service flow](#)
- [General programming guidelines \(for both master and slave mode\)](#)
- [Programming guidelines specific to master mode](#)
- [Programming guidelines specific to slave mode](#)
- [DMA application information](#)

### 12.2.6.1 Recommended interrupt service flow

The following figure shows a flowchart for the recommended I<sup>2</sup>C interrupt service routine. Deviation from the flowchart may result in unpredictable I<sup>2</sup>C bus behavior.

Figure 12-19. Recommended I<sup>2</sup>C interrupt service routine flowchart

## 12.2.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I<sup>2</sup>C module in both master and slave mode. It presents the following topics:

- [Initializing the I<sup>2</sup>C module](#)
- [Software response after a transfer](#)

### 12.2.6.2.1 Initializing the I<sup>2</sup>C module

The following table describes how to initialize the I<sup>2</sup>C module.

**Table 12-28. I<sup>2</sup>C initialization procedure**

Step	Action
1	Use <a href="#">I2C Bus Frequency Divider Register (I2C_IBFD)</a> to select the required division ratio to obtain SCL frequency from the system clock.
2	Use <a href="#">I2C Bus Address Register (I2C_IBAD)</a> to define the slave address.
3	Clear the MDIS field in <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to enable the I <sup>2</sup> C interface system.
4	Use <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to select Master/Slave mode, Transmit/Receive mode, and whether interrupts are enabled or disabled.
5	(Optional) Use <a href="#">I2C Bus Interrupt Config Register (I2C_IBIC)</a> to further refine the interrupt behavior.

### 12.2.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I<sup>2</sup>C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I<sup>2</sup>C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I<sup>2</sup>C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

### 12.2.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- [Generating START](#)
- [Transmit/receive sequence](#)
- [Generating STOP](#)
- [Generating repeated START](#)
- [Loss of arbitration](#)

#### 12.2.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I<sup>2</sup>C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I<sup>2</sup>C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)           // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[ ]Tx/Rx] = 1 // master and transmit mode, that is,
                                   // generate start condition
IBDR = calling_address          // send the calling address to the data register
while (bit 5, IBSR ==0)         // wait in loop for IBB flag to be set
```

### 12.2.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

**Table 12-29. Master transmit sequence**

Step	Action
a	Use <a href="#">I2C Bus Frequency Divider Register (I2C_IBFD)</a> to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to the IBDIS field in <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to enable the I <sup>2</sup> C interface system.
c	Use <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to select Master mode, Transmit mode, and interrupt enable.
d	Write 0 to the IBIF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> .
e	Write data to <a href="#">I2C Bus Data I/O Register (I2C_IBDR)</a> .
f	Observe changes in the TCF field of <a href="#">I2C Bus Status Register (I2C_IBSR)</a> : <ul style="list-style-type: none"> <li>• When IBSR[TCF] becomes 0, the transfer is in progress.</li> <li>• When IBSR[TCF] becomes 1, the transfer is complete.</li> </ul>
g	Wait until the IBIF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 1.
h	Read the fields in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> to determine what happened: <ul style="list-style-type: none"> <li>• If TCF = 1, the transfer completed.</li> <li>• If RXAK = 1, a No Acknowledge condition occurred.</li> <li>• If IBB = 0, the bus transitioned from Busy to Idle state.</li> <li>• If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1).</li> </ul> <p><b>NOTE:</b> You can ignore Address Detect (IAAS = 1) for master mode (it is valid only for slave mode).</p>
i	Examine the RXAK field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

**Table 12-30. Master receive sequence**

Step	Action
a	Follow steps a through i in <a href="#">Table 12-29</a> for address dispatch.
b	Write 0 to the IBIF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> .
c	Write 0 to the TXRX field in <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to select Receive mode.

*Table continues on the next page...*

**Table 12-30. Master receive sequence (continued)**

Step	Action
d	Perform a dummy read of <a href="#">I2C Bus Data I/O Register (I2C_IBDR)</a> to initiate the receive operation.
e	Wait until the TCF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 1. (This proves that the transfer is complete.)
f	Wait until the IBIF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 1.
g	Read the fields in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> to determine what happened: <ul style="list-style-type: none"> <li>• If TCF = 1, the reception completed.</li> <li>• If IBB = 0, the bus transitioned from Busy to Idle state.</li> <li>• If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1).</li> </ul> <p><b>NOTE:</b> You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.</p>
h	Read <a href="#">I2C Bus Data I/O Register (I2C_IBDR)</a> to determine the data received from the slave.

**Table 12-31. Slave transmit sequence**

Step	Action
a	Use <a href="#">I2C Bus Address Register (I2C_IBAD)</a> to define the slave address.
b	Write 0 to the IBDIS field in <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to enable the I <sup>2</sup> C interface system.
c	Examine fields in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> as follows: <ul style="list-style-type: none"> <li>• If IAAS = 1, examine IBSR[SRW].</li> <li>• If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.</li> </ul>
d	Write data to <a href="#">I2C Bus Data I/O Register (I2C_IBDR)</a> .
e	Wait until the IBIF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 1.
f	Wait until the RXAK field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 0.
g	Write 0 to the IBIF field in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> .
h	Repeat steps d through g for the next consecutive data transfers.

**Table 12-32. Slave receive sequence**

Step	Action
a	Use <a href="#">I2C Bus Address Register (I2C_IBAD)</a> to define the slave address.
b	Write 0 to the IBDIS field of <a href="#">I2C Bus Control Register (I2C_IBCR)</a> to enable the I <sup>2</sup> C interface system.
c	Examine fields in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> as follows: <ul style="list-style-type: none"> <li>• If IAAS = 1, examine IBSR[SRW].</li> <li>• If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.</li> </ul>
d	Write 0 to the IBIF field of <a href="#">I2C Bus Status Register (I2C_IBSR)</a> .
e	Perform a dummy read of <a href="#">I2C Bus Data I/O Register (I2C_IBDR)</a> to initiate the receive operation.
f	Wait until the TCF field of <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 1. (This proves that the transfer is complete.)
g	Wait until the IBIF field of <a href="#">I2C Bus Status Register (I2C_IBSR)</a> becomes 1.
h	Read the fields in <a href="#">I2C Bus Status Register (I2C_IBSR)</a> to determine what happened: <ul style="list-style-type: none"> <li>• If TCF = 1, the reception completed.</li> <li>• If IBB = 0, the bus transitioned from Busy to Idle state.</li> <li>• If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1).</li> </ul>

*Table continues on the next page...*

**Table 12-32. Slave receive sequence (continued)**

Step	Action
	<b>NOTE:</b> You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
i	Read <a href="#">I2C Bus Data I/O Register (I2C_IBDR)</a> to determine the data received from the master.

### 12.2.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```

if (tx_count == 0) or          // check to see if all data bytes have been transmitted
    (bit_0, IBSR == 1) {      // or if no ACK generated
    clear bit 5, IBCR          // generate stop condition
}
else {
    IBDR = data_to_transmit    // write byte of data to DATA register
    tx_count --                // decrement counter
}                               // return from interrupt

```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```

rx_count --                    // decrease the rx counter
if (rx_count == 1)             // 2nd last byte to be read ?
    bit 3, IBCR = 1            // disable ACK
    if (rx_count == 0)         // last byte to be read ?
        bit 5, IBCR = 0        // generate stop signal
    else
        data_received = IBDR    // read RX data and store

```

### 12.2.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```

bit 2, IBCR = 1                // generate another start (restart)
IBDR == calling_address         // transmit the calling address

```

### 12.2.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL=1 and MS/SL=0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

### 12.2.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an "end of data" signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

### 12.2.6.5 DMA application information

The DMA interface on the I<sup>2</sup>C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMAEN field in [I2C Bus Control Register \(I2C\\_IBCR\)](#) is not set when the I<sup>2</sup>C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I<sup>2</sup>C block.

The CPU should also keep the I<sup>2</sup>C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN field in [I2C Bus Control Register \(I2C\\_IBCR\)](#) works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, depending on the setting of the DMAEN field. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I<sup>2</sup>C should never be configured for slave operation.

The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place.

The sections present the following topics:

- [DMA mode, master transmit](#)
- [DMA mode, master reception](#)
- [Exiting DMA mode, system requirement considerations](#)

#### **12.2.6.5.1 DMA mode, master transmit**

The following flow diagram details exactly the operation for using a DMA controller to transmit "n" data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

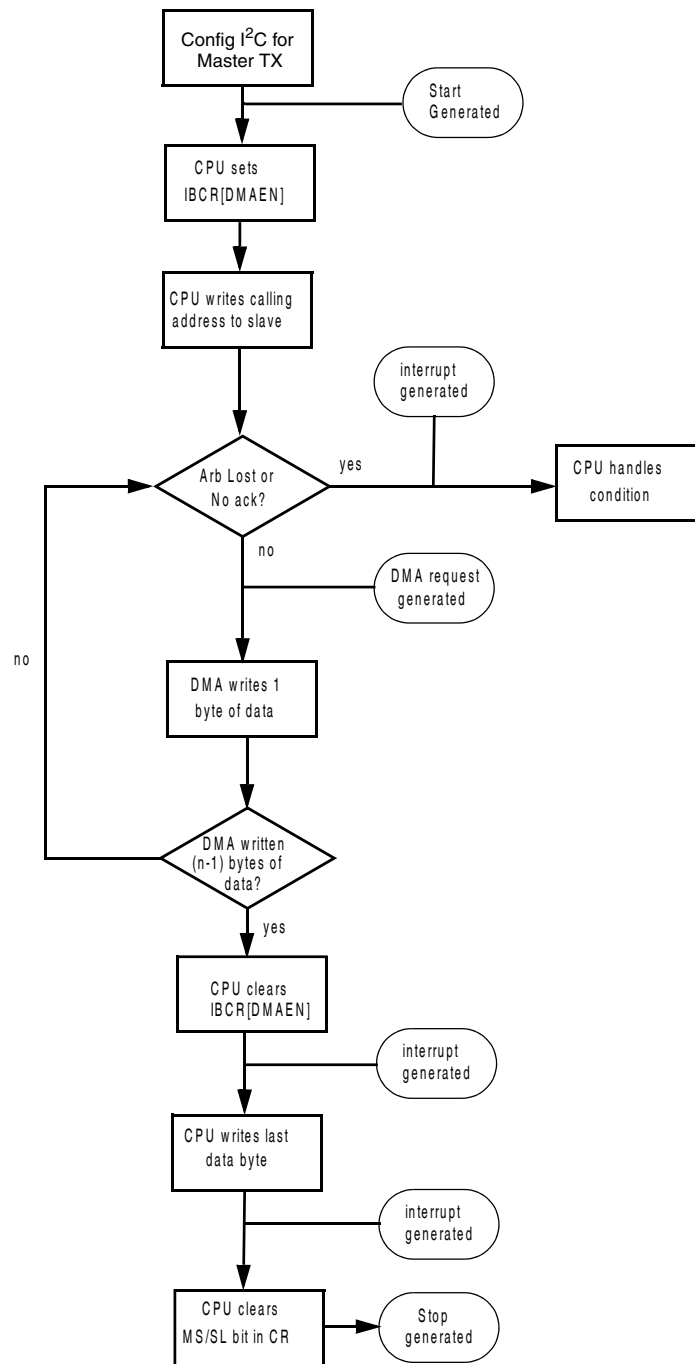

Figure 12-20. Flow-Chart of DMA mode master transmit

### 12.2.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive "n" data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

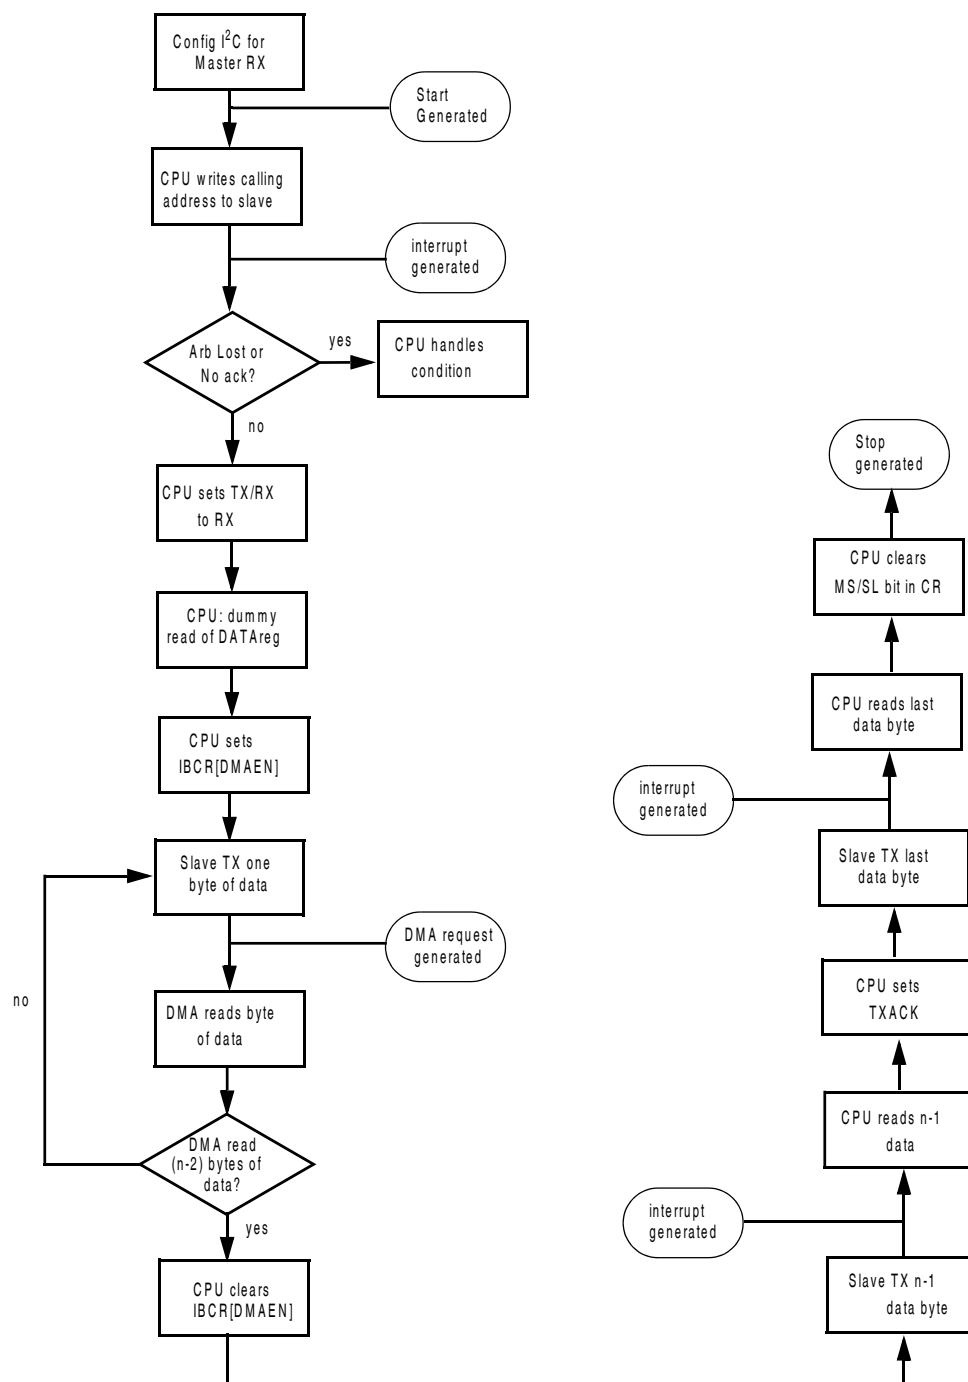

Figure 12-21. Flow-Chart of DMA mode master receive

### 12.2.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I<sup>2</sup>C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I<sup>2</sup>C module.

After the last DMA write (TX mode) to the I<sup>2</sup>C the module will immediately start the next I<sup>2</sup>C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I<sup>2</sup>C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

#### 1. Fast reaction

The DMAEN bit is cleared before the next I<sup>2</sup>C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

#### 2. Slow reaction

The DMAEN bit is cleared after the next I<sup>2</sup>C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time  $T_R$  for the system to disable DMAEN after the last DMA controller access to the I<sup>2</sup>C is the time required for one byte transfer over the I<sup>2</sup>C. For 'fast reaction' the disabling has to occur before the 9<sup>th</sup> bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

$$T_R = 8 \times T_{SCL}$$

In fast mode, with 400kbit/s,  $T_{SCL}$  is 2.5 $\mu$ s, so  $T_R$  is 20 $\mu$ s.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

#### 1. CPU intervention via Interrupt

The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act

accordingly. In case of slow reaction you can force an interrupt for the I<sup>2</sup>C in the interrupt controller to have the further transfer handled by the normal I<sup>2</sup>C interrupt routine.

### Note

The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

## 2. DMA channel linking

If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

### Note

Here you have to make sure on system level that no higher priority DMA requests occur between the two linked TCDs as those could again create a scenario of slow reaction.

## 3. DMA scatter/gather process

If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a "ready-for-I<sup>2</sup>C-transfer" state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

**Note**

Here you have to make sure at system level that no higher priority DMA requests occur during the scatter/gather process, as those could again create a scenario of slow reaction.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I<sup>2</sup>C connected via half speed IPI bus:

- Accessing the I<sup>2</sup>C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I<sup>2</sup>C could be faster):

$$4 \times T_{\text{IPI}} = 4/16 \text{ MHz} = 250 \text{ ns}$$

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

$$8 \times T_{\text{AHD}} = 8/32 \text{ MHz} = 250 \text{ ns}$$

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I<sup>2</sup>C connected via half speed IPI bus:

- Accessing the I<sup>2</sup>C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I<sup>2</sup>C could be faster):

$$4 \times T_{\text{IPI}} = 4/150 \text{ MHz} = 26.6 \text{ ns}$$

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

$$4 \times T_{\text{AHD}} = 4/150 \text{ MHz} = 26.6 \text{ ns}$$

With the DMA scatter/gather process the required IBCR access can be done in 0.5  $\mu$ s, leaving a large margin of 19.5  $\mu$ s for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

## 12.3 Universal Asynchronous Receiver/Transmitter (UART)

### 12.3.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The UART allows asynchronous serial communication with peripheral devices and CPUs.

#### 12.3.1.1 Features

The UART includes the following features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- 13-bit baud rate selection with /32 fractional divide, based on the module clock frequency
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable transmitter output polarity
- Programmable receive input polarity
- Up to 14-bit break character transmission.
- 11-bit break character detection option
- Two receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
- Address match feature in the receiver to reduce address mark wakeup ISR overhead

- Ability to select MSB or LSB to be first bit on wire
- Support for ISO 7816 protocol to interface with SIM cards and smart cards
  - Support for T=0 and T=1 protocols
  - Automatic retransmission of NACK'd packets with programmable retry threshold
  - Support for 11 and 12 ETU transfers
  - Detection of initial packet and automated transfer parameter programming
  - Interrupt-driven operation with seven ISO-7816 specific interrupts:
    - Wait time violated
    - Character wait time violated
    - Block wait time violated
    - Initial frame detected
    - Transmit error threshold exceeded
    - Receive error threshold exceeded
    - Guard time violated
- Interrupt-driven operation with flags, not specific to ISO-7816 support
  - Transmitter data buffer at or below watermark
  - Transmission complete
  - Receiver data buffer at or above watermark
  - Idle receiver input
  - Receiver data buffer overrun
  - Noise error
  - Framing error
  - Parity error
  - Active edge on receive pin
- Receiver framing error detection
- Hardware parity generation and checking

- 1/16 bit-time noise detection
- DMA interface

### 12.3.1.2 Modes of operation

The UART functions in the same way in all the normal modes.

It has the following low power mode:

- Stop mode

#### 12.3.1.2.1 Run mode

This is the normal mode of operation.

#### 12.3.1.2.2 Stop mode

The UART is inactive during Stop mode for reduced power consumption. The STOP instruction does not affect the UART register states, but the UART module clock is disabled. The UART operation resumes after an external interrupt brings the CPU out of Stop mode. Bringing the CPU out of Stop mode by reset aborts any ongoing transmission or reception and resets the UART. Entering or leaving Stop mode does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

## 12.3.2 UART signal descriptions

The UART signals are shown in the following table.

**Table 12-33. UART signal descriptions**

Signal	Description	I/O
RXD	Receive data	I
TXD	Transmit data	O

### 12.3.2.1 Detailed signal descriptions

The detailed signal descriptions of the UART are shown in the following table.

**Table 12-34. UART—Detailed signal descriptions**

Signal	I/O	Description	
RXD	I	Receive data. Serial data input to receiver.	
		<b>State meaning</b>	Whether RXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.
		<b>Timing</b>	Sampled at a frequency determined by the module clock divided by the baud rate.
TXD	O	Transmit data. Serial data output from transmitter.	
		<b>State meaning</b>	Whether TXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.
		<b>Timing</b>	Driven at the beginning or within a bit time according to the bit encoding method along with other configuration settings. Otherwise, transmissions are independent of reception timing.

### 12.3.3 Memory map and registers

This section provides a detailed description of all memory and registers.

Accessing reserved addresses within the memory map may result in unpredictable behavior, and the contents of implemented addresses may get modified as a result of that access.

Only byte accesses are supported.

#### UART memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4002_7000	UART Baud Rate Registers: High (UART0_BDH)	8	R/W	00h	<a href="#">12.3.3.1/2653</a>

**12.3.3.1 UART Baud Rate Registers: High (UARTx\_BDH)**

This register, along with the BDL register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting (SBR[12:0]), first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written.

BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 0h offset

Bit	7	6	5	4	3	2	1	0
Read	Reserved	RXEDGIE	0	SBR				
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_BDH field descriptions**

Field	Description
7 Reserved	Reserved. This field is reserved.
6 RXEDGIE	RxD Input Active Edge Interrupt Enable Enables the receive input active edge, RXEDGIF, to generate interrupt requests. 0 Hardware interrupts from RXEDGIF disabled using polling. 1 RXEDGIF interrupt request enabled.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**UARTx\_BDH field descriptions (continued)**

Field	Description
SBR	<p>UART Baud Rate Bits</p> <p>The baud rate for the UART is determined by the 13 SBR fields. See <a href="#">Baud rate generation</a> for details.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset. The baud rate generator is disabled when SBR = 0.</li> <li>Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.</li> </ul>

**12.3.3.2 UART Baud Rate Registers: Low (UARTx\_BDL)**

This register, along with the BDH register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting, SBR[12:0], first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written. BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read	SBR							
Write								
Reset	0	0	0	0	0	1	0	0

**UARTx\_BDL field descriptions**

Field	Description
SBR	<p>UART Baud Rate Bits</p> <p>The baud rate for the UART is determined by the 13 SBR fields. See <a href="#">Baud rate generation</a> for details.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset. The baud rate generator is disabled when SBR = 0.</li> <li>Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.</li> <li>When the 1/32 narrow pulse width is selected for infrared (IrDA), the baud rate fields must be even, the least significant bit is 0. See MODEM register for more details.</li> </ul>

**12.3.3.3 UART Control Register 1 (UARTx\_C1)**

This read/write register controls various optional features of the UART system.

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	LOOPS	Reserved	RSRC	M	WAKE	ILT	PE	PT
Write								
Reset	0	0	0	0	0	0	0	0

## UARTx\_C1 field descriptions

Field	Description
7 LOOPS	<p>Loop Mode Select</p> <p>When LOOPS is set, the RxD pin is disconnected from the UART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.</p> <p>0 Normal operation.</p> <p>1 Loop mode where transmitter output is internally connected to receiver input. The receiver input is determined by RSRC.</p>
6 Reserved	<p>Reserved.</p> <p>This field is reserved.</p>
5 RSRC	<p>Receiver Source Select</p> <p>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.</p> <p>0 Selects internal loop back mode. The receiver input is internally connected to transmitter output.</p> <p>1 Single wire UART mode where the receiver input is connected to the transmit pin input signal.</p>
4 M	<p>9-bit or 8-bit Mode Select</p> <p>This field must be set when C7816[ISO_7816E] is set/enabled.</p> <p>0 Normal—start + 8 data bits (MSB/LSB first as determined by MSBF) + stop.</p> <p>1 Use—start + 9 data bits (MSB/LSB first as determined by MSBF) + stop.</p>
3 WAKE	<p>Receiver Wakeup Method Select</p> <p>Determines which condition wakes the UART:</p> <ul style="list-style-type: none"> <li>Address mark in the most significant bit position of a received data character, or</li> <li>An idle condition on the receive pin input signal.</li> </ul> <p>0 Idle line wakeup.</p> <p>1 Address mark wakeup.</p>
2 ILT	<p>Idle Line Type Select</p> <p>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>In case the UART is programmed with ILT = 1, a logic of 1'b0 is automatically shifted after a received stop bit, therefore resetting the idle count.</li> <li>In case the UART is programmed for IDLE line wakeup (RWU = 1 and WAKE = 0), ILT has no effect on when the receiver starts counting logic 1s as idle character bits. In idle line wakeup, an idle character is recognized at anytime the receiver sees 10, 11, or 12 1s depending on the M, PE, and C4[M10] fields.</li> </ul> <p>0 Idle character bit count starts after start bit.</p> <p>1 Idle character bit count starts after stop bit.</p>
1 PE	<p>Parity Enable</p> <p>Enables the parity function. When parity is enabled, parity function inserts a parity bit in the bit position immediately preceding the stop bit. This field must be set when C7816[ISO_7816E] is set/enabled.</p>

Table continues on the next page...

## UARTx\_C1 field descriptions (continued)

Field	Description
	0 Parity function disabled. 1 Parity function enabled.
0 PT	Parity Type  Determines whether the UART generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. This field must be cleared when C7816[ISO_7816E] is set/enabled.  0 Even parity. 1 Odd parity.

## 12.3.3.4 UART Control Register 2 (UARTx\_C2)

This register can be read or written at any time.

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0
Read	TIE	0	RIE	ILIE	TE	RE	RWU	SBK
Write								
Reset	0	0	0	0	0	0	0	0

## UARTx\_C2 field descriptions

Field	Description
7 TIE	Transmitter Interrupt or DMA Transfer Enable.  Enables S1[TDRE] to generate interrupt requests or DMA transfer requests, based on the state of C5[TDMAS].  <b>NOTE:</b> If C2[TIE] and C5[TDMAS] are both set, then TCIE must be cleared, and D[D] must not be written unless servicing a DMA request.  0 TDRE interrupt and DMA transfer requests disabled. 1 TDRE interrupt or DMA transfer requests enabled.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 RIE	Receiver Full Interrupt or DMA Transfer Enable  Enables S1[RDRF] to generate interrupt requests or DMA transfer requests, based on the state of C5[RDMA5].  0 RDRF interrupt and DMA transfer requests disabled. 1 RDRF interrupt or DMA transfer requests enabled.
4 ILIE	Idle Line Interrupt Enable  Enables the idle line flag, S1[IDLE], to generate interrupt requests

Table continues on the next page...

## UARTx\_C2 field descriptions (continued)

Field	Description
	0 IDLE interrupt requests disabled. 1 IDLE interrupt requests enabled.
3 TE	<b>Transmitter Enable</b>  Enables the UART transmitter. TE can be used to queue an idle preamble by clearing and then setting TE. When C7816[ISO_7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block has been transmitted. This condition is detected when TL7816[TLEN] = 0 and four additional characters are transmitted.  0 Transmitter off. 1 Transmitter on.
2 RE	<b>Receiver Enable</b>  Enables the UART receiver.  0 Receiver off. 1 Receiver on.
1 RWU	<b>Receiver Wakeup Control</b>  This field can be set to place the UART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when C1[WAKE] is clear or an address match when C1[WAKE] is set. This field must be cleared when C7816[ISO_7816E] is set.  <b>NOTE:</b> RWU must be set only with C1[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by S2[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the UART will discard data. This is because the data must be received after an IDLE is detected before IDLE is allowed to reasserted.  0 Normal operation. 1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.
0 SBK	<b>Send Break</b>  Toggling SBK sends one break character from the following: See <a href="#">Transmitting break characters</a> for the number of logic 0s for the different configurations. Toggling implies clearing the SBK field before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10, 11, or 12 bits, or 13 or 14 bits). Ensure that C2[TE] is asserted at least 1 clock before assertion of this bit. <ul style="list-style-type: none"> <li>• 10, 11, or 12 logic 0s if S2[BRK13] is cleared</li> <li>• 13 or 14 logic 0s if S2[BRK13] is set.</li> </ul> This field must be cleared when C7816[ISO_7816E] is set.  0 Normal transmitter operation. 1 Queue break characters to be sent.

12.3.3.5 UART Status Register 1 (UARTx\_S1)

The S1 register provides inputs to the MCU for generation of UART interrupts or DMA requests. This register can also be polled by the MCU to check the status of its fields. To clear a flag, the status register should be read followed by a read or write to D register, depending on the interrupt flag type. Other instructions can be executed between the two steps as long the handling of I/O is not compromised, but the order of operations is important for flag clearing. When a flag is configured to trigger a DMA request, assertion of the associated DMA done signal from the DMA controller clears the flag.

NOTE

- If the condition that results in the assertion of the flag, interrupt, or DMA request is not resolved prior to clearing the flag, the flag, and interrupt/DMA request, reasserts. For example, if the DMA or interrupt service routine fails to write sufficient data to the transmit buffer to raise it above the watermark level, the flag reasserts and generates another interrupt or DMA request.
- Reading an empty data register to clear one of the flags of the S1 register causes the FIFO pointers to become misaligned. A receive FIFO flush reinitializes the pointers. A better way to prevent this situation is to always leave one byte in FIFO and this byte will be read eventually in clearing the flag bit.

Address: Base address + 4h offset

Bit	7	6	5	4	3	2	1	0
Read	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF
Write								
Reset	1	1	0	0	0	0	0	0

UARTx\_S1 field descriptions

Field	Description
7 TDRE	<p>Transmit Data Register Empty Flag</p> <p>TDRE will set when the number of datawords in the transmit buffer (D and C3[T8])is equal to or less than the number indicated by TWFIFO[TXWATER]. A character that is in the process of being transmitted is not included in the count. To clear TDRE, read S1 when TDRE is set and then write to the UART data register (D). For more efficient interrupt servicing, all data except the final value to be written to the buffer must be written to D/C3[T8]. Then S1 can be read before writing the final data value, resulting in the clearing of the TRDE flag. This is more efficient because the TDRE reasserts until the watermark has been exceeded. So, attempting to clear the TDRE with every write will be ineffective until sufficient data has been written.</p>

Table continues on the next page...

## UARTx\_S1 field descriptions (continued)

Field	Description
	<p>0 The amount of data in the transmit buffer is greater than the value indicated by TWFIPO[TXWATER].</p> <p>1 The amount of data in the transmit buffer is less than or equal to the value indicated by TWFIPO[TXWATER] at some point in time since the flag has been cleared.</p>
6 TC	<p>Transmit Complete Flag</p> <p>TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by reading S1 with TC set and then doing one of the following: When C7816[ISO_7816E] is set/enabled, this field is set after any NACK signal has been received, but prior to any corresponding guard times expiring.</p> <ul style="list-style-type: none"> <li>• Writing to D to transmit new data.</li> <li>• Queuing a preamble by clearing and then setting C2[TE].</li> <li>• Queuing a break character by writing 1 to SBK in C2.</li> </ul> <p>0 Transmitter active (sending data, a preamble, or a break).</p> <p>1 Transmitter idle (transmission activity complete).</p>
5 RDRF	<p>Receive Data Register Full Flag</p> <p>RDRF is set when the number of datawords in the receive buffer is equal to or more than the number indicated by RWFIFO[RXWATER]. A dataword that is in the process of being received is not included in the count. To clear RDRF, read S1 when RDRF is set and then read D. For more efficient interrupt and DMA operation, read all data except the final value from the buffer, using D/C3[T8]/ED. Then read S1 and the final data value, resulting in the clearing of the RDRF flag. Even if RDRF is set, data will continue to be received until an overrun condition occurs.</p> <p>0 The number of datawords in the receive buffer is less than the number indicated by RXWATER.</p> <p>1 The number of datawords in the receive buffer is equal to or greater than the number indicated by RXWATER at some point in time since this flag was last cleared.</p>
4 IDLE	<p>Idle Line Flag</p> <p>After the IDLE flag is cleared, a frame must be received (although not necessarily stored in the data buffer, for example if C2[RWU] is set). To clear IDLE, read UART status S1 with IDLE set and then read D.</p> <p>IDLE is set when either of the following appear on the receiver input:</p> <ul style="list-style-type: none"> <li>• 10 consecutive logic 1s if C1[M] = 0</li> <li>• 11 consecutive logic 1s if C1[M] = 1 and C4[M10] = 0</li> <li>• 12 consecutive logic 1s if C1[M] = 1, C4[M10] = 1, and C1[PE] = 1</li> </ul> <p>Idle detection is not supported when 7816E is set/enabled and hence this flag is ignored.</p> <p><b>NOTE:</b> When RWU is set and WAKE is cleared, an idle line condition sets the IDLE flag if RWUID is set, else the IDLE flag does not become set.</p> <p>0 Receiver input is either active now or has never become active since the IDLE flag was last cleared.</p> <p>1 Receiver input has become idle or the flag has not been cleared since it last asserted.</p>
3 OR	<p>Receiver Overrun Flag</p> <p>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the UART data registers is not affected. If the OR flag is set, no data is stored in the data buffer even if sufficient room exists. Additionally, while the OR flag is set, the RDRF and IDLE flags are blocked from asserting, that is, transition from an inactive to an active state. To clear OR, read S1 when OR is set and then read D. See functional description for more details regarding the operation of the OR bit. In 7816 mode, it is possible to configure a NACK to be returned by programming C7816[ONACK].</p>

Table continues on the next page...

**UARTx\_S1 field descriptions (continued)**

Field	Description
	<p>0 No overrun has occurred since the last time the flag was cleared.</p> <p>1 Overrun has occurred or the overrun flag has not been cleared since the last overrun occurred.</p>
2 NF	<p>Noise Flag</p> <p>NF is set when the UART detects noise on the receiver input. NF does not become set in the case of an overrun. When NF is set, it indicates only that a dataword has been received with noise since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has noise or that there is only one dataword in the buffer that was received with noise unless the receive buffer has a depth of one. To clear NF, read S1 and then read D.</p> <p>0 No noise detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1 then there may be data in the receiver buffer that was received with noise.</p> <p>1 At least one dataword was received with noise detected since the last time the flag was cleared.</p>
1 FE	<p>Framing Error Flag</p> <p>FE is set when a logic 0 is accepted as the stop bit. FE does not set in the case of an overrun. FE inhibits further data reception until it is cleared. To clear FE, read S1 with FE set and then read D. The last data in the receive buffer represents the data that was received with the frame error enabled. Framing errors are not supported when 7816E is set/enabled. However, if this flag is set, data is still not received in 7816 mode.</p> <p>0 No framing error detected.</p> <p>1 Framing error.</p>
0 PF	<p>Parity Error Flag</p> <p>PF is set when PE is set and the parity of the received data does not match its parity bit. The PF is not set in the case of an overrun condition. When PF is set, it indicates only that a dataword was received with parity error since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has a parity error or that there is only one dataword in the buffer that was received with a parity error, unless the receive buffer has a depth of one. To clear PF, read S1 and then read D. Within the receive buffer structure the received dataword is tagged if it is received with a parity error. This information is available by reading the ED register prior to reading the D register.</p> <p>0 No parity error detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1, then there may be data in the receive buffer what was received with a parity error.</p> <p>1 At least one dataword was received with a parity error since the last time this flag was cleared.</p>

### 12.3.3.6 UART Status Register 2 (UARTx\_S2)

The S2 register provides inputs to the MCU for generation of UART interrupts or DMA requests. Also, this register can be polled by the MCU to check the status of these bits. This register can be read or written at any time, with the exception of the MSBF and RXINV bits, which should be changed by the user only between transmit and receive packets.

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	0	RXEDGIF	MSBF	RXINV	RWUID	BRK13	Reserved	RAF
Write		w1c						
Reset	0	0	0	0	0	0	0	0

**UARTx\_S2 field descriptions**

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 RXEDGIF	RxD Pin Active Edge Interrupt Flag  RXEDGIF is set when an active edge occurs on the RxD pin. The active edge is falling if RXINV = 0, and rising if RXINV=1. RXEDGIF is cleared by writing a 1 to it. See for additional details. <a href="#">RXEDGIF description</a>  <b>NOTE:</b> The active edge is detected only in two wire mode and on receiving data coming from the RxD pin.  0 No active edge on the receive pin has occurred. 1 An active edge on the receive pin has occurred.
5 MSBF	Most Significant Bit First  Setting this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.  0 LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1 MSB (bit8, bit7 or bit6) is the first bit that is transmitted following the start bit, depending on the setting of C1[M] and C1[PE]. Further, the first bit received after the start bit is identified as bit8, bit7, or bit6, depending on the setting of C1[M] and C1[PE].
4 RXINV	Receive Data Inversion  Setting this field reverses the polarity of the received data input. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity. A zero is represented by a short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.

*Table continues on the next page...*

**UARTx\_S2 field descriptions (continued)**

Field	Description
	<p><b>NOTE:</b> Setting RXINV inverts the RxD input for data bits, start and stop bits, break, and idle. When C7816[ISO7816E] is set/enabled, only the data bits and the parity bit are inverted.</p> <p>0 Receive data is not inverted. 1 Receive data is inverted.</p>
3 RWUID	<p>Receive Wakeup Idle Detect</p> <p>When RWU is set and WAKE is cleared, this field controls whether the idle character that wakes the receiver sets S1[IDLE]. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>0 S1[IDLE] is not set upon detection of an idle character. 1 S1[IDLE] is set upon detection of an idle character.</p>
2 BRK13	<p>Break Transmit Character Length</p> <p>Determines whether the transmit break character is 10, 11, or 12 bits long, or 13 or 14 bits long. See for the length of the break character for the different configurations. The detection of a framing error is not affected by this field. <a href="#">Transmitting break characters</a></p> <p>0 Break character is 10, 11, or 12 bits long. 1 Break character is 13 or 14 bits long.</p>
1 Reserved	<p>Reserved.</p> <p>This field is reserved.</p>
0 RAF	<p>Receiver Active Flag</p> <p>RAF is set when the UART receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character when C7816[ISO7816E] is cleared/disabled. When C7816[ISO7816E] is enabled, the RAF is cleared if the C7816[TTYPE] = 0 expires or the C7816[TTYPE] = 1 expires.</p> <p><b>NOTE:</b> In case C7816[ISO7816E] is set and C7816[TTYPE] = 0, it is possible to configure the guard time to 12. However, if a NACK is required to be transmitted, the data transfer actually takes 13 ETU with the 13th ETU slot being a inactive buffer. Therefore, in this situation, the RAF may deassert one ETU prior to actually being inactive.</p> <p>0 UART receiver idle/inactive waiting for a start bit. 1 UART receiver active, RxD input not idle.</p>

**12.3.3.7 UART Control Register 3 (UARTx\_C3)**

Writing R8 does not have any effect. TXDIR and TXINV can be changed only between transmit and receive packets.

Address: Base address + 6h offset

Bit	7	6	5	4	3	2	1	0
Read	R8	T8	TXDIR	TXINV	ORIE	NEIE	FEIE	PEIE
Write								
Reset	0	0	0	0	0	0	0	0

## UARTx\_C3 field descriptions

Field	Description
7 R8	<p>Received Bit 8</p> <p>R8 is the ninth data bit received when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1. The R8 value corresponds to the current data value in the UARTx_D register. To read the 9th bit, read the value of UARTx_C3[R8], then read the UARTx_D register.</p>
6 T8	<p>Transmit Bit 8</p> <p>T8 is the ninth data bit transmitted when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1.</p> <p><b>NOTE:</b> If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.</p> <p>To correctly transmit the 9th bit, write UARTx_C3[T8] to the desired value, then write the UARTx_D register with the remaining data.</p>
5 TXDIR	<p>Transmitter Pin Data Direction in Single-Wire mode</p> <p>Determines whether the TXD pin is used as an input or output in the single-wire mode of operation. This field is relevant only to the single wire mode. When C7816[ISO7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block is transmitted. This condition is detected when TL7816[TLEN] = 0 and 4 additional characters are transmitted. Additionally, if C7816[ISO7816E] is set/enabled and C7816[TTYTYPE] = 0 and a NACK is being transmitted, the hardware automatically overrides this field as needed. In this situation, TXDIR does not reflect the temporary state associated with the NACK.</p> <p>0 TXD pin is an input in single wire mode. 1 TXD pin is an output in single wire mode.</p>
4 TXINV	<p>Transmit Data Inversion.</p> <p>Setting this field reverses the polarity of the transmitted data output. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity, and a zero is represented by short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p><b>NOTE:</b> Setting TXINV inverts all transmitted values, including idle, break, start, and stop bits. In loop mode, if TXINV is set, the receiver gets the transmit inversion bit when RXINV is disabled. When C7816[ISO7816E] is set/enabled then only the transmitted data bits and parity bit are inverted.</p> <p>0 Transmit data is not inverted. 1 Transmit data is inverted.</p>
3 ORIE	<p>Overrun Error Interrupt Enable</p> <p>Enables the overrun error flag, S1[OR], to generate interrupt requests.</p> <p>0 OR interrupts are disabled. 1 OR interrupt requests are enabled.</p>
2 NEIE	<p>Noise Error Interrupt Enable</p> <p>Enables the noise flag, S1[NF], to generate interrupt requests.</p> <p>0 NF interrupt requests are disabled. 1 NF interrupt requests are enabled.</p>

Table continues on the next page...

**UARTx\_C3 field descriptions (continued)**

Field	Description
1 FEIE	<p>Framing Error Interrupt Enable</p> <p>Enables the framing error flag, S1[FE], to generate interrupt requests.</p> <p>0 FE interrupt requests are disabled. 1 FE interrupt requests are enabled.</p>
0 PEIE	<p>Parity Error Interrupt Enable</p> <p>Enables the parity error flag, S1[PF], to generate interrupt requests.</p> <p>0 PF interrupt requests are disabled. 1 PF interrupt requests are enabled.</p>

**12.3.3.8 UART Data Register (UARTx\_D)**

This register is actually two separate registers. Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

**NOTE**

- In 8-bit or 9-bit data format, only UART data register (D) needs to be accessed to clear the S1[RDRF] bit (assuming receiver buffer level is less than RWFIFO[RXWATER]). The C3 register needs to be read, prior to the D register, only if the ninth bit of data needs to be captured. Similarly, the ED register needs to be read, prior to the D register, only if the additional flag data for the dataword needs to be captured.
- In the normal 8-bit mode (M bit cleared) if the parity is enabled, you get seven data bits and one parity bit. That one parity bit is loaded into the D register. So, for the data bits, mask off the parity bit from the value you read out of this register.
- When transmitting in 9-bit data format and using 8-bit write instructions, write first to transmit bit 8 in UART control register 3 (C3[T8]), then D. A write to C3[T8] stores the data in a temporary register. If D register is written first, and then the new data on data bus is stored in D, the temporary value written by the last write to C3[T8] gets stored in the C3[T8] register.

Address: Base address + 7h offset

Bit	7	6	5	4	3	2	1	0
Read	RT							
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_D field descriptions**

Field	Description
RT	Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

**12.3.3.9 UART Match Address Registers 1 (UARTx\_MA1)**

The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. These registers can be read and written at anytime.

Address: Base address + 8h offset

Bit	7	6	5	4	3	2	1	0
Read	MA							
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_MA1 field descriptions**

Field	Description
MA	Match Address

**12.3.3.10 UART Match Address Registers 2 (UARTx\_MA2)**

These registers can be read and written at anytime. The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded.

Address: Base address + 9h offset

Bit	7	6	5	4	3	2	1	0
Read	MA							
Write

### 12.3.3.11 UART Control Register 4 (UARTx\_C4)

Address: Base address + Ah offset

Bit	7	6	5	4	3	2	1	0
Read	MAEN1	MAEN2	M10			BRFA		
Write								
Reset	0	0	0	0	0	0	0	0

#### UARTx\_C4 field descriptions

Field	Description
7 MAEN1	<p>Match Address Mode Enable 1</p> <p>See <a href="#">Match address operation</a> for more information.</p> <p>0 All data received is transferred to the data buffer if MAEN2 is cleared.</p> <p>1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA1 register. If no match occurs, the data is discarded. If match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.</p>
6 MAEN2	<p>Match Address Mode Enable 2</p> <p>See <a href="#">Match address operation</a> for more information.</p> <p>0 All data received is transferred to the data buffer if MAEN1 is cleared.</p> <p>1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA2 register. If no match occurs, the data is discarded. If a match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.</p>
5 M10	<p>10-bit Mode select</p> <p>Causes a tenth, non-memory mapped bit to be part of the serial transmission. This tenth bit is generated and interpreted as a parity bit. If M10 is set, then both C1[M] and C1[PE] must also be set. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>See <a href="#">Data format (non ISO-7816)</a> for more information.</p> <p>0 The parity bit is the ninth bit in the serial transmission.</p> <p>1 The parity bit is the tenth bit in the serial transmission.</p>
BRFA	<p>Baud Rate Fine Adjust</p> <p>This bit field is used to add more timing resolution to the average baud frequency, in increments of 1/32. See <a href="#">Baud rate generation</a> for more information.</p>

### 12.3.3.12 UART Extended Data Register (UARTx\_ED)

This register contains additional information flags that are stored with a received dataword. This register may be read at any time but contains valid data only if there is a dataword in the receive FIFO.

**NOTE**

- The data contained in this register represents additional information regarding the conditions on which a dataword was received. The importance of this data varies with the application, and in some cases maybe completely optional. These fields automatically update to reflect the conditions of the next dataword whenever D is read.
- If S1[NF] and S1[PF] have not been set since the last time the receive buffer was empty, the NOISY and PARITYE fields will be zero.

Address: Base address + Ch offset

Bit	7	6	5	4	3	2	1	0
Read	NOISY	PARITYE	0					
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_ED field descriptions**

Field	Description
7 NOISY	The current received dataword contained in D and C3[R8] was received with noise. 0 The dataword was received without noise. 1 The data was received with noise.
6 PARITYE	The current received dataword contained in D and C3[R8] was received with a parity error. 0 The dataword was received without a parity error. 1 The dataword was received with a parity error.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**12.3.3.13 UART Infrared Register (UARTx\_IR)**

The IR register controls options for setting the infrared configuration.

Address: Base address + Eh offset

Bit	7	6	5	4	3	2	1	0
Read	0					IREN	TNP	
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_IR field descriptions**

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 IREN	Infrared enable  Enables/disables the infrared modulation/demodulation.  0 IR disabled. 1 IR enabled.
TNP	Transmitter narrow pulse  Enables whether the UART transmits a 1/16, 3/16, 1/32, or 1/4 narrow pulse.  00 3/16. 01 1/16. 10 1/32. 11 1/4.

**12.3.3.14 UART FIFO Parameters (UARTx\_PFIFO)**

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when C2[RE] and C2[TE] are cleared/not set and when the data buffer/FIFO is empty.

Address: Base address + 10h offset

Bit	7	6	5	4	3	2	1	0
Read	TXFE	TXFIFOSIZE			RXFE	RXFIFOSIZE		
Write								
Reset	0	*	*	*	0	*	*	*

\* Notes:

- TXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.
- RXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.

**UARTx\_PFIFO field descriptions**

Field	Description
7 TXFE	Transmit FIFO Enable  When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared

*Table continues on the next page...*

Field	Description
	<p>prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field.</p> <p>0 Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support).</p> <p>1 Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.</p>
6–4 TXFIFOSIZE	<p>Transmit FIFO. Buffer Depth</p> <p>The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only.</p> <p>000 Transmit FIFO/Buffer depth = 1 dataword.</p> <p>001 Transmit FIFO/Buffer depth = 4 datawords.</p> <p>010 Transmit FIFO/Buffer depth = 8 datawords.</p> <p>011 Transmit FIFO/Buffer depth = 16 datawords.</p> <p>100 Transmit FIFO/Buffer depth = 32 datawords.</p> <p>101 Transmit FIFO/Buffer depth = 64 datawords.</p> <p>110 Transmit FIFO/Buffer depth = 128 datawords.</p> <p>111 Reserved.</p>
3 RXFE	<p>Receive FIFO Enable</p> <p>When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field.</p> <p>0 Receive FIFO is not enabled. Buffer is depth 1. (Legacy support)</p> <p>1 Receive FIFO is enabled. Buffer is depth indicated by RXFIFOSIZE.</p>
RXFIFOSIZE	<p>Receive FIFO. Buffer Depth</p> <p>The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only.</p> <p>000 Receive FIFO/Buffer depth = 1 dataword.</p> <p>001 Receive FIFO/Buffer depth = 4 datawords.</p> <p>010 Receive FIFO/Buffer depth = 8 datawords.</p> <p>011 Receive FIFO/Buffer depth = 16 datawords.</p> <p>100 Receive FIFO/Buffer depth = 32 datawords.</p> <p>101 Receive FIFO/Buffer depth = 64 datawords.</p> <p>110 Receive FIFO/Buffer depth = 128 datawords.</p> <p>111 Reserved.</p>

### 12.3.3.15 UART FIFO Control Register (UARTx\_CFIFO)

This register provides the ability to program various control fields for FIFO operation. This register may be read or written at any time. Note that writing to TXFLUSH and RXFLUSH may result in data loss and requires careful action to prevent unintended/unpredictable behavior. Therefore, it is recommended that TE and RE be cleared prior to flushing the corresponding FIFO.

Address: Base address + 11h offset

Bit	7	6	5	4	3	2	1	0
Read	0	0	0			RXOFE	TXOFE	RXUFE
Write	TXFLUSH	RXFLUSH						
Reset	0	0	0	0	0	0	0	0

**UARTx\_CFIFO field descriptions**

Field	Description
7 TXFLUSH	Transmit FIFO/Buffer Flush  Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register.  0 No flush operation occurs. 1 All data in the transmit FIFO/Buffer is cleared out.
6 RXFLUSH	Receive FIFO/Buffer Flush  Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register.  0 No flush operation occurs. 1 All data in the receive FIFO/buffer is cleared out.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 RXOFE	Receive FIFO Overflow Interrupt Enable  When this field is set, the RXOF flag generates an interrupt to the host.  0 RXOF flag does not generate an interrupt to the host. 1 RXOF flag generates an interrupt to the host.
1 TXOFE	Transmit FIFO Overflow Interrupt Enable  When this field is set, the TXOF flag generates an interrupt to the host.  0 TXOF flag does not generate an interrupt to the host. 1 TXOF flag generates an interrupt to the host.
0 RXUFE	Receive FIFO Underflow Interrupt Enable  When this field is set, the RXUF flag generates an interrupt to the host.

*Table continues on the next page...*

**UARTx\_CFIFO field descriptions (continued)**

Field	Description
0	RXUF flag does not generate an interrupt to the host.
1	RXUF flag generates an interrupt to the host.

**12.3.3.16 UART FIFO Status Register (UARTx\_SFIFO)**

This register provides status information regarding the transmit and receiver buffers/FIFOs, including interrupt information. This register may be written to or read at any time.

Address: Base address + 12h offset

Bit	7	6	5	4	3	2	1	0
Read	TXEMPT	RXEMPT	0			RXOF	TXOF	RXUF
Write						w1c	w1c	w1c
Reset	1	1	0	0	0	0	0	0

**UARTx\_SFIFO field descriptions**

Field	Description
7 TXEMPT	Transmit Buffer/FIFO Empty  Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.  0 Transmit buffer is not empty. 1 Transmit buffer is empty.
6 RXEMPT	Receive Buffer/FIFO Empty  Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register.  0 Receive buffer is not empty. 1 Receive buffer is empty.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 RXOF	Receiver Buffer Overflow Flag  Indicates that more data has been written to the receive buffer than it can hold. This field will assert regardless of the value of CFIFO[RXOF]. However, an interrupt will be issued to the host only if CFIFO[RXOF] is set. This flag is cleared by writing a 1.  0 No receive buffer overflow has occurred since the last time the flag was cleared. 1 At least one receive buffer overflow has occurred since the last time the flag was cleared.
1 TXOF	Transmitter Buffer Overflow Flag

*Table continues on the next page...*

**UARTx\_SFIFO field descriptions (continued)**

Field	Description
	Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of CFIFO[TXOFE]. However, an interrupt will be issued to the host only if CFIFO[TXOFE] is set. This flag is cleared by writing a 1.  0 No transmit buffer overflow has occurred since the last time the flag was cleared. 1 At least one transmit buffer overflow has occurred since the last time the flag was cleared.
0 RXUF	Receiver Buffer Underflow Flag  Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of CFIFO[RXUFE]. However, an interrupt will be issued to the host only if CFIFO[RXUFE] is set. This flag is cleared by writing a 1.  0 No receive buffer underflow has occurred since the last time the flag was cleared. 1 At least one receive buffer underflow has occurred since the last time the flag was cleared.

**12.3.3.17 UART FIFO Transmit Watermark (UARTx\_TWFIFO)**

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when C2[TE] is not set. Changing the value of the watermark will not clear the S1[TDRE] flag.

Address: Base address + 13h offset

Bit	7	6	5	4	3	2	1	0
Read	TXWATER							
Write								
Reset								
	0	0	0	0	0	0	0	0

**UARTx\_TWFIFO field descriptions**

Field	Description
TXWATER	Transmit Watermark  When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt via S1[TDRE] or a DMA request via C5[TDMAS] is generated as determined by C5[TDMAS] and C2[TIE]. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by PFIFO[TXFIFOSIZE] and PFIFO[TXFE].

### 12.3.3.18 UART FIFO Transmit Count (UARTx\_TCFIFO)

This is a read only register that indicates how many datawords are currently in the transmit buffer/FIFO. It may be read at any time.

Address: Base address + 14h offset

Bit	7	6	5	4	3	2	1	0
Read	TXCOUNT							
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_TCFIFO field descriptions**

Field	Description
TXCOUNT	Transmit Counter  The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with PFIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.

### 12.3.3.19 UART FIFO Receive Watermark (UARTx\_RWFIFO)

This register provides the ability to set a programmable threshold for notification of the need to remove data from the receiver FIFO/buffer. This register may be read at any time but must be written only when C2[RE] is not asserted. Changing the value in this register will not clear S1[RDRF].

Address: Base address + 15h offset

Bit	7	6	5	4	3	2	1	0
Read	RXWATER							
Write								
Reset	0	0	0	0	0	0	0	1

**UARTx\_RWFIFO field descriptions**

Field	Description
RXWATER	Receive Watermark  When the number of datawords in the receive FIFO/buffer is equal to or greater than the value in this register field, an interrupt via S1[RDRF] or a DMA request via C5[RDMA5] is generated as determined by C5[RDMA5] and C2[R1E]. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by PFIFO[RXFIFOSIZE] and PFIFO[RXFE] and must be greater than 0.

12.3.3.20    **UART FIFO Receive Count (UARTx\_RCFIFO)**

This is a read only register that indicates how many datawords are currently in the receive FIFO/buffer. It may be read at any time.

Address: Base address + 16h offset

UARTx\_RCFIFO field descriptions

Field	Description
RXCOUNT	Receive Counter  The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with PFIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.

12.3.3.21    **UART 7816 Control Register (UARTx\_C7816)**

The C7816 register is the primary control register for ISO-7816 specific functionality. This register is specific to 7816 functionality and the values in this register have no effect on UART operation and should be ignored if ISO\_7816E is not set/enabled. This register may be read at any time but values must be changed only when ISO\_7816E is not set.

Address: Base address + 18h offset

UARTx\_C7816 field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 ONACK	Generate NACK on Overflow  When this field is set, the receiver automatically generates a NACK response if a receive buffer overrun occurs, as indicated by S1[OR]. In many systems, this results in the transmitter resending the packet that overflowed until the retransmit threshold for that transmitter is reached. A NACK is generated only if TTYPE=0. This field operates independently of ANACK. See . <a href="#">Overrun NACK considerations</a>

Table continues on the next page...

## UARTx\_C7816 field descriptions (continued)

Field	Description
	<p>0 The received data does not generate a NACK when the receipt of the data results in an overflow event.</p> <p>1 If the receiver buffer overflows, a NACK is automatically sent on a received character.</p>
3 ANACK	<p>Generate NACK on Error</p> <p>When this field is set, the receiver automatically generates a NACK response if a parity error occurs or if INIT is set and an invalid initial character is detected. A NACK is generated only if TTYPE = 0. If ANACK is set, the UART attempts to retransmit the data indefinitely. To stop retransmission attempts, clear C2[TE] or ISO_7816E and do not set until S1[TC] sets C2[TE] again.</p> <p>0 No NACK is automatically generated.</p> <p>1 A NACK is automatically generated if a parity error is detected or if an invalid initial character is detected.</p>
2 INIT	<p>Detect Initial Character</p> <p>When this field is set, all received characters are searched for a valid initial character. If an invalid initial character is identified, and ANACK is set, a NACK is sent. All received data is discarded and error flags blocked (S1[NF], S1[OR], S1[FE], S1[PF], IS7816[WT], IS7816[CWT], IS7816[BWT], IS7816[GTV]) until a valid initial character is detected. Upon detecting a valid initial character, the configuration values S2[MSBF], C3[TXINV], and S2[RXINV] are automatically updated to reflect the initial character that was received. The actual INIT data value is not stored in the receive buffer. Additionally, upon detection of a valid initial character, IS7816[INITD] is set and an interrupt issued as programmed by IE7816[INITDE]. When a valid initial character is detected, INIT is automatically cleared. This Initial Character Detect feature is supported only in T = 0 protocol mode.</p> <p>0 Normal operating mode. Receiver does not seek to identify initial character.</p> <p>1 Receiver searches for initial character.</p>
1 TTYPE	<p>Transfer Type</p> <p>Indicates the transfer protocol being used.</p> <p>See <a href="#">ISO-7816 / smartcard support</a> for more details.</p> <p>0 T = 0 per the ISO-7816 specification.</p> <p>1 T = 1 per the ISO-7816 specification.</p>
0 ISO_7816E	<p>ISO-7816 Functionality Enabled</p> <p>Indicates that the UART is operating according to the ISO-7816 protocol.</p> <p><b>NOTE:</b> This field must be modified only when no transmit or receive is occurring. If this field is changed during a data transfer, the data being transmitted or received may be transferred incorrectly.</p> <p>0 ISO-7816 functionality is turned off/not enabled.</p> <p>1 ISO-7816 functionality is turned on/enabled.</p>

### 12.3.3.22 UART 7816 Interrupt Enable Register (UARTx\_IE7816)

The IE7816 register controls which flags result in an interrupt being issued. This register is specific to 7816 functionality, the corresponding flags that drive the interrupts are not asserted when 7816E is not set/enabled. However, these flags may remain set if they are asserted while 7816E was set and not subsequently cleared. This register may be read or written to at any time.

Address: Base address + 19h offset

Bit	7	6	5	4	3	2	1	0
Read	WTE	CWTE	BWTE	INITDE	0	GTVE	TXTE	RXTE
Write								
Reset	0	0	0	0	0	0	0	0

#### UARTx\_IE7816 field descriptions

Field	Description
7 WTE	Wait Timer Interrupt Enable 0 The assertion of IS7816[WT] does not result in the generation of an interrupt. 1 The assertion of IS7816[WT] results in the generation of an interrupt.
6 CWTE	Character Wait Timer Interrupt Enable 0 The assertion of IS7816[CWT] does not result in the generation of an interrupt. 1 The assertion of IS7816[CWT] results in the generation of an interrupt.
5 BWTE	Block Wait Timer Interrupt Enable 0 The assertion of IS7816[BWT] does not result in the generation of an interrupt. 1 The assertion of IS7816[BWT] results in the generation of an interrupt.
4 INITDE	Initial Character Detected Interrupt Enable 0 The assertion of IS7816[INITD] does not result in the generation of an interrupt. 1 The assertion of IS7816[INITD] results in the generation of an interrupt.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 GTVE	Guard Timer Violated Interrupt Enable 0 The assertion of IS7816[GTV] does not result in the generation of an interrupt. 1 The assertion of IS7816[GTV] results in the generation of an interrupt.
1 TXTE	Transmit Threshold Exceeded Interrupt Enable 0 The assertion of IS7816[TXT] does not result in the generation of an interrupt. 1 The assertion of IS7816[TXT] results in the generation of an interrupt.
0 RXTE	Receive Threshold Exceeded Interrupt Enable 0 The assertion of IS7816[RXT] does not result in the generation of an interrupt. 1 The assertion of IS7816[RXT] results in the generation of an interrupt.

### 12.3.3.23 UART 7816 Interrupt Status Register (UARTx\_IS7816)

The IS7816 register provides a mechanism to read and clear the interrupt flags. All flags/interrupts are cleared by writing a 1 to the field location. Writing a 0 has no effect. All bits are "sticky", meaning they indicate that only the flag condition that occurred since the last time the bit was cleared, not that the condition currently exists. The status flags are set regardless of whether the corresponding field in the IE7816 is set or cleared. The IE7816 controls only if an interrupt is issued to the host processor. This register is specific to 7816 functionality and the values in this register have no affect on UART operation and should be ignored if 7816E is not set/enabled. This register may be read or written at anytime.

Address: Base address + 1Ah offset

Bit	7	6	5	4	3	2	1	0
Read	WT	CWT	BWT	INITD	0	GTV	TXT	RXT
Write	w1c	w1c	w1c	w1c		w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

**UARTx\_IS7816 field descriptions**

Field	Description
7 WT	<p>Wait Timer Interrupt</p> <p>Indicates that the wait time, the time between the leading edge of a character being transmitted and the leading edge of the next response character, has exceeded the programmed value. This flag asserts only when C7816[TTYPE] = 0. This interrupt is cleared by writing 1.</p> <p>0 Wait time (WT) has not been violated. 1 Wait time (WT) has been violated.</p>
6 CWT	<p>Character Wait Timer Interrupt</p> <p>Indicates that the character wait time, the time between the leading edges of two consecutive characters in a block, has exceeded the programmed value. This flag asserts only when C7816[TTYPE] = 1. This interrupt is cleared by writing 1.</p> <p>0 Character wait time (CWT) has not been violated. 1 Character wait time (CWT) has been violated.</p>
5 BWT	<p>Block Wait Timer Interrupt</p> <p>Indicates that the block wait time, the time between the leading edge of first received character of a block and the leading edge of the last character the previously transmitted block, has exceeded the programmed value. This flag asserts only when C7816[TTYPE] = 1. This interrupt is cleared by writing 1.</p> <p>0 Block wait time (BWT) has not been violated. 1 Block wait time (BWT) has been violated.</p>
4 INITD	<p>Initial Character Detected Interrupt</p> <p>Indicates that a valid initial character is received. This interrupt is cleared by writing 1.</p>

*Table continues on the next page...*

**UARTx\_IS7816 field descriptions (continued)**

Field	Description
	0 A valid initial character has not been received. 1 A valid initial character has been received.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 GTV	Guard Timer Violated Interrupt  Indicates that one or more of the character guard time, block guard time, or guard time are violated. This interrupt is cleared by writing 1.  0 A guard time (GT, CGT, or BGT) has not been violated. 1 A guard time (GT, CGT, or BGT) has been violated.
1 TXT	Transmit Threshold Exceeded Interrupt  Indicates that the transmit NACK threshold has been exceeded as indicated by ET7816[TXTHRESHOLD]. Regardless of whether this flag is set, the UART continues to retransmit indefinitely. This flag asserts only when C7816[TTYPE] = 0. If 7816E is cleared/disabled, ANACK is cleared/disabled, C2[TE] is cleared/disabled, C7816[TTYPE] = 1, or packet is transferred without receiving a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next received NACK. This interrupt is cleared by writing 1.  0 The number of retries and corresponding NACKS does not exceed the value in ET7816[TXTHRESHOLD]. 1 The number of retries and corresponding NACKS exceeds the value in ET7816[TXTHRESHOLD].
0 RXT	Receive Threshold Exceeded Interrupt  Indicates that there are more than ET7816[RXTHRESHOLD] consecutive NACKS generated in response to parity errors on received data. This flag requires ANACK to be set. Additionally, this flag asserts only when C7816[TTYPE] = 0. Clearing this field also resets the counter keeping track of consecutive NACKS. The UART will continue to attempt to receive data regardless of whether this flag is set. If 7816E is cleared/disabled, RE is cleared/disabled, C7816[TTYPE] = 1, or packet is received without needing to issue a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next transmitted NACK. This interrupt is cleared by writing 1.  0 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is less than or equal to the value in ET7816[RXTHRESHOLD]. 1 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is greater than the value in ET7816[RXTHRESHOLD].

**12.3.3.24 UART 7816 Wait Parameter Register (UARTx\_WP7816T1)**

The WP7816 register contains constants used in the generation of various wait timer counters. To save register space, this register is used differently when C7816[TTYPE] = 0 and C7816[TTYPE] = 1. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Bh offset

Bit	7	6	5	4	3	2	1	0
Read	CWI				BWI			
Write								
Reset	0	0	0	0	1	0	1	0

**UARTx\_WP7816T1 field descriptions**

Field	Description
7–4 CWI	Character Wait Time Integer (C7816[TTYPE] = 1)  Used to calculate the value used for the CWT counter. It represents a value between 0 and 15. This value is used only when C7816[TTYPE] = 1. See <a href="#">Wait time and guard time parameters</a> .
BWI	Block Wait Time Integer (C7816[TTYPE] = 1)  Used to calculate the value used for the BWT counter. It represent a value between 0 and 15. This value is used only when C7816[TTYPE] = 1. See <a href="#">Wait time and guard time parameters</a> .

**12.3.3.25 UART 7816 Wait N Register (UARTx\_WN7816)**

The WN7816 register contains a parameter that is used in the calculation of the guard time counter. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Ch offset

Bit	7	6	5	4	3	2	1	0
Read	GTN							
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_WN7816 field descriptions**

Field	Description
GTN	Guard Band N  Defines a parameter used in the calculation of GT, CGT, and BGT counters. The value represents an integer number between 0 and 255. See <a href="#">Wait time and guard time parameters</a> .

**12.3.3.26 UART 7816 Wait FD Register (UARTx\_WF7816)**

The WF7816 contains parameters that are used in the generation of various counters including GT, CGT, BGT, WT, and BWT. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Dh offset

Bit	7	6	5	4	3	2	1	0
Read	GTFD							
Write								
Reset	0	0	0	0	0	0	0	1

**UARTx\_WF7816 field descriptions**

Field	Description
GTFD	FD Multiplier

**UARTx\_WF7816 field descriptions (continued)**

Field	Description
	Used as another multiplier in the calculation of WT and BWT. This value represents a number between 1 and 255. The value of 0 is invalid. This value is not used in baud rate generation. See <a href="#">Wait time and guard time parameters</a> and <a href="#">Baud rate generation</a> .

**12.3.3.27 UART 7816 Error Threshold Register (UARTx\_ET7816)**

The ET7816 register contains fields that determine the number of NACKs that must be received or transmitted before the host processor is notified. This register may be read at anytime. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Eh offset

Bit	7	6	5	4	3	2	1	0
Read	TXTHRESHOLD				RXTHRESHOLD			
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_ET7816 field descriptions**

Field	Description
7–4 TXTHRESHOLD	<p>Transmit NACK Threshold</p> <p>The value written to this field indicates the maximum number of failed attempts (NACKs) a transmitted character can have before the host processor is notified. This field is meaningful only when C7816[TTYPE] = 0 and C7816[ANACK] = 1. The value read from this field represents the number of consecutive NACKs that have been received since the last successful transmission. This counter saturates at 4'hF and does not wrap around. Regardless of how many NACKs that are received, the UART continues to retransmit indefinitely. This flag only asserts when C7816[TTYPE] = 0. For additional information see the IS7816[TXT] field description.</p> <p>0   TXT asserts on the first NACK that is received. 1   TXT asserts on the second NACK that is received.</p>
RXTHRESHOLD	<p>Receive NACK Threshold</p> <p>The value written to this field indicates the maximum number of consecutive NACKs generated as a result of a parity error or receiver buffer overruns before the host processor is notified. After the counter exceeds that value in the field, the IS7816[RXT] is asserted. This field is meaningful only when C7816[TTYPE] = 0. The value read from this field represents the number of consecutive NACKs that have been transmitted since the last successful reception. This counter saturates at 4'hF and does not wrap around. Regardless of the number of NACKs sent, the UART continues to receive valid packets indefinitely. For additional information, see IS7816[RXT] field description.</p>

### 12.3.3.28 UART 7816 Transmit Length Register (UARTx\_TL7816)

The TL7816 register is used to indicate the number of characters contained in the block being transmitted. This register is used only when C7816[TTYPE] = 1. This register may be read at anytime. This register must be written only when C2[TE] is not enabled.

Address: Base address + 1Fh offset

Bit	7	6	5	4	3	2	1	0
Read	TLEN							
Write								
Reset	0	0	0	0	0	0	0	0

**UARTx\_TL7816 field descriptions**

Field	Description
TLEN	<p>Transmit Length</p> <p>This value plus four indicates the number of characters contained in the block being transmitted. This register is automatically decremented by 1 for each character in the information field portion of the block. Additionally, this register is automatically decremented by 1 for the first character of a CRC in the epilogue field. Therefore, this register must be programmed with the number of bytes in the data packet if an LRC is being transmitted, and the number of bytes + 1 if a CRC is being transmitted. This register is not decremented for characters that are assumed to be part of the Prologue field, that is, the first three characters transmitted in a block, or the LRC or last CRC character in the Epilogue field, that is, the last character transmitted. This field must be programed or adjusted only when C2[TE] is cleared.</p>

## 12.3.4 Functional description

This section provides a complete functional description of the UART block.

The UART allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The UART transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the UART, writes the data to be transmitted, and processes received data.

### 12.3.4.1 Transmitter

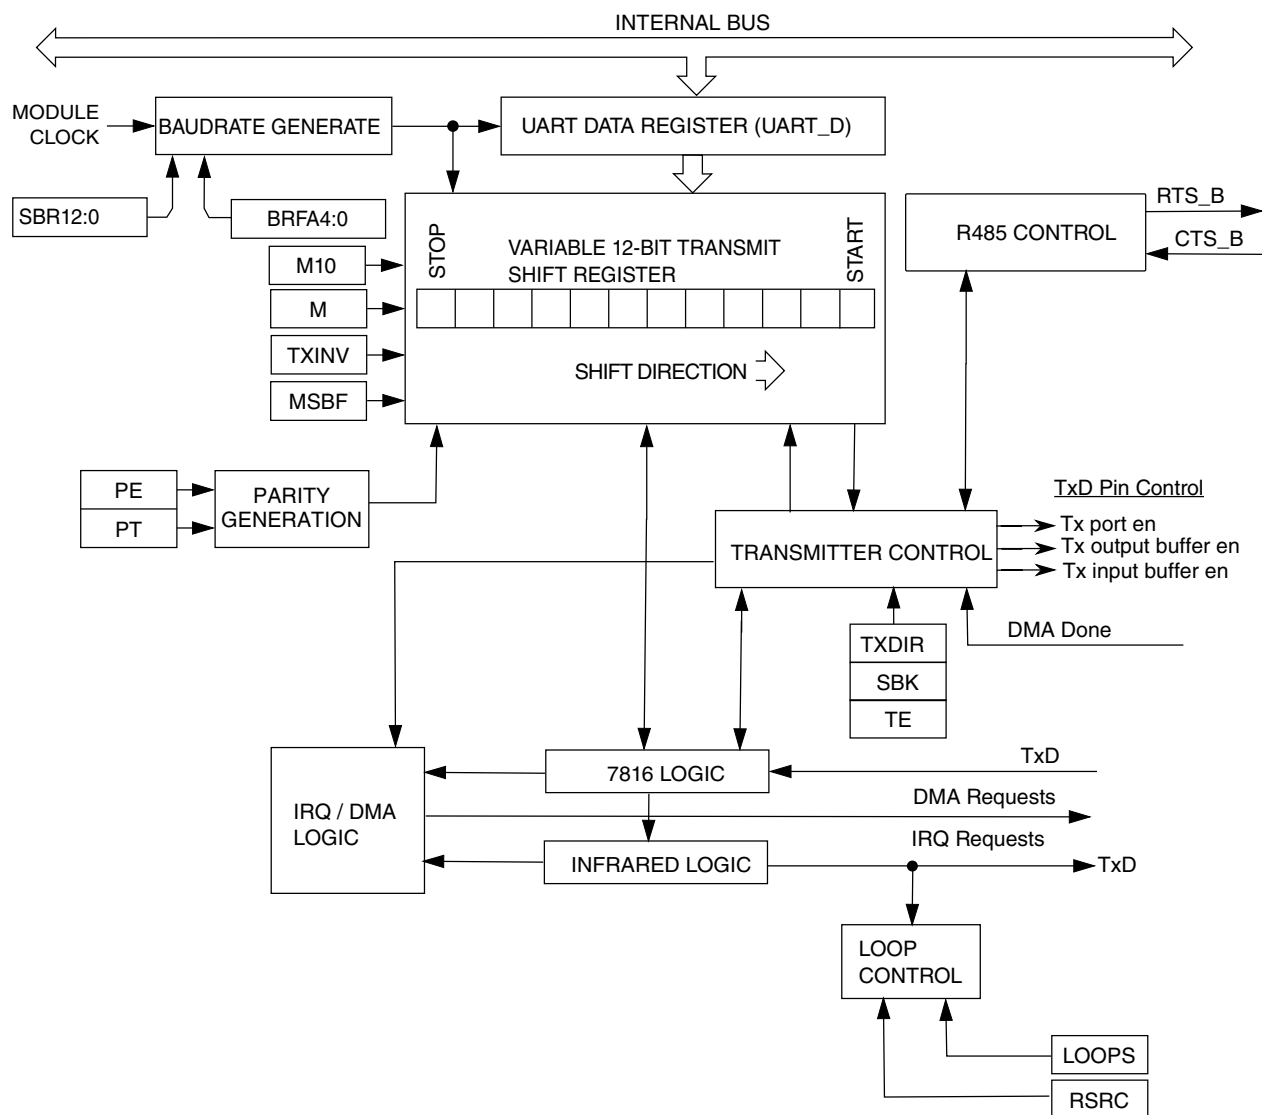

Figure 12-22. Transmitter Block Diagram

#### 12.3.4.1.1 Transmitter character length

The UART transmitter can accommodate either 8, 9, or 10-bit data characters. The state of the C1[M] and C1[PE] bits and the C4[M10] bit determine the length of data characters. When transmitting 9-bit data, bit C3[T8] is the ninth bit (bit 8).

#### 12.3.4.1.2 Transmission bit order

When S2[MSBF] is set, the UART automatically transmits the MSB of the data word as the first bit after the start bit. Similarly, the LSB of the data word is transmitted immediately preceding the parity bit, or the stop bit if parity is not enabled. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data written to D for transmission is completely independent of the S2[MSBF] setting.

### 12.3.4.1.3 Character transmission

To transmit data, the MCU writes the data bits to the UART transmit buffer using UART data registers C3[T8] and D. Data in the transmit buffer is then transferred to the transmitter shift register as needed. The transmit shift register then shifts a frame out through the transmit data output signal after it has prefaced it with any required start and stop bits. The UART data registers, C3[T8] and D, provide access to the transmit buffer structure.

The UART also sets a flag, the transmit data register empty flag S1[TDRE], and generates an interrupt or DMA request (C5[TDMAS]) whenever the number of datawords in the transmit buffer is equal to or less than the value indicated by TWFIFO[TXWATER]. The transmit driver routine may respond to this flag by writing additional datawords to the transmit buffer using C3[T8]/D as space permits.

See [Application information](#) for specific programming sequences.

Setting C2[TE] automatically loads the transmit shift register with the following preamble:

- 10 logic 1s if C1[M] = 0
- 11 logic 1s if C1[M] = 1 and C4[M10] = 0
- 12 logic 1s if C1[M] = 1, C4[M10] = 1, C1[PE] = 1

After the preamble shifts out, control logic transfers the data from the D register into the transmit shift register. The transmitter automatically transmits the correct start bit and stop bit before and after the dataword.

When C7816[ISO\_7816E] = 1, setting C2[TE] does not result in a preamble being generated. The transmitter starts transmitting as soon as the corresponding guard time expires. When C7816[TTYTYPE] = 0, the value in GT is used. When C7816[TTYTYPE] = 1, the value in BGT is used, because C2[TE] will remain asserted until the end of the block transfer. C2[TE] is automatically cleared when C7816[TTYTYPE] = 1 and the block being transmitted has completed. When C7816[TTYTYPE] = 0, the transmitter listens for a NACK indication. If no NACK is received, it is assumed that the character was correctly received. If a NACK is received, the transmitter resends the data, assuming that the number of retries for that character, that is, the number of NACKs received, is less than or equal to the value in ET7816[TXTHRESHOLD].

Hardware supports odd or even parity. When parity is enabled, the bit immediately preceding the stop bit is the parity bit.

When the transmit shift register is not transmitting a frame, the transmit data output signal goes to the idle condition, logic 1. If at any time software clears C2[TE], the transmitter enable signal goes low and the transmit signal goes idle.

If the software clears C2[TE] while a transmission is in progress, the character in the transmit shift register continues to shift out, provided S1[TC] was cleared during the data write sequence. To clear S1[TC], the S1 register must be read followed by a write to D register.

If S1[TC] is cleared during character transmission and C2[TE] is cleared, the transmission enable signal is deasserted at the completion of the current frame. Following this, the transmit data out signal enters the idle state even if there is data pending in the UART transmit data buffer. To ensure that all the data written in the FIFO is transmitted on the link before clearing C2[TE], wait for S1[TC] to set. Alternatively, the same can be achieved by setting TWFIPO[TXWATER] to 0x0 and waiting for S1[TDRE] to set.

#### 12.3.4.1.4 Transmitting break characters

Setting C2[SBK] loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on C1[M], C1[PE], S2[BRK13] and C4[M10]. See the following table.

**Table 12-35. Transmit break character length**

S2[BRK13]	C1[M]	C4[M10]	C1[PE]	Bits transmitted
0	0	—	—	10
0	1	1	0	11
0	1	1	1	12
1	0	—	—	13
1	1	—	—	14

As long as C2[SBK] is set, the transmitter logic continuously loads break characters into the transmit shift register. After the software clears C2[SBK], the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character. Break bits are not supported when C7816[ISO\_7816E] is set/enabled.

#### NOTE

When queuing a break character, it will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that, if data is queued in the data buffer to be transmitted, the break character preempts that queued data. The queued data is then transmitted after the break character is complete.

### 12.3.4.1.5 Idle characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on C1[M], C1[PE] and C4[M10]. The preamble is a synchronizing idle character that begins the first transmission initiated after setting C2[TE]. When C7816[ISO\_7816E] is set/enabled, idle characters are not sent or detected. When data is not being transmitted, the data I/O line is in an inactive state.

If C2[TE] is cleared during a transmission, the transmit data output signal becomes idle after completion of the transmission in progress. Clearing and then setting C2[TE] during a transmission queues an idle character to be sent after the dataword currently being transmitted.

#### Note

When queuing an idle character, the idle character will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that if data is queued in the data buffer to be transmitted, the idle character preempts that queued data. The queued data is then transmitted after the idle character is complete.

If C2[TE] is cleared and the transmission is completed, the UART is not the master of the TXD pin.

### 12.3.4.2 Receiver

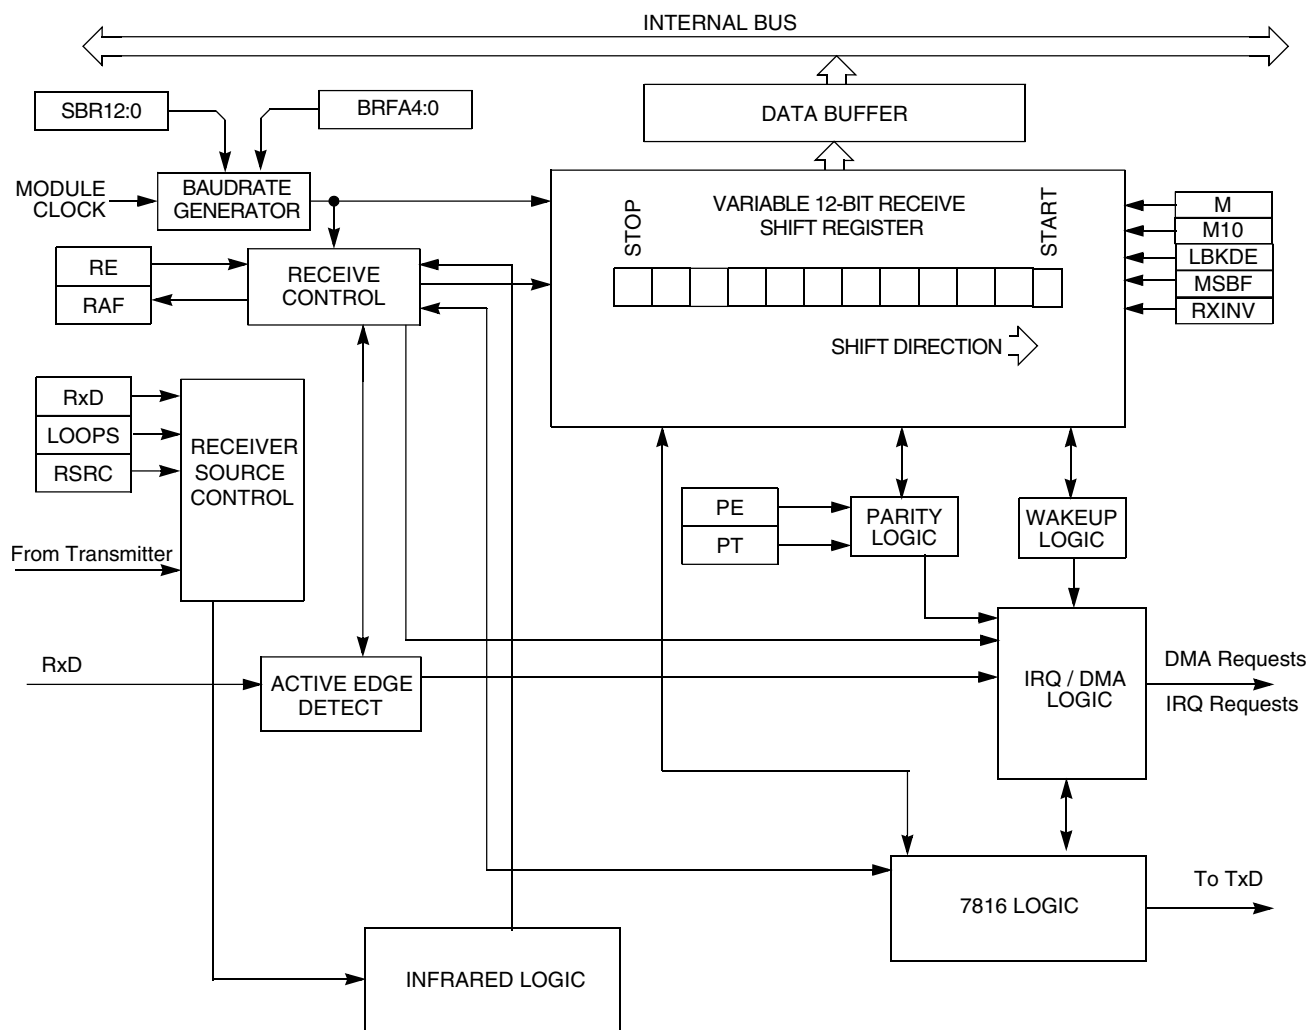

Figure 12-23. UART receiver block diagram

#### 12.3.4.2.1 Receiver character length

The UART receiver can accommodate 8-, 9-, or 10-bit data characters. The states of C1[M], C1[PE] and C4[M10] determine the length of data characters. When receiving 9 or 10-bit data, C3[R8] is the ninth bit (bit 8).

#### 12.3.4.2.2 Receiver bit ordering

When S2[MSBF] is set, the receiver operates such that the first bit received after the start bit is the MSB of the dataword. Similarly, the bit received immediately preceding the parity bit, or the stop bit if parity is not enabled, is treated as the LSB for the dataword. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data read from receive data buffer is completely independent of S2[MSBF].

### 12.3.4.2.3 Character reception

During UART reception, the receive shift register shifts a frame in from the unsynchronized receiver input signal. After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the UART receive buffer. Additionally, the noise and parity error flags that are calculated during the receive process are also captured in the UART receive buffer. The receive data buffer is accessible via the D and C3[T8] registers. Additional received information flags regarding the receive dataword can be read in ED register. S1[RDRF] is set if the number of resulting datawords in the receive buffer is equal to or greater than the number indicated by RWFIFO[RXWATER]. If the C2[RIE] is also set, RDRF generates an RDRF interrupt request. Alternatively, by programming C5[RDMAS], a DMA request can be generated.

When C7816[ISO\_7816E] is set/enabled and C7816[TTYTYPE] = 0, character reception operates slightly differently. Upon receipt of the parity bit, the validity of the parity bit is checked. If C7816[ANACK] is set and the parity check fails, or if INIT and the received character is not a valid initial character, then a NACK is sent by the receiver. If the number of consecutive receive errors exceeds the threshold set by ET7816[RXTHRESHOLD], then IS7816[RXT] is set and an interrupt generated if IE7816[RXTE] is set. If an error is detected due to parity or an invalid initial character, the data is not transferred from the receive shift register to the receive buffer. Instead, the data is overwritten by the next incoming data.

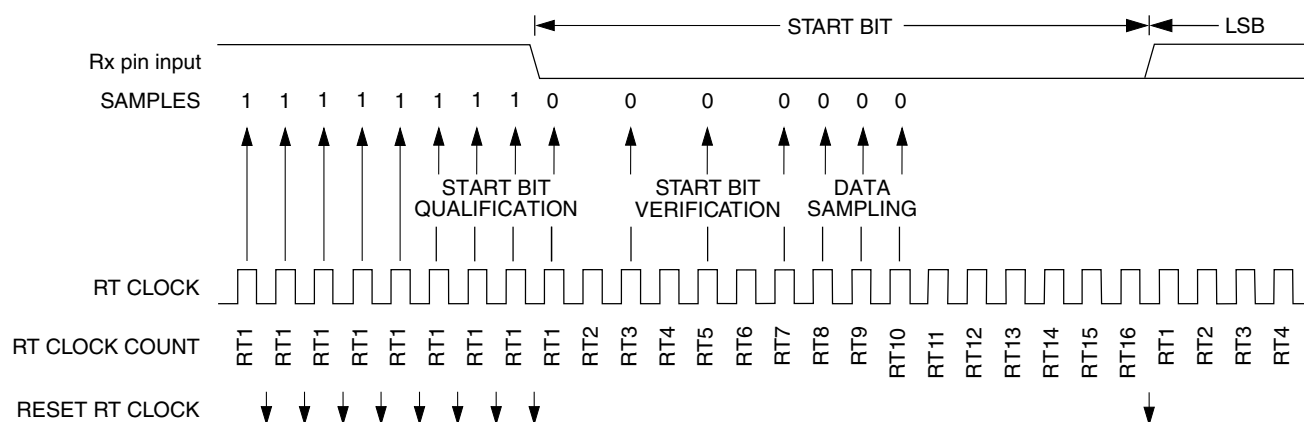

When the C7816[ISO\_7816E] is set/enabled, C7816[ONACK] is set/enabled, and the received character results in the receive buffer overflowing, a NACK is issued by the receiver. Additionally, S1[OR] is set and an interrupt is issued if required, and the data in the shift register is discarded.

### 12.3.4.2.4 Data sampling

The receiver samples the unsynchronized receiver input signal at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock (see the following figure) is re-synchronized:

- After every start bit.
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0).

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

**Figure 12-24. Receiver data sampling**

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7 when C7816[ISO\_7816E] is cleared/disabled and RT8, RT9 and RT10 when C7816[ISO\_7816E] is set/enabled. The following table summarizes the results of the start bit verification samples.

**Table 12-36. Start bit verification**

RT3, RT5, and RT7 samples RT8, RT9, RT10 samples when 7816E	Start bit verification	Noise flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. The following table summarizes the results of the data bit samples.

**Table 12-37. Data bit recovery**

RT8, RT9, and RT10 samples	Data bit determination	Noise flag
000	0	0
001	0	1
010	0	1
011	1	1

*Table continues on the next page...*

**Table 12-37. Data bit recovery (continued)**

RT8, RT9, and RT10 samples	Data bit determination	Noise flag
100	0	1
101	1	1
110	1	1
111	1	0

**Note**

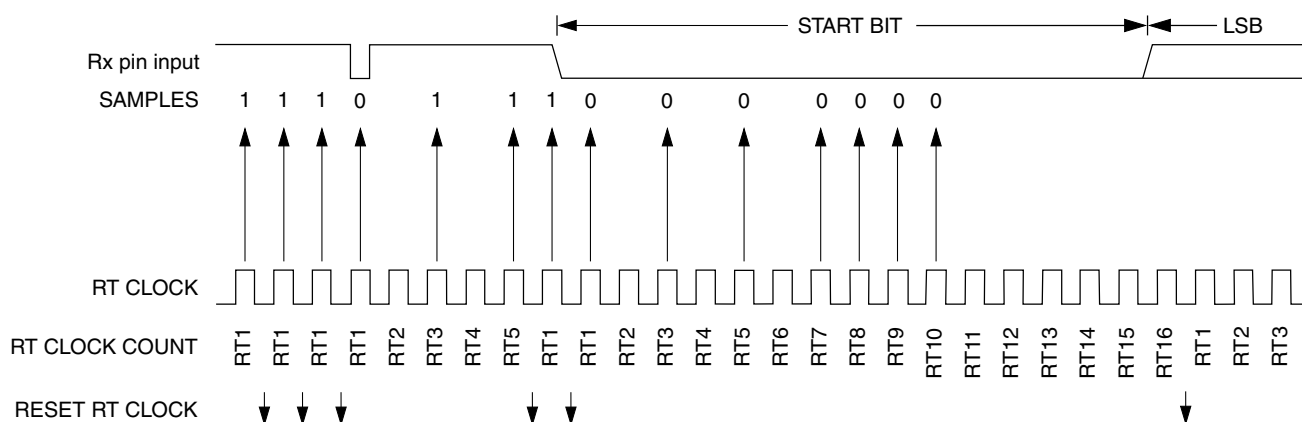

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (S1[NF]) is set and the receiver assumes that the bit is a start bit (logic 0). With the exception of when C7816[ISO\_7816E] is set/enabled, where the values of RT8, RT9 and RT10 exclusively determine if a start bit exists.

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. The following table summarizes the results of the stop bit samples. In the event that C7816[ISO\_7816E] is set/enabled and C7816[TTYTYPE] = 0, verification of a stop bit does not take place. Rather, starting with RT8 the receiver transmits a NACK as programmed until time RT9 of the following time period. Framing Error detection is not supported when C7816[ISO\_7816E] is set/enabled.

**Table 12-38. Stop bit recovery**

RT8, RT9, and RT10 samples	Framing error flag	Noise flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

In the following figure, the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. In this example C7816[ISO\_7816E] = 0. The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.

**Figure 12-25. Start bit search example 1 (C7816[ISO\_7816E] = 0)**

In the following figure, verification sample at RT3 is high. In this example C7816[ISO\_7816E] = 0. The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

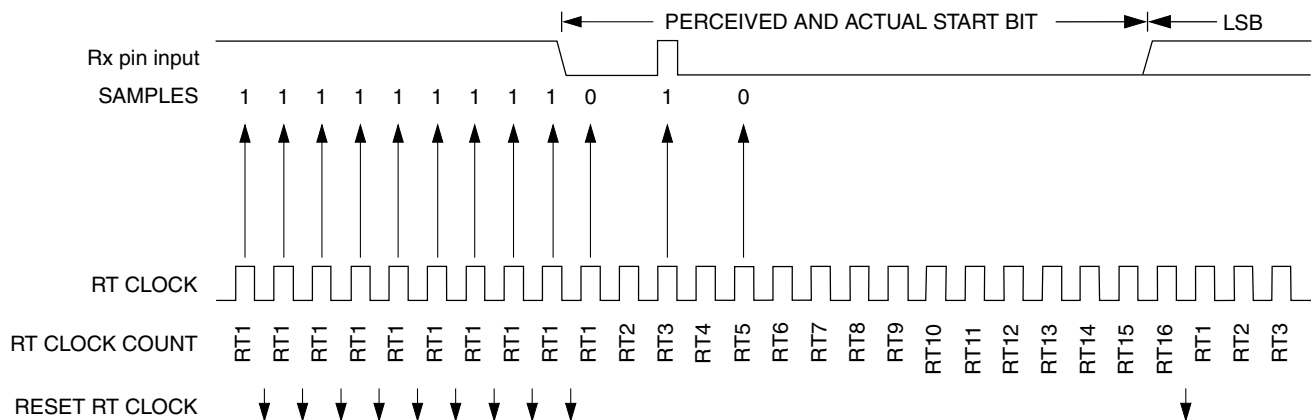

**Figure 12-26. Start bit search example 2 (C7816[ISO\_7816E] = 0)**

In the following figure, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. In this example C7816[ISO\_7816E] = 0. The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

**Figure 12-27. Start bit search example 3 (C7816[ISO\_7816E] = 0)**

The following figure shows the effect of noise early in the start bit time. In this example C7816[ISO\_7816E] = 0. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

**Figure 12-28. Start bit search example 4 (C7816[ISO\_7816E] = 0)**

The following figure shows a burst of noise near the beginning of the start bit that resets the RT clock. In this example C7816[ISO\_7816E] = 0. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.

**Figure 12-29. Start bit search example 5 ( $C7816[ISO\_7816E] = 0$ )**

In the following figure, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. In this example  $C7816[ISO\_7816E] = 0$ . This sets the noise flag but does not reset the RT clock. In start bits only, the RT8, RT9, and RT10 data samples are ignored. In this example, if  $C7816[ISO\_7816E] = 1$  then a start bit would not have been detected at all since at least two of the three samples (RT8, RT9, RT10) were high.

**Figure 12-30. Start bit search example 6**

### 12.3.4.2.5 Framing errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag,  $S1[FE]$ . A break character also sets the  $S1[FE]$  because a break character has no stop bit.  $S1[FE]$  is set at the same time that received data is placed in the receive data buffer. Framing errors are not supported when  $C7816[ISO7816E]$  is set/enabled. However, if  $S1[FE]$  is set, data will not be received when  $C7816[ISO7816E]$  is set.

### 12.3.4.2.6 Receiving break characters

The UART recognizes a break character when a start bit is followed by eight, nine, or ten logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has these effects on UART registers:

- Sets the framing error flag, S1[FE].
- Writes an all 0 dataword to the data buffer, which may cause S1[RDRF] to set, depending on the watermark and number of values in the data buffer.
- May set the overrun flag, S1[OR], noise flag, S1[NF], parity error flag, S1[PE], or the receiver active flag, S2[RAF].

The UART break character detection threshold depends on C1[M], C1[PE] and C4[M10]. See the following table.

**Table 12-39. Receive break character detection threshold**

M	M10	PE	Threshold (bits)
0	—	—	10
1	0	—	11
1	1	1	12

Break characters are not detected or supported when C7816[ISO\_7816E] is set/enabled.

### 12.3.4.2.7 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a 16-RT clock counter that filters noise and indicates when a 1 is received.

#### 12.3.4.2.7.1 Start bit detection

When S2[RXINV] is cleared, the first rising edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

#### 12.3.4.2.7.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one RT clocks can be undetected by it regardless of whether it is seen in the first or second half of the count.

#### 12.3.4.2.7.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

#### 12.3.4.2.7.4 High-bit detection

At 16-RT clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to [Low-bit detection](#). The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

#### 12.3.4.2.8 Baud rate tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic 0.

As the receiver samples an incoming frame, it resynchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

##### 12.3.4.2.8.1 Slow data tolerance

The following figure shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

**Figure 12-31. Slow data**

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 12-31](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 147 RT cycles (9 bit times  $\times$  16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((154 - 147) \div 154) \times 100 = 4.54\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 12-31](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 163 RT cycles (10 bit times  $\times$  16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((170 - 163) \div 170) \times 100 = 4.12\%$$

#### 12.3.4.2.8.2 Fast data tolerance

The following figure shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

**Figure 12-32. Fast data**

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 12-32](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 160 RT cycles (10 bit times  $\times$  16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((154 - 160) \div 154) \times 100 = 3.90\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 12-32](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 176 RT cycles (11 bit times  $\times$  16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((170 - 176) \div 170) \times 100 = 3.53\%$$

#### 12.3.4.2.9 Receiver wakeup

C1[WAKE] determines how the UART is brought out of the standby state to process an incoming message. C1[WAKE] enables either idle line wakeup or address mark wakeup.

Receiver wakeup is not supported when C7816[ISO\_7816E] is set/enabled because multi-receiver systems are not allowed.

##### 12.3.4.2.9.1 Idle input line wakeup (C1[WAKE] = 0)

In this wakeup method, an idle condition on the unsynchronized receiver input signal clears C2[RWU] and wakes the UART. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another idle character appears on the unsynchronized receiver input signal.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

When C2[RWU] is 1 and S2[RWUID] is 0, the idle character that wakes the receiver does not set S1[IDLE] or the receive data register full flag, S1[RDRF]. The receiver wakes and waits for the first data character of the next message which is stored in the receive data buffer. When S2[RWUID] and C2[RWU] are set and C1[WAKE] is cleared, any idle condition sets S1[IDLE] and generates an interrupt if enabled.

Idle input line wakeup is not supported when C7816[ISO\_7816E] is set/enabled.

#### 12.3.4.2.9.2 Address mark wakeup (C1[WAKE] = 1)

In this wakeup method, a logic 1 in the bit position immediately preceding the stop bit of a frame clears C2[RWU] and wakes the UART. A logic 1 in the bit position immediately preceding the stop bit marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another address frame appears on the unsynchronized receiver input signal.

A logic 1 in the bit position immediately preceding the stop bit clears the receiver's C2[RWU] after the stop bit is received and places the received data into the receiver data buffer. Note that if Match Address operation is enabled i.e. C4[MAEN1] or C4[MAEN2] is set, then received frame is transferred to receive buffer only if the comparison matches.

Address mark wakeup allows messages to contain idle characters but requires that the bit position immediately preceding the stop bit be reserved for use in address frames.

If module is in standby mode and nothing triggers to wake the UART, no error flag is set even if an invalid error condition is detected on the receiving data line.

Address mark wakeup is not supported when C7816[ISO\_7816E] is set/enabled.

#### 12.3.4.2.9.3 Match address operation

Match address operation is enabled when C4[MAEN1] or C4[MAEN2] is set. In this function, a frame received by the RX pin with a logic 1 in the bit position of the address mark is considered an address and is compared with the associated MA1 or MA2 register. The frame is transferred to the receive buffer, and S1[RDRF] is set, only if the comparison matches. All subsequent frames received with a logic 0 in the bit position of the address mark are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs, then no transfer is made to

the receive data buffer, and all following frames with logic 0 in the bit position of the address mark are also discarded. If both C4[MAEN1] and C4[MAEN2] are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Match address operation functions in the same way for both MA1 and MA2 registers. Note that the position of the address mark is the same as the Parity Bit when parity is enabled for 8 bit and 9 bit data formats.

- If only one of C4[MAEN1] and C4[MAEN2] is asserted, a marked address is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If C4[MAEN1] and C4[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either register.

Address match operation is not supported when C7816[ISO\_7816E] is set/enabled.

### 12.3.4.3 Baud rate generation

A 13-bit modulus counter and a 5-bit fractional fine-adjust counter in the baud rate generator derive the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to SBR[12:0] determines the module clock divisor. The SBR bits are in the UART baud rate registers, BDH and BDL. The baud rate clock is synchronized with the module clock and drives the receiver. The fractional fine-adjust counter adds fractional delays to the baud rate clock to allow fine trimming of the baud rate to match the system baud rate. The transmitter is driven by the baud rate clock divided by 16. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to two sources of error:

- Integer division of the module clock may not give the exact target frequency. This error can be reduced with the fine-adjust counter.
- Synchronization with the module clock can cause phase shift.

The [Table 12-40](#) lists the available baud divisor fine adjust values.

UART baud rate = UART module clock / (16 × (SBR[12:0] + BRFD))

The following table lists some examples of achieving target baud rates with a module clock frequency of 10.2 MHz, with and without fractional fine adjustment.

**Table 12-40. Baud rates (example: module clock = 10.2 MHz)**

Bits SBR (decimal)	Bits BRFA	BRFD value	Receiver clock (Hz)	Transmitter clock (Hz)	Target Baud rate	Error (%)
17	00000	0	600,000.0	37,500.0	38,400	2.3
16	10011	$19/32=0.59375$	614,689.3	38,418.08	38,400	0.047

#### 12.3.4.4 Data format (non ISO-7816)

Each data character is contained in a frame that includes a start bit and a stop bit. The rest of the data format depends upon C1[M], C1[PE], S2[MSBF] and C4[M10].

##### 12.3.4.4.1 Eight-bit configuration

Clearing C1[M] configures the UART for 8-bit data characters, that is, eight bits are memory mapped in D. A frame with eight data bits has a total of 10 bits. The most significant bit of the eight data bits can be used as an address mark to wake the receiver. If the most significant bit is used in this way, then it serves as an address or data indication, leaving the remaining seven bits as actual data. When C1[PE] is set, the eighth data bit is automatically calculated as the parity bit. See the following table.

**Table 12-42. Configuration of 8-bit data format**

UART_C1[PE]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	1	8	0	0	1
0	1	7	1 <sup>1</sup>	0	1
1	1	7	0	1	1

1. The address bit identifies the frame as an address character. See [Receiver wakeup](#).

### 12.3.4.4.2 Nine-bit configuration

When C1[M] is set and C4[M10] is cleared, the UART is configured for 9-bit data characters. If C1[PE] is enabled, the ninth bit is either C3[T8/R8] or the internally generated parity bit. This results in a frame consisting of a total of 11 bits. In the event that the ninth data bit is selected to be C3[T8], it will remain unchanged after transmission and can be used repeatedly without rewriting it, unless the value needs to be changed. This feature may be useful when the ninth data bit is being used as an address mark.

When C1[M] and C4[M10] are set, the UART is configured for 9-bit data characters, but the frame consists of a total of 12 bits. The 12 bits include the start and stop bits, the 9 data character bits, and a tenth internal data bit. Note that if C4[M10] is set, C1[PE] must also be set. In this case, the tenth bit is the internally generated parity bit. The ninth bit can either be used as an address mark or a ninth data bit.

See the following table.

**Table 12-43. Configuration of 9-bit data formats**

C1[PE]	UC1[M]	C1[M10]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	0	0	See <a href="#">Eight-bit configuration</a>				
0	0	1	Invalid configuration				
0	1	0	1	9	0	0	1
0	1	0	1	8	1 <sup>1</sup>	0	1
0	1	1	Invalid Configuration				
1	0	0	See <a href="#">Eight-bit configuration</a>				
1	0	1	Invalid Configuration				
1	1	0	1	8	0	1	1
1	1	1	1	9	0	1	1
1	1	1	1	8	1 <sup>1</sup>	1	1

1. The address bit identifies the frame as an address character.

#### Note

Unless in 9-bit mode with M10 set, do not use address mark wakeup with parity enabled.

### 12.3.4.4.3 Timing examples

Timing examples of these configurations in the NRZ mark/space data format are illustrated in the following figures. The timing examples show all of the configurations in the following sub-sections along with the LSB and MSB first variations.

### 12.3.4.4.3.1 Eight-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

**Figure 12-33. Eight bits of data with LSB first**

**Figure 12-34. Eight bits of data with MSB first**

### 12.3.4.4.3.2 Eight-bit format with parity enabled

**Figure 12-35. Seven bits of data with LSB first and parity**

**Figure 12-36. Seven bits of data with MSB first and parity**

### 12.3.4.4.3.3 Nine-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

**Figure 12-37. Nine bits of data with LSB first**

**Figure 12-38. Nine bits of data with MSB first**

### 12.3.4.4.3.4 Nine-bit format with parity enabled

**Figure 12-39. Eight bits of data with LSB first and parity**

**Figure 12-40. Eight bits of data with MSB first and parity**

#### 12.3.4.4.3.5 Non-memory mapped tenth bit for parity

The most significant memory-mapped bit can be used for address mark wakeup.

**Figure 12-41. Nine bits of data with LSB first and parity**

**Figure 12-42. Nine bits of data with MSB first and parity**

#### 12.3.4.5 Single-wire operation

Normally, the UART uses two pins for transmitting and receiving. In single wire operation, the RXD pin is disconnected from the UART and the UART implements a half-duplex serial connection. The UART uses the TXD pin for both receiving and transmitting.

**Figure 12-43. Single-wire operation (C1[LOOPS] = 1, C1[RSRC] = 1)**

Enable single wire operation by setting C1[LOOPS] and the receiver source field, C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Setting C1[RSRC] connects the receiver input to the output of the TXD pin driver. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO\_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

### 12.3.4.6 Loop operation

In loop operation, the transmitter output goes to the receiver input. The unsynchronized receiver input signal is disconnected from the UART.

**Figure 12-44. Loop operation (C1[LOOPS] = 1, C1[RSRC] = 0)**

Enable loop operation by setting C1[LOOPS] and clearing C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Clearing C1[RSRC] connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO\_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

### 12.3.4.7 ISO-7816/smartcard support

The UART provides mechanisms to support the ISO-7816 protocol that is commonly used to interface with smartcards. The ISO-7816 protocol is an NRZ, single wire, half-duplex interface. The TxD pin is used in open-drain mode because the data signal is used for both transmitting and receiving. There are multiple subprotocols within the ISO-7816 standard. The UART supports both T = 0 and T = 1 protocols. The module also provides for automated initial character detection and configuration, which allows for support of both direct convention and inverse convention data formats. A variety of interrupts specific to 7816 are provided in addition to the general interrupts to assist software. Additionally, the module is able to provide automated NACK responses and has programmed automated retransmission of failed packets. An assortment of programmable timeouts and guard band times are also supported.

The term elemental time unit (ETU) is frequently used in the context of ISO-7816. This concept is used to relate the frequency that the system (UART) is running at and the frequency that data is being transmitted and received. One ETU represents the time it takes to transmit or receive a single bit. For example, a standard 7816 packet, excluding any guard time or NACK elements is 10 ETUs (start bit, 8 data bits, and a parity bit). Guard times and wait times are also measured in ETUs.,

**NOTE**

The ISO-7816 specification may have certain configuration options that are reserved. To maintain maximum flexibility to support future 7816 enhancements or devices that may not strictly conform to the specification, the UART does not prevent those options being used. Further, the UART may provide configuration options that exceed the flexibility of options explicitly allowed by the 7816 specification. Failure to correctly configure the UART may result in unexpected behavior or incompatibility with the ISO-7816 specification.

**12.3.4.7.1 Initial characters**

In ISO-7816 with T = 0 mode, the UART can be configured to use C7816[INIT] to detect the next valid initial character, referred to by the ISO-7816 specifically as a TS character. When the initial character is detected, the UART provides the host processor with an interrupt if IE7816[INITDE] is set. Additionally, the UART will alter S2[MSBF], C3[TXINV], and S2[RXINV] automatically, based on the initial character. The corresponding initial character and resulting register settings are listed in the following table.

**Table 12-44. Initial character automated settings**

Initial character (bit 1-10)	Initial character (hex)	MSBF	TXINV	RXINV
LHHL LLL LLH inverse convention	3F	1	1	1
LHHL HHH LLH direct convention	3B	0	0	0

S2[MSBF], C3[TXINV], and S2[RXINV] must be reset to their default values before C7816[INIT] is set. Once C7816[INIT] is set, the receiver searches all received data for the first valid initial character. Detecting a Direct Convention Initial Character will cause no change to S2[MSBF], C3[TXINV], and S2[RXINV], while detecting an Inverse Convention Initial Character will cause these fields to set automatically. All data received, which is not a valid initial character, is ignored and all flags resulting from the invalid data are blocked from asserting. If C7816[ANACK] is set, a NACK is returned for invalid received initial characters and an RXT interrupt is generated as programmed.

### 12.3.4.7.2 Protocol T = 0

When T = 0 protocol is selected, a relatively complex error detection scheme is used. Data characters are formatted as illustrated in the following figure. This scheme is also used for answer to reset and Peripheral Pin Select (PPS) formats.

**Figure 12-45. ISO-7816 T = 0 data format**

As with other protocols supported by the UART, the data character includes a start bit. However, in this case, there are two stop bits rather than the typical single stop bit. In addition to a standard even parity check, the receiver has the ability to generate and return a NACK during the second half of the first stop bit period. The NACK must be at least one time period (ETU) in length and no more than two time periods (ETU) in length. The transmitter must wait for at least two time units (ETU) after detection of the error signal before attempting to retransmit the character.

It is assumed that the UART and the device (smartcard) know in advance which device is receiving and which is transmitting. No special mechanism is supplied by the UART to control receive and transmit in the mode other than C2[TE] and C2[RE]. Initial Character Detect feature is also supported in this mode.

### 12.3.4.7.3 Protocol T = 1

When T = 1 protocol is selected, the NACK error detection scheme is not used. Rather, the parity bit is used on a character basis and a CRC or LRC is used on the block basis, that is, for each group of characters. In this mode, the data format allows for a single stop bit although additional inactive bit periods may be present between the stop bit and the next start bit. Data characters are formatted as illustrated in the following figure.

**Figure 12-46. ISO 7816 T=1 data format**

The smallest data unit that is transferred is a block. A block is made up of several data characters and may vary in size depending on the block type. The UART does not provide a mechanism to decode the block type. As part of the block, an LRC or CRC is included. The UART does not calculate the CRC or LRC for transmitted blocks, nor does

it verify the validity of the CRC or LRC for received blocks. The 7816 protocol requires that the initiator and the smartcard (device) takes alternate turns in transmitting and receiving blocks. When the UART detects that the last character in a block has been transmitted it will automatically clear C2[TE], C3[TXDIR] and enter receive mode. Therefore, the software must program the transmit buffer with the next data to be transmitted and then enable C2[TE] and set C3[TXDIR], once the software has determined that the last character of the received block has been received. The UART detects that the last character of the transmit block has been sent when TL7816[TLEN] = 0 and four additional characters have been sent. The four additional characters are made up of three prior to TL7816[TLEN] decrementing (prologue) and one after TL7816[TLEN] = 0, the final character of the epilogue.

#### 12.3.4.7.4 Wait time and guard time parameters

The ISO-7816 specification defines several wait time and guard time parameters. The UART allows for flexible configuration and violation detection of these settings. On reset, the wait time (IS7816[WT]) defaults to 9600 ETUs and guard time (GT) to 12 ETUs. These values are controlled by parameters in the WP7816, WN7816, and WF7816 registers. Additionally, the value of C7816[TTYTYPE] also factors into the calculation. The formulae used to calculate the number ETUs for each wait time and guard time value are shown in [Table 12-45](#).

Wait time (WT) is defined as the maximum allowable time between the leading edge of a character transmitted by the smartcard device and the leading edge of the previous character that was transmitted by the UART or the device. Similarly, character wait time (CWT) is defined as the maximum allowable time between the leading edge of two characters within the same block. Block wait time (BWT) is defined as the maximum time between the leading edge character of the last block received by the smartcard device and the leading edge of the first character transmitted by the smartcard device.

Guard time (GT) is defined as the minimum allowable time between the leading edge of two consecutive characters. Character guard time (CGT) is the minimum allowable time between the leading edges of two consecutive characters in the same direction, that is, transmission or reception. Block guard time (BGT) is the minimum allowable time between the leading edges of two consecutive characters in opposite directions, that is, transmission then reception or reception then transmission.

The GT and WT counters reset whenever C7816[TTYTYPE] = 1 or C7816[ISO\_7816E] = 0 or a new dataword start bit has been received or transmitted as specified by the counter descriptions. The CWT, CGT, BWT, BGT counters reset whenever C7816[TTYTYPE] = 0 or C7816[ISO\_7816E] = 0 or a new dataword start bit is received or transmitted as specified by the counter descriptions. When C7816[TTYTYPE] = 1, some of the counter values require an assumption regarding the first data transferred when the UART first

starts. This assumption is required when the 7816E is disabled, when transition from C7816[TTYPE] = 0 to C7816[TTYPE] = 1 or when coming out of reset. In this case, it is assumed that the previous non-existent transfer was a received transfer.

The UART will automatically handle GT, CGT, and BGT such that the UART will not send a packet before the corresponding guard time expiring.

**Table 12-45. Wait and guard time calculations**

Parameter	Reset value [ETU]	C7816[TTYPE] = 0 [ETU]	C7816[TTYPE] = 1 [ETU]
Wait time (WT)	9600	$((WI + 1) \times 960 \times (GTFD + 1)) - 1$	Not used
Character wait time (CWT)	Not used	Not used	$11 + 2^{(CWI - 1)}$
Block wait time (BWT)	Not used	Not used	$10 + 2^{BWI} \times 960 \times (GTFD + 1)$
Guard time (GT)	12	<b>GTN not equal to 255</b> $12 + GTN$ <b>GTN equal to 255</b> 12	Not used
Character guard time (CGT)	Not used	Not used	<b>GTN not equal to 255</b> $12 + GTN$ <b>GTN equal to 255</b> 11
Block guard time (BGT)	Not used	Not used	22

#### 12.3.4.7.5 Baud rate generation

The value in WF7816[GTFD] does not impact the clock frequency. SBR and BRFD are used to generate the clock frequency. This clock frequency is used by the UART only and is not seen by the smartcard device. The transmitter clocks operates at 1/16 the frequency of the receive clock so that the receiver is able to sample the received value 16 times during the ETU.

#### 12.3.4.7.6 UART restrictions in ISO-7816 operation

Due to the flexibility of the UART module, there are several features and interrupts that are not supported while running in ISO-7816 mode. These restrictions are documented within the register field definitions.

### 12.3.4.8 Infrared interface

The UART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the UART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This design covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The UART has an infrared transmit encoder and receive decoder. The UART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the MCU. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the UART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active low pulses.

The infrared submodule receives its clock sources from the UART. One of these two clocks are selected in the infrared submodule to generate either 3/16, 1/16, 1/32, or 1/4 narrow pulses during transmission.

#### 12.3.4.8.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent in the middle of the bit with a duration of 1/32, 1/16, 3/16, or 1/4 of a bit time. A narrow high pulse is transmitted for a zero bit when C3[TXINV] is cleared, while a narrow low pulse is transmitted for a zero bit when C3[TXINV] is set.

#### 12.3.4.8.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each zero received and no pulse is expected for each one received. A narrow high pulse is expected for a zero bit when S2[RXINV] is cleared, while a narrow low pulse is expected for a zero bit when S2[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

### 12.3.5 Reset

All registers reset to a particular value are indicated in [Memory map and registers](#).

### 12.3.6 System level interrupt sources

There are several interrupt signals that are sent from the UART. Details regarding the individual operation of each interrupt are contained under various sub-sections of [Memory map and registers](#). However, [RXEDGIF description](#) also outlines additional details regarding the RXEDGIF interrupt because of its complexity of operation. Any of the UART interrupt requests listed in the table can be used to bring the CPU out of Wait mode.

#### 12.3.6.1 RXEDGIF description

S2[RXEDGIF] is set when an active edge is detected on the RxD pin. Therefore, the active edge can be detected only when in two wire mode. A RXEDGIF interrupt is generated only when S2[RXEDGIF] is set. If RXEDGIE is not enabled before S2[RXEDGIF] is set, an interrupt is not generated.

##### 12.3.6.1.1 RxD edge detect sensitivity

Edge sensitivity can be software programmed to be either falling or rising. The polarity of the edge sensitivity is selected using S2[RXINV]. To detect the falling edge, S2[RXINV] is programmed to 0. To detect the rising edge, S2[RXINV] is programmed to 1.

Synchronizing logic is used prior to detect edges. Prior to detecting an edge, the receive data on RxD input must be at the deasserted logic level. A falling edge is detected when the RxD input signal is seen as a logic 1 (the deasserted level) during one module clock cycle, and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input is seen as a logic 0 during one module clock cycle and then a logic 1 during the next cycle.

##### 12.3.6.1.2 Clearing RXEDGIF interrupt request

Writing a logic 1 to S2[RXEDGIF] immediately clears the RXEDGIF interrupt request even if the RxD input remains asserted. S2[RXEDGIF] remains set if another active edge is detected on RxD while attempting to clear S2[RXEDGIF] by writing a 1 to it.

### 12.3.6.1.3 Exit from low-power modes

The receive input active edge detect circuit is still active on low power modes (Wait and Stop). An active edge on the receive input brings the CPU out of low power mode if the interrupt is not masked ( $S2[RXEDGIF] = 1$ ).

## 12.3.7 DMA operation

In the transmitter,  $S1[TDRE]$  can be configured to assert a DMA transfer request. In the receiver,  $S1[RDRF]$  can be configured to assert a DMA transfer request. The following table shows the configuration field settings required to configure each flag for DMA operation.

**Table 12-46. DMA configuration**

Flag	Request enable bit	DMA select bit
TDRE	TIE = 1	TDMAS = 1
RDRF	RIE = 1	RDMAS = 1

When a flag is configured for a DMA request, its associated DMA request is asserted when the flag is set. When  $S1[RDRF]$  is configured as a DMA request, the clearing mechanism of reading  $S1$ , followed by reading  $D$ , does not clear the associated flag. The DMA request remains asserted until an indication is received that the DMA transactions are done. When this indication is received, the flag bit and the associated DMA request is cleared. If the DMA operation failed to remove the situation that caused the DMA request, another request is issued.

## 12.3.8 Application information

This section describes the UART application information.

### 12.3.8.1 Transmit/receive data buffer operation

The UART has a transmit data buffer of depth one and a receive data buffer of depth one. This allows for a dataword to wait to be transmitted while another data is being transmitted. Similarly, it allows for a dataword to be received while a that dataword has already been received waits to be read by the host. The parameter  $TWFIFO[TXWATER] = 0$  and  $RWFIFO[RXWATER] = 1$ . This means that  $S1[TDRE]$  asserts whenever a dataword moves from the transmit buffer to the transmit shift register.  $S1[RDRF]$  asserts whenever a dataword is moved from the receive shift register to the receive buffer.

### 12.3.8.2 ISO-7816 initialization sequence

This section outlines how to program the UART for ISO-7816 operation. Elements such as procedures to power up or power down the smartcard, and when to take those actions, are beyond the scope of this description. To set up the UART for ISO-7816 operation:

1. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL. According to the 7816 specification the initial (default) baud rating setting should be  $F_i = 372$  and  $D_i = 1$  and a maximum frequency of 5 MHz. In other words, the BDH, BDL, and C4 registers should be programmed such that the transmission frequency provided to the smartcard device must be  $1/372$ th of the clock and must not exceed 5 MHz.
2. Write to C1 to configure word length, parity, and other configuration fields (LOOPS, RSRC) and set  $C1[M] = 1$ ,  $C1[PE] = 1$ , and  $C1[PT] = 0$ .
3. Write to set  $S2[RWUID] = 0$
4. Write to set up interrupt enable fields desired ( $C3[ORIE]$ ,  $C3[NEIE]$ ,  $C3[PEIE]$ , and  $C3[FEIE]$ )
5. Write to set  $C4[MAEN1] = 0$  and  $C4[MAEN2] = 0$ .
6. Write to C5 register and configure DMA control register fields as desired for application.
7. Write to set  $C7816[INIT] = 1$ ,  $C7816[TTYPE] = 0$ , and  $C7816[ISO\_7816E] = 1$ . Program  $C7816[ONACK]$  and  $C7816[ANACK]$  as desired.
8. Write to IE7816 to set interrupt enable parameters as desired.
9. Write to ET7816 and set as desired.
10. Write to set  $C2[ILIE] = 0$ ,  $C2[RE] = 1$ ,  $C2[TE] = 1$ ,  $C2[RWU] = 0$ , and  $C2[SBK] = 0$ . Set up interrupt enables  $C2[TIE]$ ,  $C2[TCIE]$ , and  $C2[RIE]$  as desired.

At this time, the UART will start listening for an initial character. After being identified, it will automatically adjust  $S2[MSBF]$ ,  $C3[TXINV]$ , and  $S2[RXINV]$ . The software must then receive and process an answer to reset. Upon processing the answer to reset, the software must write to set  $C2[RE] = 0$  and  $C2[TE] = 0$ . The software should then adjust 7816 specific and UART generic parameters to match and configure data that was

received during the answer on reset period. After the new settings have been programmed, including the new baud rate and C7816[TTYTYPE], C2[RE] and C2[TE] can be reenabled as required.

### 12.3.8.2.1 Transmission procedure for (C7816[TTYTYPE] = 0)

When the protocol selected is C7816[TTYTYPE] = 0, it is assumed that the software has a prior knowledge of who should be transmitting and receiving. Therefore, no mechanism is provided for automated transmission/receipt control. The software must monitor S1[TDRE], or configure for an interrupt, and provide additional data for transmission, as appropriate. Additionally, software should set C2[TE] = 1 and control TXDIR whenever it is the UART's turn to transmit information. For ease of monitoring, it is suggested that only data be transmitted until the next receiver/transmit switchover is loaded into the transmit FIFO/buffer.

### 12.3.8.2.2 Transmission procedure for (C7816[TTYTYPE] = 1)

When the protocol selected is C7816[TTYTYPE] = 1, data is transferred in blocks. Before starting a transmission, the software must write the size, in number of bytes, for the Information Field portion of the block into TLEN. If a CRC is being transmitted for the block, the value in TLEN must be one more than the size of the information field. The software must then set C2[TE] = 1 and C2[RE] = 1. The software must then monitor S1[TDRE]/interrupt and write the prologue, information, and epilogue field to the transmit buffer. TLEN automatically decrements, except for prologue bytes and the final epilogue byte. When the final epilogue byte has been transmitted, the UART automatically clears C2[TE] and C3[TXDIR] to 0, and the UART automatically starts capturing the response to the block that was transmitted. After the software has detected the receipt of the response, the transmission process must be repeated as needed with sufficient urgency to ensure that the block wait time and character wait times are not violated.

### 12.3.8.3 Initialization sequence (non ISO-7816)

To initiate a UART transmission:

1. Configure the UART.
  - a. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL.

- b. Write to C1 to configure word length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, and PT). Write to C4, MA1, and MA2 to configure.
  - c. Enable the transmitter, interrupts, receiver, and wakeup as required, by writing to C2 (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK), S2 (MSBF and BRK13), and C3 (ORIE, NEIE, PEIE, and FEIE). A preamble or idle character is then shifted out of the transmitter shift register.
2. Transmit procedure for each byte.
  - a. Monitor S1[TDRE] by reading S1 or responding to the TDRE interrupt. The amount of free space in the transmit buffer directly using TCFIFO[TXCOUNT] can also be monitored.
  - b. If the TDRE flag is set, or there is space in the transmit buffer, write the data to be transmitted to (C3[T8]/D). A new transmission will not result until data exists in the transmit buffer.
3. Repeat step 2 for each subsequent transmission.

### Note

During normal operation, S1[TDRE] is set when the shift register is loaded with the next data to be transmitted from the transmit buffer and the number of datawords contained in the transmit buffer is less than or equal to the value in TWFIFO[TXWATER]. This occurs 9/16ths of a bit time after the start of the stop bit of the previous frame.

To separate messages with preambles with minimum idle line time, use this sequence between messages.

1. Write the last dataword of the first message to C3[T8]/D.
2. Wait for S1[TDRE] to go high with TWFIFO[TXWATER] = 0, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting C2[TE].
4. Write the first and subsequent datawords of the second message to C3[T8]/D.

### 12.3.8.4 Overrun (OR) flag implications

To be flexible, the overrun flag (OR) operates slightly differently depending on the mode of operation. There may be implications that need to be carefully considered. This section clarifies the behavior and the resulting implications. Regardless of mode, if a dataword is received while S1[OR] is set, S1[RDRF] and S1[IDLE] are blocked from asserting. If S1[RDRF] or S1[IDLE] were previously asserted, they will remain asserted until cleared.

#### 12.3.8.4.1 Overrun operation

The assertion of S1[OR] indicates that a significant event has occurred. The assertion indicates that received data has been lost because there was a lack of room to store it in the data buffer. Therefore, while S1[OR] is set, no further data is stored in the data buffer until S1[OR] is cleared. This ensures that the application will be able to handle the overrun condition.

In most applications, because the total amount of lost data is known, the application will attempt to return the system to a known state. Before S1[OR] is cleared, all received data will be dropped. For this, the software does the following.

1. Remove data from the receive data buffer. This could be done by reading data from the data buffer and processing it if the data in the FIFO was still valuable when the overrun event occurred.
2. Clear S1[OR].

Note that, in some applications, if an overrun event is responded to fast enough, the lost data can be recovered. For example, when C7816[ISO\_7816E] is asserted, C7816[TTYTYPE]=1 and C7816[ONACK] = 1, the application may reasonably be able to determine whether the lost data will be resent by the device. In this scenario, flushing the receiver data buffer may not be required. Rather, if S1[OR] is cleared, the lost data may be resent and therefore may be recoverable.

### 12.3.8.5 Overrun NACK considerations

When C7816[ISO\_7816E] is enabled and C7816[TTYTYPE] = 0, the retransmission feature of the 7816 protocol can be used to help avoid lost data when the data buffer overflows. Using C7816[ONACK], the module can be programmed to issue a NACK on an overflow event. Assuming that the smartcard device has implemented retransmission, the lost data will be retransmitted. While useful, there is a programming implication that may require special consideration. The need to transmit a NACK must be determined and committed to prior to the dataword being fully received. While the NACK is being

received, it is possible that the application code will read the data buffer such that sufficient room will be made to store the dataword that is being NACKed. Even if room has been made in the data buffer after the transmission of a NACK is completed, the received data will always be discarded as a result of an overflow and the ET7816[RXTHRESHOLD] value will be incremented by one. However, if sufficient space now exists to write the received data which was NACK'ed, S1[OR] will be blocked and kept from asserting.

### 12.3.8.6 Match address registers

The two match address registers allow a second match address function for a broadcast or general call address to the serial bus, as an example.

### 12.3.8.7 IrDA minimum pulse width

The IrDA specifies a minimum pulse width of 1.6  $\mu$ s. The UART hardware does not include a mechanism to restrict/force the pulse width to be greater than or equal to 1.6  $\mu$ s. However, configuring the baud rate to 115.2 kbit/s and the narrow pulse width to 3/16 of a bit time results in a pulse width of 1.6  $\mu$ s.

### 12.3.8.8 Clearing 7816 wait timer (WT, BWT, CWT) interrupts

The 7816 wait timer interrupts associated with IS7816[WT], IS7816[BWT], and IS7816[CWT] will automatically reassert if they are cleared and the wait time is still violated. This behavior is similar to most of the other interrupts on the UART. In most cases, if the condition that caused the interrupt to trigger still exists when the interrupt is cleared, then the interrupt will reassert. For example, consider the following scenario:

1. IS7816[WT] is programmed to assert after 9600 cycles of unresponsiveness.
2. The 9600 cycles pass without a response resulting in the WT interrupt asserting.
3. The IS7816[WT] is cleared at cycle 9700 by the interrupt service routine.
4. After the WT interrupt has been cleared, the smartcard remains unresponsive. At cycle 9701 the WT interrupt will be reasserted.

If the intent of clearing the interrupt is such that it does not reassert, the interrupt service routine must remove or clear the condition that originally caused the interrupt to assert prior to clearing the interrupt. There are multiple ways that this can be accomplished, including ensuring that an event that results in the wait timer resetting occurs, such as, the transmission of another packet.

### 12.3.8.9 Legacy and reverse compatibility considerations

Recent versions of the UART have added several new features. Whenever reasonably possible, reverse compatibility was maintained. However, in some cases this was either not feasible or the behavior was deemed as not intended. This section describes several differences to legacy operation that resulted from these recent enhancements. If application code from previous versions is used, it must be reviewed and modified to take the following items into account. Depending on the application code, additional items that are not listed here may also need to be considered.

1. Various reserved registers and register bits are used, such as, MSFB and M10.
2. This module now generates an error when invalid address spaces are used.
3. While documentation indicated otherwise, in some cases it was possible for S1[IDLE] to assert even if S1[OR] was set.
4. S1[OR] will be set only if the data buffer (FIFO) does not have sufficient room. Previously, the data buffer was always a fixed size of one and the S1[OR] flag would set so long as S1[RDRF] was set even if there was room in the data buffer. While the clearing mechanism has remained the same for S1[RDRF], keeping the OR flag assertion tied to the RDRF event rather than the data buffer being full would have greatly reduced the usefulness of the buffer when its size is larger than one.
5. Previously, when C2[RWU] was set (and WAKE = 0), the IDLE flag could reassert up to every bit period causing an interrupt and requiring the host processor to reassert C2[RWU]. This behavior has been modified. Now, when C2[RWU] is set (and WAKE = 0), at least one non-idle bit must be detected before an idle can be detected.

## 12.4 Serial Peripheral Interface (SPI)

### 12.4.1 Introduction

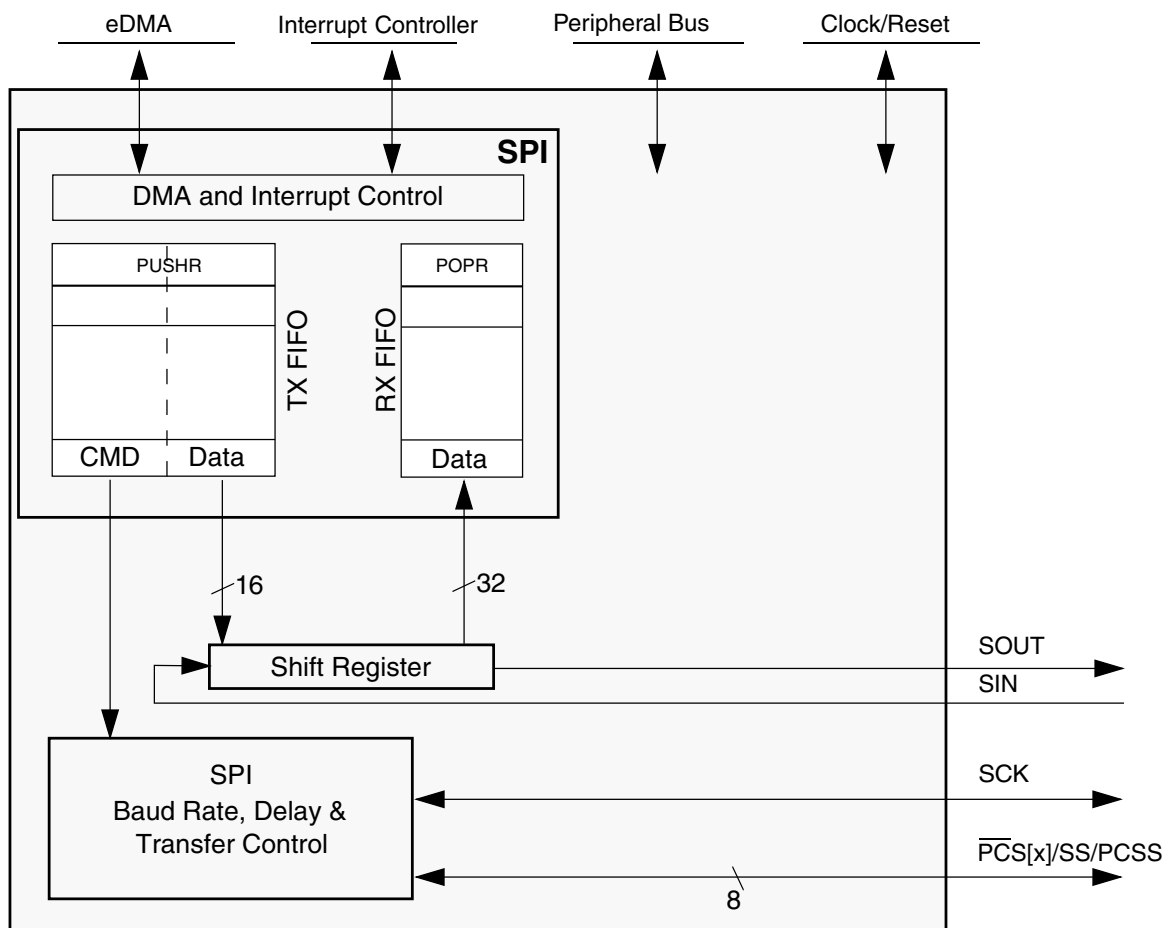

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device.

### 12.4.1.1 Block Diagram

The block diagram of this module is as follows:

**Figure 12-47. SPI Block Diagram**

### 12.4.1.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries

- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - four transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 16
    - SPI frames longer than 16 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
  - Parity control
- 6 peripheral chip selects (PCSeS), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSeS) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - Transfer of current frame complete (TCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
- Global interrupt request line

- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
  - Support for Stop mode

### 12.4.1.3 Interface configurations

#### 12.4.1.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

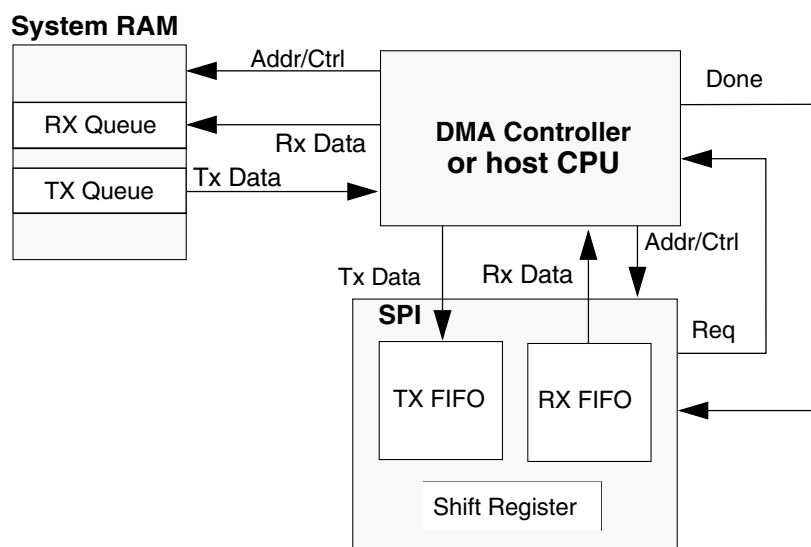

Figure 12-48. SPI with queues and DMA

#### 12.4.1.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- Chip-specific modes:
  - External Stop mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

#### **12.4.1.4.1 Master Mode**

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- SOUT
- PCS[x]

#### **12.4.1.4.2 Slave Mode**

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{\text{SS}}$  signals are configured as inputs and driven by an SPI bus master.

#### **12.4.1.4.3 Module Disable Mode**

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

#### **12.4.1.4.4 External Stop Mode**

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

## 12.4.2 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

**Table 12-47. Module signal descriptions**

Signal	Master mode	Slave mode	I/O
PCS0/ $\overline{\text{SS}}$	Peripheral Chip Select 0 (O)	Slave Select (I)	I/O
PCS[1:3]	Peripheral Chip Selects 1–3	(Unused)	O
PCS4	Peripheral Chip Select 4		O
PCS5/ $\overline{\text{PCSS}}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	(Unused)	O
SCK	Serial Clock (O)	Serial Clock (I)	I/O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O

### 12.4.2.1 PCS0/ $\overline{\text{SS}}$ —Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

#### NOTE

Do not tie the SPI slave select pin to ground. Otherwise, SPI cannot function properly.

### 12.4.2.2 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 12.4.2.3 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

#### 12.4.2.4 PCS5/PCSS—Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

#### 12.4.2.5 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

#### 12.4.2.6 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

#### 12.4.2.7 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

### 12.4.3 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

## SPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 12.4.3.1 Module Configuration Register (SPIx\_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MSTR	CONT_SCKE	DCONF		0	MTFE	PCSSE	ROOE	Reserved		PCISIS

**SPIx\_MCR field descriptions**

Field	Description
31 MSTR	Master/Slave Mode Select  Enables either Master mode (if supported) or Slave mode (if supported) operation.  0 Enables Slave mode 1 Enables Master mode
30 CONT_SCKE	Continuous SCK Enable  Enables the Serial Communication Clock (SCK) to run continuously.

*Table continues on the next page...*

**SPIx\_MCR field descriptions (continued)**

Field	Description
	0 Continuous SCK disabled. 1 Continuous SCK enabled.
29–28 DCONF	SPI Configuration.  Selects among the different configurations of the module.  00 SPI 01 Reserved 10 Reserved 11 Reserved
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 MTFE	Modified Transfer Format Enable  Enables a modified transfer format to be used.  0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
25 PCSSE	Peripheral Chip Select Strobe Enable  Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal.  0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
24 ROOE	Receive FIFO Overflow Overwrite Enable  In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register.  0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
23–22 Reserved	Always write the reset value to this field.  This field is reserved.
21–16 PC SIS	Peripheral Chip Select x Inactive State  Determines the inactive state of PCSx. Refer to the chip-specific SPI information for the number of PCS signals used in this chip.  <b>NOTE:</b> The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the SPI interface.  0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
15 Reserved	This field is reserved.
14 MDIS	Module Disable  Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default

*Table continues on the next page...*

**SPIx\_MCR field descriptions (continued)**

Field	Description
	<p>reset value of 0. When the module is used in Slave Mode, it is recommended to leave this bit 0, because a slave doesn't have control over master transactions.</p> <p>0 Enables the module clocks. 1 Allows external logic to disable the module clocks.</p>
13 DIS_TXF	<p>Disable Transmit FIFO</p> <p>When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared.</p> <p>0 TX FIFO is enabled. 1 TX FIFO is disabled.</p>
12 DIS_RXF	<p>Disable Receive FIFO</p> <p>When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared.</p> <p>0 RX FIFO is enabled. 1 RX FIFO is disabled.</p>
11 CLR_TXF	<p>Clear TX FIFO</p> <p>Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero.</p> <p>0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.</p>
10 CLR_RXF	<p>CLR_RXF</p> <p>Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero.</p> <p>0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.</p>
9–8 SMPL_PT	<p>Sample Point</p> <p>Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0.</p> <p>00 0 protocol clock cycles between SCK edge and SIN sample 01 1 protocol clock cycle between SCK edge and SIN sample 10 2 protocol clock cycles between SCK edge and SIN sample 11 Reserved</p>
7–3 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
2 FCPCS	<p>Fast Continuous PCS Mode.</p> <p>This bit enables the masking of “After SCK (<math>t_{ASC}</math>)” and “PCS to SCK (<math>t_{CSC}</math>)” delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHR register. The firmware should select appropriate masks when providing continuous frames via the PUSHR register.</p>

*Table continues on the next page...*

**SPIx\_MCR field descriptions (continued)**

Field	Description
	0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHHR register.
1 PES	Parity Error Stop  Controls SPI operation when a parity error is detected in a received SPI frame.  0 SPI frame transmission continues. 1 SPI frame transmission stops.
0 HALT	Halt  The HALT bit starts and stops frame transfers. See <a href="#">Start and Stop of Module transfers</a>  0 Start transfers. 1 Stop transfers.

**12.4.3.2 Transfer Count Register (SPIx\_TCR)**

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SPIx\_TCR field descriptions**

Field	Description
31–16 SPI_TCNT	SPI Transfer Counter  Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 12.4.3.3 Clock and Transfer Attributes Register (In Master Mode) (SPIx\_CTARn)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

When the module is configured as a SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

Address: Base address + Ch offset + (4d × i), where i=0d to 3d

#### SPIx\_CTARn field descriptions

Field	Description																				
31 DBR	<p>Double Baud Rate</p> <p>Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate.</p> <p><b>Table 12-48. SPI SCK Duty Cycle</b></p> <table><tr><th>DBR</th><th>CPHA</th><th>PBR</th><th>SCK Duty Cycle</th></tr><tr><td>0</td><td>any</td><td>any</td><td>50/50</td></tr><tr><td>1</td><td>0</td><td>00</td><td>50/50</td></tr><tr><td>1</td><td>0</td><td>01</td><td>33/66</td></tr><tr><td>1</td><td>0</td><td>10</td><td>40/60</td></tr></table>	DBR	CPHA	PBR	SCK Duty Cycle	0	any	any	50/50	1	0	00	50/50	1	0	01	33/66	1	0	10	40/60

30–27 FMSZ	<div>Frame Size</div> <div>The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4.</div>																								
26 CPOL	<div>Clock Polarity</div> <div>Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge.</div> <div><b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.</div> <div><div>0</div>The inactive state value of SCK is low.</div> <div><div>1</div>The inactive state value of SCK is high.</div>																								
25 CPHA	<div>Clock Phase</div> <div>Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.</div> <div><div>0</div>Data is captured on the leading edge of SCK and changed on the following edge.</div> <div><div>1</div>Data is changed on the leading edge of SCK and captured on the following edge.</div>																								
24 LSBFE	<div>LSB First</div> <div>Specifies whether the LSB or MSB of the frame is transferred first.</div> <div><div>0</div>Data is transferred MSB first.</div> <div><div>1</div>Data is transferred LSB first.</div>																								
23–22 PCSSCK	<div>PCS to SCK Delay Prescaler</div> <div>Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer <a href="#">PCS to SCK Delay (t<sub>csc</sub>)</a> for more details.</div>																								

Table continues on the next page...

## SPIx\_CTARn field descriptions (continued)

Field	Description								
	00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.								
21–20 PASC	After SCK Delay Prescaler  Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. Refer <a href="#">After SCK Delay (t<sub>ASC</sub>)</a> for more details.  00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.								
19–18 PDT	Delay after Transfer Prescaler  Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer <a href="#">Delay after Transfer (t<sub>DT</sub>)</a> for more details.  00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.								
17–16 PBR	Baud Rate Prescaler  Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate.  00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.								
15–12 CSSCK	PCS to SCK Delay Scaler  Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK.$ The following table lists the delay scaler values.  <b>Table 12-49. Delay Scaler Encoding</b> <table border="1"> <thead> <tr> <th>Field Value</th><th>Delay Scaler Value</th></tr> </thead> <tbody> <tr> <td>0000</td><td>2</td></tr> <tr> <td>0001</td><td>4</td></tr> <tr> <td>0010</td><td>8</td></tr> </tbody> </table>	Field Value	Delay Scaler Value	0000	2	0001	4	0010	8

**SPIx\_CTARn\_SLAVE field descriptions**

Field	Description
31 Reserved	Always write the reset value to this field.  This field is reserved.
30–27 FMSZ	Frame Size  The number of bits transferred per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.
26 CPOL	Clock Polarity  Selects the inactive state of the Serial Communications Clock (SCK).  <b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.  0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
25 CPHA	Clock Phase  Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.  0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
24 PE	Parity Enable  Enables parity bit transmission and reception for the frame.  0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
23 PP	Parity Polarity  Controls polarity of the parity bit transmitted and checked.  0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
22 Reserved	This field is reserved.
Reserved	This field is reserved.

12.4.3.5 Status Register (SPIx\_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: Base address + 2Ch offset

SPIx\_SR field descriptions

Field	Description
31 TCF	Transfer Complete Flag  Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it.  0    Transfer not complete. 1    Transfer complete.

Table continues on the next page...

**SPIx\_SR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
30 TXRXS	<p>TX and RX Status</p> <p>Reflects the run status of the module.</p> <p>0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).</p>
29 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
28 EOQF	<p>End of Queue Flag</p> <p>Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared.</p> <p>0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.</p>
27 TFUF	<p>Transmit FIFO Underflow Flag</p> <p>Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for SPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it.</p> <p>0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.</p>
26 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
25 TFFF	<p>Transmit FIFO Fill Flag</p> <p>Indicates whether there is an available location to be filled in the FIFO. Either DMA or an interrupt can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request.</p> <p><b>NOTE:</b> The reset value of this bit is 0 when the module is disabled, (MCR[MDIS]=1).</p> <p>0 TX FIFO is full. 1 TX FIFO is not full.</p>
24 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
23 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
22 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
21 SPEF	<p>SPI Parity Error Flag</p> <p>Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it.</p> <p>0 No parity error. 1 Parity error has occurred.</p>

*Table continues on the next page...*

**SPIx\_SR field descriptions (continued)**

Field	Description
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 RFOF	Receive FIFO Overflow Flag  Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it.  0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 RFDF	Receive FIFO Drain Flag  Provides a method for the module to request that entries be removed from the RX FIFO. Note that this bit is set if at least one location can be read from the FIFO. The RFDF bit can be cleared by acknowledgement from the DMA controller when the RX FIFO is empty.  0 RX FIFO is empty. 1 This bit auto-clears on every RXFR read performed.
16 Reserved	This field is reserved.
15–12 TXCTR	TX FIFO Counter  Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
11–8 TXNXTPTR	Transmit Next Pointer  Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
7–4 RXCTR	RX FIFO Counter  Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
POPNXTPTR	Pop Next Pointer  Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

### 12.4.3.6 DMA/Interrupt Request Select and Enable Register (SPIx\_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Field	Description
	0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.
26 Reserved	Always write the reset value to this field.  This field is reserved.
25 TFFF_RE	Transmit FIFO Fill Request Enable  Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request.  0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
24 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select  Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request.  0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
23 Reserved	Always write the reset value to this field.  This field is reserved.
22 Reserved	Always write the reset value to this field.  This field is reserved.
21 SPEF_RE	SPI Parity Error Request Enable  Enables the SPEF flag in the SR to generate an interrupt request.  0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
20 Reserved	Always write the reset value to this field.  This field is reserved.
19 RFOF_RE	Receive FIFO Overflow Request Enable  Enables the RFOF flag in the SR to generate an interrupt request.  0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
18 Reserved	Always write the reset value to this field.  This field is reserved.
17 RFDF_RE	Receive FIFO Drain Request Enable  Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request.  0 RFDF interrupt or DMA requests are disabled. 1 RFDF interrupt or DMA requests are enabled.

*Table continues on the next page...*

**SPIx\_RSER field descriptions (continued)**

Field	Description
16 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select  Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request.  0 Interrupt request. 1 DMA request.
15 Reserved	Always write the reset value to this field.  This field is reserved.
14 Reserved	Always write the reset value to this field.  This field is reserved.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**12.4.3.7 PUSH TX FIFO Register In Master Mode (SPIx\_PUSHR)**

Specifies data to be transferred to the TX FIFO. An 8- or 16-bit write access transfers all 32 bits to the TX FIFO. In Master mode, the register transfers 16 bits of data and 16 bits of command information. A read access of PUSHR returns the topmost TX FIFO entry.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

**SPIx\_PUSHR\_SLAVE field descriptions**

Field	Description
31–16 Reserved	This field is reserved.
TXDATA	<p>Transmit Data</p> <p>Holds SPI data to be transferred according to the associated SPI command.</p>

12.4.3.9 POP RX FIFO Register (SPIx\_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: Base address + 38h offset

SPIx\_POPR field descriptions

Field	Description
RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

12.4.3.10 Transmit FIFO Registers (SPIx\_TXFRn)

TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRx registers does not alter the state of the TX FIFO.

Address: Base address + 3Ch offset + (4d × i), where i=0d to 3d

SPIx\_TXFRn field descriptions

Field	Description
31–16 TXCMD_ TXDATA	Transmit Command or Transmit Data In Master mode the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, this field is reserved.
TXDATA	Transmit Data Contains the SPI data to be shifted out.

### 12.4.3.11 Receive FIFO Registers (SPIx\_RXFRn)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO.

Address: Base address + 7Ch offset + (4d × i), where i=0d to 3d

**SPIx\_RXFRn field descriptions**

Field	Description
RXDATA	Receive Data Contains the received SPI data.

## 12.4.4 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module has the following configuration

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

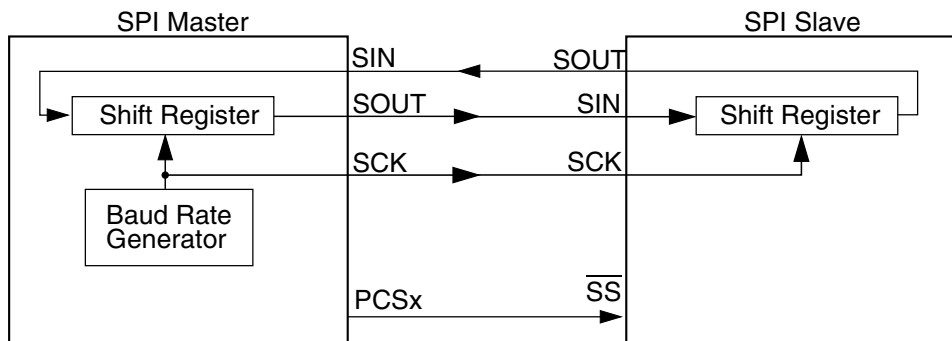

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPIx\_MCR is 0b00.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See [Clock and Transfer Attributes Register \(In Master Mode\) \(SPI\\_CTARn\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the

slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

**Figure 12-49. Serial protocol overview**

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The SPI configuration shares transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

#### 12.4.4.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

### 12.4.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

#### 12.4.4.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(SPI\\_PUSHR\)](#) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out

on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

#### 12.4.4.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

#### 12.4.4.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS\_TXF] bit disables the TX FIFO, and setting the MCR[DIS\_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO is disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

#### 12.4.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

#### 12.4.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO by writing to the PUSHHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

#### 12.4.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR\_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

#### 12.4.4.2.5 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

#### **12.4.4.2.5.1 Filling the RX FIFO**

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

#### **12.4.4.2.5.2 Draining the RX FIFO**

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX\_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

### **12.4.4.3 Module baud rate and clock delay generation**

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

**Figure 12-50. Communications clock prescalers and scalers**

#### 12.4.4.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

**Table 12-51. Baud rate computation example**

$f_p$	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

#### NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

#### 12.4.4.3.2 PCS to SCK Delay ( $t_{csc}$ )

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 12-52](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR<sub>x</sub> registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

**Table 12-52. PCS to SCK delay computation example**

$f_{sys}$	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 $\mu$ s

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 12.4.4.3.3 After SCK Delay ( $t_{ASC}$ )

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 12-52](#) and [Figure 12-53](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR<sub>x</sub> registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

**Table 12-53. After SCK Delay computation example**

$f_p$	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 $\mu$ s

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 12.4.4.3.4 Delay after Transfer ( $t_{DT}$ )

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 12-52](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR<sub>x</sub> registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

**Table 12-54. Delay after Transfer computation example**

$f_p$	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the  $t_{DT}$  delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

### 12.4.4.3.5 Peripheral Chip Select Strobe Enable ( $\overline{\text{PCSS}}$ )

The  $\overline{\text{PCSS}}$  signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR,  $\overline{\text{PCSS}}$  provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the  $\overline{\text{PCSS}}$  signal relative to PCS signals.

**Figure 12-51. Peripheral Chip Select Strobe timing**

The delay between the assertion of the PCS signals and the assertion of  $\overline{\text{PCSS}}$  is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_P} \times \text{PCSSCK}$$

At the end of the transfer, the delay between  $\overline{\text{PCSS}}$  negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_P} \times \text{PASC}$$

The following table shows an example of how to compute the  $t_{\text{pcssck}}$  delay.

**Table 12-55. Peripheral Chip Select Strobe Assert computation example**

$f_P$	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the  $t_{\text{pasc}}$  delay.

**Table 12-56. Peripheral Chip Select Strobe Negate computation example**

$f_P$	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The  $\overline{\text{PCSS}}$  signal is not supported when Continuous Serial Communication SCK mode is enabled.

**NOTE**

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

**12.4.4.4 Transfer formats**

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

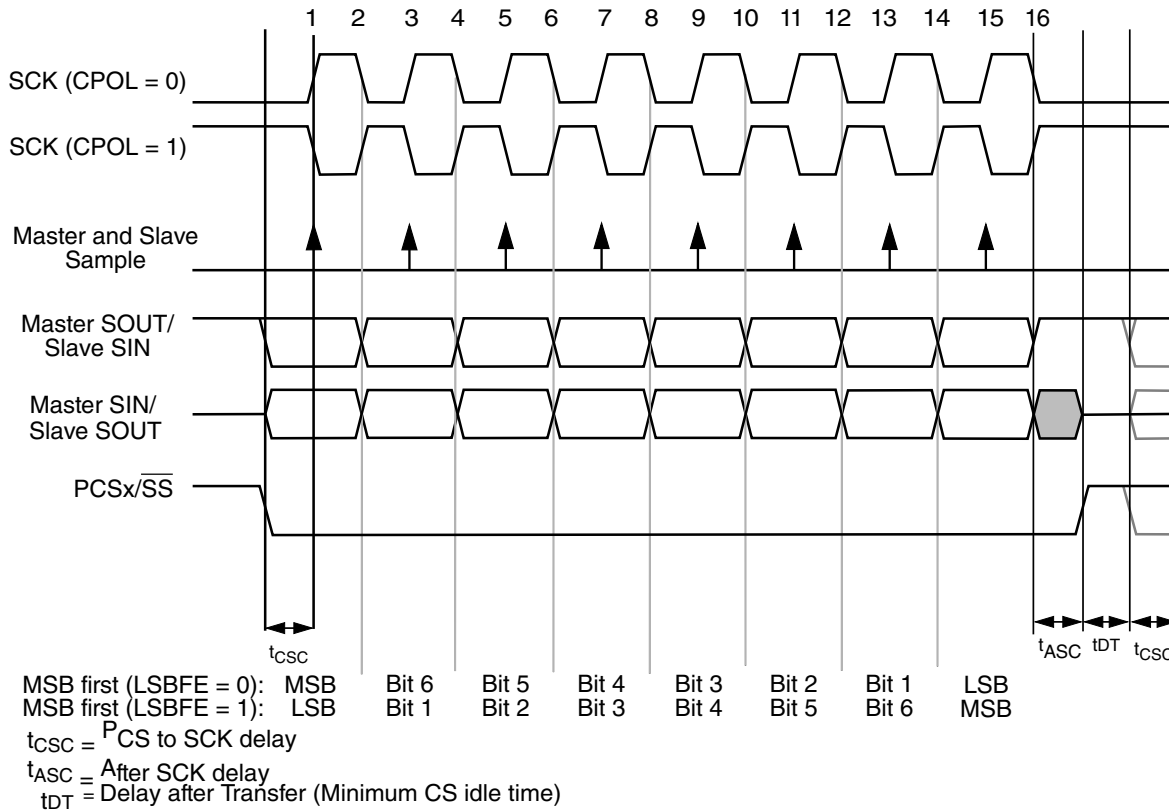

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

#### 12.4.4.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

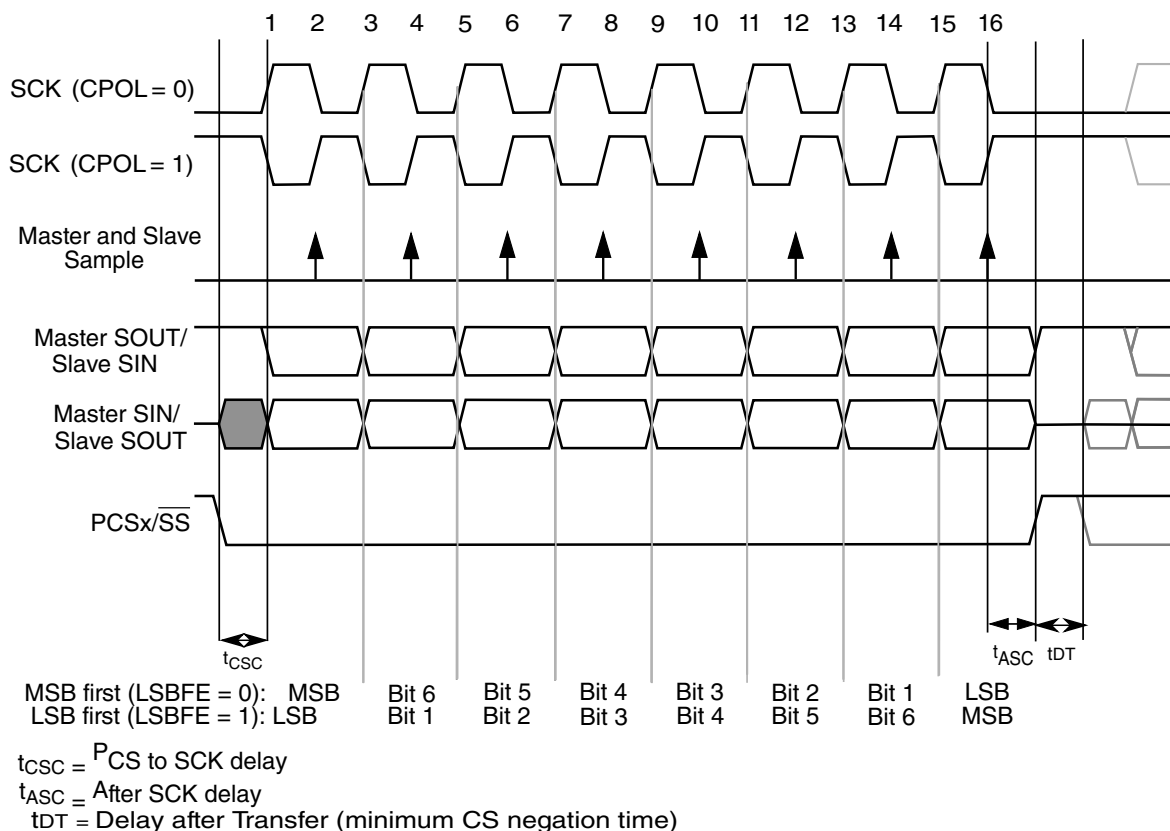

**Figure 12-52. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)**

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the  $t_{CSC}$  delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signals. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 12.4.4.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

**Figure 12-53. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)**

The master initiates the transfer by asserting the PCS signal to the slave. After the  $t_{CSC}$  delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signal. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 12.4.4.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI\_MCR[SMPL\_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL\_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- $T_{csc}$  - PCS to SCK assertion delay
- $T_{acs}$  - After SCK PCS negation delay
- $T_{su_{ms}}$  - master SIN setup time
- $T_{hd_{ms}}$  - master SIN hold time
- $T_{vd_{sl}}$  - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$  - data setup time on slave data input
- $T_{hd_{sl}}$  - data hold time on slave data input
- $T_{sys}$  - protocol clock period.

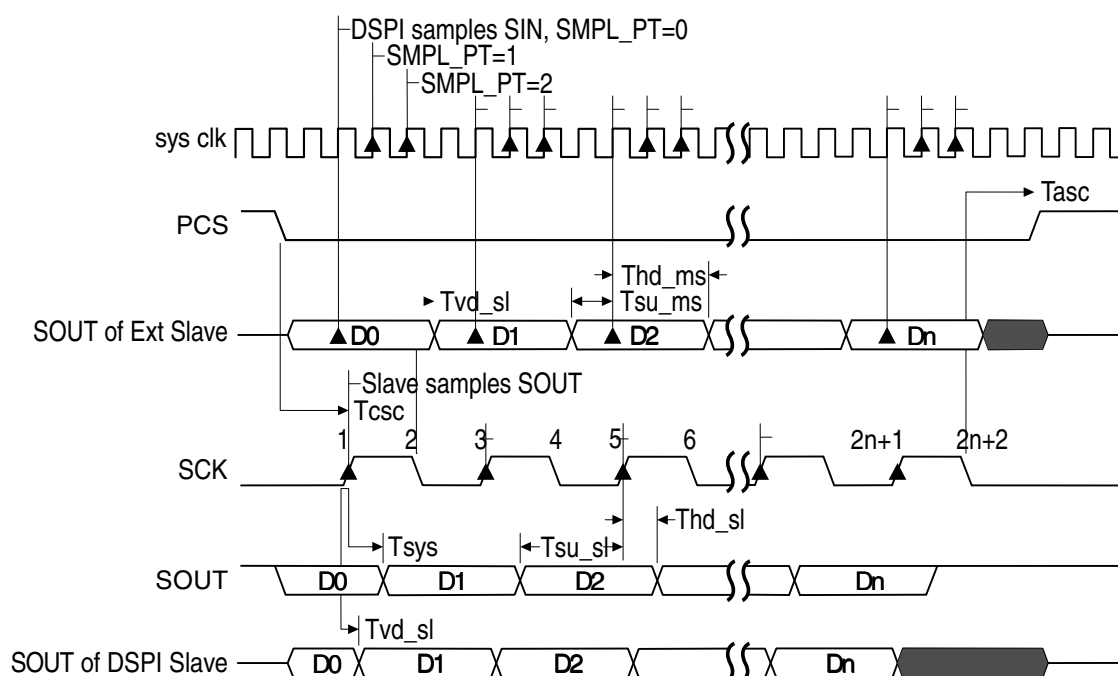

The following figure shows the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

### Note

In the following diagrams,  $f_{\text{sys}}$  represents the protocol clock frequency from which the Baud frequency  $f_{\text{sck}}$  is derived.

**Figure 12-54. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{\text{sck}} = f_{\text{sys}}/4$ )**

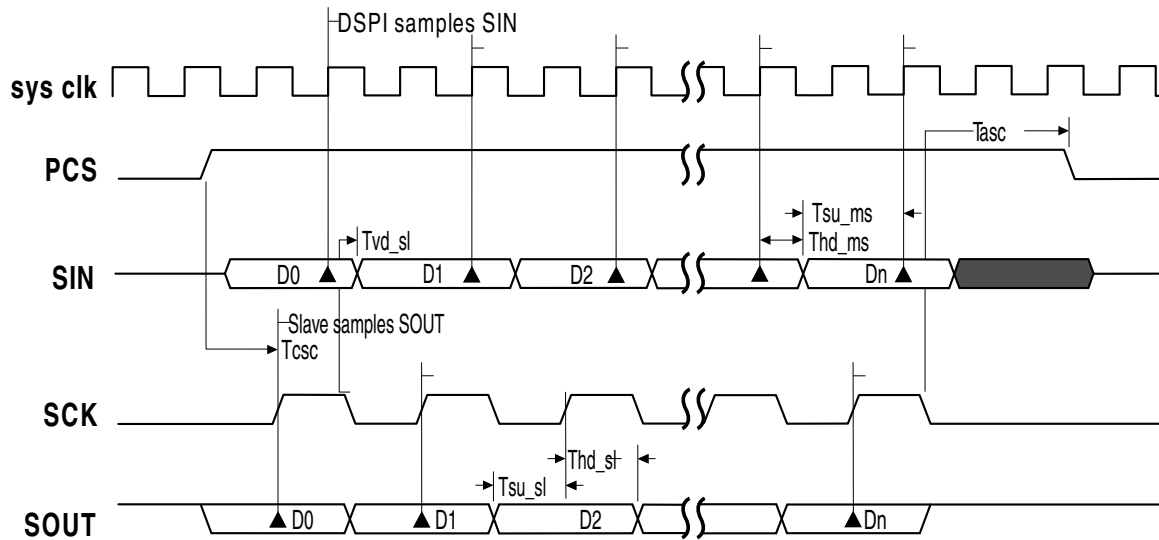

Figure 12-55. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/2$ )

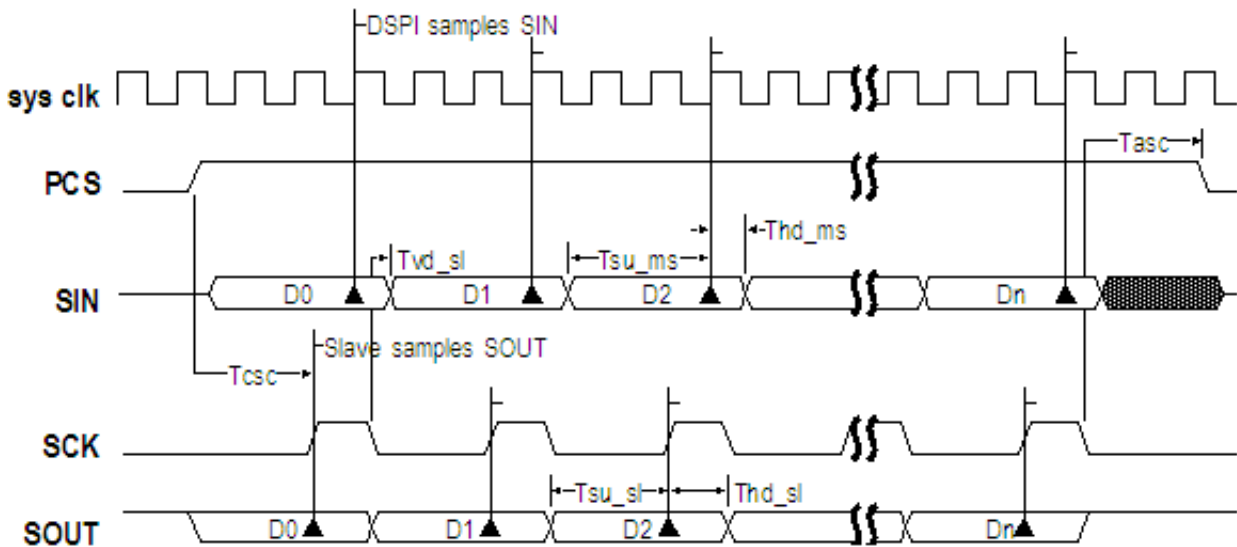

Figure 12-56. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/3$ )

#### 12.4.4.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave

samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

### NOTE

When MTFE=1 with continuous SCK enabled (MCR [CONT\_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSH[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

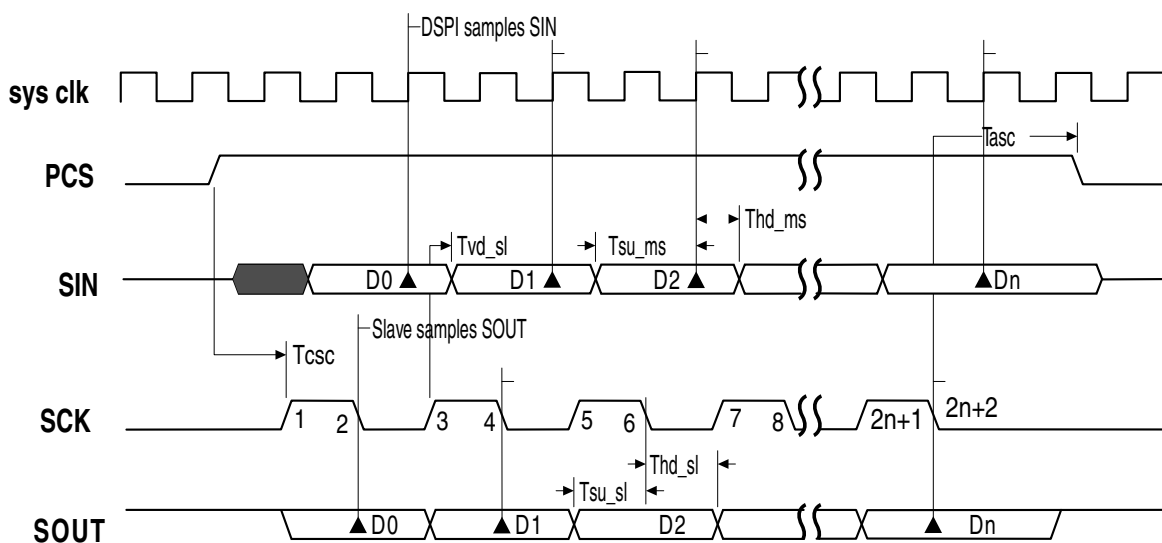

Figure 12-57. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/2$ )

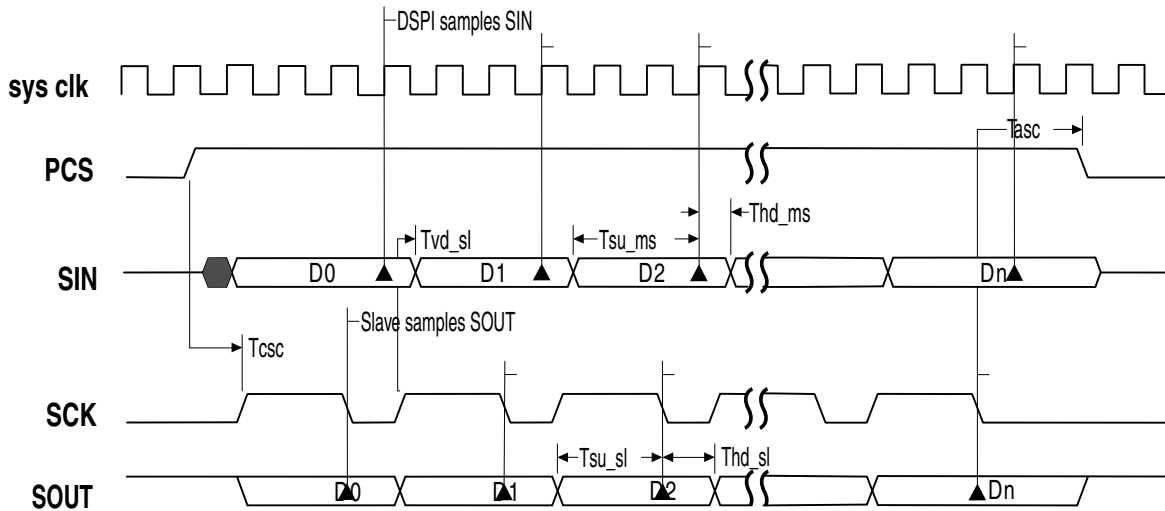

Figure 12-58. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/3$ )

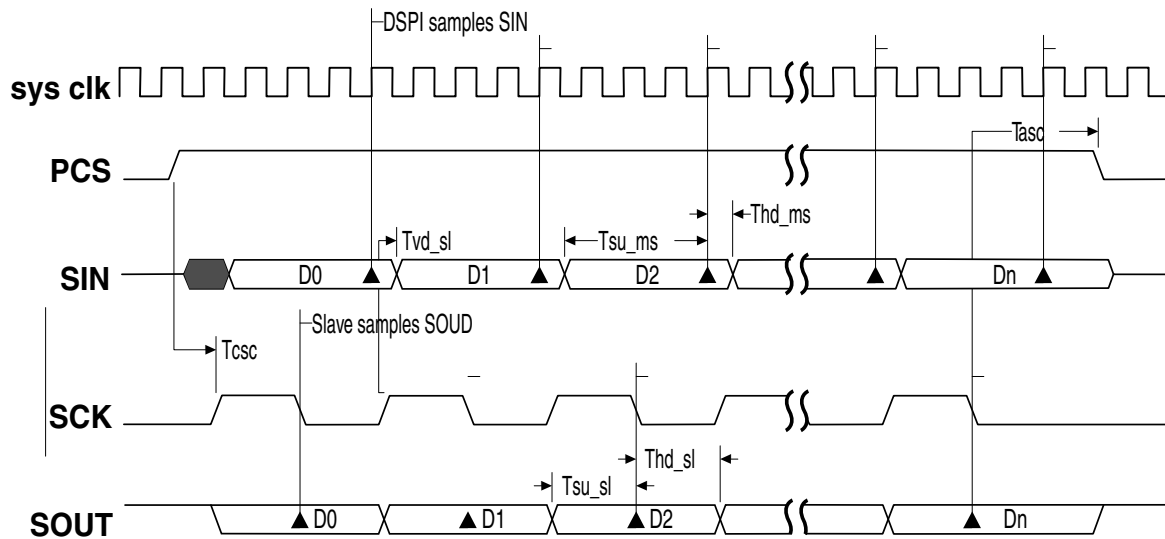

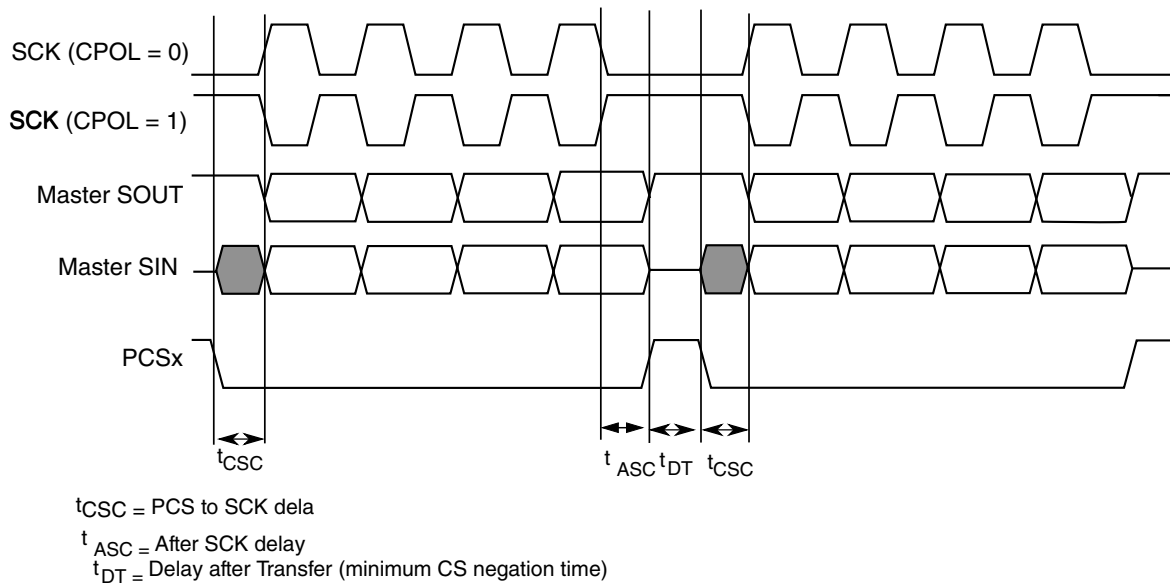

Figure 12-59. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/4$ )

#### 12.4.4.4.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

**Figure 12-60. Example of non-continuous format (CPHA=1, CONT=0)**

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers ( $t_{DT}$ ) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

**Figure 12-61. Example of continuous transfer (CPHA=1, CONT=1)**

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX\_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

### NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

#### 12.4.4.4.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to [Continuous Selection Format](#) except that the inter command delays,  $t_{ASC}$  and  $t_{CSC}$ , can be masked out and are not inserted by the hardware.

### NOTE

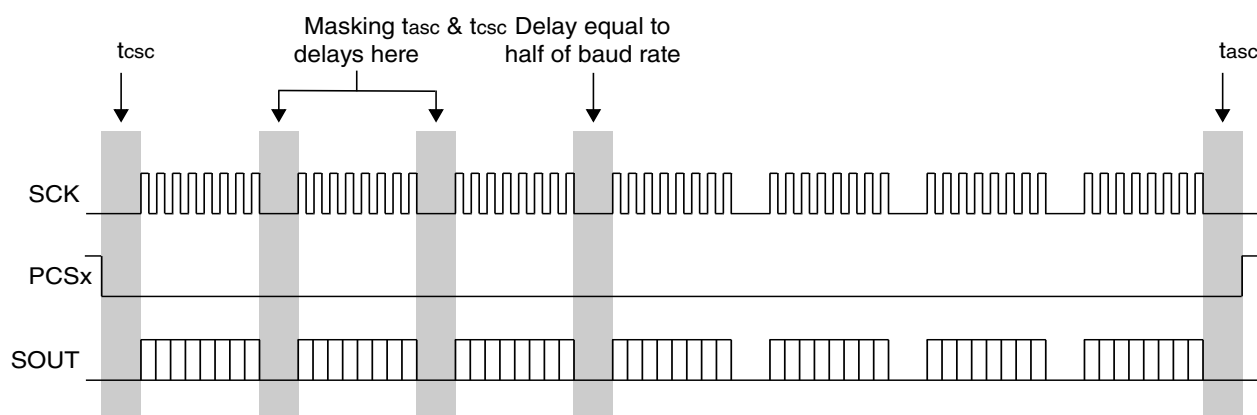

The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing '1' into FCPCS bit of the MCR register. When this bit is asserted, MASC and MCSC bits of the PUSHHR register perform the function of mask bits for the transmit frame. These bits individually mask the  $t_{ASC}$  and  $t_{CSC}$  delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and to speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHHR register.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” ( $t_{ASC}$ ) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only  $t_{ASC}$  is not allowed. If  $t_{ASC}$  is masked then  $t_{CSC}$  must be masked too.
- Masking of both  $t_{ASC}$  and  $t_{CSC}$  delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only  $t_{CSC}$  is allowed. In this case, the delay between two frames is equal to the  $t_{ASC}$  time and thus the user software must ensure that the  $t_{ASC}$  time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here too.

The following figure shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both  $t_{ASC}$  and  $t_{CSC}$  delays masked except for the last frame that terminated the transfer. The last frame has  $t_{ASC}$  delay at its end.

**Figure 12-62. Example of Fast Continuous Selection Format**

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

#### 12.4.4.5 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT\_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT\_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer ( $t_{DT}$ ) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

#### NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR\_TXF] field before initiating transfer.

**Figure 12-63. Continuous SCK Timing Diagram (CONT=0)**

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

**Figure 12-64. Continuous SCK timing diagram (CONT=1)**

### 12.4.4.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the  $\overline{SS}$  signal is asserted and any time when transmit data is ready and  $\overline{SS}$  signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the  $\overline{SS}$  negates before that last SCK edge, the data from shift register is lost.

### 12.4.4.7 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

#### 12.4.4.7.1 Parity for SPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

### 12.4.4.8 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

**Table 12-57. Interrupt and DMA request conditions**

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
Transfer Complete	TCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

#### 12.4.4.8.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF\_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

#### 12.4.4.8.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF\_RE bit in the RSER is set. The TFFF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

#### NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

#### 12.4.4.8.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF\_RE bit is set in the RSER.

#### 12.4.4.8.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF\_RE bit in the RSER is set, an interrupt request is generated.

#### 12.4.4.8.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF\_RE bit in the RSER is set. The RFDF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated. Configure the DMA to drain only one FIFO location per transfer.

#### 12.4.4.8.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF\_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

#### 12.4.4.8.7 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF\_RE bit in the RSER must be set for the interrupt request to be generated.

#### 12.4.4.9 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

##### 12.4.4.9.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not

accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

#### 12.4.4.9.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS\_TXF and DIS\_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

### 12.4.5 Initialization/application information

This section describes how to initialize the module.

#### 12.4.5.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.

3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO by writing a 1 to the CLR\_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR\_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI\_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

### **12.4.5.2 Switching Master and Slave mode**

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR\_TXF and CLR\_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

### 12.4.5.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

### 12.4.5.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

**Table 12-58. Baud rate values (bps)**

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

### 12.4.5.5 Delay settings

The following table shows the values for the Delay after Transfer ( $t_{DT}$ ) and CS to SCK Delay ( $T_{CSC}$ ) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

**NOTE**

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

**Table 12-59. Delay values**

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 $\mu$ s
	32	320.0 ns	960.0 ns	1.6 $\mu$ s	2.2 $\mu$ s
	64	640.0 ns	1.9 $\mu$ s	3.2 $\mu$ s	4.5 $\mu$ s
	128	1.3 $\mu$ s	3.8 $\mu$ s	6.4 $\mu$ s	9.0 $\mu$ s
	256	2.6 $\mu$ s	7.7 $\mu$ s	12.8 $\mu$ s	17.9 $\mu$ s
	512	5.1 $\mu$ s	15.4 $\mu$ s	25.6 $\mu$ s	35.8 $\mu$ s
	1024	10.2 $\mu$ s	30.7 $\mu$ s	51.2 $\mu$ s	71.7 $\mu$ s
	2048	20.5 $\mu$ s	61.4 $\mu$ s	102.4 $\mu$ s	143.4 $\mu$ s
	4096	41.0 $\mu$ s	122.9 $\mu$ s	204.8 $\mu$ s	286.7 $\mu$ s
	8192	81.9 $\mu$ s	245.8 $\mu$ s	409.6 $\mu$ s	573.4 $\mu$ s
	16384	163.8 $\mu$ s	491.5 $\mu$ s	819.2 $\mu$ s	1.1 ms
	32768	327.7 $\mu$ s	983.0 $\mu$ s	1.6 ms	2.3 ms
	65536	655.4 $\mu$ s	2.0 ms	3.3 ms	4.6 ms

### 12.4.5.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 12-65. TX FIFO pointers and counter

#### 12.4.5.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXTPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

#### 12.4.5.6.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

# Chapter 13

## Timers

### 13.1 FlexTimer Module (FTM)

#### 13.1.1 Introduction

##### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

##### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

#### 13.1.1.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the Timer PWM Module – TPM, used for many years on our HCS08 family of 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Fault control inputs
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, fault control, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

More than one FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

### **13.1.1.2 Features**

The FTM features include:

- FTM source clock is selectable.
  - The source clock can be the system clock, the fixed frequency clock, or an external clock
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
  - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter

- It can be a free-running counter or a counter with initial and final value
- The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:
  - The capture can occur on rising edges, falling edges or both edges
  - An input filter can be selected for some channels
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Initialization trigger
- Software control of PWM outputs
- Up to 4 fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions

- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

### 13.1.1.3 Modes of operation

When the chip is in an active BDM mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

### 13.1.1.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CHn (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

#### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

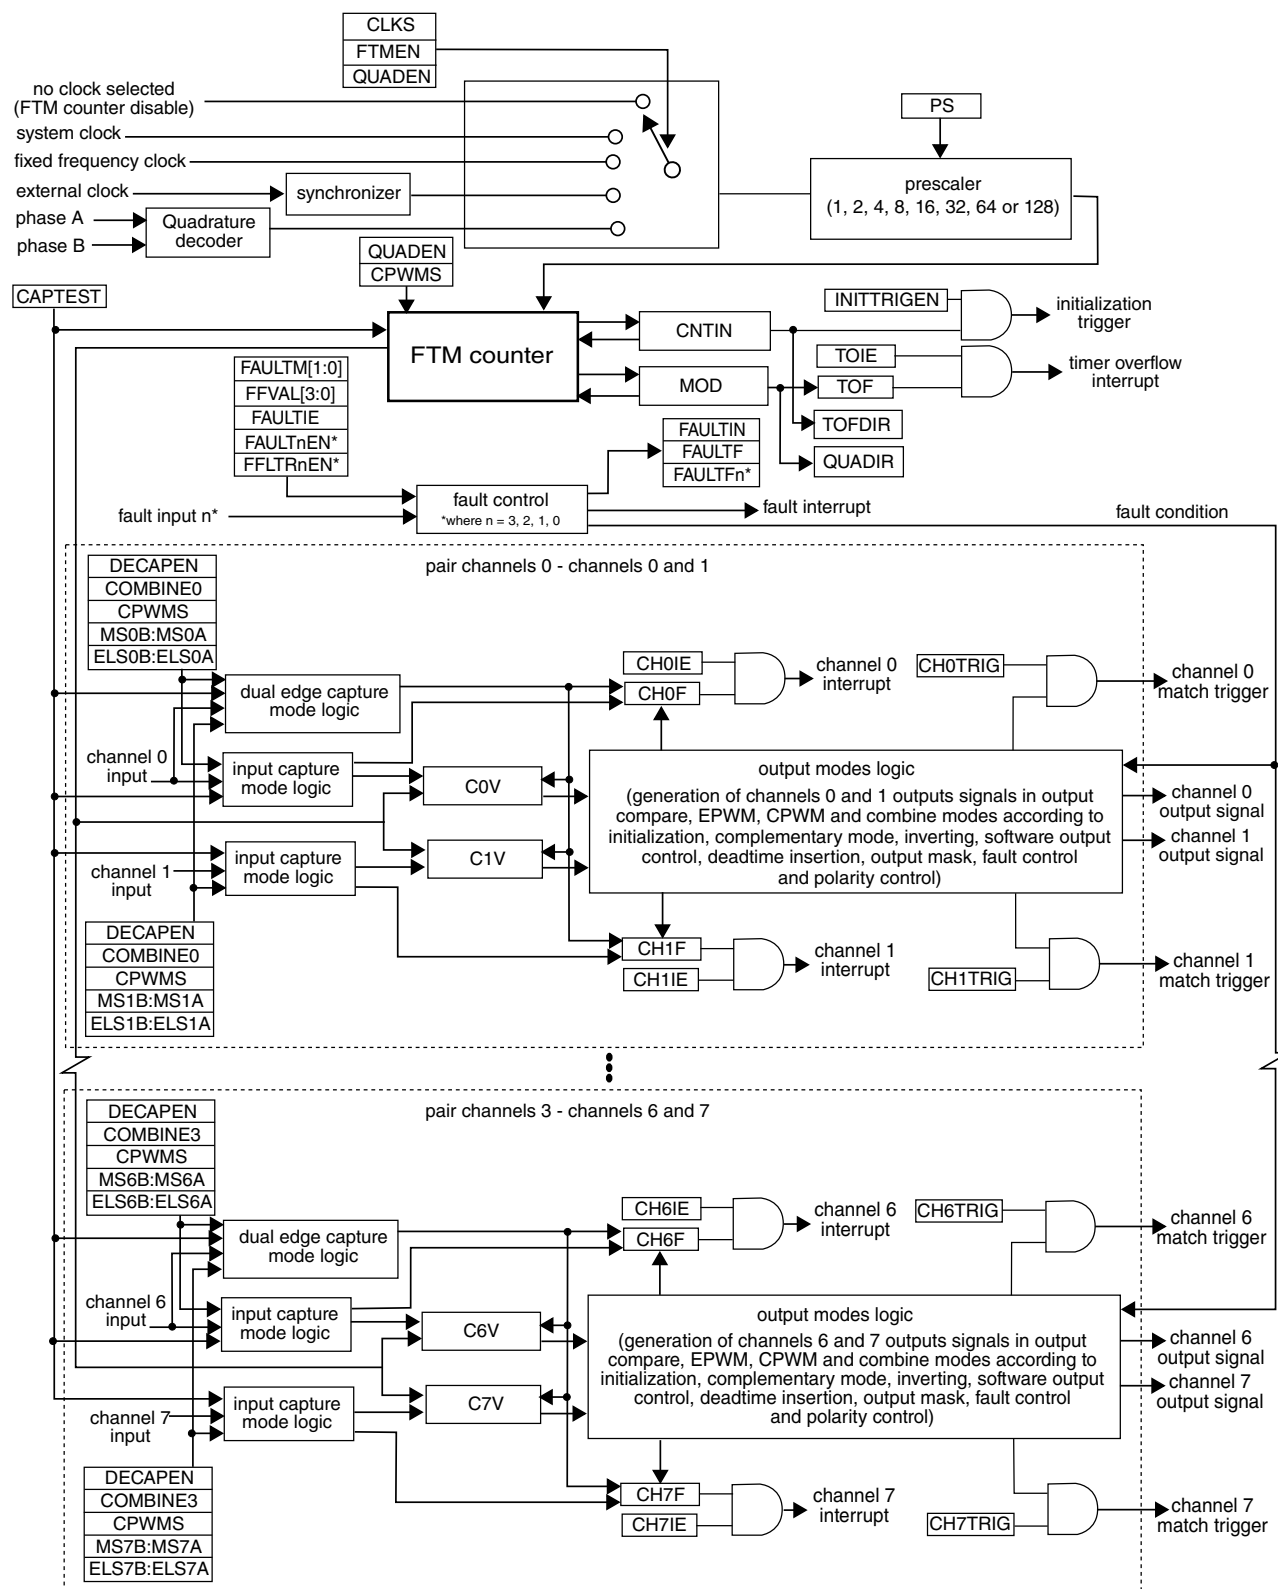

Figure 13-1. FTM block diagram

## 13.1.2 FTM signal descriptions

Table 13-1 shows the user-accessible signals for the FTM.

**Table 13-1. FTM signal descriptions**

Signal	Description	I/O	Function
EXTCLK	External clock. FTM external clock can be selected to drive the FTM counter.	I	The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.
CHn	FTM channel (n), where n can be 7-0	I/O	Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.
FAULTj	Fault input (j), where j can be 3-0	I	The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINEm register. Note that each FAULTj input may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Because there are several FAULTj inputs, maximum of 4 for the FTM module, each one of these inputs is activated by the FAULTJEN bit in the FLTCTRL register.
PHA	Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A.	I	The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .
PHB	Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B.	I	The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .

## 13.1.3 Memory map and register definition

### 13.1.3.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

**Note**

Do not write in the region from the CNTIN register through the PWMLOAD register when FTMEN = 0.

**NOTE**

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

**13.1.3.2 Register descriptions**

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

PS	<p>Prescale Factor Selection</p> <p>Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits. This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128</p>

**13.1.3.4 Counter (FTMx\_CNT)**

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter Value

**13.1.3.5 Modulo (FTMx\_MOD)**

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see [Counter](#).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset

Field	Description
5 MSB	Channel Mode Select  Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See <a href="#">Table 13-2</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
4 MSA	Channel Mode Select  Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See <a href="#">Table 13-2</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
3 ELSB	Edge or Level Select  The functionality of ELSB and ELSA depends on the channel mode. See <a href="#">Table 13-2</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
2 ELSA	Edge or Level Select  The functionality of ELSB and ELSA depends on the channel mode. See <a href="#">Table 13-2</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DMA	DMA Enable  Enables DMA transfers for the channel.  0    Disable DMA transfers. 1    Enable DMA transfers.

**13.1.3.7 Channel (n) Value (FTMx\_CnV)**

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
VAL	Channel Value  Captured FTM counter value of the input modes or the match value for the output modes

### 13.1.3.8 Counter Initial Value (FTMx\_CNTIN)

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### FTMx\_CNTIN field descriptions

Field	Description
31–16 Reserved	This field is reserved.
INIT	Initial Value Of The FTM Counter

### 13.1.3.9 Capture And Compare Status (FTMx\_STATUS)

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

Address: Base address + 50h offset

**13.1.3.10 Features Mode Selection (FTMx\_MODE)**

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Fault control mode and interrupt
- Capture Test mode
- PWM synchronization

## FlexTimer Module (FTM)

- Write protection
- Channel output initialization

These controls relate to all channels within this module.

Address: Base address + 54h offset

### FTMx\_MODE field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 FAULTIE	Fault Interrupt Enable  Enables the generation of an interrupt when a fault is detected by FTM and the FTM fault control is enabled.  0 Fault control interrupt is disabled. 1 Fault control interrupt is enabled.
6–5 FAULTM	Fault Control Mode  Defines the FTM fault control mode.  This field is write protected. It can be written only when MODE[WPDIS] = 1.  00 Fault control is disabled for all channels. 01 Fault control is enabled for even channels only (channels 0, 2, 4, and 6), and the selected mode is the manual fault clearing. 10 Fault control is enabled for all channels, and the selected mode is the manual fault clearing. 11 Fault control is enabled for all channels, and the selected mode is the automatic fault clearing.
4 CAPTEST	Capture Test Mode Enable  Enables the capture test mode.  This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 Capture test mode is disabled. 1 Capture test mode is enabled.
3 PWMSYNC	PWM Synchronization Mode

Table continues on the next page...

**FTMx\_MODE field descriptions (continued)**

Field	Description
	<p>Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See <a href="#">PWM synchronization</a>. The PWMSYNC bit configures the synchronization when SYNCMODE is 0.</p> <p>0 No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization.</p> <p>1 Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.</p>
2 WPDIS	<p>Write Protection Disable</p> <p>When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect.</p> <p>0 Write protection is enabled.</p> <p>1 Write protection is disabled.</p>
1 INIT	<p>Initialize The Channels Output</p> <p>When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect.</p> <p>The INIT bit is always read as 0.</p>
0 FTMEN	<p>FTM Enable</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 TPM compatibility. Free running counter and synchronization compatible with TPM.</p> <p>1 Free running counter and synchronization are different from TPM behavior.</p>

**13.1.3.11 Synchronization (FTMx\_SYNC)**

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

**NOTE**

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See [PWM synchronization](#).

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWSYNC	PWM Synchronization Software Trigger  Selects the software trigger as the PWM synchronization trigger. The software trigger happens when a 1 is written to SWSYNC bit.  0 Software trigger is not selected. 1 Software trigger is selected.
6 TRIG2	PWM Synchronization Hardware Trigger 2  Enables hardware trigger 2 to the PWM synchronization. Hardware trigger 2 happens when a rising edge is detected at the trigger 2 input signal.  0 Trigger is disabled. 1 Trigger is enabled.
5 TRIG1	PWM Synchronization Hardware Trigger 1  Enables hardware trigger 1 to the PWM synchronization. Hardware trigger 1 happens when a rising edge is detected at the trigger 1 input signal.

Table continues on the next page...

## FTMx\_SYNC field descriptions (continued)

Field	Description
	0 Trigger is disabled. 1 Trigger is enabled.
4 TRIG0	PWM Synchronization Hardware Trigger 0  Enables hardware trigger 0 to the PWM synchronization. Hardware trigger 0 occurs when a rising edge is detected at the trigger 0 input signal.  0 Trigger is disabled. 1 Trigger is enabled.
3 SYNCHOM	Output Mask Synchronization  Selects when the OUTMASK register is updated with the value of its buffer.  0 OUTMASK register is updated with the value of its buffer in all rising edges of the system clock. 1 OUTMASK register is updated with the value of its buffer only by the PWM synchronization.
2 REINIT	FTM Counter Reinitialization By Synchronization ( <a href="#">FTM counter synchronization</a> )  Determines if the FTM counter is reinitialized when the selected trigger for the synchronization is detected. The REINIT bit configures the synchronization when SYNCMODE is zero.  0 FTM counter continues to count normally. 1 FTM counter is updated with its initial value when the selected trigger is detected.
1 CNTMAX	Maximum Loading Point Enable  Selects the maximum loading point to PWM synchronization. See <a href="#">Boundary cycle and loading points</a> . If CNTMAX is 1, the selected loading point is when the FTM counter reaches its maximum value (MOD register).  0 The maximum loading point is disabled. 1 The maximum loading point is enabled.
0 CNTMIN	Minimum Loading Point Enable  Selects the minimum loading point to PWM synchronization. See <a href="#">Boundary cycle and loading points</a> . If CNTMIN is one, the selected loading point is when the FTM counter reaches its minimum value (CNTIN register).  0 The minimum loading point is disabled. 1 The minimum loading point is enabled.

0 CH0OI	Channel 0 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.

## 13.1.3.13 Output Mask (FTMx\_OUTMASK)

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

4 CH4OM	Channel 4 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
3 CH3OM	Channel 3 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
2 CH2OM	Channel 2 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
1 CH1OM	Channel 1 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
0 CH0OM	Channel 0 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.

### 13.1.3.14 Function For Linked Channels (FTMx\_COMBINE)

This register contains the control bits used to configure the fault control, synchronization, deadtime insertion, Dual Edge Capture mode, Complementary, and Combine mode for each pair of channels (n) and (n+1), where n equals 0, 2, 4, and 6.

Address: Base address + 64h offset

#### FTMx\_COMBINE field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FAULTEN3	Fault Control Enable For n = 6 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
29 SYNCEN3	Synchronization Enable For n = 6 Enables PWM synchronization of registers C(n)V and C(n+1)V.  0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
28 DTEN3	Deadtime Enable For n = 6 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1.

It can be written only when MODE[WPDIS] = 1.</p> <p>0 The deadtime insertion in this pair of channels is disabled.</p> <p>1 The deadtime insertion in this pair of channels is enabled.</p>
11 DECAP1	<p>Dual Edge Capture Mode Captures For n = 2</p> <p>Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits.</p> <p>This field applies only when DECAPEN = 1.</p> <p>DECAP bit is cleared automatically by hardware if Dual Edge Capture – One-Shot mode is selected and when the capture of channel (n+1) event is made.</p> <p>0 The dual edge captures are inactive.</p> <p>1 The dual edge captures are active.</p>
10 DECAPEN1	<p>Dual Edge Capture Mode Enable For n = 2</p> <p>Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to <a href="#">Table 13-2</a>.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 The Dual Edge Capture mode in this pair of channels is disabled.</p> <p>1 The Dual Edge Capture mode in this pair of channels is enabled.</p>
9 COMP1	<p>Complement Of Channel (n) For n = 2</p> <p>Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 The channel (n+1) output is the same as the channel (n) output.</p> <p>1 The channel (n+1) output is the complement of the channel (n) output.</p>
8 COMBINE1	<p>Combine Channels For n = 2</p> <p>Enables the combine feature for channels (n) and (n+1).</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Channels (n) and (n+1) are independent.</p> <p>1 Channels (n) and (n+1) are combined.</p>

Table continues on the next page...

## FTMx\_COMBINE field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FAULTEN0	Fault Control Enable For n = 0  Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
5 SYNCEN0	Synchronization Enable For n = 0  Enables PWM synchronization of registers C(n)V and C(n+1)V.  0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
4 DTEN0	Deadtime Enable For n = 0  Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
3 DECAP0	Dual Edge Capture Mode Captures For n = 0  Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made.  0 The dual edge captures are inactive. 1 The dual edge captures are active.
2 DECAPEN0	Dual Edge Capture Mode Enable For n = 0  Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to <a href="#">Table 13-2</a> . This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
1 COMP0	Complement Of Channel (n) For n = 0  Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.

*Table continues on the next page...*

**FTMx\_COMBINE field descriptions (continued)**

Field	Description
0 COMBINE0	<p>Combine Channels For <math>n = 0</math></p> <p>Enables the combine feature for channels (n) and (n+1).</p> <p>This field is write protected. It can be written only when <math>MODE[WPDIS] = 1</math>.</p> <p>0 Channels (n) and (n+1) are independent.  1 Channels (n) and (n+1) are combined.</p>

**13.1.3.15 Deadtime Insertion Control (FTMx\_DEADTIME)**

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																								DTPS		DTVAL

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**FTMx\_DEADTIME field descriptions**

Field	Description
31–8 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
7–6 DTPS	<p>Deadtime Prescaler Value</p> <p>Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter.</p> <p>This field is write protected. It can be written only when <math>MODE[WPDIS] = 1</math>.</p> <p>0x Divide the system clock by 1.  10 Divide the system clock by 4.  11 Divide the system clock by 16.</p>
DTVAL	<p>Deadtime Value</p> <p>Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS.</p> <p>Deadtime insert value = <math>(DTPS \times DTVAL)</math>.</p> <p>DTVAL selects the number of deadtime counts inserted as follows:</p> <p>When DTVAL is 0, no counts are inserted.  When DTVAL is 1, 1 count is inserted.  When DTVAL is 2, 2 counts are inserted.</p> <p>This pattern continues up to a possible 63 counts.</p> <p>This field is write protected. It can be written only when <math>MODE[WPDIS] = 1</math>.</p>

### 13.1.3.16 FTM External Trigger (FTMx\_EXTTRIG)

This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period. See [Channel trigger output](#) and [Initialization trigger](#).

Channels 6 and 7 are not used to generate channel triggers.

Address: Base address + 6Ch offset

## FTMx\_EXTTRIG field descriptions

Field	Description
31–8 Reserved	This field is reserved.
7 TRIGF	<p>Channel Trigger Flag</p> <p>Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect.</p> <p>If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF.</p> <p>0 No channel trigger was generated. 1 A channel trigger was generated.</p>
6 INITTRIGEN	<p>Initialization Trigger Enable</p> <p>Enables the generation of the trigger when the FTM counter is equal to the CNTIN register.</p> <p>0 The generation of initialization trigger is disabled. 1 The generation of initialization trigger is enabled.</p>
5 CH1TRIG	<p>Channel 1 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.</p>
4 CH0TRIG	<p>Channel 0 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.</p>
3 CH5TRIG	<p>Channel 5 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.</p>
2 CH4TRIG	<p>Channel 4 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.</p>
1 CH3TRIG	<p>Channel 3 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.</p>
0 CH2TRIG	<p>Channel 2 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p>

*Table continues on the next page...*

**FTMx\_EXTTRIG field descriptions (continued)**

Field	Description
0	The generation of the channel trigger is disabled.
1	The generation of the channel trigger is enabled.

**13.1.3.17 Channels Polarity (FTMx\_POL)**

This register defines the output polarity of the FTM channels.

**NOTE**

The safe value that is driven in a channel output when the fault control is enabled and a fault condition is detected is the inactive state of the channel. That is, the safe value of a channel is the value of its POL bit.

Address: Base address + 70h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**FTMx\_POL field descriptions**

Field	Description
31–8 Reserved	This field is reserved.
7 POL7	Channel 7 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
6 POL6	Channel 6 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
5 POL5	Channel 5 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1.

*Table continues on the next page...*

**FTMx\_POL field descriptions (continued)**

Field	Description
	0 The channel polarity is active high. 1 The channel polarity is active low.
4 POL4	Channel 4 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
3 POL3	Channel 3 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
2 POL2	Channel 2 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
1 POL1	Channel 1 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
0 POL0	Channel 0 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.

### 13.1.3.18 Fault Mode Status (FTMx\_FMS)

This register contains the fault detection flags, write protection enable bit, and the logic OR of the enabled fault inputs.

Address: Base address + 74h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

R	0								FAULTF	WPEN	FAULTIN	0	FAULTF3	FAULTF2	FAULTF1	FAULTF0
W									0				0	0	0	0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**FTMx\_FMS field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 FAULTF	<p>Fault Detection Flag</p> <p>Represents the logic OR of the individual FAULTFj bits where j = 3, 2, 1, 0. Clear FAULTF by reading the FMS register while FAULTF is set and then writing a 0 to FAULTF while there is no existing fault condition at the enabled fault inputs. Writing a 1 to FAULTF has no effect.</p> <p>If another fault condition is detected in an enabled fault input before the clearing sequence is completed, the sequence is reset so FAULTF remains set after the clearing sequence is completed for the earlier fault condition. FAULTF is also cleared when FAULTFj bits are cleared individually.</p> <p>0 No fault condition was detected. 1 A fault condition was detected.</p>

*Table continues on the next page...*

## FTMx\_FMS field descriptions (continued)

Field	Description
6 WPEN	<p>Write Protection Enable</p> <p>The WPEN bit is the negation of the WPDIS bit. WPEN is set when 1 is written to it. WPEN is cleared when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPEN has no effect.</p> <p>0 Write protection is disabled. Write protected bits can be written. 1 Write protection is enabled. Write protected bits cannot be written.</p>
5 FAULTIN	<p>Fault Inputs</p> <p>Represents the logic OR of the enabled fault inputs after their filter (if their filter is enabled) when fault control is enabled.</p> <p>0 The logic OR of the enabled fault inputs is 0. 1 The logic OR of the enabled fault inputs is 1.</p>
4 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
3 FAULTF3	<p>Fault Detection Flag 3</p> <p>Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input.</p> <p>Clear FAULTF3 by reading the FMS register while FAULTF3 is set and then writing a 0 to FAULTF3 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF3 has no effect. FAULTF3 bit is also cleared when FAULTF bit is cleared.</p> <p>If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF3 remains set after the clearing sequence is completed for the earlier fault condition.</p> <p>0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.</p>
2 FAULTF2	<p>Fault Detection Flag 2</p> <p>Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input.</p> <p>Clear FAULTF2 by reading the FMS register while FAULTF2 is set and then writing a 0 to FAULTF2 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF2 has no effect. FAULTF2 bit is also cleared when FAULTF bit is cleared.</p> <p>If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF2 remains set after the clearing sequence is completed for the earlier fault condition.</p> <p>0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.</p>
1 FAULTF1	<p>Fault Detection Flag 1</p> <p>Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input.</p> <p>Clear FAULTF1 by reading the FMS register while FAULTF1 is set and then writing a 0 to FAULTF1 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF1 has no effect. FAULTF1 bit is also cleared when FAULTF bit is cleared.</p>

*Table continues on the next page...*

**FTMx\_FMS field descriptions (continued)**

Field	Description
	<p>If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF1 remains set after the clearing sequence is completed for the earlier fault condition.</p> <p>0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.</p>
0 FAULTF0	<p>Fault Detection Flag 0</p> <p>Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input.</p> <p>Clear FAULTF0 by reading the FMS register while FAULTF0 is set and then writing a 0 to FAULTF0 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF0 has no effect. FAULTF0 bit is also cleared when FAULTF bit is cleared.</p> <p>If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF0 remains set after the clearing sequence is completed for the earlier fault condition.</p> <p>0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.</p>

**13.1.3.19 Input Capture Filter Control (FTMx\_FILTER)**

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

**NOTE**

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

Address: Base address + 78h offset

FTMx\_FLTCTRL field descriptions (continued)

Field	Description
	0 Fault input is disabled. 1 Fault input is enabled.
0 FAULT0EN	Fault Input 0 Enable Enables the fault input. This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 Fault input is disabled. 1 Fault input is enabled.

13.1.3.21 Quadrature Decoder Control And Status (FTMx\_QDCTRL)

This register has the control and status bits for the Quadrature Decoder mode.

Address: Base address + 80h offset

**FTMx\_QDCTRL field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PHAFLTREN	Phase A Input Filter Enable  Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero.  0 Phase A input filter is disabled. 1 Phase A input filter is enabled.
6 PHBFLTREN	Phase B Input Filter Enable  Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero.  0 Phase B input filter is disabled. 1 Phase B input filter is enabled.
5 PHAPOL	Phase A Input Polarity  Selects the polarity for the quadrature decoder phase A input.  0 Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.
4 PHBPOL	Phase B Input Polarity  Selects the polarity for the quadrature decoder phase B input.  0 Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.
3 QUADMODE	Quadrature Decoder Mode  Selects the encoding mode used in the Quadrature Decoder mode.  0 Phase A and phase B encoding mode. 1 Count and direction encoding mode.
2 QUADIR	FTM Counter Direction In Quadrature Decoder Mode  Indicates the counting direction.  0 Counting direction is decreasing (FTM counter decrement). 1 Counting direction is increasing (FTM counter increment).
1 TOFDIR	Timer Overflow Direction In Quadrature Decoder Mode  Indicates if the TOF bit was set on the top or the bottom of counting.  0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register). 1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).

*Table continues on the next page...*

**FTMx\_QDCTRL field descriptions (continued)**

Field	Description
0 QUADEN	<p>Quadrature Decoder Mode Enable</p> <p>Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See <a href="#">Table 13-2</a>.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Quadrature Decoder mode is disabled. 1 Quadrature Decoder mode is enabled.</p>

**13.1.3.22 Configuration (FTMx\_CONF)**

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**FTMx\_CONF field descriptions**

Field	Description
31–11 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
10 GTBEOUT	<p>Global Time Base Output</p> <p>Enables the global time base signal generation to other FTMs.</p> <p>0 A global time base signal generation is disabled. 1 A global time base signal generation is enabled.</p>
9 GTBEEN	Global Time Base Enable

Table continues on the next page...

## FTMx\_CONF field descriptions (continued)

Field	Description
	Configures the FTM to use an external global time base signal that is generated by another FTM. 0 Use of an external global time base is disabled. 1 Use of an external global time base is enabled.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 BDMODE	BDM Mode Selects the FTM behavior in BDM mode. See <a href="#">BDM mode</a> .
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
NUMTOF	TOF Frequency Selects the ratio between the number of counter overflows to the number of times the TOF bit is set. NUMTOF = 0: The TOF bit is set for each counter overflow. NUMTOF = 1: The TOF bit is set for the first counter overflow but not for the next overflow. NUMTOF = 2: The TOF bit is set for the first counter overflow but not for the next 2 overflows. NUMTOF = 3: The TOF bit is set for the first counter overflow but not for the next 3 overflows. This pattern continues up to a maximum of 31.

## 13.1.3.23 FTM Fault Input Polarity (FTMx\_FLTPOL)

This register defines the fault inputs polarity.

Address: Base address + 88h offset

**FTMx\_SYNCONF field descriptions**

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 HWSOC	Software output control synchronization is activated by a hardware trigger. 0 A hardware trigger does not activate the SWOCTRL register synchronization. 1 A hardware trigger activates the SWOCTRL register synchronization.
19 HWINVC	Inverting control synchronization is activated by a hardware trigger. 0 A hardware trigger does not activate the INVCTRL register synchronization. 1 A hardware trigger activates the INVCTRL register synchronization.
18 HWOM	Output mask synchronization is activated by a hardware trigger. 0 A hardware trigger does not activate the OUTMASK register synchronization. 1 A hardware trigger activates the OUTMASK register synchronization.
17 HWWRBUF	MOD, CNTIN, and CV registers synchronization is activated by a hardware trigger. 0 A hardware trigger does not activate MOD, CNTIN, and CV registers synchronization. 1 A hardware trigger activates MOD, CNTIN, and CV registers synchronization.
16 HWRSTCNT	FTM counter synchronization is activated by a hardware trigger. 0 A hardware trigger does not activate the FTM counter synchronization. 1 A hardware trigger activates the FTM counter synchronization.

*Table continues on the next page...*

**FTMx\_SYNCONF field descriptions (continued)**

Field	Description
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 SWSOC	Software output control synchronization is activated by the software trigger. 0 The software trigger does not activate the SWOCTRL register synchronization. 1 The software trigger activates the SWOCTRL register synchronization.
11 SWINVC	Inverting control synchronization is activated by the software trigger. 0 The software trigger does not activate the INVCTRL register synchronization. 1 The software trigger activates the INVCTRL register synchronization.
10 SWOM	Output mask synchronization is activated by the software trigger. 0 The software trigger does not activate the OUTMASK register synchronization. 1 The software trigger activates the OUTMASK register synchronization.
9 SWWRBUF	MOD, CNTIN, and CV registers synchronization is activated by the software trigger. 0 The software trigger does not activate MOD, CNTIN, and CV registers synchronization. 1 The software trigger activates MOD, CNTIN, and CV registers synchronization.
8 SWRSTCNT	FTM counter synchronization is activated by the software trigger. 0 The software trigger does not activate the FTM counter synchronization. 1 The software trigger activates the FTM counter synchronization.
7 SYNCMODE	Synchronization Mode Selects the PWM Synchronization mode. 0 Legacy PWM synchronization is selected. 1 Enhanced PWM synchronization is selected.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SWOC	SWOCTRL Register Synchronization 0 SWOCTRL register is updated with its buffer value at all rising edges of system clock. 1 SWOCTRL register is updated with its buffer value by the PWM synchronization.
4 INVC	INVCTRL Register Synchronization 0 INVCTRL register is updated with its buffer value at all rising edges of system clock. 1 INVCTRL register is updated with its buffer value by the PWM synchronization.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CNTINC	CNTIN Register Synchronization 0 CNTIN register is updated with its buffer value at all rising edges of system clock. 1 CNTIN register is updated with its buffer value by the PWM synchronization.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 HWTRIGMODE	Hardware Trigger Mode

*Table continues on the next page...*

**FTMx\_SYNCONF field descriptions (continued)**

Field	Description
0	FTM clears the TRIGj bit when the hardware trigger j is detected, where j = 0, 1,2.
1	FTM does not clear the TRIGj bit when the hardware trigger j is detected, where j = 0, 1,2.

**13.1.3.25 FTM Inverting Control (FTMx\_INVCTRL)**

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

Address: Base address + 90h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**FTMx\_INVCTRL field descriptions**

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 INV3EN	Pair Channels 3 Inverting Enable  0 Inverting is disabled. 1 Inverting is enabled.
2 INV2EN	Pair Channels 2 Inverting Enable  0 Inverting is disabled. 1 Inverting is enabled.
1 INV1EN	Pair Channels 1 Inverting Enable  0 Inverting is disabled. 1 Inverting is enabled.

Table continues on the next page...

**FTMx\_INVCTRL field descriptions (continued)**

Field	Description
0 INV0EN	Pair Channels 0 Inverting Enable  0 Inverting is disabled. 1 Inverting is enabled.

**13.1.3.26 FTM Software Output Control (FTMx\_SWOCTRL)**

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

Address: Base address + 94h offset

0 CH0SEL	Channel 0 Select 0 Do not include the channel in the matching process. 1 Include the channel in the matching process.

**13.1.4 Functional description**

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

**FlexTimer Module (FTM)**

FTM counting is up.  
Channel (n) is in high-true EPWM mode.  
PS[2:0] = 001  
CNTIN = 0x0000  
MOD = 0x0004  
CnV = 0x0002

**Figure 13-2. Notation used**

**13.1.4.1 Clock source**

The FTM has only one clock domain: the system clock.

**13.1.4.1.1 Counter clock source**

The CLKS[1:0] bits in the SC register selects clock sources for the FTM counter or disables the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

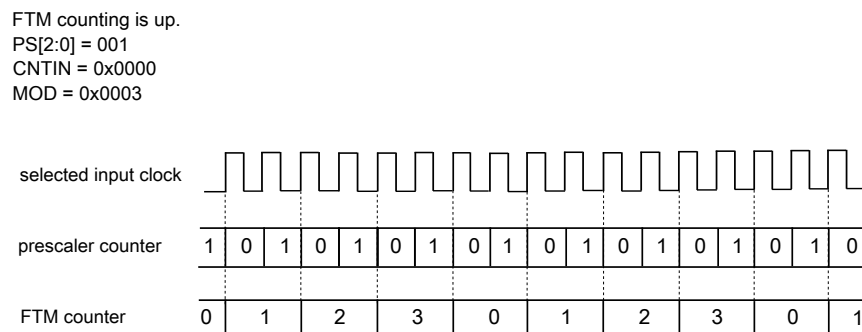

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration; see the chip-specific FTM information for further details. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to assure that counter transitions are properly aligned to system clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

### 13.1.4.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

**Figure 13-3. Example of the prescaler counter**

### 13.1.4.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- [Up counting](#)
- [Up-down counting](#)
- [Quadrature Decoder mode](#)

#### 13.1.4.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is  $(MOD - CNTIN + 0x0001) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

FTM counting is up.  
CNTIN = 0xFFFFC (in two's complement is equal to -4)  
MOD = 0x0004

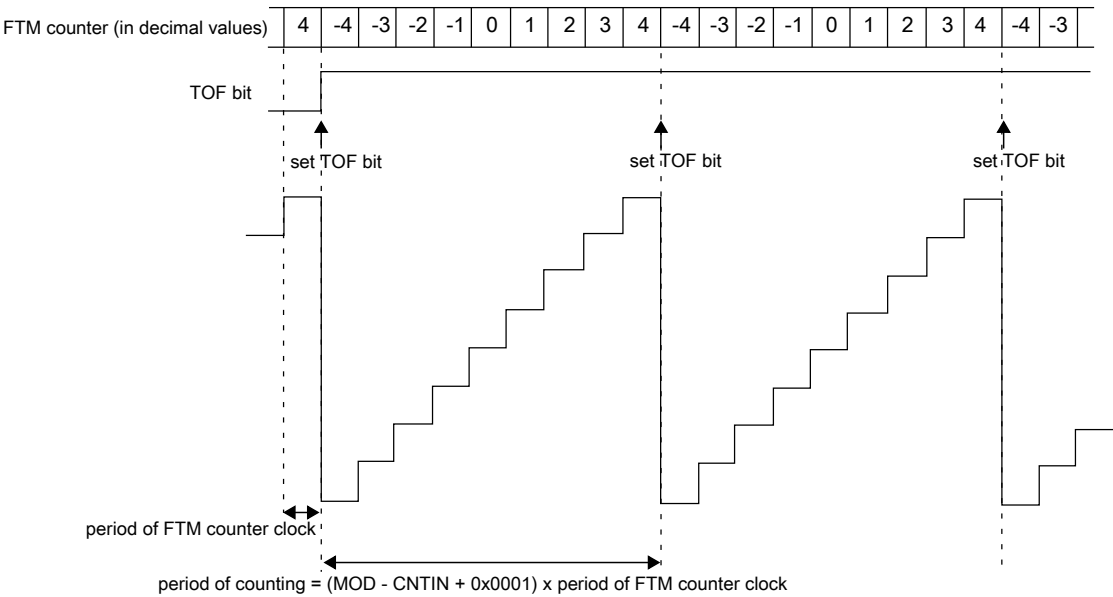

Figure 13-4. Example of FTM up and signed counting

Table 13-4. FTM counting based on CNTIN value

When	Then
CNTIN = 0x0000	The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.
CNTIN[15] = 1	The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed.
CNTIN[15] = 0 and CNTIN ≠ 0x0000	The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.

FTM counting is up

CNTIN = 0x0000

MOD = 0x0004

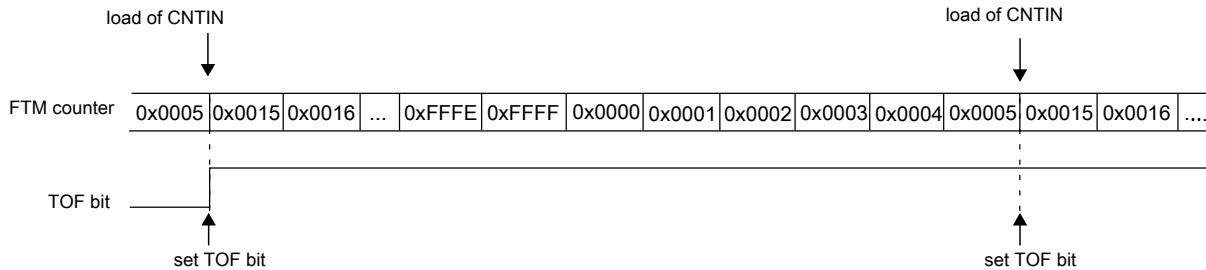

**Figure 13-5. Example of FTM up counting with CNTIN = 0x0000**

### Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

FTM counting is up  
 MOD = 0x0005  
 CNTIN = 0x0015

**Figure 13-6. Example of up counting when the value of CNTIN is greater than the value of MOD**

### 13.1.4.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

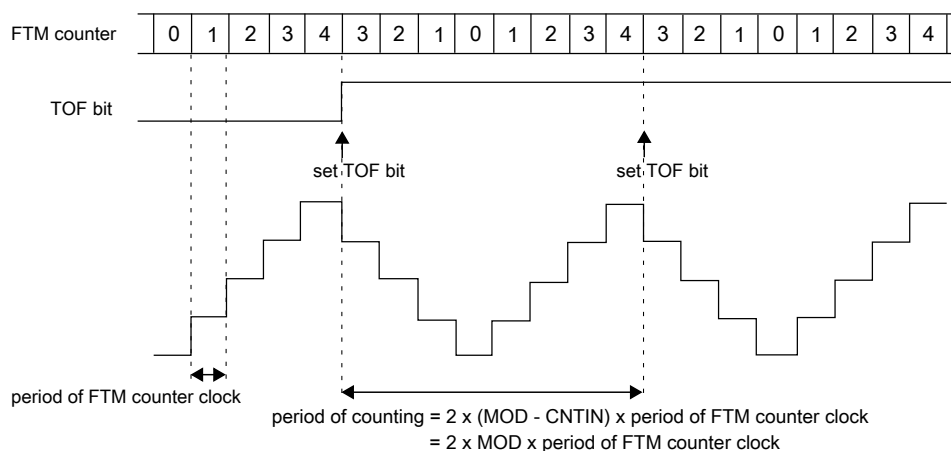

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is  $2 \times (\text{MOD} - \text{CNTIN}) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

FTM counting is up-down  
 CNTIN = 0x0000  
 MOD = 0x0004

**Figure 13-7. Example of up-down counting when CNTIN = 0x0000**

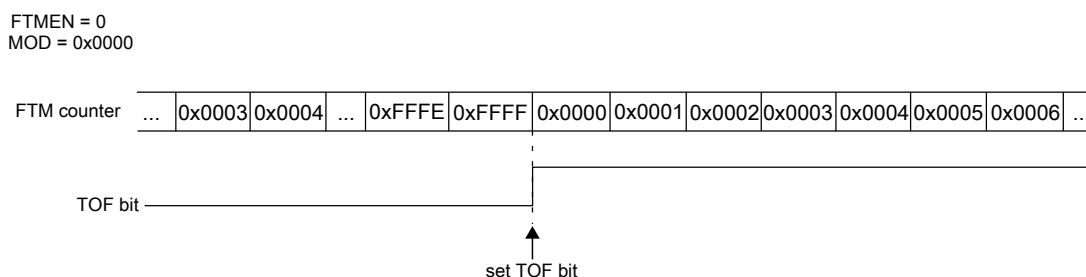

### Note

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if  $\text{CnV} > \text{CNTIN}$ , or
- if  $\text{CnV} = 0$  or if  $\text{CnV}[15] = 1$ . In this case, 0% CPWM is generated.

#### 13.1.4.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

**Figure 13-8. Example when the FTM counter is free running**

The FTM counter is also a free running counter when:

- FTMEN = 1

- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

#### 13.1.4.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- [FTM counter synchronization](#).

#### 13.1.4.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

**Figure 13-9. Periodic TOF when NUMTOF = 0x02**

**Figure 13-10. Periodic TOF when NUMTOF = 0x00**

### 13.1.4.4 Input Capture mode

The Input Capture mode is selected when:

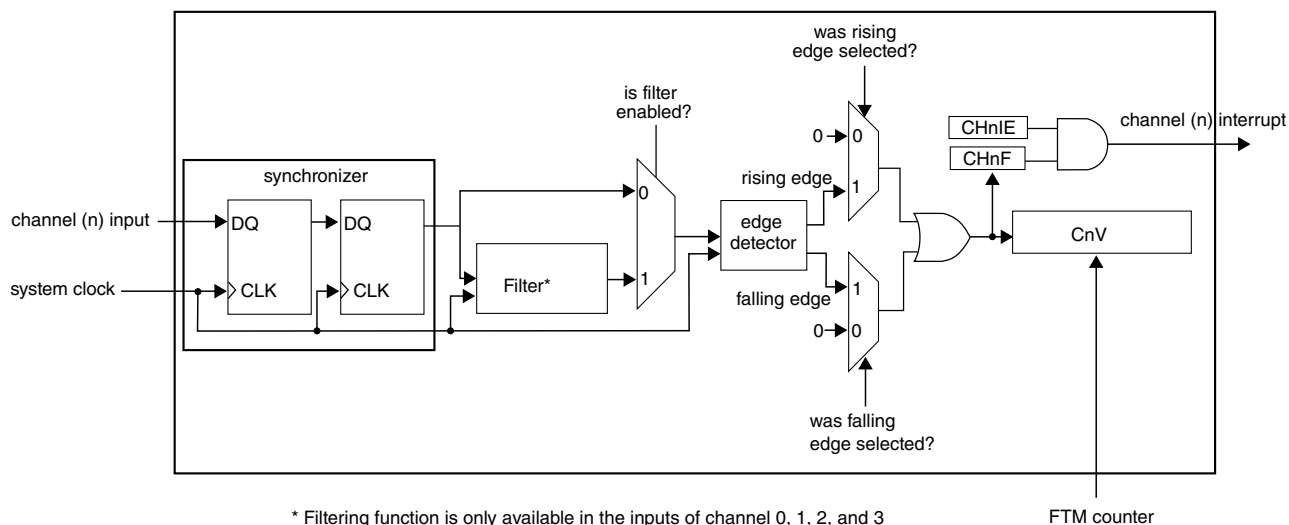

- $DECAPEN = 0$
- $COMBINE = 0$
- $CPWMS = 0$
- $MSnB:MSnA = 0:0$ , and
- $ELSnB:ELSnA \neq 0:0$

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

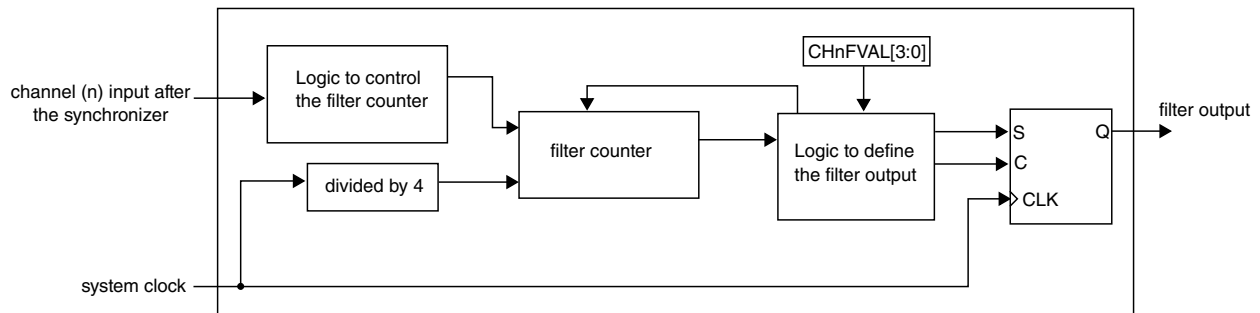

**Figure 13-11. Input Capture mode**

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

#### 13.1.4.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

**Figure 13-12. Channel input filter**

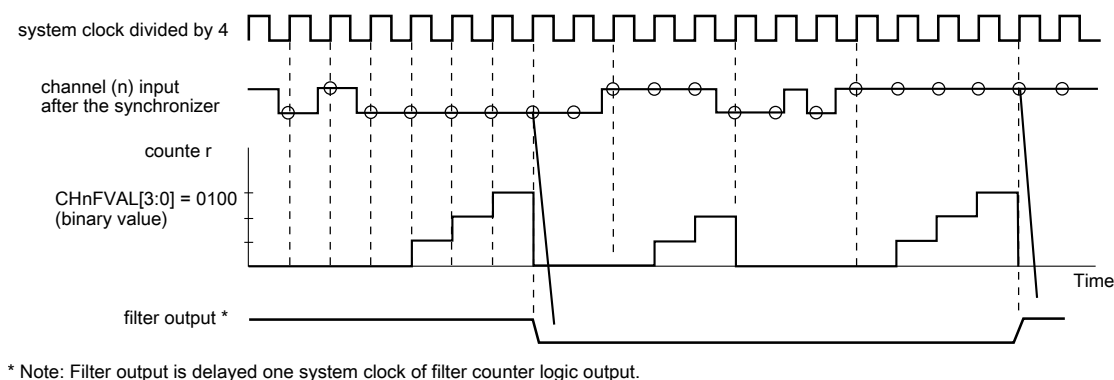

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by CHnFVAL[3:0] ( $\times 4$  system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If  $(CHnFVAL[3:0] \neq 0000)$ , then the input signal is delayed by the minimum pulse width ( $CHnFVAL[3:0] \times 4$  system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer, one rising edge to the filter output, plus one more to the edge detector. In other words, CHnF is set  $(4 + 4 \times CHnFVAL[3:0])$  system clock periods after a valid edge occurs on the channel input.

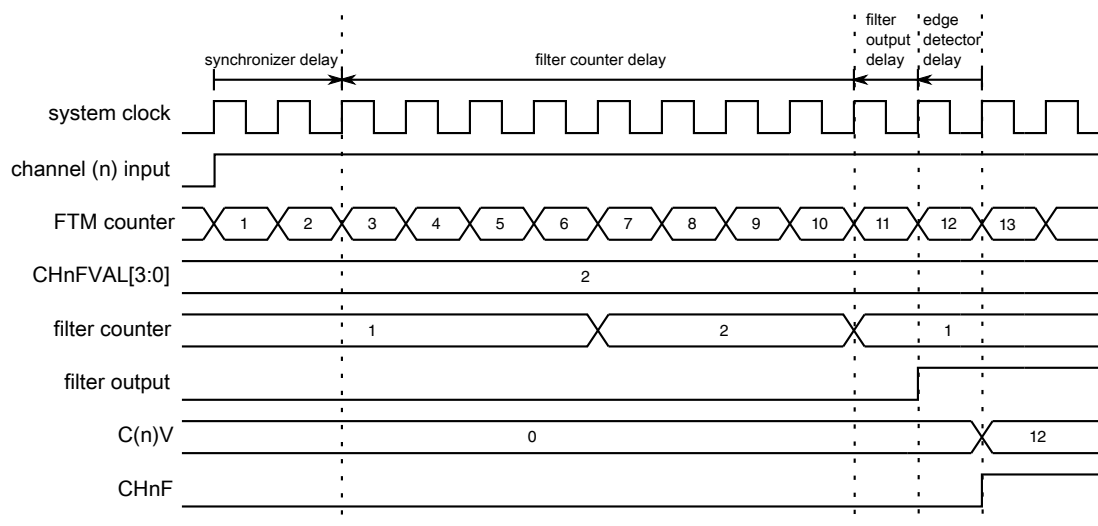

The clock for the counter in the channel input filter is the system clock divided by 4.

**Figure 13-13. Channel input filter example**

The figure below shows an example of input capture with filter enabled and the delay added by each part of the input capture logic. Note that the input signal is delayed only by the synchronizer and edge detector logic if the filter is disabled.

**Figure 13-14. Input capture example**

### 13.1.4.5 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB:MSnA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

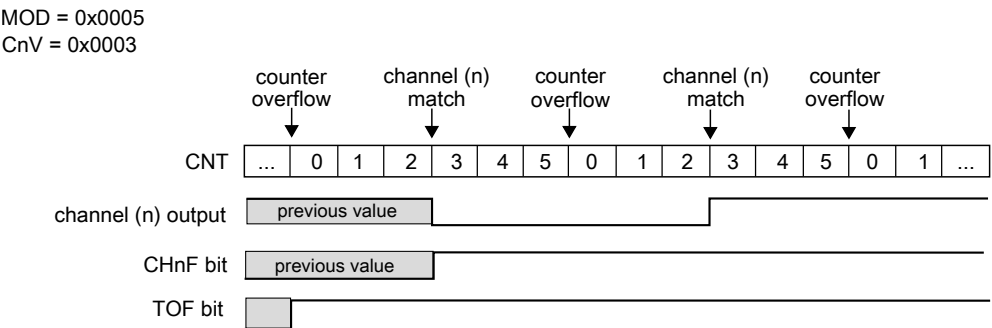

Figure 13-15. Example of the Output Compare mode when the match toggles the channel output

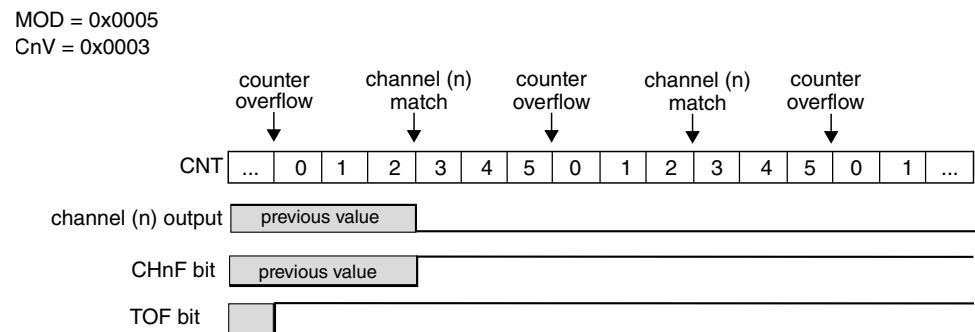

Figure 13-16. Example of the Output Compare mode when the match clears the channel output

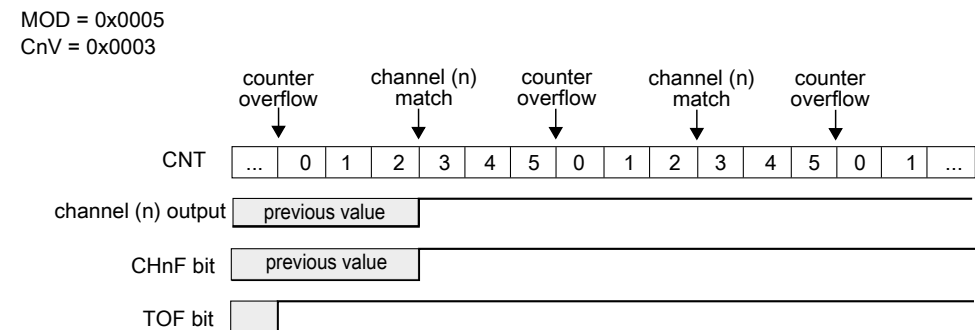

Figure 13-17. Example of the Output Compare mode when the match sets the channel output

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

### 13.1.4.6 Edge-Aligned PWM (EPWM) mode

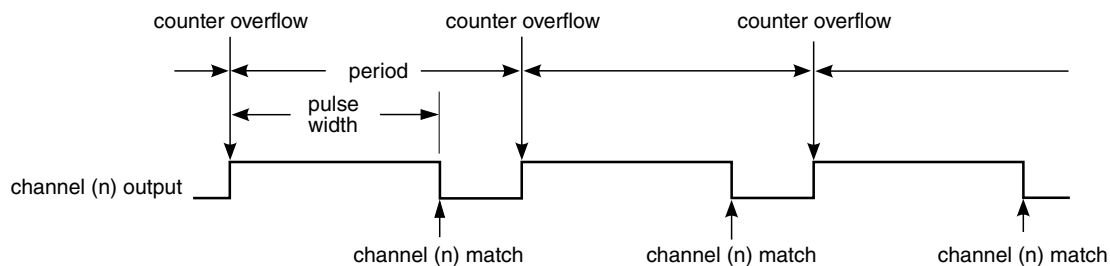

The Edge-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB = 1

The EPWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the pulse width (duty cycle) is determined by  $(CnV - CNTIN)$ .

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

**Figure 13-18. EPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not controlled by FTM.

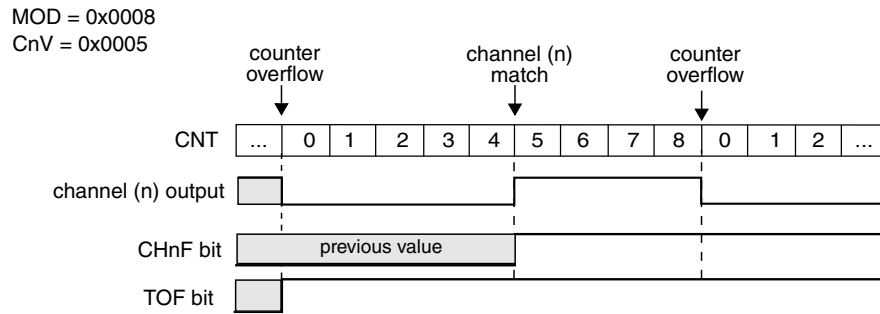

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

MOD = 0x0008  
CnV = 0x0005

**Figure 13-19. EPWM signal with  $ELSnB:ELSnA = 1:0$**

If ( $ELSnB:ELSnA = X:1$ ), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

**Figure 13-20. EPWM signal with  $ELSnB:ELSnA = X:1$**

If ( $CnV = 0x0000$ ), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match.

If ( $CnV > MOD$ ), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

### Note

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if  $CnV = CNTIN$ ,
- EPWM signal between 0% and 100% if  $CNTIN < CnV \leq MOD$ ,
- 100% EPWM signal when  $CNTIN > CnV$  or  $CnV > MOD$ .

### 13.1.4.7 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

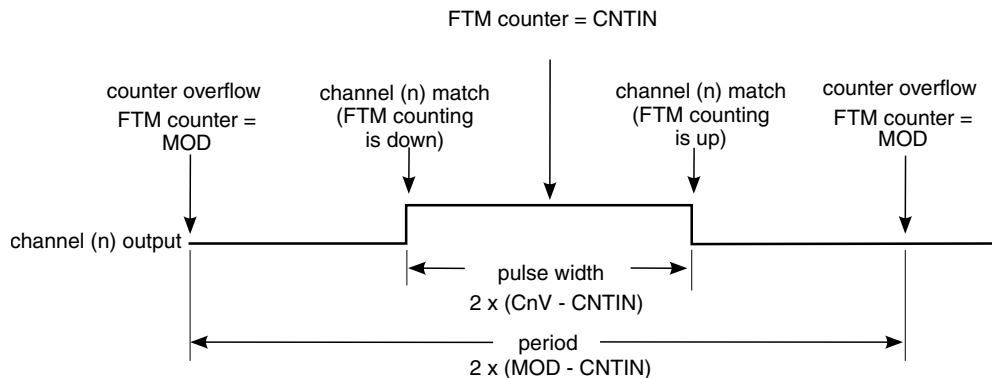

The CPWM pulse width (duty cycle) is determined by  $2 \times (\text{CnV} - \text{CNTIN})$  and the period is determined by  $2 \times (\text{MOD} - \text{CNTIN})$ . See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

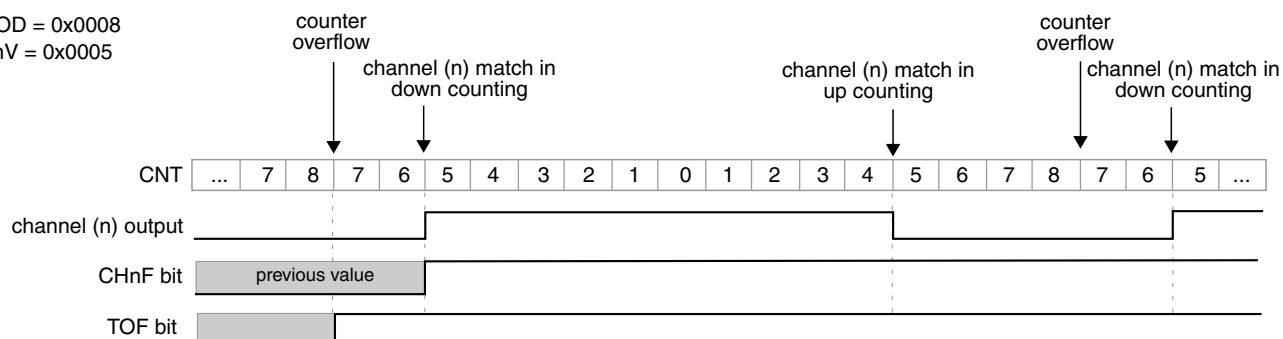

**Figure 13-21. CPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

## FlexTimer Module (FTM)

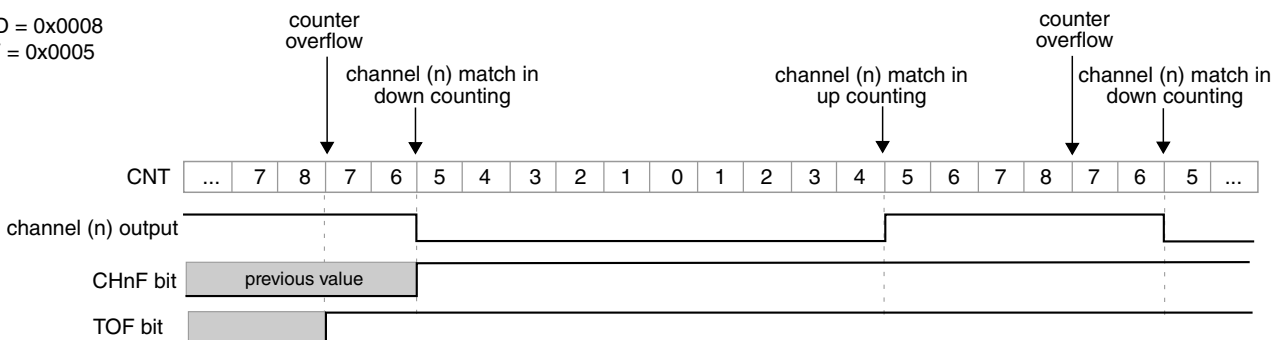

MOD = 0x0008  
CnV = 0x0005

**Figure 13-22. CPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

MOD = 0x0008  
CnV = 0x0005

**Figure 13-23. CPWM signal with ELSnB:ELSnA = X:1**

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

### 13.1.4.8 Combine mode

The Combine mode is selected when:

- QUADEN = 0

- $DECAPEN = 0$
- $COMBINE = 1$ , and
- $CPWMS = 0$

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the PWM pulse width (duty cycle) is determined by  $(IC(n+1)V - C(n)V)$ .

The  $CHnF$  bit is set and the channel (n) interrupt is generated (if  $CHnIE = 1$ ) at the channel (n) match (FTM counter =  $C(n)V$ ). The  $CH(n+1)F$  bit is set and the channel (n+1) interrupt is generated, if  $CH(n+1)IE = 1$ , at the channel (n+1) match (FTM counter =  $C(n+1)V$ ).

If  $(ELSnB:ELSnA = 1:0)$ , then the channel (n) output is forced low at the beginning of the period (FTM counter =  $CNTIN$ ) and at the channel (n+1) match (FTM counter =  $C(n+1)V$ ). It is forced high at the channel (n) match (FTM counter =  $C(n)V$ ). See the following figure.

If  $(ELSnB:ELSnA = X:1)$ , then the channel (n) output is forced high at the beginning of the period (FTM counter =  $CNTIN$ ) and at the channel (n+1) match (FTM counter =  $C(n+1)V$ ). It is forced low at the channel (n) match (FTM counter =  $C(n)V$ ). See the following figure.

In Combine mode, the  $ELS(n+1)B$  and  $ELS(n+1)A$  bits are not used in the generation of the channels (n) and (n+1) output. However, if  $(ELSnB:ELSnA = 0:0)$  then the channel (n) output is not controlled by FTM, and if  $(ELS(n+1)B:ELS(n+1)A = 0:0)$  then the channel (n+1) output is not controlled by FTM.

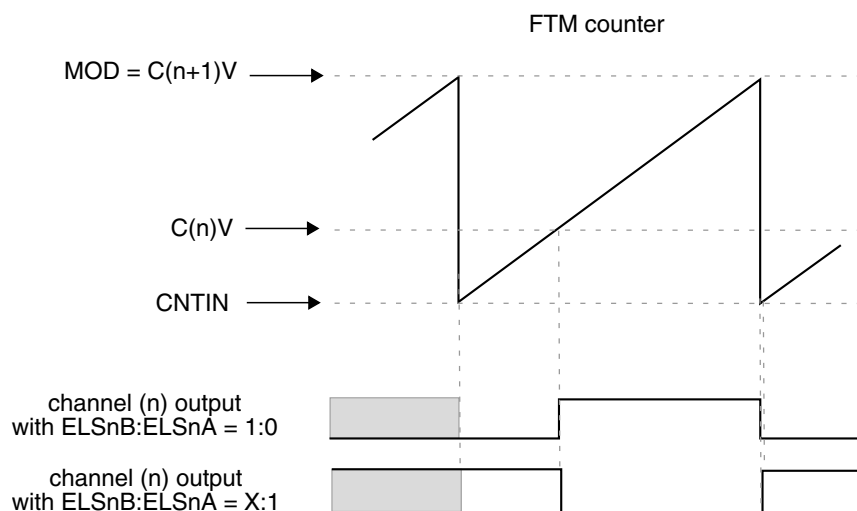

**Figure 13-24. Combine mode**

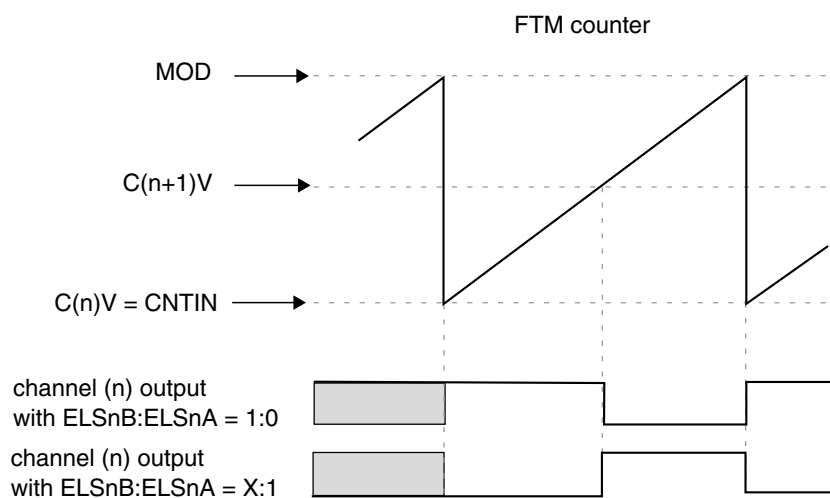

The following figures illustrate the PWM signals generation using Combine mode.

**Figure 13-25. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V < C(n+1)V)$**

**Figure 13-26. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n+1)V = MOD)$**

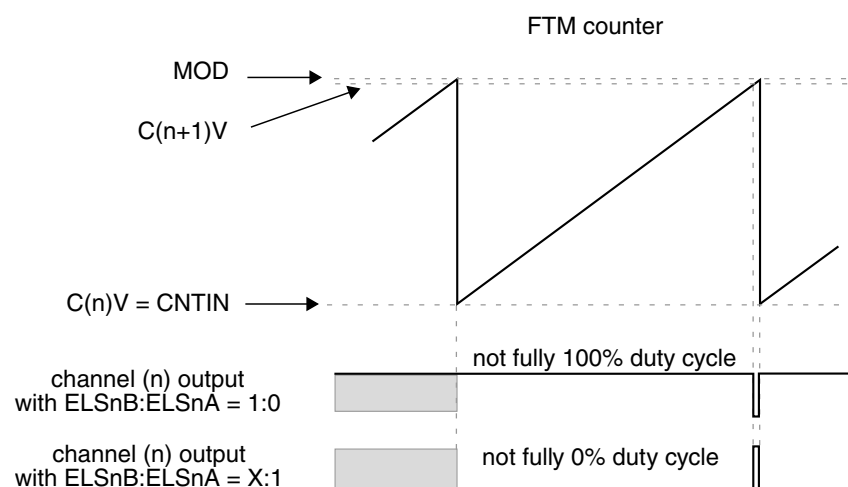

**Figure 13-27. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 13-28. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n)V$  is Almost Equal to  $CNTIN$ ) and  $(C(n+1)V = MOD)$**

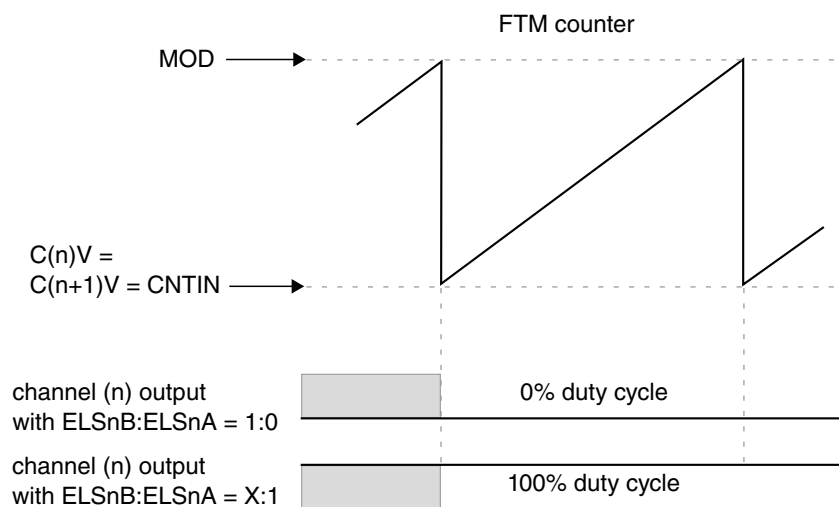

**Figure 13-29. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n+1)V$  is Almost Equal to  $MOD$ )**

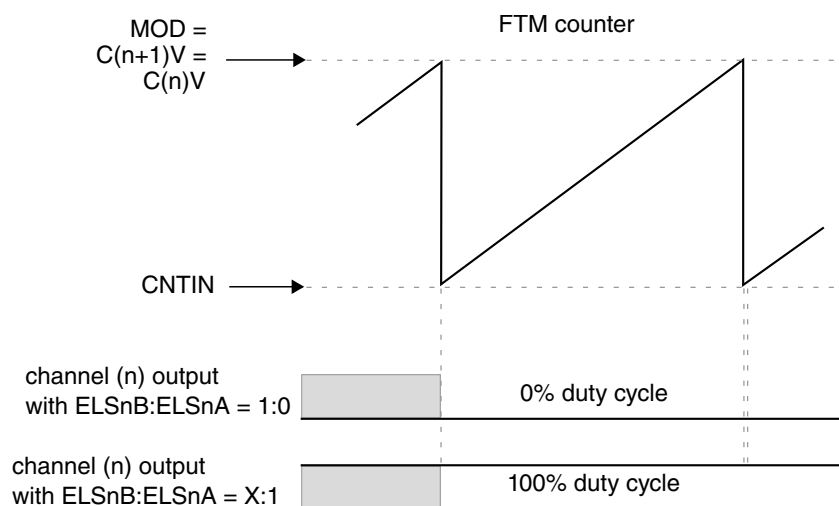

**Figure 13-30. Channel (n) output if  $C(n)V$  and  $C(n+1)V$  are not between  $CNTIN$  and  $MOD$**

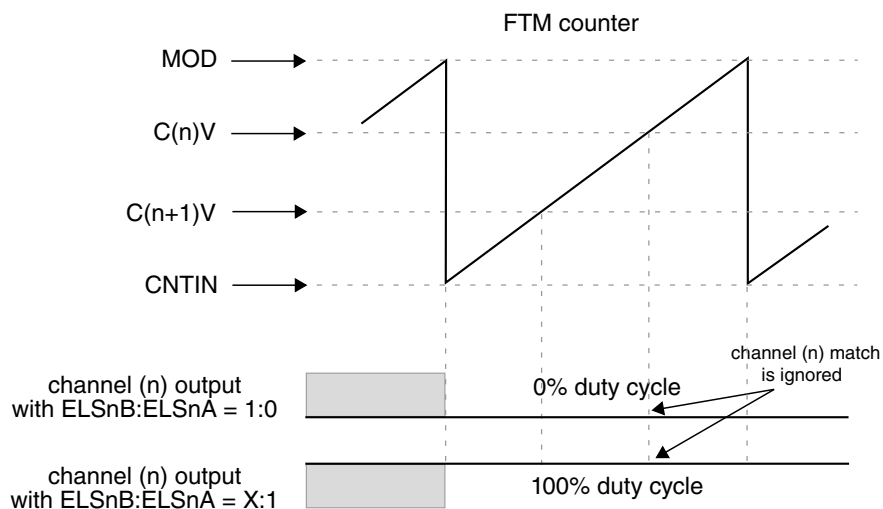

**Figure 13-31. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $C(n)V = C(n+1)V$**

**Figure 13-32. Channel (n) output if  $(C(n)V = C(n+1)V = CNTIN)$**

**Figure 13-33. Channel (n) output if  $(C(n)V = C(n+1)V = MOD)$**

**Figure 13-34. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V > C(n+1)V)$**

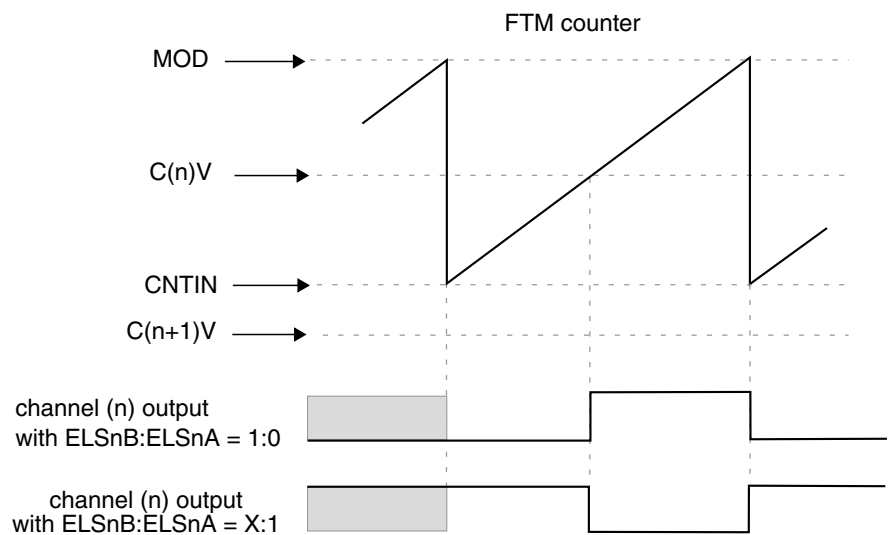

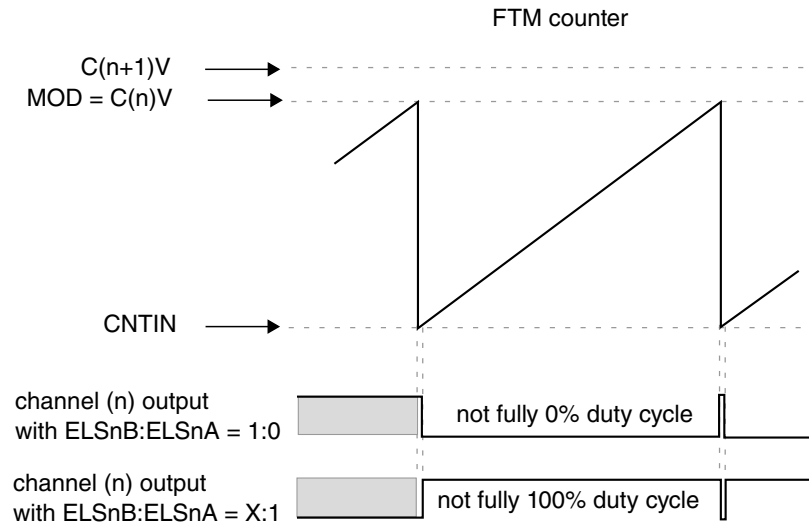

Figure 13-36. Channel (n) output if  $(C(n+1)V < CNTIN)$  and  $(CNTIN < C(n)V < MOD)$

**Figure 13-37. Channel (n) output if  $(C(n)V > MOD)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 13-38. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V < MOD)$**

**Figure 13-39. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V = MOD)$**

#### 13.1.4.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter =  $C(n)V$ , is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter =  $C(n+1)V$ . So, Combine mode allows the generation of asymmetrical PWM signals.

#### 13.1.4.9 Complementary mode

The Complementary mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0

**Figure 13-40. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = 1:0)**

**Figure 13-41. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = X:1)**

## NOTE

The complementary mode is not available in Output Compare mode.

### 13.1.4.10 Registers updated from write buffers

#### 13.1.4.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

**Table 13-5. CNTIN register update**

When	Then CNTIN register is updated
CLKS[1:0] = 0:0	When CNTIN register is written, independent of FTMEN bit.
<ul style="list-style-type: none"> <li>FTMEN = 0, or</li> <li>CNTINC = 0</li> </ul>	At the next system clock after CNTIN was written.
<ul style="list-style-type: none"> <li>FTMEN = 1,</li> <li>SYNCMODE = 1, and</li> <li>CNTINC = 1</li> </ul>	By the <a href="#">CNTIN register synchronization</a> .

### 13.1.4.10.2 MOD register update

The following table describes when MOD register is updated:

**Table 13-6. MOD register update**

When	Then MOD register is updated
CLKS[1:0] = 0:0	When MOD register is written, independent of FTMEN bit.
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 0</li> </ul>	According to the CPWMS bit, that is: <ul style="list-style-type: none"> <li>• If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>• If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul>
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 1</li> </ul>	By the <a href="#">MOD register synchronization</a> .

### 13.1.4.10.3 CnV register update

The following table describes when CnV register is updated:

**Table 13-7. CnV register update**

When	Then CnV register is updated
CLKS[1:0] = 0:0	When CnV register is written, independent of FTMEN bit.
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 0</li> </ul>	According to the selected mode, that is: <ul style="list-style-type: none"> <li>• If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written.</li> <li>• If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>• If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul>
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 1</li> </ul>	According to the selected mode, that is: <ul style="list-style-type: none"> <li>• If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the <a href="#">C(n)V and C(n+1)V register synchronization</a>.</li> <li>• If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the <a href="#">C(n)V and C(n+1)V register synchronization</a>.</li> </ul>

### 13.1.4.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

#### Note

The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

#### 13.1.4.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when  $TRIGn = 1$ , where  $n = 0, 1$  or  $2$  corresponding to each one of the input signals, respectively. The hardware trigger input  $n$  is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the  $TRIGn$  bit is cleared when 0 is written to it or when the trigger  $n$  event is detected.

In this case, if two or more hardware triggers are enabled (for example,  $TRIG0$  and  $TRIG1 = 1$ ) and only trigger 1 event occurs, then only  $TRIG1$  bit is cleared. If a trigger  $n$  event occurs together with a write setting  $TRIGn$  bit, then the synchronization is initiated, but  $TRIGn$  bit remains set due to the write operation.

Note  
All hardware trigger inputs have the same behavior.

**Figure 13-42. Hardware trigger event with HWTRIGMODE = 0**

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

### NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

#### 13.1.4.11.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see [Boundary cycle and loading points](#) and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

**Figure 13-43. Software trigger event**

#### 13.1.4.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In **Up counting** mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in **Up-down counting** mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

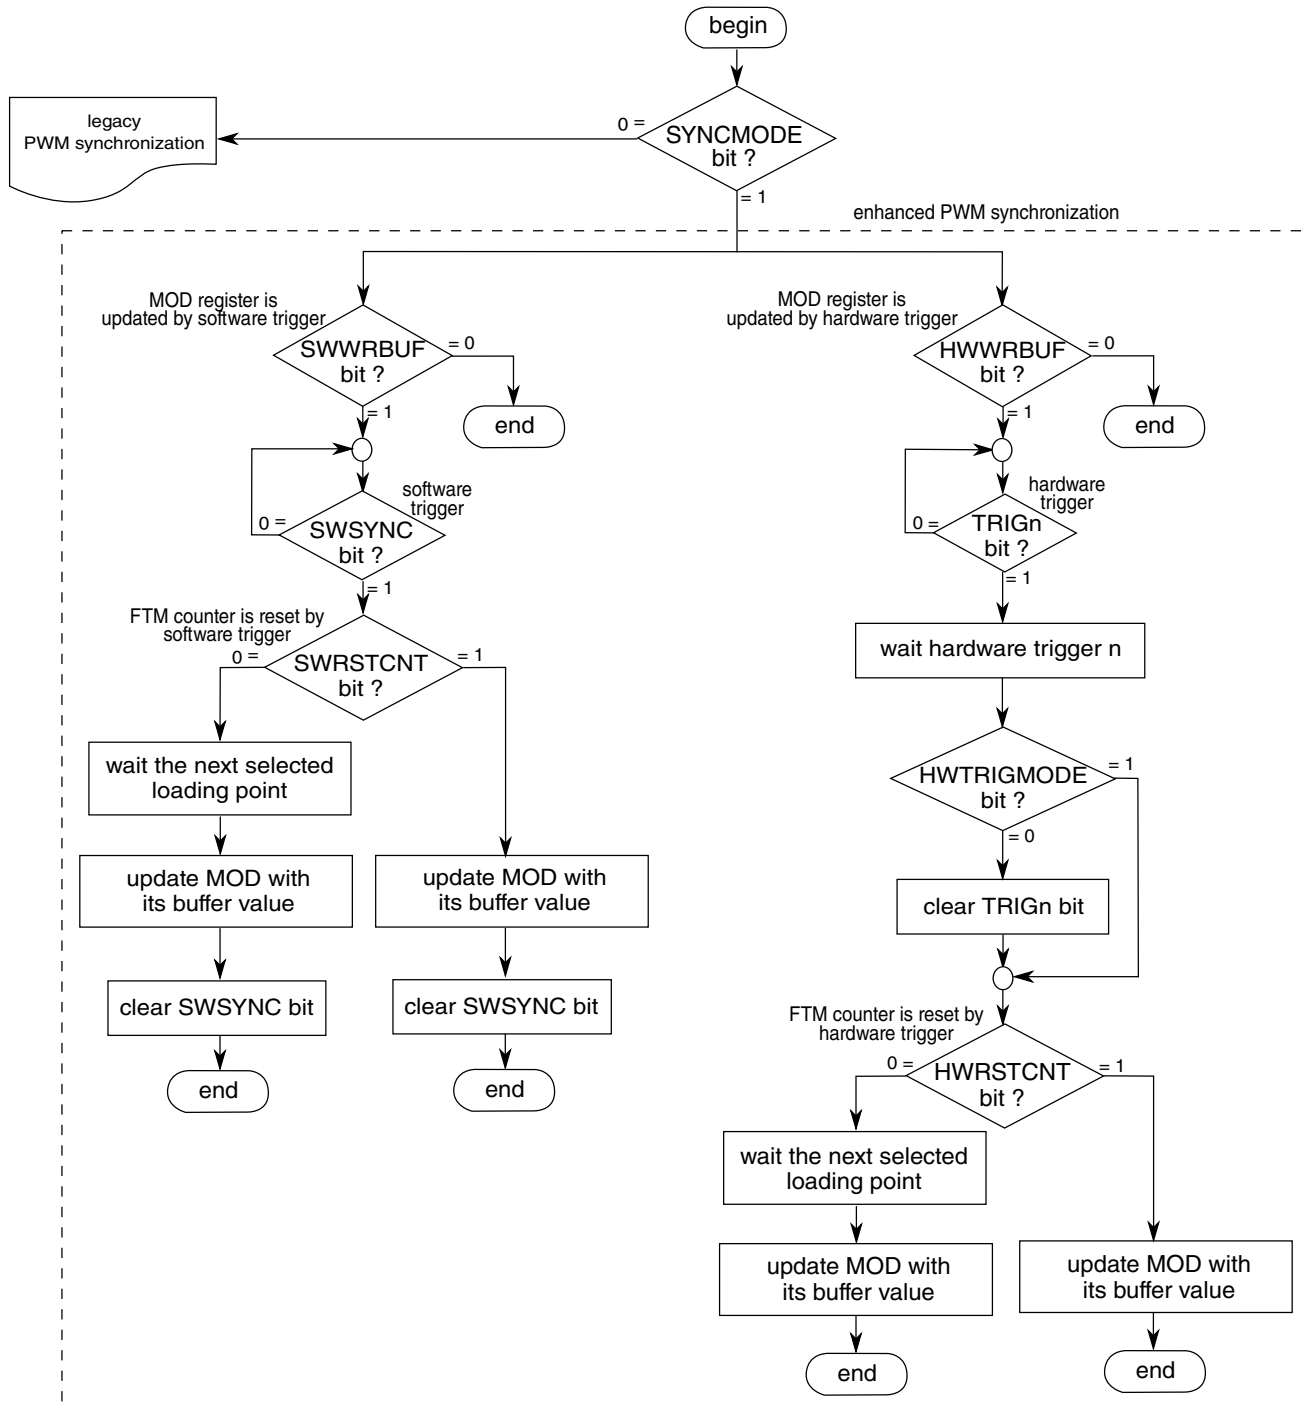

**Figure 13-44. Boundary cycles and loading points**

#### 13.1.4.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

**Figure 13-45. MOD register synchronization flowchart**

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), and ( $\text{REINIT} = 0$ ), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the trigger enable bit ( $\text{TRIGn}$ ) is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 13-46. MOD synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), ( $\text{REINIT} = 0$ ), and software trigger was used**

**Figure 13-47. MOD synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{HWTRIGMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), ( $\text{REINIT} = 0$ ), and a hardware trigger was used**

If ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), and ( $\text{REINIT} = 1$ ), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared according to the following example. If the trigger event was a hardware trigger, then the  $\text{TRIGn}$  bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 13-48. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used**

**Figure 13-49. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used**

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

**Figure 13-50. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)**

#### 13.1.4.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see [MOD register synchronization](#).

#### 13.1.4.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

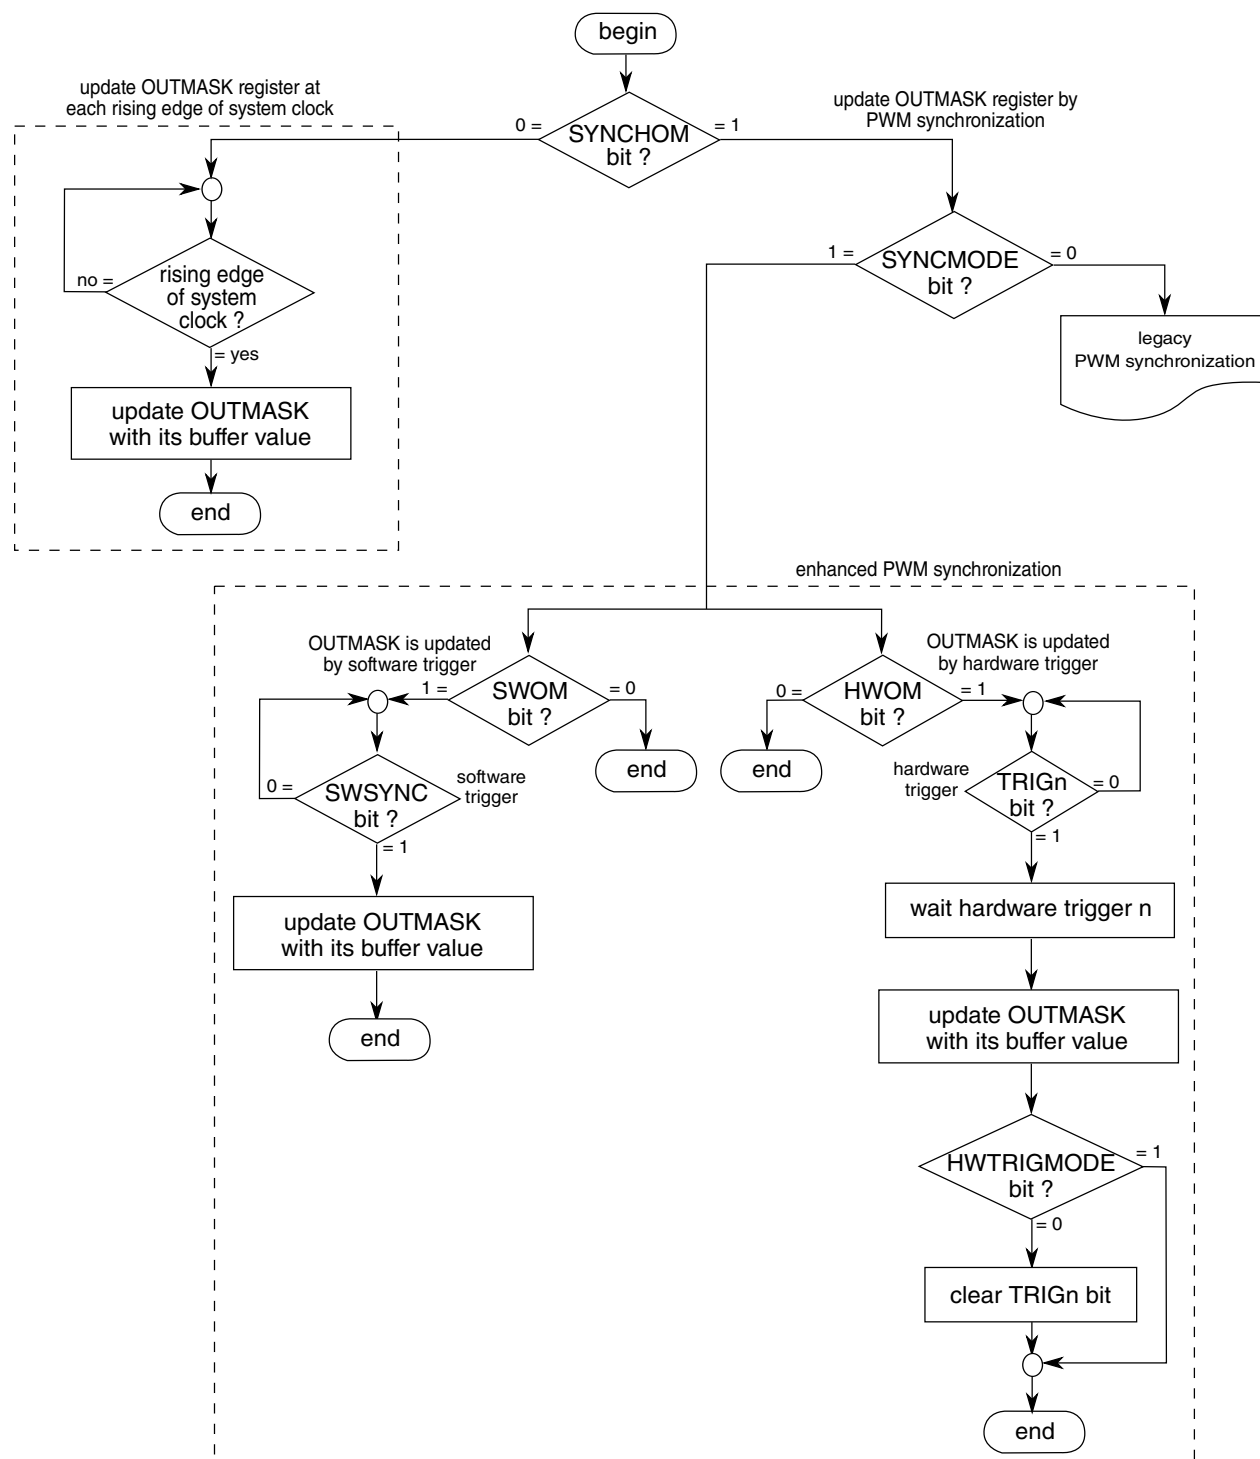

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the [MOD register synchronization](#). However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

#### 13.1.4.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

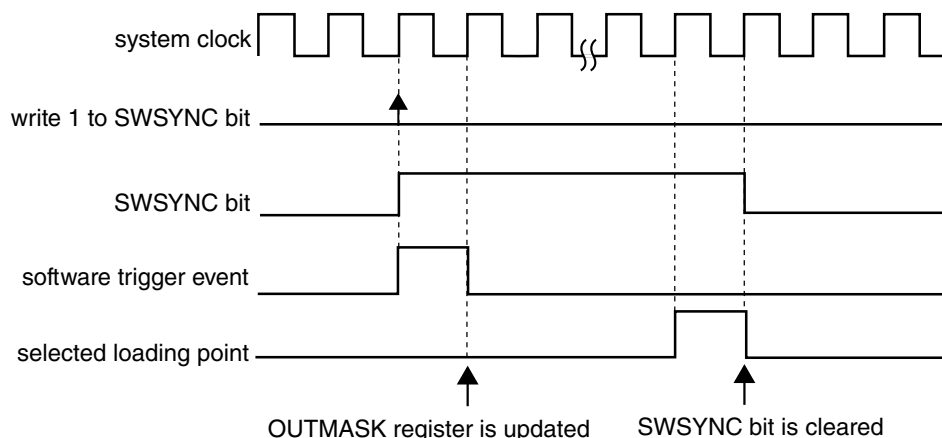

**Figure 13-51. OUTMASK register synchronization flowchart**

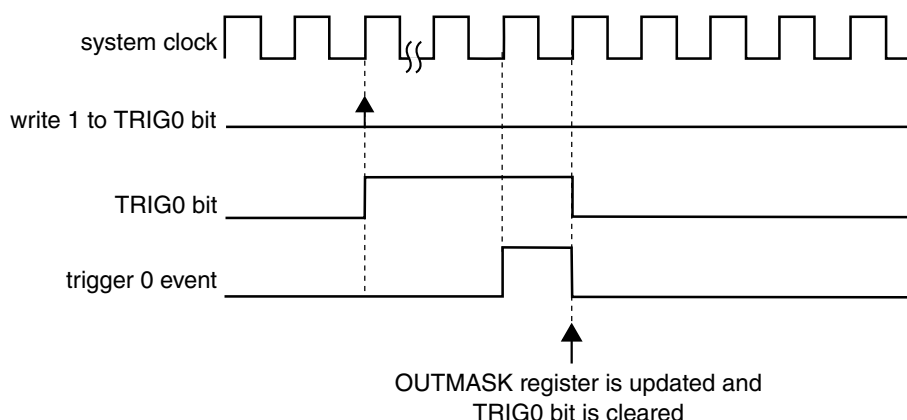

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If ( $\text{SYNCMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), and ( $\text{PWMSYNC} = 0$ ), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the  $\text{TRIGN}$  bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

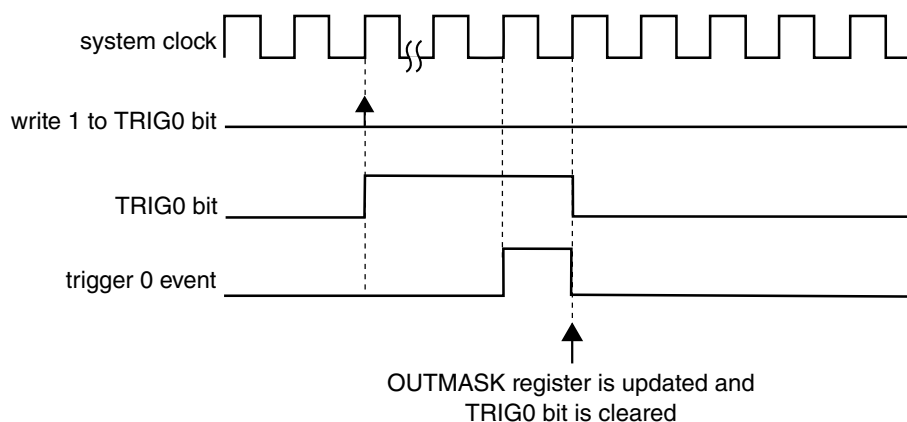

**Figure 13-52. OUTMASK synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), ( $\text{PWMSYNC} = 0$ ) and software trigger was used**

**Figure 13-53. OUTMASK synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{HWTRIGMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), ( $\text{PWMSYNC} = 0$ ), and a hardware trigger was used**

If ( $\text{SYNCMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), and ( $\text{PWMSYNC} = 1$ ), then this synchronization is made on the next enabled hardware trigger. The  $\text{TRIGN}$  bit is cleared according to [Hardware trigger](#). An example with a hardware trigger follows.

**Figure 13-54. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used**

#### 13.1.4.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

Figure 13-55. INVCTRL register synchronization flowchart

### 13.1.4.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

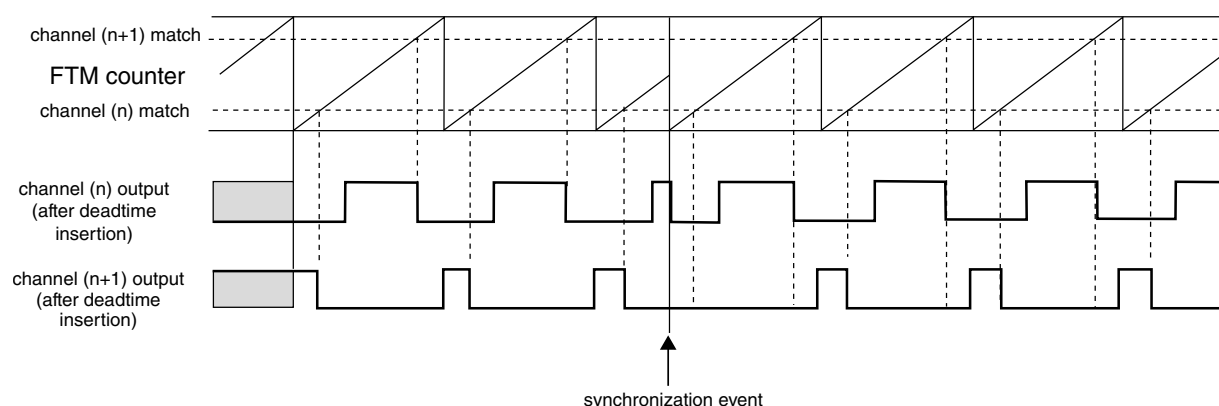

Figure 13-56. SWOCTRL register synchronization flowchart

### 13.1.4.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

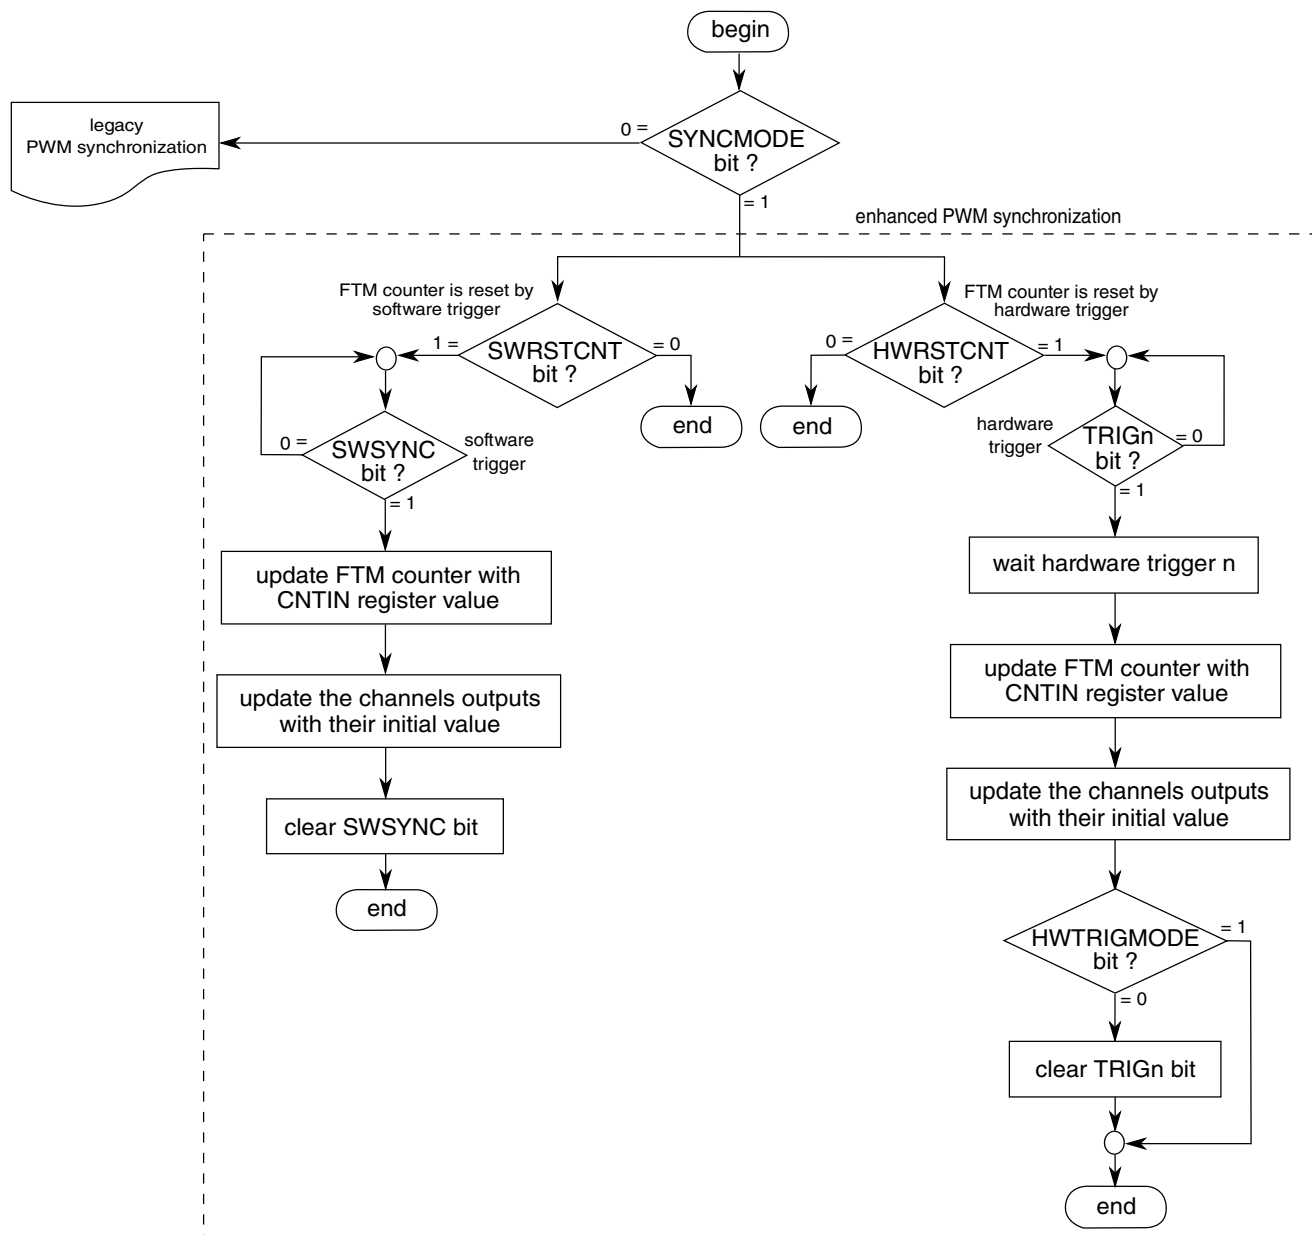

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n+1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

**Figure 13-57. FTM counter synchronization**

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

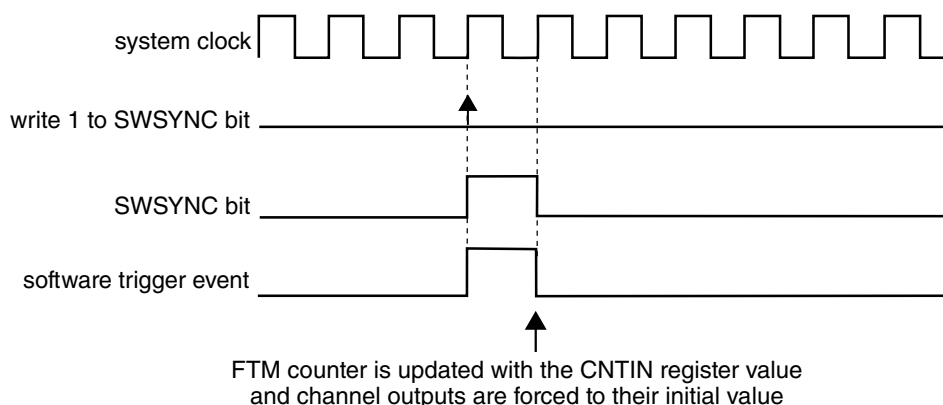

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

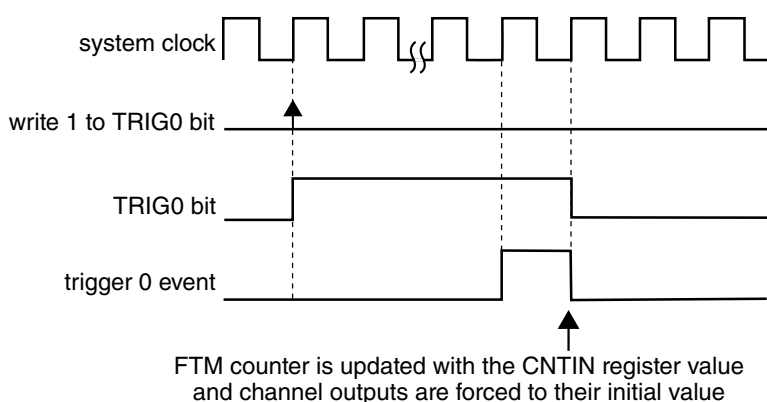

**Figure 13-58. FTM counter synchronization flowchart**

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGN bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

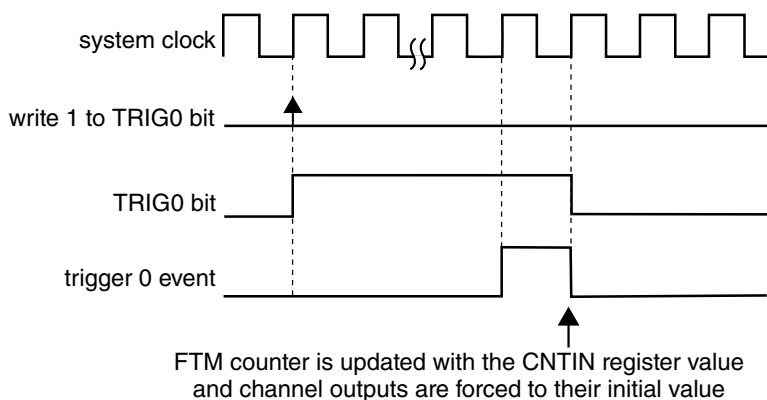

**Figure 13-59. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used**

**Figure 13-60. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#).

**Figure 13-61. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used**

### 13.1.4.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INVm = 1 (where m represents a channel pair)

The INVm bit in INVCTRL register is updated with its buffer value according to [INVCTRL register synchronization](#)

In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 13-62. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode**

Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 13-63. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode**

### Note

The inverting feature is not available in Output Compare mode.

#### 13.1.4.13 Software output control

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

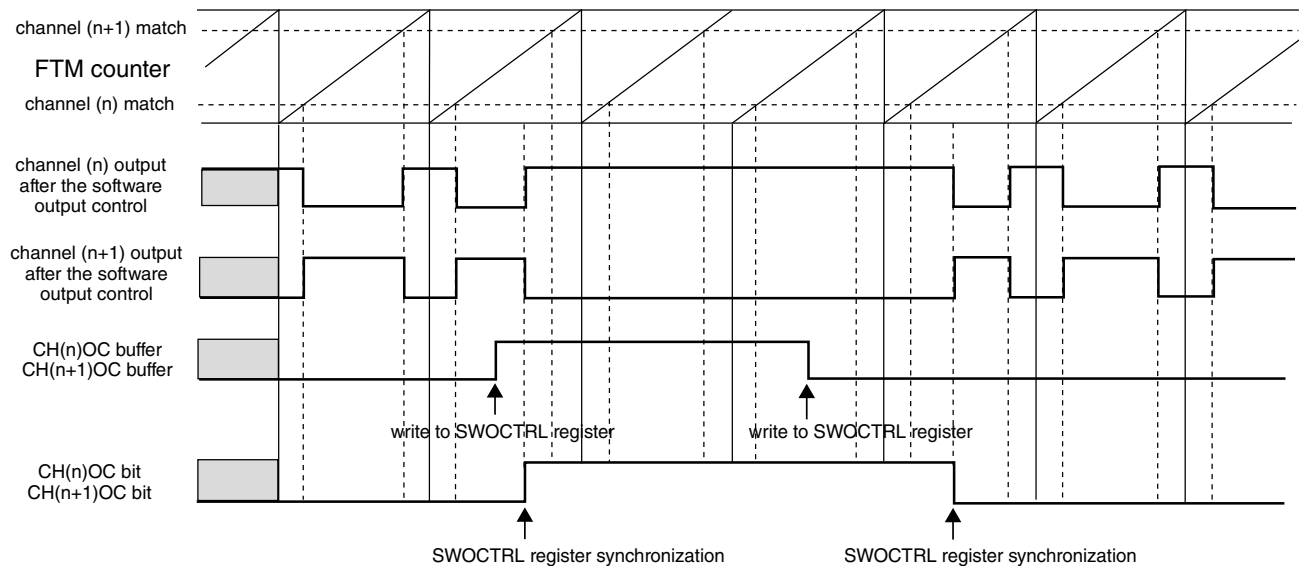

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CHnOC = 1

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to [SWOCTRL register synchronization](#).

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

NOTE

CH(n)OCV = 1 and CH(n+1)OCV = 0.

**Figure 13-64. Example of software output control in Combine and Complementary mode**

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

**Table 13-8. Software output control behavior when (COMP = 0)**

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to one

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

**Table 13-9. Software output control behavior when (COMP = 1)**

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to zero

### Note

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

#### 13.1.4.14 Deadtime insertion

The deadtime insertion is enabled when (DTEN = 1) and (DTVAL[5:0] is non-zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTPS[1:0] bits define the prescaler for the system clock and the DTVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If  $POL(n) = 0$ ,  $POL(n+1) = 0$ , and the deadtime is enabled, then when the channel (n) match (FTM counter =  $C(n)V$ ) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter =  $C(n+1)V$ ) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If  $POL(n) = 1$ ,  $POL(n+1) = 1$ , and the deadtime is enabled, then when the channel (n) match (FTM counter =  $C(n)V$ ) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

when the channel (n+1) match (FTM counter =  $C(n+1)V$ ) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared.

**Figure 13-65. Deadtime insertion with  $ELSnB:ELSnA = 1:0$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

**Figure 13-66. Deadtime insertion with  $ELSnB:ELSnA = X:1$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

### NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

#### 13.1.4.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ( $((C(n)+1)V - C(n)V) \times \text{system clock}$ ), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ( $((MOD - CNTIN + 1 - (C(n+1)V - C(n)V)) \times \text{system clock}$ ), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

**Figure 13-67. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle**

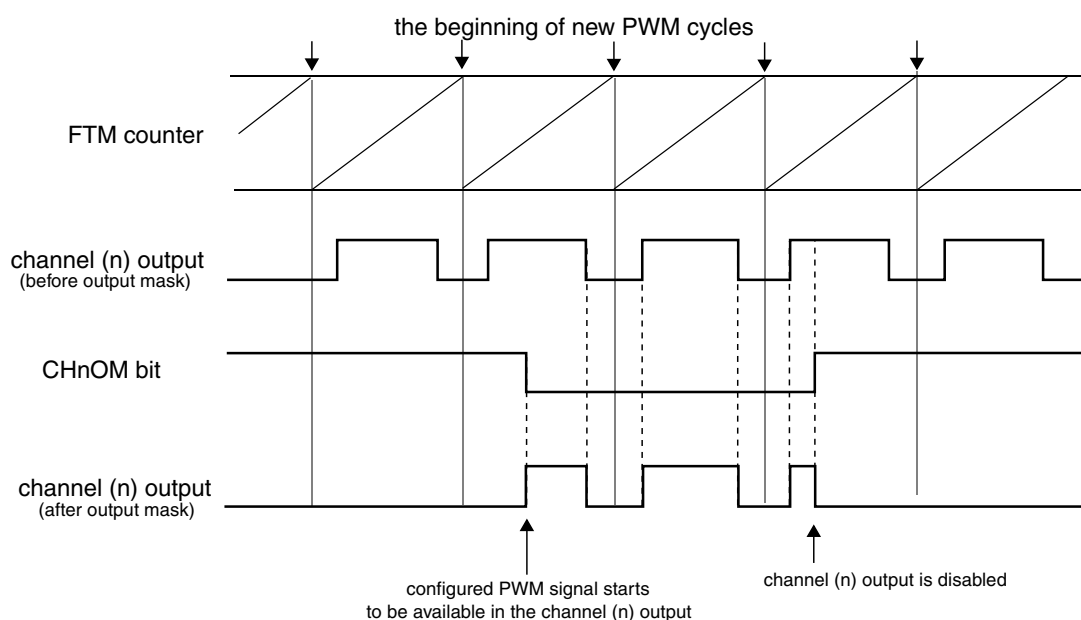

**Figure 13-68. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle**

### 13.1.4.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see [OUTMASK register synchronization](#).

If  $CHnOM = 1$ , then the channel (n) output is forced to its inactive state ( $POLn$  bit value). If  $CHnOM = 0$ , then the channel (n) output is unaffected by the output mask. See the following figure.

**Figure 13-69. Output mask with  $POLn = 0$**

The following table shows the output mask result before the polarity control.

**Table 13-10. Output mask result for channel (n) before the polarity control**

CHnOM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	

### 13.1.4.16 Fault control

The fault control is enabled if (FAULTM[1:0]  $\neq$  0:0).

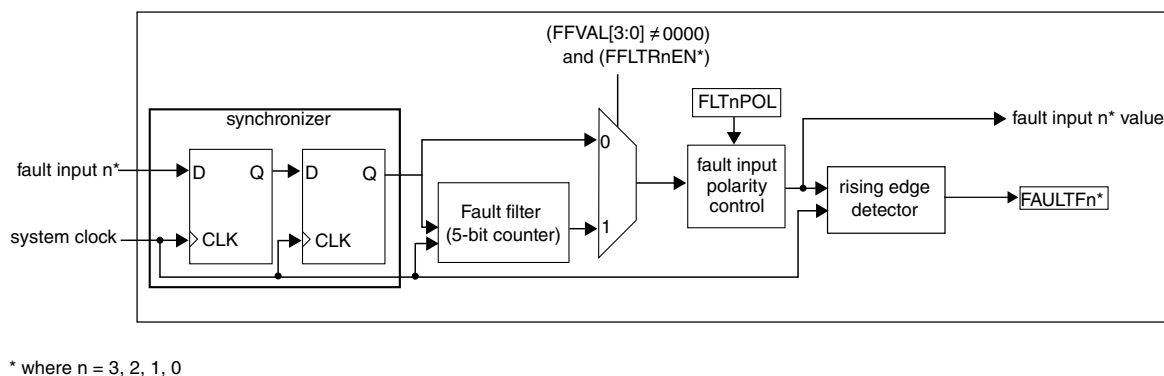

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

First, each fault input signal is synchronized by the system clock; see the synchronizer block in the following figure. Following synchronization, the fault input n signal enters the filter block. When there is a state change in the fault input n signal, the 5-bit counter is reset and starts counting up. As long as the new state is stable on the fault input n, the counter continues to increment. If the 5-bit counter overflows, that is, the counter exceeds the value of the FFVAL[3:0] bits, the new fault input n value is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the fault input n signal before validation (counter overflow), the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by FFVAL[3:0] bits ( $\times$  system clock) is regarded as a glitch and is not passed on to the edge detector.

The fault input n filter is disabled when the FFVAL[3:0] bits are zero or when FAULTnEN = 0. In this case, the fault input n signal is delayed 2 rising edges of the system clock and the FAULTFn bit is set on 3th rising edge of the system clock after a rising edge occurs on the fault input n.

If FFVAL[3:0]  $\neq$  0000 and FAULTnEN = 1, then the fault input n signal is delayed (3 + FFVAL[3:0]) rising edges of the system clock, that is, the FAULTFn bit is set (4 + FFVAL[3:0]) rising edges of the system clock after a rising edge occurs on the fault input n.

**Figure 13-70. Fault input n control block diagram**

If the fault control and fault input n are enabled and a rising edge at the fault input n signal is detected, a fault condition has occurred and the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

**Figure 13-71. FAULTF and FAULTIN bits and fault interrupt**

If the fault control is enabled ( $\text{FAULTM}[1:0] \neq 0:0$ ), a fault condition has occurred and ( $\text{FAULTEN} = 1$ ), then outputs are forced to their safe values:

- Channel (n) output takes the value of  $\text{POL}(n)$
- Channel (n+1) takes the value of  $\text{POL}(n+1)$

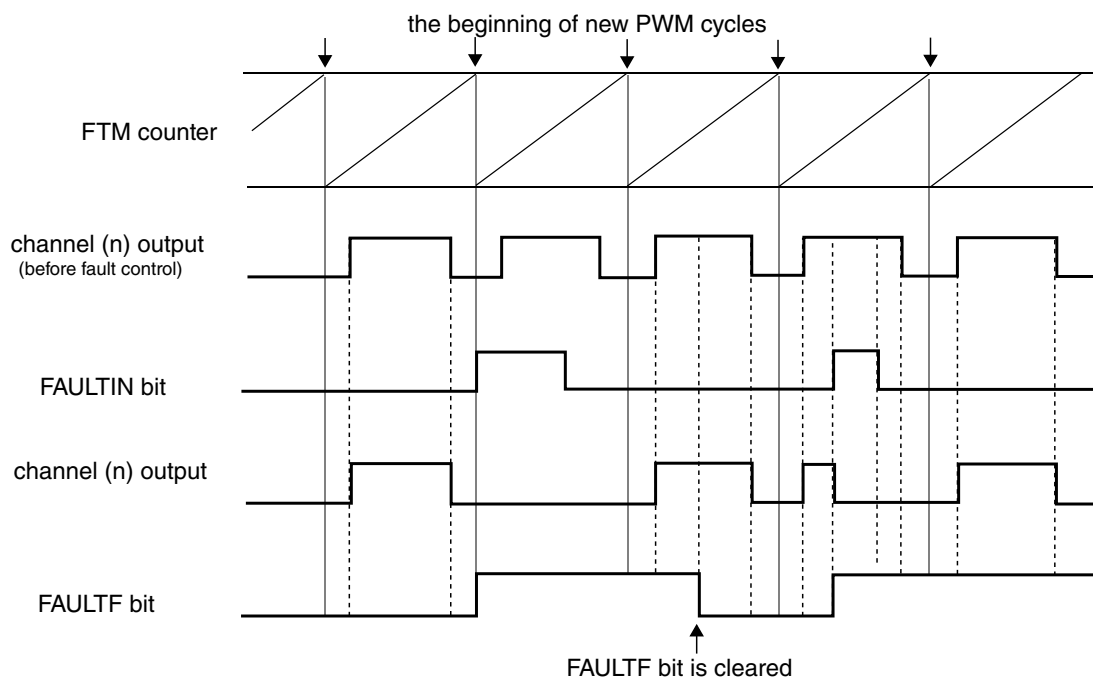

The fault interrupt is generated when ( $\text{FAULTF} = 1$ ) and ( $\text{FAULTIE} = 1$ ). This interrupt request remains set until:

- Software clears the FAULTF bit by reading FAULTF bit as 1 and writing 0 to it
- Software clears the FAULTIE bit
- A reset occurs

#### 13.1.4.16.1 Automatic fault clearing

If the automatic fault clearing is selected ( $\text{FAULTM}[1:0] = 1:1$ ), then the channels output disabled by fault control is again enabled when the fault input signal (FAULTIN) returns to zero and a new PWM cycle begins. See the following figure.

## NOTE

The channel (n) output is after the fault control with automatic fault clearing and POLn = 0.

**Figure 13-72. Fault control with automatic fault clearing**

### 13.1.4.16.2 Manual fault clearing

If the manual fault clearing is selected (FAULTM[1:0] = 0:1 or 1:0), then the channels output disabled by fault control is again enabled when the FAULTF bit is cleared and a new PWM cycle begins. See the following figure.

NOTE  
The channel (n) output is after the fault control with manual fault clearing and POLn = 0.

**Figure 13-73. Fault control with manual fault clearing**

### 13.1.4.16.3 Fault inputs polarity control

The FLTjPOL bit selects the fault input j polarity, where j = 0, 1, 2, 3:

- If FLTjPOL = 0, the fault j input polarity is high, so the logical one at the fault input j indicates a fault.
- If FLTjPOL = 1, the fault j input polarity is low, so the logical zero at the fault input j indicates a fault.

### 13.1.4.17 Polarity control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

### 13.1.4.18 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

**Table 13-11. Initialization behavior when (COMP = 0 and DTEN = 0)**

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	0	is forced to zero	is forced to zero
0	1	is forced to zero	is forced to one
1	0	is forced to one	is forced to zero
1	1	is forced to one	is forced to one

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

**Table 13-12. Initialization behavior when (COMP = 1 or DTEN = 1)**

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	X	is forced to zero	is forced to one
1	X	is forced to one	is forced to zero

#### Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

### 13.1.4.19 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

pair channels (m) - channels (n) and (n+1)

**NOTE**

The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

**Figure 13-74. Priority of the features used at the generation of channels (n) and (n+1) outputs signals**

**Note**

The **Initialization** feature must not be used with **Inverting** and **Software output control** features.

### 13.1.4.20 Channel trigger output

If CH(j)TRIG bit of the FTM External Trigger (FTM\_EXTTRIG) register is set, where  $j = 0, 1, 2, 3, 4$ , or  $5$ , then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal which has one FTM clock period width and is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

**Figure 13-75. Channel match trigger**

### 13.1.4.21 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.
- When there is a write to CNT register.
- When there is the [FTM counter synchronization](#).
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.

The following figures show these cases.

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

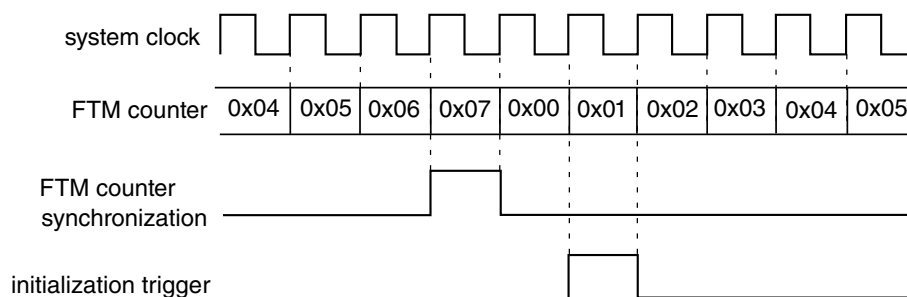

**Figure 13-76. Initialization trigger is generated when the FTM counting achieves the CNTIN register value**

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 13-77. Initialization trigger is generated when there is a write to CNT register**

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 13-78. Initialization trigger is generated when there is the FTM counter synchronization**

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 13-79. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits**

The initialization trigger output provides a trigger signal that is used for on-chip modules.

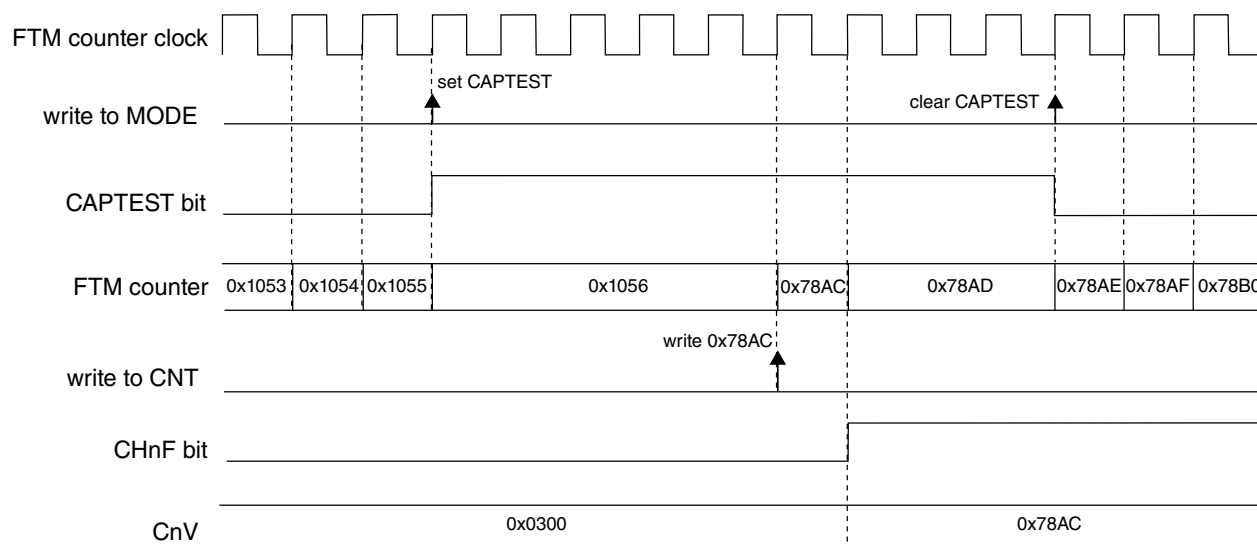

### 13.1.4.22 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for [Input Capture mode](#) and FTM counter must be configured to the [Up counting](#).

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

## NOTE

- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

**Figure 13-80. Capture Test mode**

### 13.1.4.23 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

**Table 13-13. Channel DMA transfer request**

DMA	CHnIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHnF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHnF = 1).	The channel interrupt is not generated.

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

**Table 13-14. Clear CHnF bit when DMA = 1**

CHnIE	How CHnF Bit Can Be Cleared
0	CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit.
1	CHnF bit is cleared when the channel DMA transfer is done.

### 13.1.4.24 Dual Edge Capture mode

The Dual Edge Capture mode is selected if DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.

**Figure 13-81. Dual Edge Capture mode block diagram**

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n+1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the C(n)V and C(n+1)V registers are read. The only requirement is that C(n)V must be read before C(n+1)V.

### Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in [Free running counter](#).

#### 13.1.4.24.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

#### 13.1.4.24.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the CH(n)F and CH(n+1)F bits to start new measurements.

#### 13.1.4.24.3 Pulse width measurement

If the channel (n) is configured to capture rising edges ( $ELS(n)B:ELS(n)A = 0:1$ ) and the channel (n+1) to capture falling edges ( $ELS(n+1)B:ELS(n+1)A = 1:0$ ), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges ( $ELS(n)B:ELS(n)A = 1:0$ ) and the channel (n+1) to capture rising edges ( $ELS(n+1)B:ELS(n+1)A = 0:1$ ), then the negative polarity pulse width is measured.

The pulse width measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by  $ELS(n)B:ELS(n)A$  bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by  $ELS(n+1)B:ELS(n+1)A$  bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

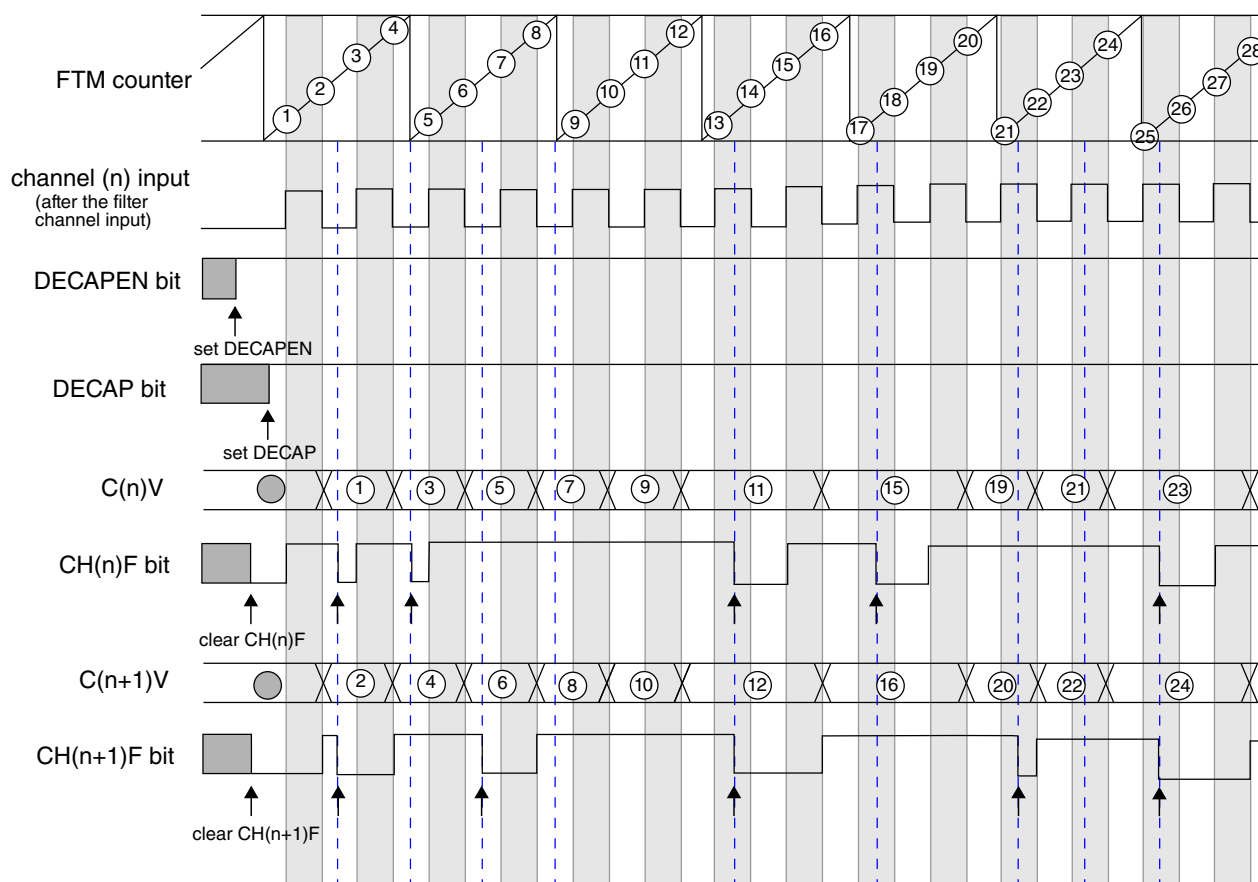

## Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 13-82. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

**Figure 13-83. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement**

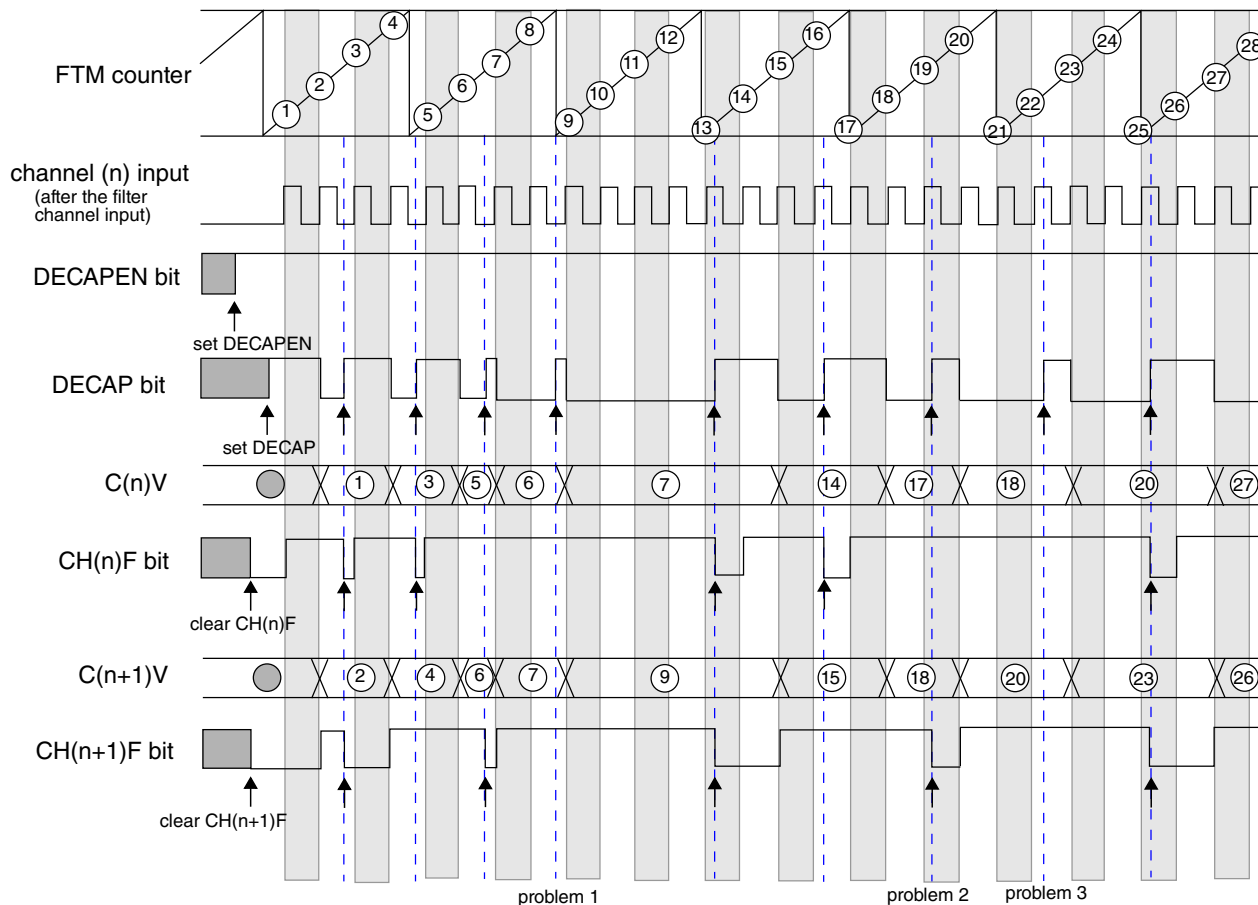

#### 13.1.4.24.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges ( $ELS(n)B:ELS(n)A = 0:1$  and  $ELS(n+1)B:ELS(n+1)A = 0:1$ ), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges ( $ELS(n)B:ELS(n)A = 1:0$  and  $ELS(n+1)B:ELS(n+1)A = 1:0$ ), then the period between two consecutive falling edges is measured.

The period measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the

measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

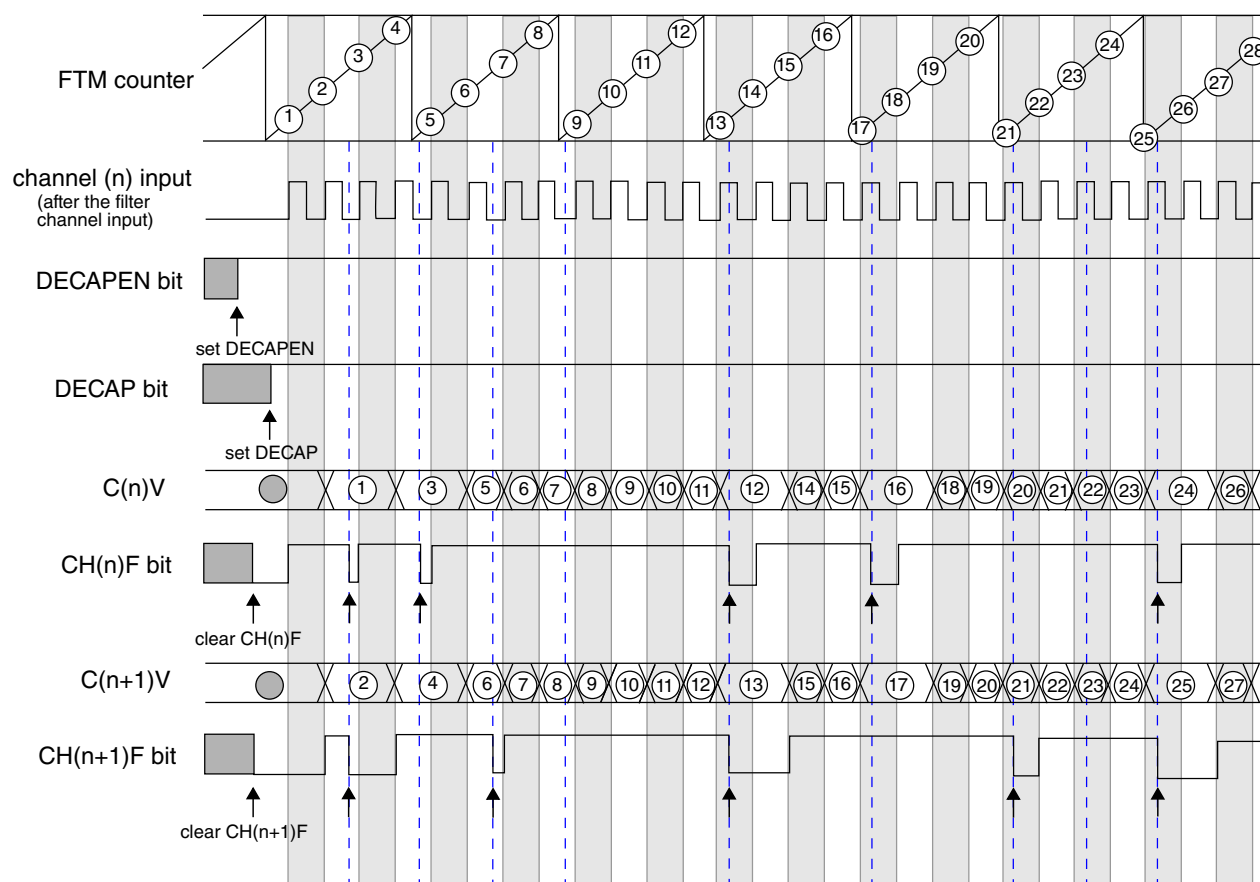

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 13-84. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

**Figure 13-85. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges**

#### 13.1.4.24.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal.

C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

**Figure 13-86. Dual Edge Capture mode read coherency mechanism**

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

### 13.1.4.25 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

**Figure 13-87. Quadrature Decoder block diagram**

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; [Filter for Input Capture mode](#). The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n+1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

### Note

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

### Note

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADM0DE selects the encoding mode used in the Quadrature Decoder mode. If QUADM0DE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

**Figure 13-88. Quadrature Decoder – Count and Direction Encoding mode**

If QUADM0DE = 0, then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

**Figure 13-89. Quadrature Decoder – Phase A and Phase B Encoding mode**

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

**Figure 13-90. FTM Counter overflow in up counting for Quadrature Decoder mode**

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

**Figure 13-91. FTM counter overflow in down counting for Quadrature Decoder mode**

### 13.1.4.25.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

**Figure 13-92. Motor position jittering in a mid count value**

The following figure shows motor jittering produced by the phase B and A pulses respectively:

**Figure 13-93. Motor position jittering near maximum and minimum count value**

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

### 13.1.4.26 BDM mode

When the chip is in BDM mode, the BDMMODE[1:0] bits select the behavior of the FTM counter, the CH(n)F bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

**Table 13-15. FTM behavior when the chip is in BDM mode**

BDMMODE	FTM Counter	CH(n)F Bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
00	Stopped	can be set	Functional mode	Writes to these registers bypass the registers buffers
01	Stopped	is not set	The channels outputs are forced to their safe value according to POLn bit	Writes to these registers bypass the registers buffers
10	Stopped	is not set	The channels outputs are frozen when the chip enters in BDM mode	Writes to these registers bypass the registers buffers

*Table continues on the next page...*

**Table 13-15. FTM behavior when the chip is in BDM mode (continued)**

BDMMODE	FTM Counter	CH(n)F Bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
11	Functional mode	can be set	Functional mode	Functional mode

Note that if BDMMODE[1:0] = 2'b00 then the channels outputs remain at the value when the chip enters in BDM mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this BDM mode.

- Write any value to CNT register; see [Counter reset](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see [FTM counter synchronization](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See [Initialization](#).

### Note

The BDMMODE[1:0] = 2'b00 must not be used with the [Fault control](#). Even if the fault control is enabled and a fault condition exists, the channels outputs values are updated as above.

### Note

If CLKS[1:0] = 2'b00 in BDM, a non-zero value is written to CLKS in BDM, and CnV = CNTIN when the BDM is disabled, then the CHnF bit is set (since if the channel is a 0% EPWM signal) when the BDM is disabled.

#### 13.1.4.27 Intermediate load

The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

**Table 13-16. When possible loading points are enabled**

Loading point	Enabled
When the FTM counter wraps from MOD value to CNTIN value	Always
At the channel (j) match (FTM counter = C(j)V)	When CHjSEL = 1

The following figure shows some examples of enabled loading points.

**NOTE**

- (a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0  
 (e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0  
 (f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

**Figure 13-94. Loading points for intermediate load**

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

**Table 13-17. Conditions for loads occurring at the next enabled loading point**

When a new value was written	Then
To the MOD register	The MOD register is updated with its write buffer value.

Table continues on the next page...

**Table 13-17. Conditions for loads occurring at the next enabled loading point (continued)**

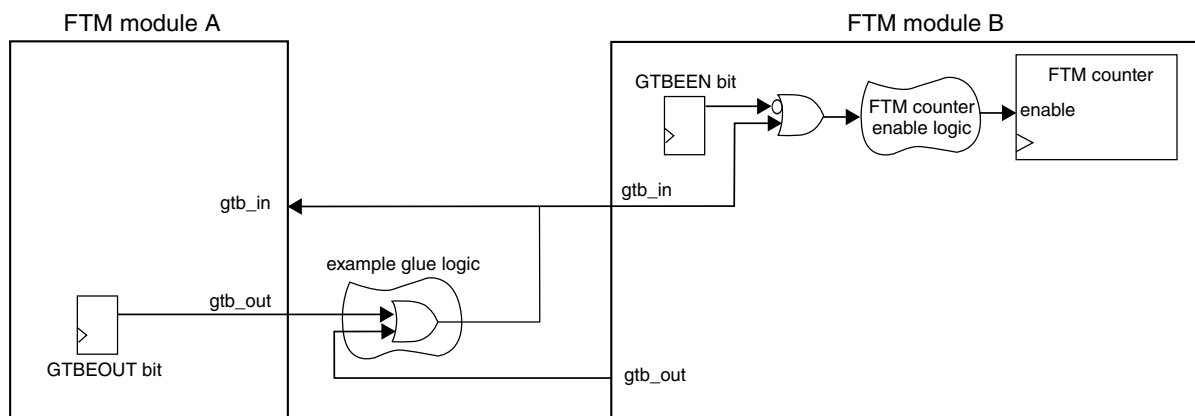

When a new value was written	Then
To the CNTIN register and CNTINC = 1	The CNTIN register is updated with its write buffer value.
To the C(n)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n)V register is updated with its write buffer value.
To the C(n+1)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n+1)V register is updated with its write buffer value.

**NOTE**

- If ELSjB and ELSjA bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELSjB and ELSjA bits are zero, then the generated signal is not available on channel (j) output.
- If CHjIE = 1, then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.

**13.1.4.28 Global time base (GTB)**

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

**Figure 13-95. Global time base (GTB) block diagram**

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb\_in*, and the output signal *gtb\_out*. The GTBEEN bit enables *gtb\_in* to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when *gtb\_in* is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the *gtb\_out* signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the *gtb\_in* and *gtb\_out* signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

### NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the *gtb\_in* signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

#### 13.1.4.28.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

### 13.1.5 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 00b);
- the timer overflow interrupt is zero, see [Timer Overflow Interrupt](#);
- the channels interrupts are zero, see [Channel \(n\) Interrupt](#);
- the fault interrupt is zero, see [Fault Interrupt](#);
- the channels are in input capture mode, see [Input Capture mode](#);
- the channels outputs are zero;
- the channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0:0) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).

**Figure 13-96. FTM behavior after reset when the channel (n) is in Combine mode**

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control ([Software output control](#)) or the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

**Figure 13-97. FTM behavior after reset when the channel (n) is in Output Compare mode**

## 13.1.6 FTM Interrupts

### 13.1.6.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 13.1.6.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

### 13.1.6.3 Fault Interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

## 13.1.7 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer operation. This procedure can also be used to do a new configuration of the FlexTimer operation.

- Define the POL bits.
- Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels output are in the safe value.
- (Re)Configuration FTM counter and channels to generation of periodic signals - Disable the clock. If the selected mode is Quadrature Decoder, then disable this mode. Examples of the (re)configuration:
  - Write to MOD.
  - Write to CNTIN.
  - Select OC, EPWM, CPWM, Combine, Complement modes for all channels that will be used
  - Select the high-true and low-true channels modes.
  - Write to CnV for all channels that will be used .
  - (Re)Configure deadtime and fault control.
  - Do not use the SWOC without SW synchronization (see item 6).
  - Do not use the Inverting without SW synchronization (see item 6).
  - Do not use the Initialization.
  - Do not change the polarity control.
  - Do not configure the HW synchronization
- Write any value to CNT. The FTM Counter is reset and the channels output are updated according to new configuration.

- Enable the clock. Write to CLKS[1:0] bits a value different from zero. If in the Quadrature Decoder mode, enable this mode.
- Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
  - Select synchronization for Output Mask Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
  - Write to SYNCONF.
    - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0).
    - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1].
    - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1].
    - SW Synchronization for SWOM (always): SWOM = 1. No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2'b00): SWWRBUF = 0 and CNTINC = 0.
    - SW Synchronization for counter reset (always): SWRSTCNT = 1.
    - Enhanced synchronization (always): SYNCMODE = 1
  - If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.
  - If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.
  - Write to OUTMASK to enable the masked channels.
- Generate the Software Trigger Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

## 13.2 Periodic Interrupt Timer (PIT)

### 13.2.1 Introduction

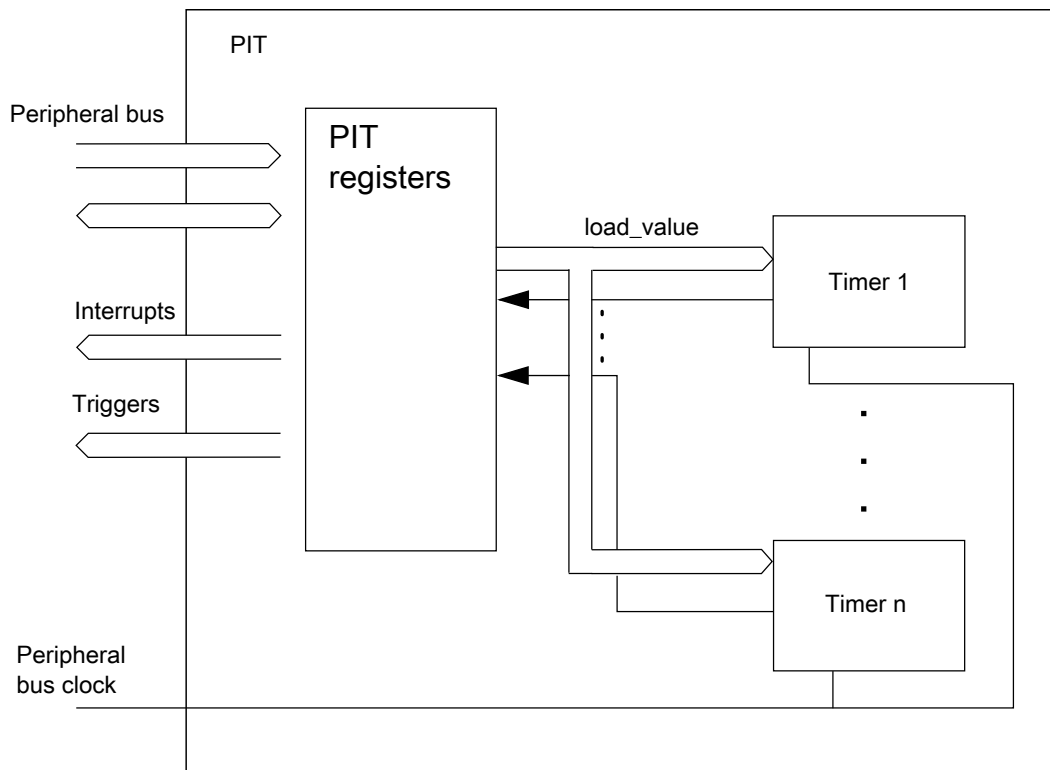

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

### 13.2.1.1 Block diagram

The following figure shows the block diagram of the PIT module.

**Figure 13-98. Block diagram of the PIT**

#### NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

### 13.2.1.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

## 13.2.2 Signal description

The PIT module has no external pins.

## 13.2.3 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.

**PIT memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 13.2.3.1 PIT Module Control Register (PIT\_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

Address: 4003\_7000h base + 0h offset = 4003\_7000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0													Reserved	MDIS	FRZ
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

**PIT\_MCR field descriptions**

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved.
1 MDIS	Module Disable - (PIT section)  Disables the standard timers. This field must be enabled before any other setup is done.  0 Clock for standard PIT timers is enabled. 1 Clock for standard PIT timers is disabled.

*Table continues on the next page...*

**PIT\_MCR field descriptions (continued)**

Field	Description
0 FRZ	Freeze  Allows the timers to be stopped when the device enters the Debug mode.  0 Timers continue to run in Debug mode. 1 Timers are stopped in Debug mode.

**13.2.3.2 PIT Upper Lifetime Timer Register (PIT\_LTMR64H)**

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 4003\_7000h base + E0h offset = 4003\_70E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LTH																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PIT\_LTMR64H field descriptions**

Field	Description
LTH	Life Timer value  Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

**13.2.3.3 PIT Lower Lifetime Timer Register (PIT\_LTMR64L)**

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 4003\_7000h base + E4h offset = 4003\_70E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### PIT\_LTMR64L field descriptions

Field	Description
LTL	Life Timer value  Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

### 13.2.3.4 Timer Load Value Register (PIT\_LDVALn)

These registers select the timeout period for the timer interrupts.

Access: User read/write

Address: 4003\_7000h base + 100h offset + (16d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TSV																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### PIT\_LDVALn field descriptions

Field	Description
TSV	Timer Start Value  Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

### 13.2.3.5 Current Timer Value Register (PIT\_CVALn)

These registers indicate the current timer position.

Access: User read only

Address: 4003\_7000h base + 104h offset + (16d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TVL																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PIT\_CVAL<sub>n</sub> field descriptions**

Field	Description
TVL	<p>Current Timer Value</p> <p>Represents the current timer value, if the timer is enabled.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• If the timer is disabled, do not use this field as its value is unreliable.</li> <li>• The timer uses a downcounter. The timer values are frozen in Debug mode if MCR[FRZ] is set.</li> </ul>

**13.2.3.6 Timer Control Register (PIT\_TCTRL<sub>n</sub>)**

These registers contain the control bits for each timer.

Access: User read/write

Address: 4003\_7000h base + 108h offset + (16d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															TIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PIT\_TFLGn field descriptions**

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 TIF	Timer Interrupt Flag  Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request.  0 Timeout has not yet occurred. 1 Timeout has occurred.

**13.2.4 Functional description**

This section provides the functional description of the module.

### 13.2.4.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

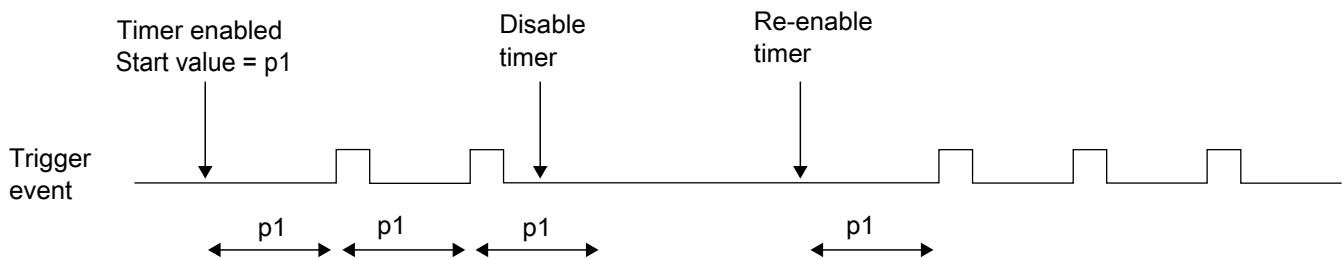

#### 13.2.4.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

**Figure 13-99. Stopping and starting a timer**

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

**Figure 13-100. Modifying running timer period**

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

**Figure 13-101. Dynamically setting a new load value**

### 13.2.4.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

### 13.2.4.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

### 13.2.4.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

## 13.2.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every  $5.12 \text{ ms} / 20 \text{ ns} = 256,000$  cycles and Timer 3 every  $30 \text{ ms} / 20 \text{ ns} = 1,500,000$  cycles. The value for the LDVAL register trigger is calculated as:

$\text{LDVAL trigger} = (\text{period} / \text{clock period}) - 1$

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

### 13.2.6 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

### 13.2.7 Example configuration for the lifetime timer

To configure the lifetime timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;  
current_uptime = current_uptime + PIT_LTMR64L;
```

### 13.3 Low-Power Timer (LPTMR)

#### 13.3.1 Introduction

**NOTE**

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

##### 13.3.1.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

##### 13.3.1.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

**Table 13-18. Modes of operation**

Modes	Description
Run	The LPTMR operates normally.
Wait	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.

*Table continues on the next page...*

**Table 13-18. Modes of operation (continued)**

Modes	Description
Stop	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Low-Leakage	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Debug	The LPTMR operates normally in Pulse Counter mode, but counter does not increment in Time Counter mode.

## 13.3.2 LPTMR signal descriptions

**Table 13-19. LPTMR signal descriptions**

Signal	I/O	Description
LPTMR0_ALT <i>n</i>	I	Pulse Counter Input pin

### 13.3.2.1 Detailed signal descriptions

**Table 13-20. LPTMR interface—detailed signal descriptions**

Signal	I/O	Description	
LPTMR_ALT <i>n</i>	I	Pulse Counter Input  The LPTMR can select one of the input pins to be used in Pulse Counter mode.	
		State meaning	Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment.  Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment.
		Timing	Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.

## 13.3.3 Memory map and register definition

## LPTMRx\_CSR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TCF	Timer Compare Flag  TCF is set when the LPTMR is enabled and the CNR equals the CMR and increments. TCF is cleared when the LPTMR is disabled or a logic 1 is written to it.  0 The value of CNR is not equal to CMR and increments. 1 The value of CNR is equal to CMR and increments.
6 TIE	Timer Interrupt Enable  When TIE is set, the LPTMR Interrupt is generated whenever TCF is also set.  0 Timer interrupt disabled. 1 Timer interrupt enabled.
5–4 TPS	Timer Pin Select

Table continues on the next page...

## LPTMRx\_CSR field descriptions (continued)

Field	Description
	Configures the input source to be used in Pulse Counter mode. TPS must be altered only when the LPTMR is disabled. The input connections vary by device. See the chip configuration details for information on the connections to these inputs.  00 Pulse counter input 0 is selected. 01 Pulse counter input 1 is selected. 10 Pulse counter input 2 is selected. 11 Pulse counter input 3 is selected.
3 TPP	Timer Pin Polarity  Configures the polarity of the input source in Pulse Counter mode. TPP must be changed only when the LPTMR is disabled.  0 Pulse Counter input source is active-high, and the CNR will increment on the rising-edge. 1 Pulse Counter input source is active-low, and the CNR will increment on the falling-edge.
2 TFC	Timer Free-Running Counter  When clear, TFC configures the CNR to reset whenever TCF is set. When set, TFC configures the CNR to reset on overflow. TFC must be altered only when the LPTMR is disabled.  0 CNR is reset whenever TCF is set. 1 CNR is reset on overflow.
1 TMS	Timer Mode Select  Configures the mode of the LPTMR. TMS must be altered only when the LPTMR is disabled.  0 Time Counter mode. 1 Pulse Counter mode.
0 TEN	Timer Enable  When TEN is clear, it resets the LPTMR internal logic, including the CNR and TCF. When TEN is set, the LPTMR is enabled. While writing 1 to this field, CSR[5:1] must not be altered.  0 LPTMR is disabled and internal logic is reset. 1 LPTMR is enabled.

## 13.3.3.2 Low Power Timer Prescale Register (LPTMRx\_PSR)

Address: 4004\_0000h base + 4h offset = 4004\_0004h

## 13.3.4 Functional description

### 13.3.4.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

### 13.3.4.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

#### NOTE

The clock source selected need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

#### NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency  $f_{LPTMR}$  defined in the device datasheet.

### 13.3.4.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

#### NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

#### 13.3.4.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every  $2^2$  to  $2^{16}$  prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

#### 13.3.4.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

#### 13.3.4.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

If	Then
The selected input source remains deasserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising edges	The glitch filter output will also deassert.
The selected input source remains asserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising-edges	The glitch filter output will also assert.

#### NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every  $2^2$  to  $2^{16}$  prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

#### 13.3.4.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

#### 13.3.4.4 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

#### 13.3.4.5 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

The CNR continues incrementing when the core is halted in Debug mode when configured for Pulse Counter mode, the CNR will stop incrementing when the core is halted in Debug mode when configured for Time Counter mode.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

### 13.3.4.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

When	Then
The CMR is set to 0 with CSR[TFC] clear	The LPTMR hardware trigger will assert on the first compare and does not deassert.
The CMR is set to a nonzero value, or, if CSR[TFC] is set	The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR.

### 13.3.4.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

## 13.4 Programmable Delay Block (PDB)

### 13.4.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Programmable Delay Block (PDB) provides controllable delays from either an internal or an external trigger, or a programmable interval tick, to the hardware trigger inputs of ADCs and/or generates the interval triggers to DACs, so that the precise timing between ADC conversions and/or DAC updates can be achieved.

### 13.4.1.1 Features

- Up to 15 trigger input sources and one software trigger source
- Up to 8 configurable PDB channels for ADC hardware trigger
  - One PDB channel is associated with one ADC
  - One trigger output for ADC hardware trigger and up to 8 pre-trigger outputs for ADC trigger select per PDB channel
  - Trigger outputs can be enabled or disabled independently
  - One 16-bit delay register per pre-trigger output
  - Optional bypass of the delay registers of the pre-trigger outputs
  - Operation in One-Shot or Continuous modes
  - Optional back-to-back mode operation, which enables the ADC conversions complete to trigger the next PDB channel
  - One programmable delay interrupt
  - One sequence error interrupt
  - One channel flag and one sequence error flag per pre-trigger
  - DMA support
- Up to 8 DAC interval triggers
  - One interval trigger output per DAC
  - One 16-bit delay interval register per DAC trigger output
  - Optional bypass of the delay interval trigger registers
  - Optional external triggers

#### NOTE

The number of PDB input and output triggers are chip-specific. See the chip-specific PDB information for details.

### 13.4.1.2 Implementation

In this section, the following letters refer to the number of output triggers:

- $N$ —Total available number of PDB channels.
- $n$ —PDB channel number, valid from 0 to  $N-1$ .
- $M$ —Total available pre-trigger per PDB channel.
- $m$ —Pre-trigger number, valid from 0 to  $M-1$ .
- $X$ —Total number of DAC interval triggers.
- $x$ —DAC interval trigger output number, valid from 0 to  $X-1$ .
- $Y$ —Total number of Pulse-Out's.
- $y$ —Pulse-Out number, valid value is from 0 to  $Y-1$ .

### NOTE

The number of module output triggers to core is chip-specific. For module to core output triggers implementation, see the chip configuration information.

#### 13.4.1.3 Back-to-back acknowledgment connections

PDB back-to-back operation acknowledgment connections are chip-specific. For implementation, see the chip configuration information.

#### 13.4.1.4 Block diagram

This diagram illustrates the major components of the PDB.

**Figure 13-102. PDB block diagram**

In this diagram, only one PDB channel  $n$ , one DAC interval trigger  $x$ , and one Pulse-Out  $y$  are shown. The PDB-enabled control logic and the sequence error interrupt logic are not shown.

### 13.4.1.5 Modes of operation

PDB ADC trigger operates in the following modes:

- Disabled—Counter is off, all pre-trigger and trigger outputs are low if PDB is not in back-to-back operation of Bypass mode.
- Debug—Counter is paused when processor is in Debug mode, and the counter for the DAC trigger is also paused in Debug mode.
- Enabled One-Shot—Counter is enabled and restarted at count zero upon receiving a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1. In each PDB channel, an enabled pre-trigger asserts once per trigger input event. The trigger output asserts whenever any of the pre-triggers is asserted.
- Enabled Continuous—Counter is enabled and restarted at count zero. The counter is rolled over to zero again when the count reaches the value specified in the modulus register, and the counting is restarted. This enables a continuous stream of pre-triggers/trigger outputs as a result of a single trigger input event.
- Enabled Bypassed—The pre-trigger and trigger outputs assert immediately after a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1, that is the delay registers are bypassed. It is possible to bypass any one or more of the delay registers; therefore, this mode can be used in conjunction with One-Shot or Continuous mode.

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–18 LDMOD	Load Mode Select  Selects the mode to load the MOD, IDLY, CH $n$ DLY $m$ , INT $x$ , and POyDLY registers, after 1 is written to LDOK.  00 The internal registers are loaded with the values from their buffers immediately after 1 is written to LDOK. 01 The internal registers are loaded with the values from their buffers when the PDB counter reaches the MOD register value after 1 is written to LDOK. 10 The internal registers are loaded with the values from their buffers when a trigger input event is detected after 1 is written to LDOK. 11 The internal registers are loaded with the values from their buffers when either the PDB counter reaches the MOD register value or a trigger input event is detected, after 1 is written to LDOK.
17 PDBEIE	PDB Sequence Error Interrupt Enable  Enables the PDB sequence error interrupt. When this field is set, any of the PDB channel sequence error flags generates a PDB sequence error interrupt.

*Table continues on the next page...*

**PDB\_SC field descriptions (continued)**

Field	Description
	0 PDB sequence error interrupt disabled. 1 PDB sequence error interrupt enabled.
16 SWTRIG	Software Trigger  When PDB is enabled and the software trigger is selected as the trigger input source, writing 1 to this field resets and restarts the counter. Writing 0 to this field has no effect. Reading this field results 0.
15 DMAEN	DMA Enable  When DMA is enabled, the PDBIF flag generates a DMA request instead of an interrupt.  0 DMA disabled. 1 DMA enabled.
14–12 PRESCALER	Prescaler Divider Select  000 Counting uses the peripheral clock divided by multiplication factor selected by MULT. 001 Counting uses the peripheral clock divided by twice of the multiplication factor selected by MULT. 010 Counting uses the peripheral clock divided by four times of the multiplication factor selected by MULT. 011 Counting uses the peripheral clock divided by eight times of the multiplication factor selected by MULT. 100 Counting uses the peripheral clock divided by 16 times of the multiplication factor selected by MULT. 101 Counting uses the peripheral clock divided by 32 times of the multiplication factor selected by MULT. 110 Counting uses the peripheral clock divided by 64 times of the multiplication factor selected by MULT. 111 Counting uses the peripheral clock divided by 128 times of the multiplication factor selected by MULT.
11–8 TRGSEL	Trigger Input Source Select  Selects the trigger input source for the PDB. The trigger input source can be internal or external (EXTRG pin), or the software trigger. Refer to chip configuration details for the actual PDB input trigger connections.  0000 Trigger-In 0 is selected. 0001 Trigger-In 1 is selected. 0010 Trigger-In 2 is selected. 0011 Trigger-In 3 is selected. 0100 Trigger-In 4 is selected. 0101 Trigger-In 5 is selected. 0110 Trigger-In 6 is selected. 0111 Trigger-In 7 is selected. 1000 Trigger-In 8 is selected. 1001 Trigger-In 9 is selected. 1010 Trigger-In 10 is selected. 1011 Trigger-In 11 is selected. 1100 Trigger-In 12 is selected. 1101 Trigger-In 13 is selected. 1110 Trigger-In 14 is selected. 1111 Software trigger is selected.

*Table continues on the next page...*

**PDB\_SC field descriptions (continued)**

Field	Description
7 PDBEN	PDB Enable  0 PDB disabled. Counter is off. 1 PDB enabled.
6 PDBIF	PDB Interrupt Flag  This field is set when the counter value is equal to the IDLY register. Writing zero clears this field.
5 PDBIE	PDB Interrupt Enable  Enables the PDB interrupt. When this field is set and DMAEN is cleared, PDBIF generates a PDB interrupt.  0 PDB interrupt disabled. 1 PDB interrupt enabled.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 MULT	Multiplication Factor Select for Prescaler  Selects the multiplication factor of the prescaler divider for the counter clock.  00 Multiplication factor is 1. 01 Multiplication factor is 10. 10 Multiplication factor is 20. 11 Multiplication factor is 40.
1 CONT	Continuous Mode Enable  Enables the PDB operation in Continuous mode.  0 PDB operation in One-Shot mode 1 PDB operation in Continuous mode
0 LDOK	Load OK  Writing 1 to LDOK bit updates the MOD, IDLY, CHnDLYm, DACINTx, and POyDLY registers with the values previously written to their internal buffers (and stored there). The new values of MOD, IDLY, CHnDLYm, DACINTx, and POyDLY registers will take effect according to the setting of the LDMOD field (Load Mode Select). Before 1 is written to the LDOK field, the values in the internal buffers of these registers are not effective, and new values cannot be written to the internal buffers until the existing values in the internal buffers are loaded into their corresponding registers. <ul style="list-style-type: none"> <li>LDOK can be written only when PDBEN is set, or LDOK can be written at the same time when PDBEN is written to 1.</li> <li>LDOK is automatically cleared when the values in the internal buffers are loaded into the registers or when PDBEN bit (PDB Enable) is cleared.</li> <li>Writing 0 to LDOK has no effect.</li> </ul>

### 13.4.2.2 Modulus register (PDB\_MOD)

**Note:** This register is internally buffered, and any values written to the register are written to its internal buffer instead; in other words, the internal device bus does not write directly to this register. The value in this register's internal buffer is loaded into this register only after "1" is written to the SC[LDOK] bit.

Address: 4003\_6000h base + 4h offset = 4003\_6004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																MOD

## PDB\_IDLY field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
IDLY	PDB Interrupt Delay  Specifies the delay value to schedule the PDB interrupt. It can be used to schedule an independent interrupt at some point in the PDB cycle. If enabled, a PDB interrupt is generated, when the counter is equal to the IDLY. Reading this field returns the value of internal register that is effective for the current cycle of the PDB.

## 13.4.2.5 Channel n Control register 1 (PDB\_CHnC1)

Each PDB channel has one control register, CHnC1. The bits in this register control the functionality of each PDB channel operation.

Address: 4003\_6000h base + 10h offset + (40d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### PDB\_CHnC1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 BB	PDB Channel Pre-Trigger Back-to-Back Operation Enable  These bits enable the PDB ADC pre-trigger operation as back-to-back mode. Only lower M pre-trigger bits are implemented in this MCU. Back-to-back operation enables the ADC conversions complete to trigger the next PDB channel pre-trigger and trigger output, so that the ADC conversions can be triggered on next set of configuration and results registers. Application code must only enable the back-to-back operation of the PDB pre-triggers at the leading of the back-to-back connection chain.  0 PDB channel's corresponding pre-trigger back-to-back operation disabled. 1 PDB channel's corresponding pre-trigger back-to-back operation enabled.
15–8 TOS	PDB Channel Pre-Trigger Output Select  Selects the PDB ADC pre-trigger outputs. Only lower M pre-trigger fields are implemented in this MCU.  0 PDB channel's corresponding pre-trigger is in bypassed mode. The pre-trigger asserts one peripheral clock cycle after a rising edge is detected on selected trigger input source or software trigger is selected and SWTRIG is written with 1. 1 PDB channel's corresponding pre-trigger asserts when the counter reaches the channel delay register and one peripheral clock cycle after a rising edge is detected on selected trigger input source or software trigger is selected and SETRIG is written with 1.
EN	PDB Channel Pre-Trigger Enable  These bits enable the PDB ADC pre-trigger outputs. Only lower M pre-trigger bits are implemented in this MCU.  0 PDB channel's corresponding pre-trigger disabled. 1 PDB channel's corresponding pre-trigger enabled.

### 13.4.2.6 Channel n Status register (PDB\_CHnS)

Address: 4003\_6000h base + 14h offset + (40d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**PDB\_DACINTn field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
INT	DAC Interval  Specifies the interval value for DAC interval trigger. DAC interval trigger triggers DAC[1:0] update when the DAC interval counter is equal to the DACINT. Reading this field returns the value of internal register that is effective for the current PDB cycle.

**13.4.3 Functional description**

### 13.4.3.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared to several different digital values. If the PDB is enabled, then a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on a selected trigger input source, or if a software trigger is selected and SC[SWTRIG] is written with 1. For each channel, a delay  $m$  determines the time between assertion of the trigger input event to the time at which changes in the pre-trigger  $m$  output signal are started. The time is defined as:

- Trigger input event to pre-trigger  $m = (\text{prescaler} \times \text{multiplication factor} \times \text{delay } m) + 2$  peripheral clock cycles
- Add 1 additional peripheral clock cycle to determine the time when the channel trigger output changes.

Each channel is associated with 1 ADC block. PDB channel  $n$  pre-trigger outputs 0 to  $M$ ; each pre-trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block before the actual trigger occurs. When the ADC receives the rising edge of the trigger, the ADC will start the conversion according to the precondition determined by the pre-triggers. The ADC contains  $M$  sets of configuration and result registers, allowing it to alternate conversions between  $M$  different analog sources (like a ping-pong game). The pre-trigger outputs are used to specify which signal will be sampled next. When a pre-trigger  $m$  is asserted, the ADC conversion is triggered with set  $m$  of the configuration and result registers.

The waveforms shown in the following diagram show the pre-trigger and trigger outputs of PDB channel  $n$ . The delays can be independently set using the CHnDLY $m$  registers, and the pre-triggers can be enabled or disabled in CHnC1[EN[ $m$ ]].

**Figure 13-103. Pre-trigger and trigger outputs**

The delay in CHnDLY $m$  register can be optionally bypassed, if CHnC1[TOS[ $m$ ]] is cleared. In this case, when the trigger input event occurs, the pre-trigger  $m$  is asserted after 2 peripheral clock cycles.

The PDB can be configured for back-to-back operation. Back-to-back operation enables the ADC conversion completions to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on the next set of configuration and results registers. When back-to-back operation is enabled by setting `CHnC1[BB[m]]`, then the delay  $m$  is ignored and the pre-trigger  $m$  is asserted 2 peripheral cycles after the acknowledgment  $m$  is received. The acknowledgment connections in this MCU are described in [Back-to-back acknowledgment connections](#).

When a pre-trigger from a PDB channel  $n$  is asserted, the associated lock of the pre-trigger becomes active. The associated lock is released by the rising edge of the corresponding `ADCnSC1[COCO]`; the `ADCnSC1[COCO]` should be cleared after the conversion result is read, so that the next rising edge of `ADCnSC1[COCO]` can be generated to clear the lock later. The lock becomes inactive when:

- the rising edge of corresponding `ADCnSC1[COCO]` occurs,
- or the corresponding PDB pre-trigger is disabled,
- or the PDB is disabled

The channel  $n$  trigger output is suppressed when any of the locks of the pre-triggers in channel  $n$  is active. If a new pre-trigger  $m$  asserts when there is active lock in the PDB channel  $n$ , then a register flag bit `CHnS[ERR[m]]` (associated with the pre-trigger  $m$ ) is set. If `SC[PDBEIE]` is set, then the sequence error interrupt is generated. A sequence error typically happens because the delay  $m$  is set too short and the pre-trigger  $m$  asserts before the previously triggered ADC conversion finishes.

When the PDB counter reaches the value set in `IDLY` register, the `SC[PDBIF]` flag is set. A PDB interrupt can be generated if `SC[PDBIE]` is set and `SC[DMAEN]` is cleared. If `SC[DMAEN]` is set, then the PDB requests a DMA transfer when the `SC[PDBIF]` flag is set.

The modulus value in the `MOD` register is used to reset the counter back to zero at the end of the count. If `SC[CONT]` is set, then the counter will then resume a new count; otherwise, the counter operation will stop until the next trigger input event occurs.

### 13.4.3.2 PDB trigger input source selection

The PDB has up to 15 trigger input sources, namely Trigger-In 0 to Trigger-In 14. They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through `SC[SWTRIG]`.

For the trigger input sources implemented in this MCU, see chip configuration information.

### 13.4.3.3 DAC interval trigger outputs

PDB can generate the interval triggers for DACs to update their outputs periodically. DAC interval counter  $x$  is reset and started when a trigger input event occurs if DACINTC $x$ [EXT] is cleared. When the interval counter  $x$  is equal to the value set in DACINT $x$  register, the DAC interval trigger  $x$  output generates a pulse of one peripheral clock cycle width to update the DAC $x$ . If DACINTC $x$ [EXT] is set, the DAC interval counter is bypassed and the interval trigger output  $x$  generates a pulse following the detection of a rising edge on the DAC external trigger input. The counter and interval trigger can be disabled by clearing the DACINTC $x$ [TOE].

DAC interval counters are also reset when the PDB counter reaches the MOD register value; therefore, when the PDB counter rolls over to zero, the DAC interval counters starts anew.

The DAC interval trigger pulse and the ADC pre-trigger/trigger pulses together allow precise timing of DAC updates and ADC measurements. This is outlined in the typical use case described in the following diagram.

**Figure 13-104. PDB ADC triggers and DAC interval triggers use case**

## NOTE

Because the DAC interval counters share the prescaler with PDB counter, PDB must be enabled if the DAC interval trigger outputs are used in the applications.

### 13.4.3.4 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus register (MOD)
- PDB Interrupt Delay register (IDLY)
- PDB Channel  $n$  Delay  $m$  register (CH $n$ DLY $m$ )
- DAC Interval  $x$  register (DACINT $x$ )
- PDB Pulse-Out  $y$  Delay register (POyDLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized as shown in the table below.

**Table 13-21. Circumstances of update to the delay registers**

SC[LDMOD]	Update to the delay registers
00	The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].
01	The PDB counter reaches the MOD register value after 1 is written to SC[LDOK].
10	A trigger input event is detected after 1 is written to SC[LDOK].
11	Either the PDB counter reaches the MOD register value, or a trigger input event is detected, after 1 is written to SC[LDOK].

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

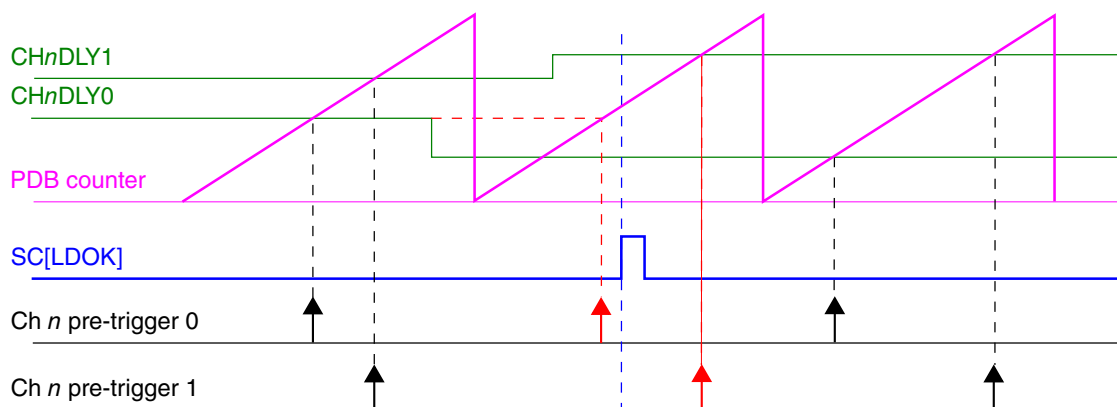

Figure 13-105. Registers update with SC[LDMOD] = 00

Figure 13-106. Registers update with SC[LDMOD] = x1

### 13.4.3.5 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

Table 13-22. PDB interrupt summary

Interrupt	Flags	Enable bit
PDB Interrupt	SC[PDBIF]	SC[PDBIE] = 1 and SC[DMAEN] = 0
PDB Sequence Error Interrupt	CHnS[ERRm]	SC[PDSEIE] = 1

### 13.4.3.6 DMA

If SC[DMAEN] is set, PDB can generate a DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt is not issued.

## 13.4.4 Application information

### 13.4.4.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use a prescaler set to 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

# Chapter 14

## DMA

### 14.1 Enhanced Direct Memory Access (eDMA)

#### 14.1.1 Introduction

##### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

##### 14.1.1.1 eDMA system block diagram

[Figure 14-1](#) illustrates the components of the eDMA system, including the eDMA module ("engine").

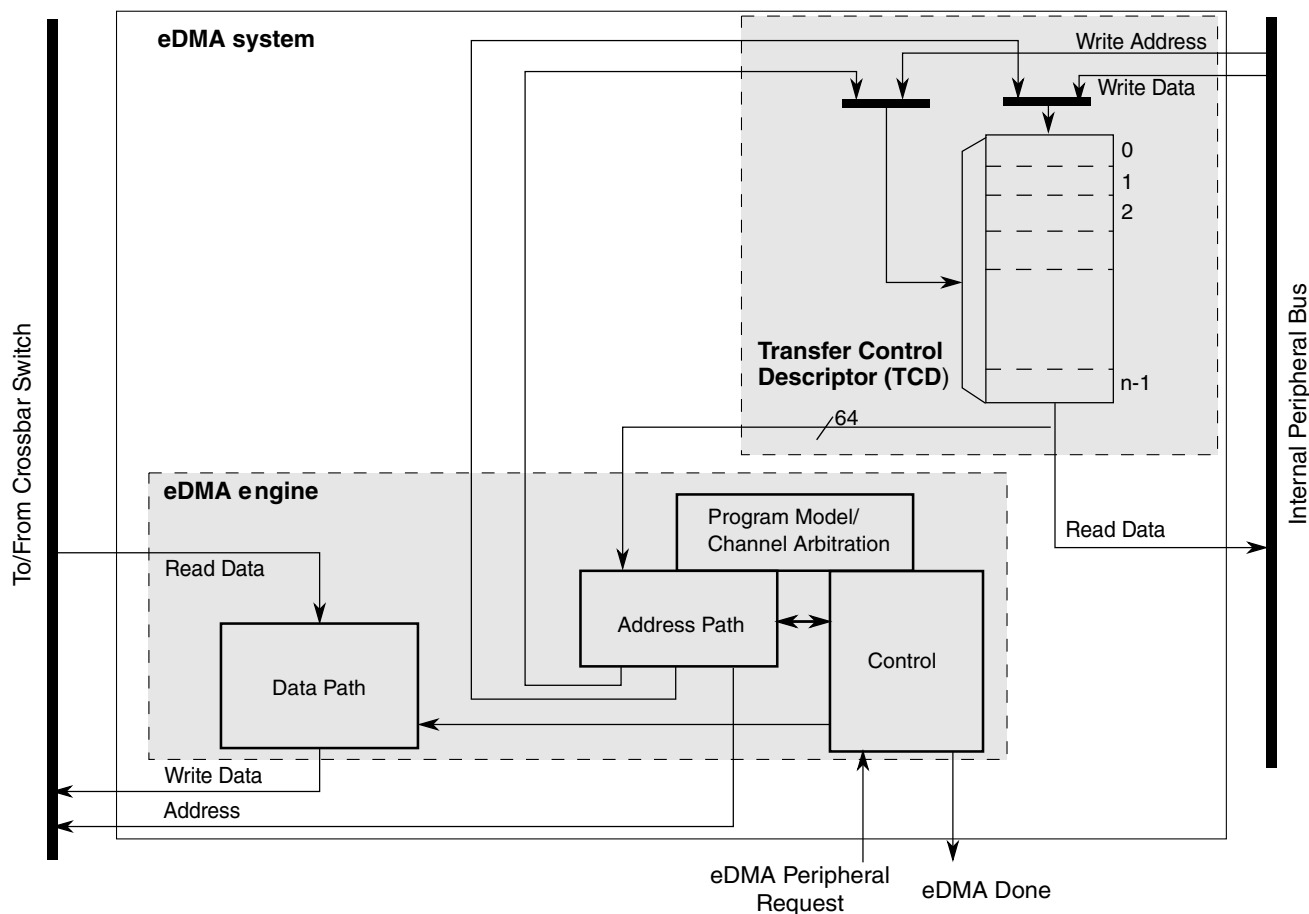

Figure 14-1. eDMA system block diagram

14.1.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 14-1. eDMA engine submodules

Submodule	Function
Address path	<p>This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI<sub>n</sub>[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.</p> <p>When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes</p>

Table continues on the next page...

**Table 14-1. eDMA engine submodules (continued)**

Submodule	Function
	the new values for the TCDn_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCDn_CITER field, and a possible fetch of the next TCDn from memory as part of a scatter/gather operation.
Data path	<p>This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.</p> <p>The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).</p>
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

**Table 14-2. Transfer control descriptor memory**

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

### 14.1.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module,  $n$  is used to reference the channel number.

### **14.1.2 Modes of operation**

The eDMA operates in the following modes:

**Table 14-3. Modes of operation**

Mode	Description
Normal	<p>In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.</p> <p>A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.</p>
Debug	<p>DMA operation is configurable in Debug mode via the control register:</p> <ul style="list-style-type: none"> <li>• If CR[EDBG] is cleared, the DMA continues to operate.</li> <li>• If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.</li> </ul>
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

### 14.1.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

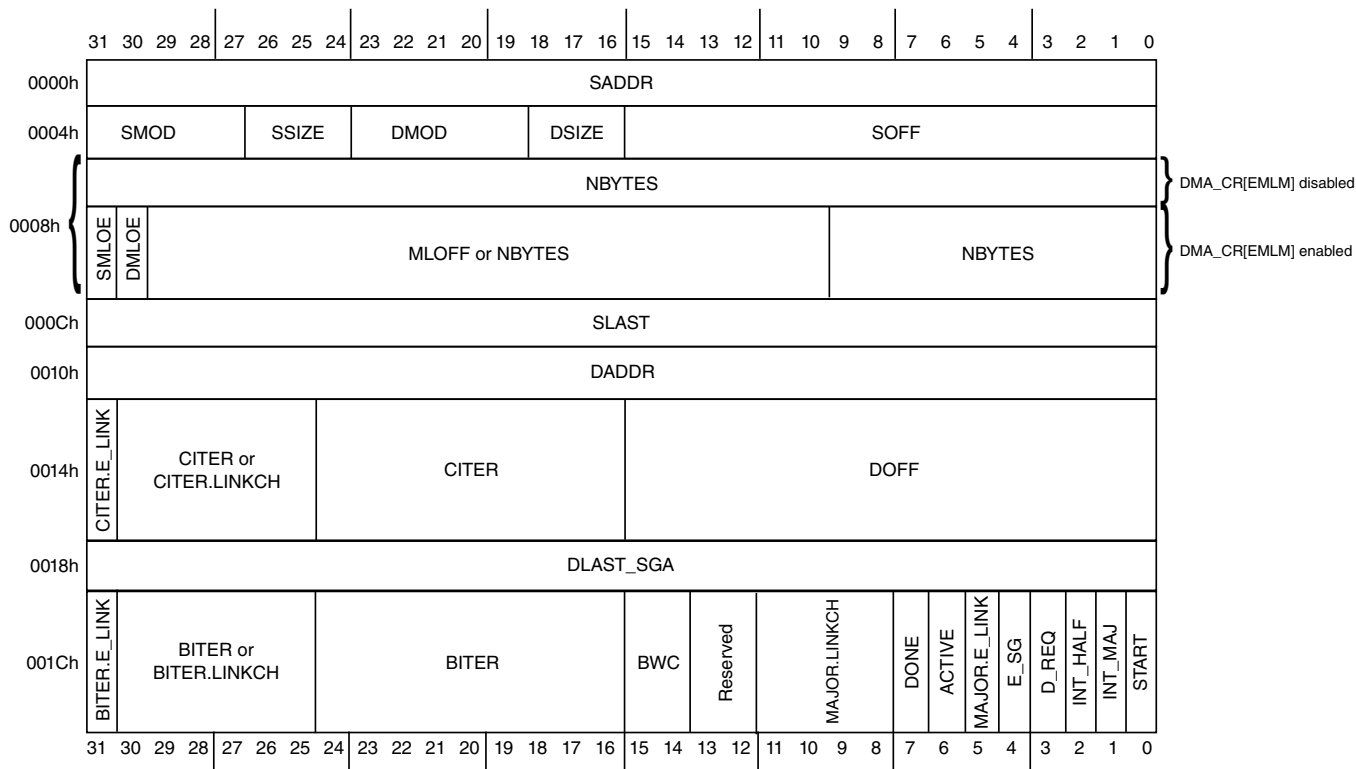

#### 14.1.3.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD<sub>n</sub> definition is presented as 11 registers of 16 or 32 bits.

#### 14.1.3.2 TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

### 14.1.3.3 TCD structure

### 14.1.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

#### DMA memory map

### 14.1.3.5 Control Register (DMAx\_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

#### NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn\_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration

error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn\_SADDR) or destination address (TCDn\_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn\_SADDR), to the final destination address (TCDn\_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn\_SLAST and TCDn\_DLAST\_SGA) are used to compute the next TCDn\_SADDR and TCDn\_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn\_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn\_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

## DMAx\_CR field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 CX	Cancel Transfer  0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
16 ECX	Error Cancel Transfer  0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 GRP1PRI	Channel Group 1 Priority  Group 1 priority level when fixed priority group arbitration is enabled.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 GRP0PRI	Channel Group 0 Priority  Group 0 priority level when fixed priority group arbitration is enabled.
7 EMLM	Enable Minor Loop Mapping  0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
6 CLM	Continuous Link Mode  <b>NOTE:</b> Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.  0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
5 HALT	Halt DMA Operations  0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.

Table continues on the next page...

**DMAx\_CR field descriptions (continued)**

Field	Description
4 HOE	Halt On Error  0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
3 ERGA	Enable Round Robin Group Arbitration  0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
2 ERCA	Enable Round Robin Channel Arbitration  0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
1 EDBG	Enable Debug  0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
0 Reserved	This field is reserved. Reserved

**14.1.3.6 Error Status Register (DMAx\_ES)**

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See [Fault reporting and handling](#) for more details.

## DMAx\_ES field descriptions

Field	Description
31 VLD	Logical OR of all ERR status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
30–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ECX	Transfer Canceled 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
15 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
14 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
7 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
6 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
5 DAE	Destination Address Error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
4 DOE	Destination Offset Error

Table continues on the next page...

**DMAx\_ES field descriptions (continued)**

Field	Description
	0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
3 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. <ul style="list-style-type: none"> <li>• TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or</li> <li>• TCDn_CITER[CITER] is equal to zero, or</li> <li>• TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]</li> </ul>
2 SGE	Scatter/Gather Configuration Error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
1 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

**14.1.3.7 Enable Request Register (DMAx\_ERQ)**

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

### 14.1.3.8 Enable Error Interrupt Register (DMAx\_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

**14.1.3.9 Clear Enable Error Interrupt Register (DMAx\_CEEI)**

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 18h offset

	0 Clear only the EEI bit specified in the CEEI field 1 Clear all bits in EEI
5 Reserved	This field is reserved.
CEEI	Clear Enable Error Interrupt  Clears the corresponding bit in EEI

**14.1.3.10 Set Enable Error Interrupt Register (DMAx\_SEEI)**

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 19h offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	SAEE	0			SEEI		
Reset	0	0	0	0	0	0	0	0

**DMAx\_SEEI field descriptions**

Field	Description
7 NOP	No Op enable  0 Normal operation 1 No operation, ignore the other bits in this register
6 SAEE	Sets All Enable Error Interrupts  0 Set only the EEI bit specified in the SEEI field. 1 Sets all bits in EEI
5 Reserved	This field is reserved.
SEEI	Set Enable Error Interrupt  Sets the corresponding bit in EEI

### 14.1.3.11 Clear Enable Request Register (DMAx\_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Ah offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAER	0			CERQ		
Reset	0	0	0	0	0	0	0	0

**DMAx\_CERQ field descriptions**

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAER	Clear All Enable Requests 0 Clear only the ERQ bit specified in the CERQ field 1 Clear all bits in ERQ
5 Reserved	This field is reserved.
CERQ	Clear Enable Request Clears the corresponding bit in ERQ.

14.1.3.12 Set Enable Request Register (DMAx\_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Bh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	SAER	0			SERQ		
Reset	0	0	0	0	0	0	0	0

DMAx\_SERQ field descriptions

Field	Description
7 NOP	No Op enable  0 Normal operation 1 No operation, ignore the other bits in this register
6 SAER	Set All Enable Requests  0 Set only the ERQ bit specified in the SERQ field 1 Set all bits in ERQ
5 Reserved	This field is reserved.
SERQ	Set Enable Request  Sets the corresponding bit in ERQ.

### 14.1.3.13 Clear DONE Status Bit Register (DMAx\_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Ch offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CADN	0			CDNE		
Reset	0	0	0	0	0	0	0	0

#### DMAx\_CDNE field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
5 Reserved	This field is reserved.
CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

14.1.3.14 Set START Bit Register (DMAx\_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Dh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	SAST	0			SSRT		
Reset	0	0	0	0	0	0	0	0

DMAx\_SSRT field descriptions

Field	Description
7 NOP	No Op enable  0 Normal operation 1 No operation, ignore the other bits in this register
6 SAST	Set All START Bits (activates all channels)  0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
5 Reserved	This field is reserved.
SSRT	Set START Bit  Sets the corresponding bit in TCDn_CSR[START]

### 14.1.3.15 Clear Error Register (DMAx\_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Eh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAEI	0			CERR		
Reset	0	0	0	0	0	0	0	0

**DMAx\_CERR field descriptions**

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAEI	Clear All Error Indicators 0 Clear only the ERR bit specified in the CERR field 1 Clear all bits in ERR
5 Reserved	This field is reserved.
CERR	Clear Error Indicator Clears the corresponding bit in ERR

14.1.3.16 Clear Interrupt Request Register (DMAx\_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Fh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0				0		
Write	NOP	CAIR	0			CINT		
Reset	0	0	0	0	0	0	0	0

DMAx\_CINT field descriptions

Field	Description
7 NOP	No Op enable  0 Normal operation 1 No operation, ignore the other bits in this register
6 CAIR	Clear All Interrupt Requests  0 Clear only the INT bit specified in the CINT field 1 Clear all bits in INT
5 Reserved	This field is reserved.
CINT	Clear Interrupt Request  Clears the corresponding bit in INT

14.1.3.17 Interrupt Request Register (DMAx\_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software’s responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

0 INT0	Interrupt Request 0 0 The interrupt request for corresponding channel is cleared 1 The interrupt request for corresponding channel is active

**14.1.3.18 Error Register (DMAx\_ERR)**

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

**14.1.3.19 Hardware Request Status Register (DMAx\_HRS)**

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

**NOTE**

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

**14.1.3.20 Channel n Priority Register (DMAx\_DCHPRIn)**

When fixed-priority channel arbitration is enabled ( $CR[ERCA] = 0$ ), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: Base address + 100h offset + (1d × i), where i=0d to 31d

Bit	7	6	5	4	3	2	1	0
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

\* Notes:

- GRPPRI field: See bit field description.
- CHPRI field: See bit field description.

**DMAx\_DCHPRIn field descriptions**

Field	Description
7 ECP	Enable Channel Preemption.  0 Channel n cannot be suspended by a higher priority channel's service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.

*Table continues on the next page...*

**DMAx\_DCHPRIn field descriptions (continued)**

Field	Description
6 DPA	Disable Preempt Ability.  0 Channel n can suspend a lower priority channel. 1 Channel n cannot suspend any channel, regardless of channel priority.
5–4 GRPPRI	Channel n Current Group Priority  Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored.  <b>NOTE:</b> Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
CHPRI	Channel n Arbitration Priority  Channel priority when fixed-priority arbitration is enabled  <b>NOTE:</b> Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.

**14.1.3.21 TCD Source Address (DMAx\_TCDn\_SADDR)**

Address: Base address + 1000h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*

\* Notes:

- x = Undefined at reset.

#### DMAx\_TCDn\_ATTR field descriptions

Field	Description
15–11 SMOD	Source Address Modulo  0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
10–8 SSIZE	Source data transfer size  <b>NOTE:</b> Using a Reserved value causes a configuration error.

*Table continues on the next page...*

7–3 DMOD	Destination Address Modulo  See the SMOD definition
DSIZE	Destination data transfer size  See the SSIZE definition

**14.1.3.24 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMAx\_TCDn\_NBYTES\_MLNO)**

This register, or one of the next two registers (TCD\_NBYTES\_MLOFFNO, TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD\_NBYTES\_MLOFFNO and TCD\_NBYTES\_MLOFFYES register descriptions for the definition of TCD word 2.

Address: Base address + 1008h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DMAx\_TCDn\_NBYTES\_MLNO field descriptions**

Field	Description
NBYTES	Minor Byte Transfer Count  Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can,

**DMAx\_TCDn\_NBYTES\_MLNO field descriptions (continued)**

Field	Description
	however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.
	<b>NOTE:</b> An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

### 14.1.3.25 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMAx\_TCDn\_NBYTES\_MLOFFNO)

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD\_NBYTES\_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

Address: Base address + 1008h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

\* Notes:

- x = Undefined at reset.

**DMAx\_TCDn\_NBYTES\_MLOFFNO field descriptions**

Field	Description
31 SMLOE	Source Minor Loop Offset Enable  Selects whether the minor loop offset is applied to the source address upon minor loop completion.  0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset enable  Selects whether the minor loop offset is applied to the destination address upon minor loop completion.  0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
NBYTES	Minor Byte Transfer Count  Number of bytes to be transferred in each service request of the channel.  As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

**14.1.3.26 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMAx\_TCDn\_NBYTES\_MLOFFYES)**

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD\_NBYTES\_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

Address: Base address + 1008h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Enhanced Direct Memory Access (eDMA)

\* Notes:

- x = Undefined at reset.

### DMAX\_TCDn\_NBYTES\_MLOFFYES field descriptions

Field	Description
31 SMLOE	Source Minor Loop Offset Enable  Selects whether the minor loop offset is applied to the source address upon minor loop completion.  0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset enable  Selects whether the minor loop offset is applied to the destination address upon minor loop completion.  0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
29–10 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
NBYTES	Minor Byte Transfer Count  Number of bytes to be transferred in each service request of the channel.  As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

### 14.1.3.27 TCD Last Source Address Adjustment (DMAX\_TCDn\_SLAST)

Address: Base address + 100Ch offset + (32d × i), where i=0d to 31d

\* Notes:

- x = Undefined at reset.

## DMAx\_TCDn\_SLAST field descriptions

Field	Description
SLAST	<p>Last Source Address Adjustment</p> <p>Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.</p> <p>This register uses two's complement notation; the overflow bit is discarded.</p>

## 14.1.3.28 TCD Destination Address (DMAx\_TCDn\_DADDR)

Address: Base address + 1010h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

\* Notes:

- x = Undefined at reset.

#### DMAx\_TCDn\_CITER\_ELINKYES field descriptions

Field	Description
15 ELINK	<p>Enable channel-to-channel linking on minor-loop complete</p> <p>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.</p> <p>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.</p> <p><b>NOTE:</b> This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.</p> <p>0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled</p>
14 Reserved	This field is reserved.
13–9 LINKCH	<p>Minor Loop Link Channel Number</p> <p>If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.</p>
CITER	<p>Current Major Iteration Count</p> <p>This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.</p>

Table continues on the next page...

**DMAx\_TCDn\_CITER\_ELINKYES field descriptions (continued)**

Field	Description
	<p><b>NOTE:</b> When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.</p> <p><b>NOTE:</b> If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</p>

**14.1.3.31 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMAx\_TCDn\_CITER\_ELINKNO)**

If TCDn\_CITER[ELINK] is cleared, the TCDn\_CITER register is defined as follows.

Address: Base address + 1016h offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8
Read	ELINK	CITER

\* Notes:

- x = Undefined at reset.

#### DMAx\_TCDn\_CSR field descriptions

Field	Description
15–14 BWC	<p>Bandwidth Control</p> <p>Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.</p> <p><b>NOTE:</b> If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.</p> <p>00 No eDMA engine stalls. 01 Reserved 10 eDMA engine stalls for 4 cycles after each R/W. 11 eDMA engine stalls for 8 cycles after each R/W.</p>
13 Reserved	This field is reserved.
12–8 MAJORLINKCH	<p>Major Loop Link Channel Number</p> <p>If (MAJORELINK = 0) then:</p> <ul style="list-style-type: none"> <li>• No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted.</li> </ul> <p>Otherwise:</p> <ul style="list-style-type: none"> <li>• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.</li> </ul>
7 DONE	<p>Channel Done</p> <p>This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated.</p> <p><b>NOTE:</b> This bit must be cleared to write the MAJORELINK or ESG bits.</p>

Table continues on the next page...

## DMAx\_TCDn\_CSR field descriptions (continued)

Field	Description
6 ACTIVE	<p>Channel Active</p> <p>This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.</p>
5 MAJORELINK	<p>Enable channel-to-channel linking on major loop complete</p> <p>As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.</p> <p><b>NOTE:</b> To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</p> <p>0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.</p>
4 ESG	<p>Enable Scatter/Gather Processing</p> <p>As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory.</p> <p><b>NOTE:</b> To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</p> <p>0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.</p>
3 DREQ	<p>Disable Request</p> <p>If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero.</p> <p>0 The channel's ERQ bit is not affected. 1 The channel's ERQ bit is cleared when the major loop is complete.</p>
2 INTHALF	<p>Enable an interrupt when major counter is half complete.</p> <p>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER &gt;&gt; 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress.</p> <p><b>NOTE:</b> If BITER = 1, do not use INTHALF. Use INTMAJOR instead.</p> <p>0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.</p>
1 INTMAJOR	<p>Enable an interrupt when major iteration count completes.</p> <p>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero.</p> <p>0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.</p>

Table continues on the next page...

## DMAx\_TCDn\_CSR field descriptions (continued)

Field	Description
0 START	<p>Channel Start</p> <p>If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution.</p> <p>0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.</p>

### 14.1.3.34 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMAx\_TCDn\_BITER\_ELINKYES)

If the TCDn\_BITER[ELINK] bit is set, the TCDn\_BITER register is defined as follows.

Address: Base address + 101Eh offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8
Read	ELINK				LINKCH			BITER
Write		0						
Reset	x*	x*	x*	x*	x*	x*	x*	x*
Bit	7	6	5	4	3	2	1	0
Read					BITER			
Write								
Reset	x*	x*	x*	x*	x*	x*	x*	x*

\* Notes:

- x = Undefined at reset.

## DMAx\_TCDn\_BITER\_ELINKYES field descriptions

Field	Description
15 ELINK	<p>Enables channel-to-channel linking on minor loop complete</p> <p>As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.</p> <p><b>NOTE:</b> When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.</p> <p>0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled</p>
14 Reserved	This field is reserved.

If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</p>

## 14.1.4 Functional description

The operation of the eDMA is described in the following subsections.

### 14.1.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

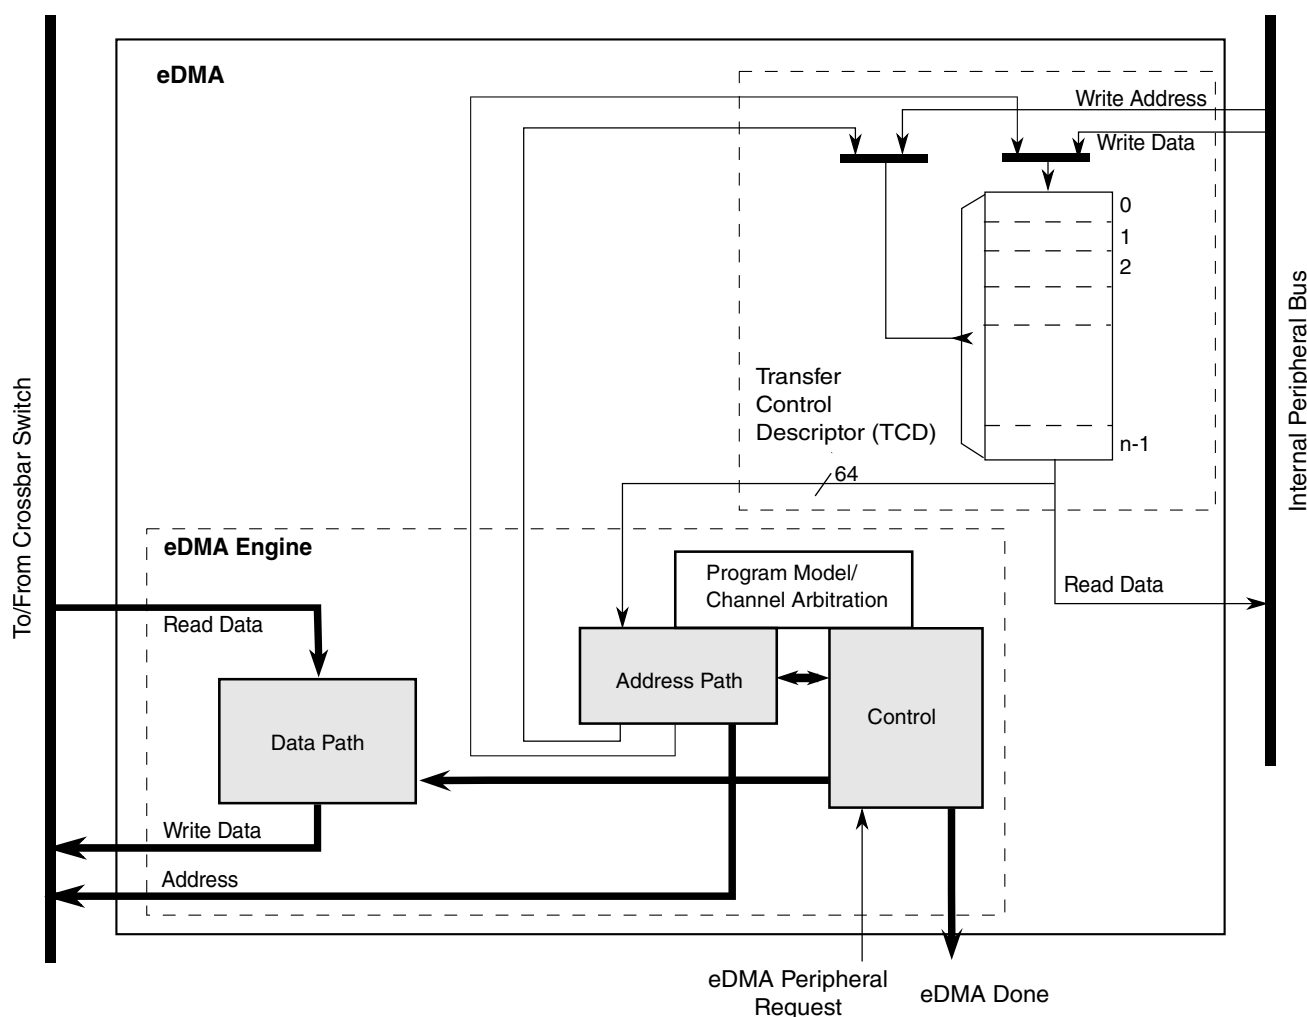

As shown in the following diagram, the first segment involves the channel activation:

**Figure 14-2. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel  $n$ . Channel activation via software and the  $TCDn\_CSR[START]$  bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for  $TCDn$ . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel  $x$  or  $y$  registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel  $x$  or  $y$  registers.

The following diagram illustrates the second part of the basic data flow:

**Figure 14-3. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

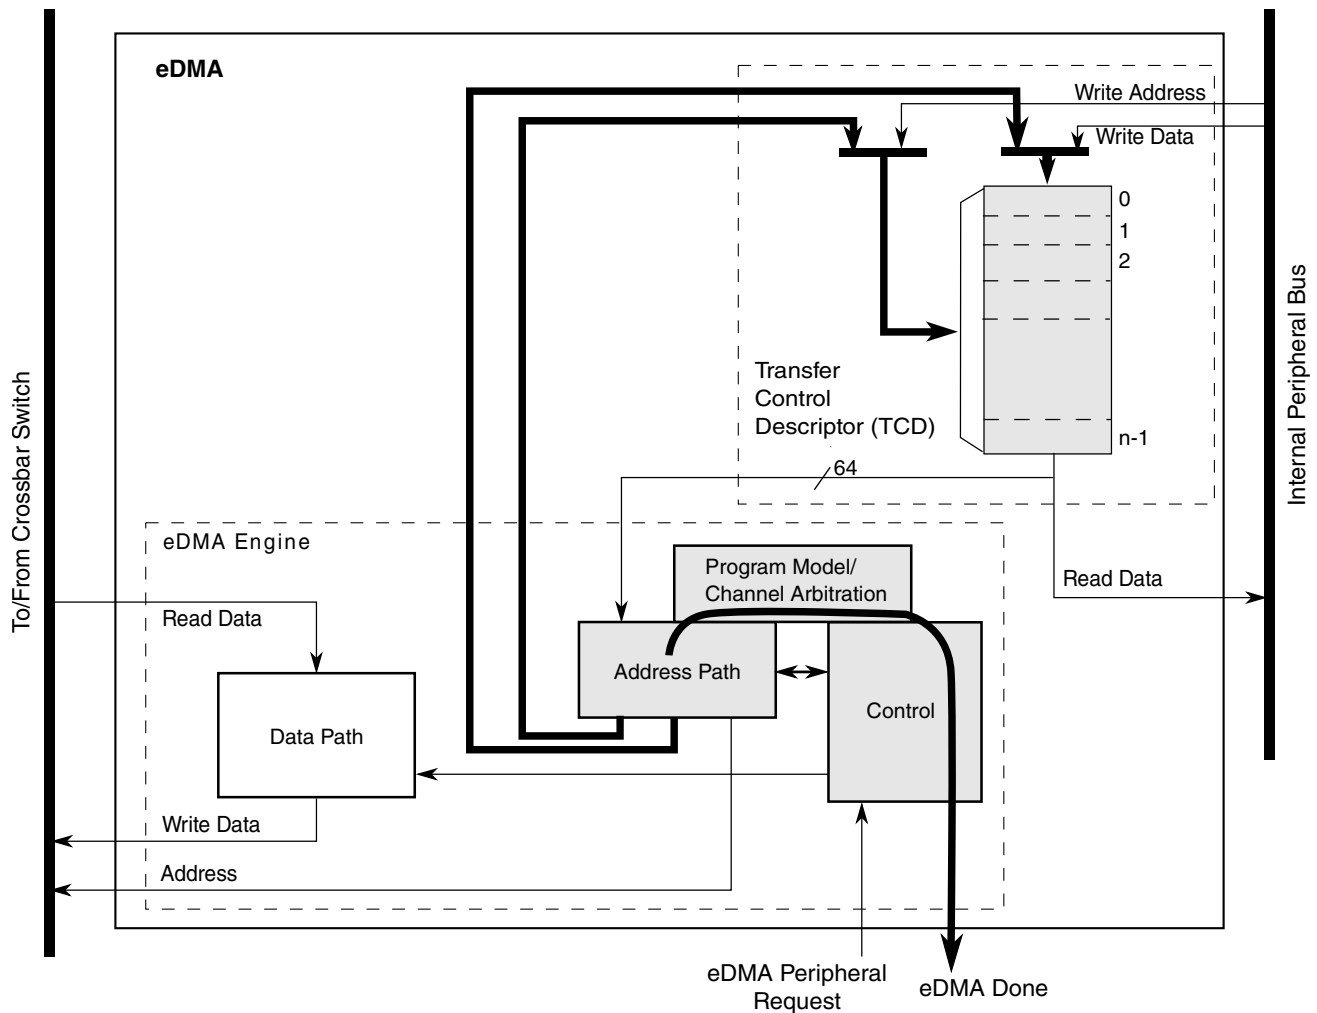

Figure 14-4. eDMA operation, part 3

#### 14.1.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx\_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

### NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST\_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn\_CITER[E\_LINK] bit does not equal the TCDn\_BITER[E\_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error

occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx\_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA\_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

### NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx\_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 14.1.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

### 14.1.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

#### 14.1.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

### NOTE

All architectures will not meet the assumptions listed above.  
See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

**Table 14-4. eDMA peak transfer rates (Mbytes/sec)**

System Speed, Width	Internal SRAM-to- Internal SRAM	32 bit internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32 bit internal peripheral bus
66.7 MHz, 64 bit	266.7	66.6	53.3
83.3 MHz, 64 bit	333.3	83.3	66.7
100.0 MHz, 64 bit	400.0	100.0	80.0
133.3 MHz, 64 bit	533.3	133.3	106.7
150.0 MHz, 64 bit	600.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

#### 14.1.4.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 14-5. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD <sub>n</sub> _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD <sub>n</sub> word 7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD <sub>n</sub> fields into the local memory. The TCD <sub>n</sub> word 7 is read and checked for channel linking or scatter/gather requests.
14	15	The appropriate fields in the first part of the TCD <sub>n</sub> are written back into the local memory.
15	16	The fields in the second part of the TCD <sub>n</sub> are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles ( $4 + (4+5)/2 + 3$ ). This is the time from Cycle 4 to Cycle  $x + 5$ . The resulting peak request rate, as a function of the system frequency, is shown in the following table.

**Table 14-6. eDMA peak request rate (MReq/sec)**

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

$$\text{PEAKreq} = \text{freq} / [ \text{entry} + (1 + \text{read\_ws}) + (1 + \text{write\_ws}) + \text{exit} ]$$

where:

**Table 14-7. Peak request formula operands**

Operand	Description
PEAKreq	Peak request rate
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase
exit	Channel shutdown (3 cycles)

#### 14.1.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 1) + (1 + 3) + 3 ] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an internal peripheral bus to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 2) + (1 + 1) + 3 ] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate would be:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a `TCDn_CSR[START]` bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

### Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

## 14.1.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 14.1.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the `DCHPRIn` registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:

- Software: setting the TCD $n$ \_CSR[START]
- Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD $n$ \_SADDR, to the destination, as defined by TCD $n$ \_DADDR, continue until the number of bytes specified by TCD $n$ \_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD $n$ \_SADDR, TCD $n$ \_DADDR, and TCD $n$ \_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 14-8. TCD Control and Status fields**

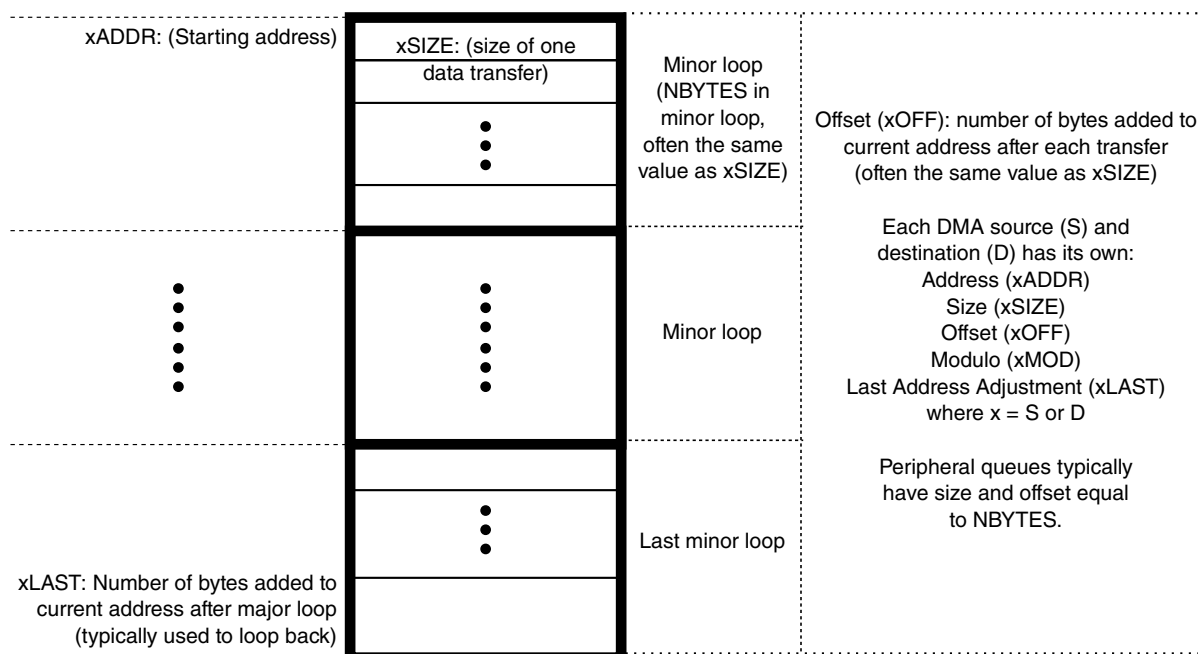

TCD $n$ _CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

**Figure 14-5. Example of multiple loop iterations**

The following figure lists the memory array terms and how the TCD settings interrelate.

**Figure 14-6. Memory array terms**

### 14.1.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx\_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

### 14.1.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 14.1.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

### 14.1.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration, Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

## 14.1.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

### 14.1.5.4.1 Single request

To perform a simple transfer of  $n$  bytes of data with one activation, set the major loop to one ( $\text{TCDn\_CITER} = \text{TCDn\_BITER} = 1$ ). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the  $\text{TCDn\_CSR}[\text{DONE}]$  bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCDn\_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes:  $\text{TCDn\_SADDR} = 0\text{x}1000$ ,  $\text{TCDn\_DADDR} = 0\text{x}2000$ ,  $\text{TCDn\_CITER} = 1$  ( $\text{TCDn\_BITER}$ ).
7. The eDMA engine writes:  $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$ ,  $\text{TCDn\_CSR}[\text{DONE}] = 1$ ,  $\text{INT}[n] = 1$ .
8. The channel retires and the eDMA goes idle or services the next channel.

#### 14.1.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:  $\text{TCDn\_CSR}[\text{DONE}] = 0$ ,  $\text{TCDn\_CSR}[\text{START}] = 0$ ,  $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$ .
4. eDMA engine reads: channel  $\text{TCDn}$  data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
  - a. Read byte from location  $0\text{x}1000$ , read byte from location  $0\text{x}1001$ , read byte from  $0\text{x}1002$ , read byte from  $0\text{x}1003$ .
  - b. Write 32-bits to location  $0\text{x}2000 \rightarrow$  first iteration of the minor loop.
  - c. Read byte from location  $0\text{x}1004$ , read byte from location  $0\text{x}1005$ , read byte from  $0\text{x}1006$ , read byte from  $0\text{x}1007$ .
  - d. Write 32-bits to location  $0\text{x}2004 \rightarrow$  second iteration of the minor loop.
  - e. Read byte from location  $0\text{x}1008$ , read byte from location  $0\text{x}1009$ , read byte from  $0\text{x}100A$ , read byte from  $0\text{x}100B$ .
  - f. Write 32-bits to location  $0\text{x}2008 \rightarrow$  third iteration of the minor loop.

- g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
- h. Write 32-bits to location 0x200C → last iteration of the minor loop.
- 6. eDMA engine writes:  $TCDn\_SADDR = 0x1010$ ,  $TCDn\_DADDR = 0x2010$ ,  $TCDn\_CITER = 1$ .
- 7. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ .
- 8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
- 9. Second hardware, that is, eDMA peripheral, requests channel service.
- 10. The channel is selected by arbitration for servicing.
- 11. eDMA engine writes:  $TCDn\_CSR[DONE] = 0$ ,  $TCDn\_CSR[START] = 0$ ,  $TCDn\_CSR[ACTIVE] = 1$ .
- 12. eDMA engine reads: channel TCD data from local memory to internal register file.
- 13. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
  - b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
  - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
  - d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
  - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
  - f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
  - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
  - h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
- 14. eDMA engine writes:  $TCDn\_SADDR = 0x1000$ ,  $TCDn\_DADDR = 0x2000$ ,  $TCDn\_CITER = 2$  ( $TCDn\_BITER$ ).
- 15. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ ,  $TCDn\_CSR[DONE] = 1$ ,  $INT[n] = 1$ .

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

#### 14.1.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a  $2^4$  byte (16-byte) size queue.

**Table 14-9. Modulo example**

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

#### 14.1.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

##### 14.1.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD $n$ \_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD $n$ \_CSR[START] bit and the TCD $n$ \_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD $n$ \_CSR[START] was set. Polling the TCD $n$ \_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD $n$ _CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD $n$ \_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD $n$ _CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD $n$ \_CSR[DONE] bit.

The TCD $n$ \_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

#### 14.1.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD $n$ \_SADDR, TCD $n$ \_DADDR, and TCD $n$ \_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

### 14.1.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The `TCDn_CSR[ACTIVE]` bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two `TCDn_CSR[ACTIVE]` bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

### 14.1.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the `TCDn_CSR[START]` bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The `TCDn_CITER[E_LINK]` field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set `TCD12_CSR[START]` bit
2. Minor loop done → set `TCD12_CSR[START]` bit
3. Minor loop done → set `TCD12_CSR[START]` bit
4. Minor loop done, major loop done → set `TCD7_CSR[START]` bit

When minor loop linking is enabled ( $\text{TCDn\_CITER}[\text{E\_LINK}] = 1$ ), the  $\text{TCDn\_CITER}[\text{CITER}]$  field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled ( $\text{TCDn\_CITER}[\text{E\_LINK}] = 0$ ), the  $\text{TCDn\_CITER}[\text{CITER}]$  field uses a 15-bit vector to form the current iteration count. The bits associated with the  $\text{TCDn\_CITER}[\text{LINKCH}]$  field are concatenated onto the CITER value to increase the range of the CITER.

### Note

The  $\text{TCDn\_CITER}[\text{E\_LINK}]$  bit and the  $\text{TCDn\_BITER}[\text{E\_LINK}]$  bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e., use another channel's TCD, at the end of a loop.

**Table 14-10. Channel Linking Parameters**

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

## 14.1.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 14.1.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 14.1.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e\_link bit during channel execution (see the diagram in [TCD structure](#)). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e\_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e\_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e\_link bit.
2. Read back the TCD.major.e\_link bit.
3. Test the TCD.major.e\_link request status:
  - If TCD.major.e\_link = 1, the dynamic link attempt was successful.
  - If TCD.major.e\_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e\_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

### 14.1.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e\_sg bit at the same time the eDMA engine

is retiring the channel. The TCD.e\_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e\_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e\_link and TCD.e\_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link or TCD.e\_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

#### 14.1.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e\_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCD.dlast\_sga field with the scatter/gather address.
4. Write 1b to the TCD.e\_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e\_sg request status and TCD.major.linkch value:

If e\_sg = 1b, the dynamic link attempt was successful.

If `e_sg = 0b` and the `major.linkch (ID)` did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If `e_sg = 0b` and the `major.linkch (ID)` changed, the dynamic link attempt was successful (the new TCD's `e_sg` value cleared the `e_sg` bit).

#### 14.1.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the `TCD.dlast_sga` field as a TCD identification (ID).

1. Write 1b to the `TCD.d_req` bit.

Should a dynamic scatter/gather attempt fail, setting the `d_req` bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (`daddr`) that was calculated using a scatter/gather address (written in the next step) instead of a `dlast` final offset value.

2. Write the `TCD.dlast_sga` field with the scatter/gather address.
3. Write 1b to the `TCD.e_sg` bit.
4. Read back the `TCD.e_sg` bit.
5. Test the `TCD.e_sg` request status:

If `e_sg = 1b`, the dynamic link attempt was successful.

If `e_sg = 0b`, read the 32 bit `TCD dlast_sga` field.

If `e_sg = 0b` and the `dlast_sga` did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If `e_sg = 0b` and the `dlast_sga` changed, the dynamic link attempt was successful (the new TCD's `e_sg` value cleared the `e_sg` bit).

## 14.2 Direct Memory Access Multiplexer (DMAMUX)

### 14.2.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

#### 14.2.1.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

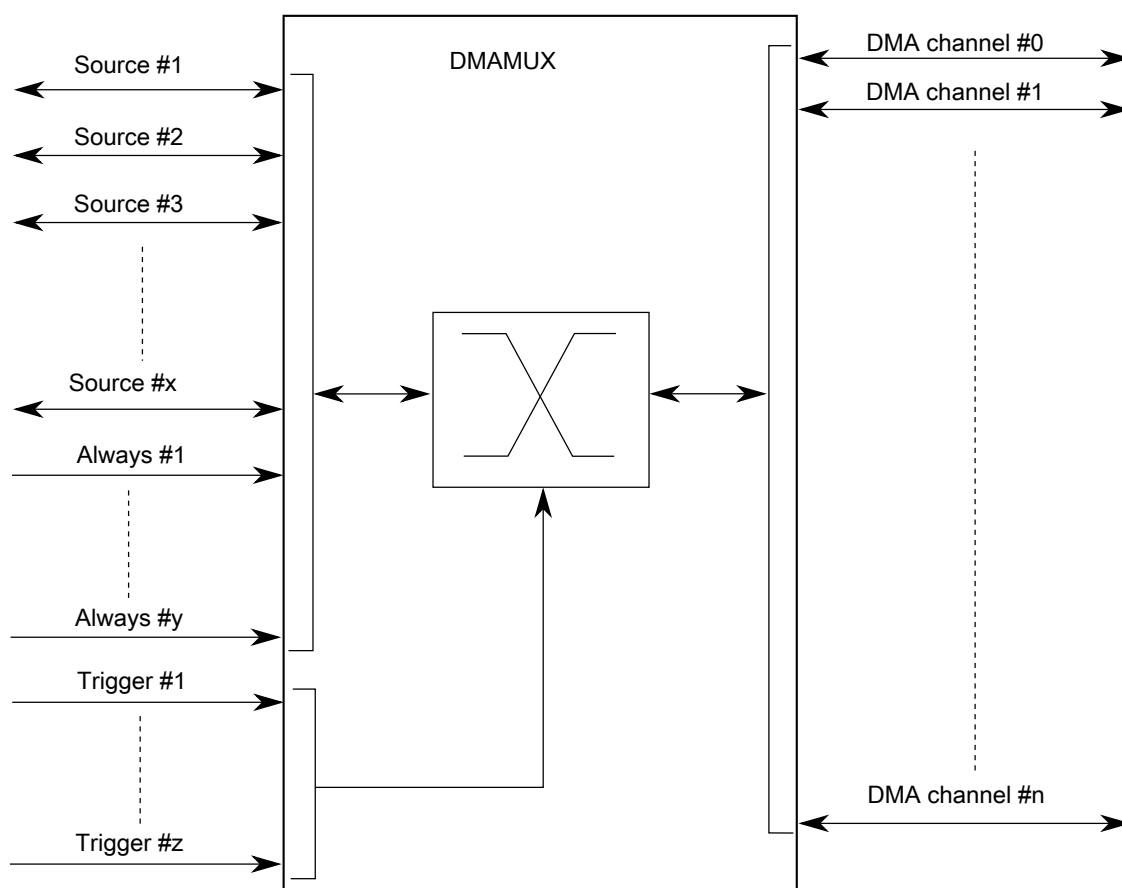

Figure 14-7. DMAMUX block diagram

### 14.2.1.2 Features

The DMAMUX module provides these features:

- Up to 53 peripheral slots and up to 10 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

### 14.2.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

## 14.2.2 External signal description

The DMAMUX has no external pins.

### 14.2.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

**DMAMUX memory map**

## 14.2.3.1 Channel Configuration register (DMAMUXx\_CHCFGn)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

## NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: Base address + 0h offset + (1d × i), where i=0d to 15d

Bit	7	6	5	4	3	2	1	0
Read	ENBL	TRIG	SOURCE					
Write								
Reset	0	0	0	0	0	0	0	0

## DMAMUXx\_CHCFGn field descriptions

Field	Description
7 ENBL	<p>DMA Channel Enable</p> <p>Enables the DMA channel.</p> <p>0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel.</p> <p>1 DMA channel is enabled</p>
6 TRIG	<p>DMA Channel Trigger Enable</p> <p>Enables the periodic trigger capability for the triggered DMA channel.</p> <p>0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode)</p> <p>1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.</p>
SOURCE	DMA Channel Source (Slot)

Table continues on the next page...

**DMAMUXx\_CHCFGn field descriptions (continued)**

Field	Description
	Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

## 14.2.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

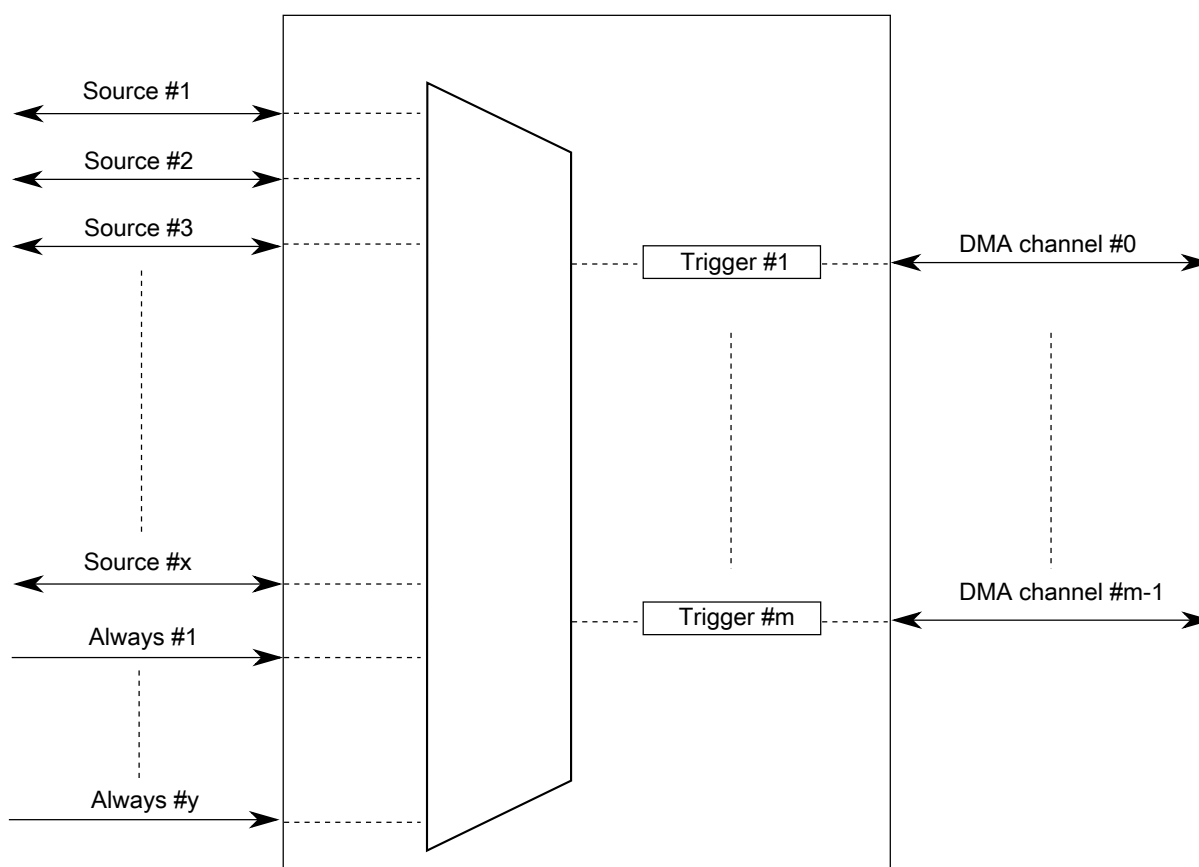

### 14.2.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

#### Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

**Figure 14-8. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

**Figure 14-9. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

**Figure 14-10. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5  $\mu$ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

#### 14.2.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in [Modes of operation](#).

### 14.2.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are 10 additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

## 14.2.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 14.2.5.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 14.2.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

#### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.

3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
```

```
:  
:  
*CHCFG8 = 0x00;  
*CHCFG8 = 0x87;
```

# Chapter 15

## Audio

### 15.1 Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)

#### 15.1.1 Introduction

##### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The I<sup>2</sup>S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I<sup>2</sup>S, AC97, TDM, and codec/DSP interfaces.

##### 15.1.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 1 data line
- Receiver with independent bit clock and frame sync supporting 1 data line
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error

### 15.1.1.2 Block diagram

The following block diagram also shows the module clocks.

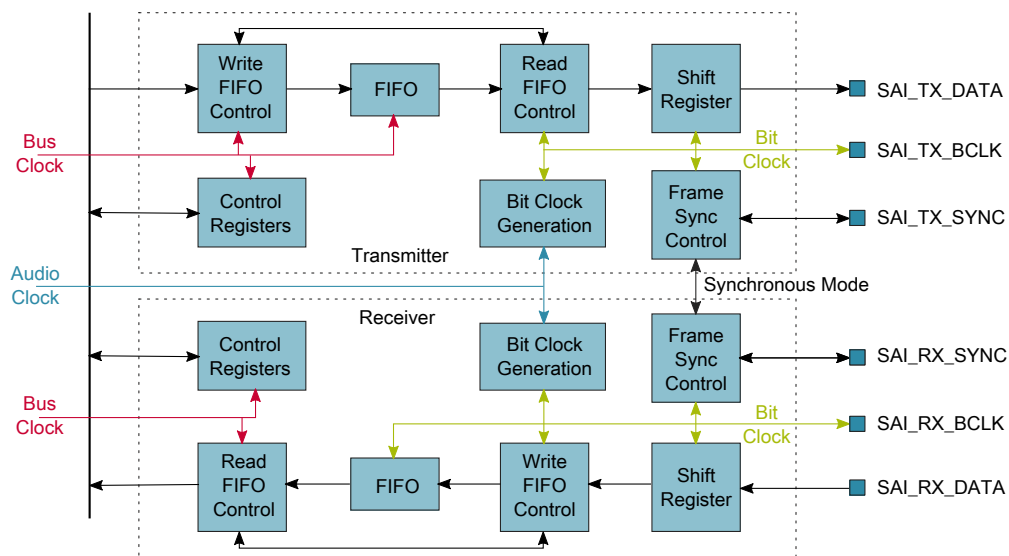

Figure 15-1. I²S/SAI block diagram

### 15.1.1.3 Modes of operation

The module operates in these power modes: Run mode, stop modes, and Debug mode.

#### 15.1.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

#### 15.1.1.3.2 Stop modes

In Stop mode, the transmitter is disabled after completing the current transmit frame, and the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

#### 15.1.1.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

## 15.1.2 External signals

Name	Function	I/O
SAI_TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
SAI_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
SAI_TX_DATA	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
SAI_RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
SAI_RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
SAI_RX_DATA	Receive Data. The receive data is sampled synchronously by the bit clock.	I
SAI_MCLK	Audio Master Clock.	I

## 15.1.3 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

### I2S memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4002_F000	SAI Transmit Control Register (I2S0_TCSR)	32	R/W	0000_0000h	<a href="#">15.1.3.1/3109</a>
4002_F004	SAI Transmit Configuration 1 Register (I2S0_TCR1)	32	R/W	0000_0000h	<a href="#">15.1.3.2/3112</a>

## I2Sx\_TCSR field descriptions

Field	Description
31 TE	Transmitter Enable  Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame.

Table continues on the next page...

**I2Sx\_TCSR field descriptions (continued)**

Field	Description
	0 Transmitter is disabled. 1 Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable  Configures transmitter operation in Stop mode. This field is ignored and the transmitter is disabled in all stop modes.  0 Transmitter disabled in Stop mode. 1 Transmitter enabled in Stop mode.
29 DBGE	Debug Enable  Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode.  0 Transmitter is disabled in Debug mode, after completing the current frame. 1 Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable  Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame.  0 Transmit bit clock is disabled. 1 Transmit bit clock is enabled.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FR	FIFO Reset  Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set.  0 No effect. 1 FIFO reset.
24 SR	Software Reset  When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.  0 No effect. 1 Software reset.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 WSF	Word Start Flag  Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.  0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag

*Table continues on the next page...*

**I2Sx\_TCSR field descriptions (continued)**

Field	Description
	Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag.  0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag  Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag.  0 Transmit underrun not detected. 1 Transmit underrun detected.
17 FWF	FIFO Warning Flag  Indicates that an enabled transmit FIFO is empty.  0 No enabled transmit FIFO is empty. 1 Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag  Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark.  0 Transmit FIFO watermark has not been reached. 1 Transmit FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable  Enables/disables word start interrupts.  0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable  Enables/disables sync error interrupts.  0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable  Enables/disables FIFO error interrupts.  0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable  Enables/disables FIFO warning interrupts.  0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable

*Table continues on the next page...*

**I2Sx\_TCSR field descriptions (continued)**

Field	Description
	Enables/disables FIFO request interrupts.  0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable  Enables/disables DMA requests.  0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable  Enables/disables DMA requests.  0 Disables the DMA request. 1 Enables the DMA request.

**15.1.3.2 SAI Transmit Configuration 1 Register (I2Sx\_TCR1)**

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	0								DIV							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### I2Sx\_TCR2 field descriptions

Field	Description
31–30 SYNC	<p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation.</p> <p>00 Asynchronous mode. 01 Synchronous with receiver.</p>
29 BCS	<p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC).</p> <p>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC).</p> <p>0 Use the normal bit clock source. 1 Swap the bit clock source.</p>
28 BCI	<p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock.</p> <p>0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.</p>
27–26 MSEL	MCLK Select

## I2Sx\_TCR3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TCE	Transmit Channel Enable  Enables the corresponding data channel for transmit operation. A channel must be enabled before its FIFO is accessed.  0 Transmit data channel N is disabled. 1 Transmit data channel N is enabled.
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
WDFL	Word Flag Configuration  Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

## 15.1.3.5 SAI Transmit Configuration 4 Register (I2Sx\_TCR4)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R		0		0	0		0			0

## I2Sx\_TCR4 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

**I2Sx\_TCR4 field descriptions (continued)**

Field	Description
20–16 FRSZ	Frame size  Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 SYWD	Sync Width  Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MF	MSB First  Configures whether the LSB or the MSB is transmitted first.  0    LSB is transmitted first. 1    MSB is transmitted first.
3 FSE	Frame Sync Early  0    Frame sync asserts with the first bit of the frame. 1    Frame sync asserts one bit before the first bit of the frame.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FSP	Frame Sync Polarity  Configures the polarity of the frame sync.  0    Frame sync is active high. 1    Frame sync is active low.
0 FSD	Frame Sync Direction  Configures the direction of the frame sync.  0    Frame sync is generated externally in Slave mode. 1    Frame sync is generated internally in Master mode.

**15.1.3.6 SAI Transmit Configuration 5 Register (I2Sx\_TCR5)**

This register must not be altered when TCSR[TE] is set.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0										0						0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## I2Sx\_TCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width  Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 W0W	Word 0 Width  Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted  Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 15.1.3.7 SAI Transmit Data Register (I2Sx\_TDRn)

Address: Base address + 20h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	TDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## I2Sx\_TDRn field descriptions

Field	Description
TDR	Transmit Data Register  The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

### 15.1.3.8 SAI Transmit FIFO Register (I2Sx\_TFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + 40h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0								WFP						
W

R	0								RFP							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### I2Sx\_TFRn field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

### 15.1.3.9 SAI Transmit Mask Register (I2Sx\_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TWM

**I2Sx\_RCSR field descriptions**

Field	Description
31 RE	<p>Receiver Enable</p> <p>Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Receiver is disabled. 1 Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.</p>
30 STOPE	<p>Stop Enable</p> <p>Configures receiver operation in Stop mode. This bit is ignored and the receiver is disabled in all stop modes.</p> <p>0 Receiver disabled in Stop mode. 1 Receiver enabled in Stop mode.</p>
29 DBGE	<p>Debug Enable</p> <p>Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode.</p> <p>0 Receiver is disabled in Debug mode, after completing the current frame. 1 Receiver is enabled in Debug mode.</p>
28 BCE	<p>Bit Clock Enable</p> <p>Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame.</p> <p>0 Receive bit clock is disabled. 1 Receive bit clock is enabled.</p>
27–26 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
25 FR	<p>FIFO Reset</p> <p>Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set.</p> <p>0 No effect. 1 FIFO reset.</p>
24 SR	<p>Software Reset</p> <p>Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.</p> <p>0 No effect. 1 Software reset.</p>
23–21 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
20 WSF	<p>Word Start Flag</p> <p>Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.</p>

*Table continues on the next page...*

**I2Sx\_RCSR field descriptions (continued)**

Field	Description
	0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag  Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag.  0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag  Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag.  0 Receive overflow not detected. 1 Receive overflow detected.
17 FWF	FIFO Warning Flag  Indicates that an enabled receive FIFO is full.  0 No enabled receive FIFO is full. 1 Enabled receive FIFO is full.
16 FRF	FIFO Request Flag  Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark.  0 Receive FIFO watermark not reached. 1 Receive FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable  Enables/disables word start interrupts.  0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable  Enables/disables sync error interrupts.  0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable  Enables/disables FIFO error interrupts.  0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable  Enables/disables FIFO warning interrupts.

*Table continues on the next page...*

**I2Sx\_RCSR field descriptions (continued)**

Field	Description
	0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable  Enables/disables FIFO request interrupts.  0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable  Enables/disables DMA requests.  0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable  Enables/disables DMA requests.  0 Disables the DMA request. 1 Enables the DMA request.

#### I2Sx\_RCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width  Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 WOW	Word 0 Width  Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted  Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 15.1.3.16 SAI Receive Data Register (I2Sx\_RDRn)

Reading this register introduces one additional peripheral clock wait state on each read.

Address: Base address + A0h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**I2Sx\_RDR<sub>n</sub> field descriptions**

Field	Description
RDR	Receive Data Register  The corresponding RCR3[RCE] bit must be set before accessing the channel's receive data register. Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

**15.1.3.17 SAI Receive FIFO Register (I2Sx\_RFR<sub>n</sub>)**

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + C0h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**I2Sx\_RFR<sub>n</sub> field descriptions**

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer  FIFO write pointer for receive data channel.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFP	Read FIFO Pointer  FIFO read pointer for receive data channel.

**15.1.3.18 SAI Receive Mask Register (I2Sx\_RMR)**

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Address: Base address + E0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### I2Sx\_RMR field descriptions

Field	Description
RWM	<p>Receive Word Mask</p> <p>Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame.</p> <p>0 Word N is enabled.</p> <p>1 Word N is masked.</p>

## 15.1.4 Functional description

This section provides a complete functional description of the block.

### 15.1.4.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

#### 15.1.4.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

#### 15.1.4.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

#### 15.1.4.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

##### NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

#### 15.1.4.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

##### 15.1.4.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

#### 15.1.4.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

### 15.1.4.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

#### 15.1.4.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

#### 15.1.4.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

#### 15.1.4.5 Data FIFO

Each transmit and receive channel includes a FIFO of size  $32 \times 32$ -bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

### 15.1.4.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 15-2](#) for LSB First configurations and [Figure 15-3](#) for MSB First configurations.

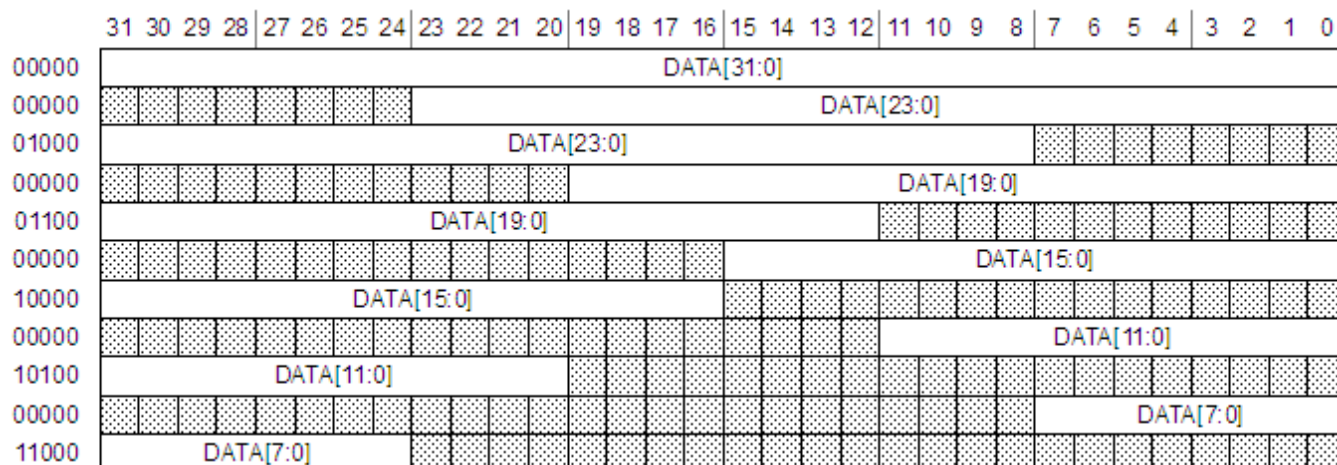

Figure 15-2. SAI first bit shifted, LSB first

Figure 15-3. SAI first bit shifted, MSB first

#### 15.1.4.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

#### 15.1.4.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

#### 15.1.4.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

#### 15.1.4.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

#### 15.1.4.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

#### 15.1.4.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels repeat the last valid word read from the transmit FIFO until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

The FIFO error flag can generate only an interrupt.

#### 15.1.4.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

#### 15.1.4.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

## 15.2 Enhanced Serial Audio Interface (ESAI)

### 15.2.1 Overview

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, Sony/Phillips Digital Interface (SPDIF) transceivers, and other DSPs.

The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. It is a superset of the 56300 Family ESSI peripheral and of the 56000 Family SAI peripheral.

All serial transfers in the module are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is similar in that it is also intended for periodic transfers; however, it supports up to 32 words (time slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

The following figure shows the ESAI block diagram.

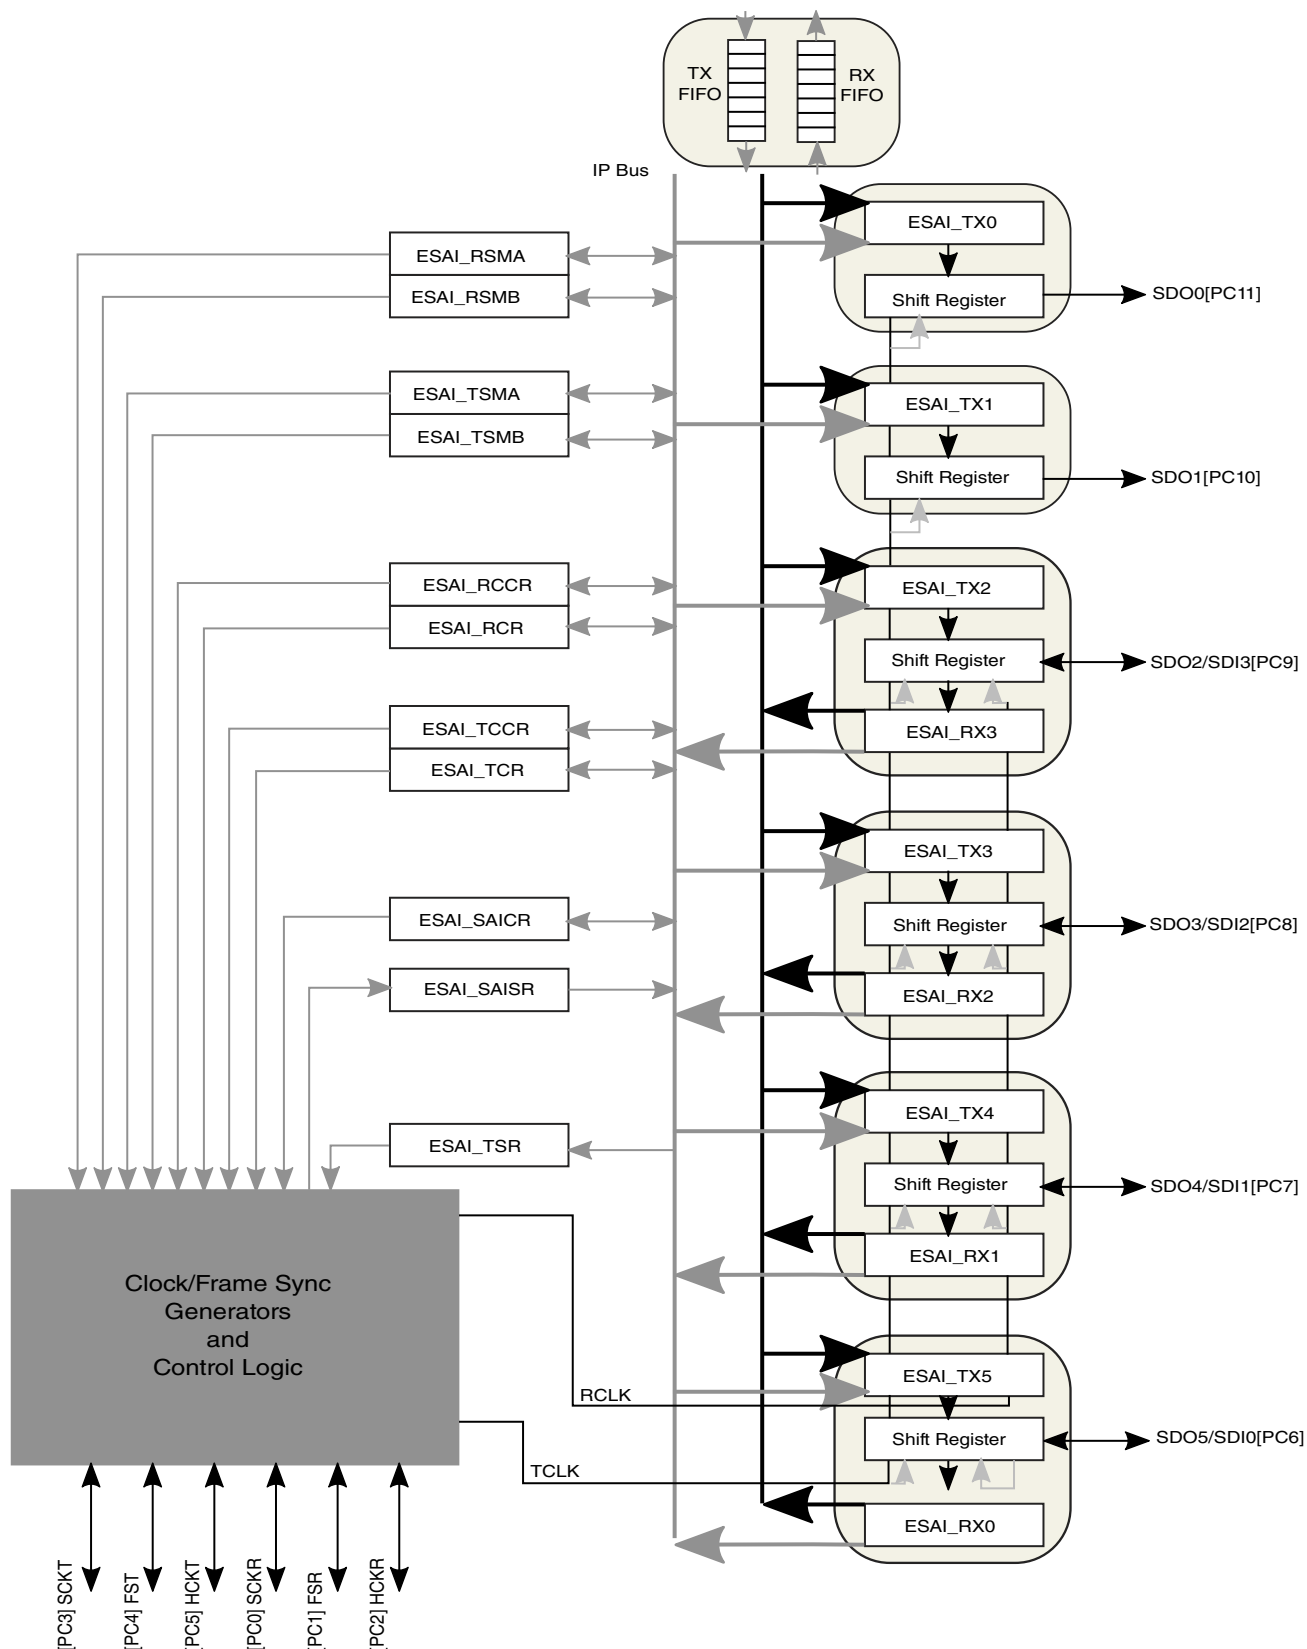

Figure 15-4. ESAI Block Diagram

VFxxx Controller Reference Manual, Rev. 0, 10/2016

### 15.2.1.1 Features

- Independent (asynchronous mode) or shared (synchronous mode) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Up to six transmitters and four receivers with SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins shared by transmitters 2 to 5 and receivers 0 to 3. SDO0 and SDO1 pins are used by transmitters 0 and 1 only.
- Programmable data interface modes such as I2S, LSB aligned, MSB aligned
- Programmable word length (8, 12, 16, 20 or 24bits)
- Flexible selection between system clock or external oscillator as input clock source, programmable internal clock divider and frame sync generation
- AC97 support
- Time Slot Mask Registers for reduced ARM platform overhead (for both Transmit and Receive)
- 128-word Transmit FIFO shared by six transmitters
- 128-word Receive FIFO shared by four receivers

### 15.2.1.2 Modes of Operation

ESAI has three basic operating modes and many data/operation formats.

ESAI operating mode are selected by the ESAI control registers (ESAI\_TCCR, ESAI\_TCR, ESAI\_RCCR, ESAI\_RCR, and ESAI\_SAICR). The main operating modes are described in the following section.

#### 15.2.1.2.1 Normal/Network/On-Demand Mode Selection

Selecting between the normal mode and network mode is accomplished by clearing or setting the TMOD0-TMOD1 bits in the ESAI\_TCR register for the transmitter section, as well as in the RMOD0-RMOD1 bits in the ESAI\_RCR register for the receiver section.

For normal mode, the ESAI functions with one data word of I/O per frame (per enabled transmitter or receiver). The normal mode is typically used to transfer data to or from a single device.

For the network mode, 2 to 32 time slots per frame may be selected. During each frame, 0 to 32 data words of I/O may be received or transmitted. In either case, the transfers are periodic. The frame sync signal indicates the first time slot in the frame. Network mode is typically used in time division multiplexed (TDM) networks of codecs, DSPs with multiple words per frame, or multi-channel devices.

Selecting the network mode and setting the frame rate divider to zero (DC=00000) selects the on-demand mode. This special case does not generate a periodic frame sync. A frame sync pulse is generated only when data is available to transmit. The on-demand mode requires that the transmit frame sync be internal (output) and the receive frame sync be external (input). Therefore, for simplex operation, the synchronous mode could be used; however, for full-duplex operation, the asynchronous mode must be used. Data transmission that is data driven is enabled by writing data into each TX. Although the ESAI is double buffered, only one word can be written to each TX, even if the transmit shift register is empty. The receive and transmit interrupts function as usual using TDE and RDF; however, transmit underruns are impossible for on-demand transmission and are disabled.

### 15.2.1.2.2 Synchronous/Asynchronous Operating Modes

The transmit and receive sections of the ESAI may be synchronous or asynchronous, that is, the transmitter and receiver sections may use common clock and synchronization signals (synchronous operating mode), or they may have their own separate clock and sync signals (asynchronous operating mode).

The SYN bit in the ESAI\_SAICR register selects synchronous or asynchronous operation. Because the ESAI is designed to operate either synchronously or asynchronously, separate receive and transmit interrupts are provided.

When SYN is cleared, the ESAI transmitter and receiver clocks and frame sync sources are independent. If SYN is set, the ESAI transmitter and receiver clocks and frame sync come from the transmitter section (either external or internal sources).

Data clock and frame sync signals can be generated internally by the ARM Core or may be obtained from external sources. If internally generated, the ESAI clock generator is used to derive high frequency clock, bit clock and frame sync signals from the ARM Core internal system clock.

### 15.2.1.2.3 Frame Sync Selection

The frame sync can be either a bit-long or word-long signal.

The transmitter frame format is defined by the TFSL bit in the ESAI\_TCR register. The receiver frame format is defined by the RFSL bit in the ESAI\_RCR register.

1. In the word-long frame sync format, the frame sync signal is asserted during the entire word data transfer period. This frame sync length is compatible with codecs, SPI serial peripherals, serial A/D and D/A converters, shift registers and telecommunication PCM serial I/O.

2. In the bit-long frame sync format, the frame sync signal is asserted for one bit clock immediately before the data transfer period. This frame sync length is compatible with Intel and National components, codecs and telecommunication PCM serial I/O.

The relative timing of the word length frame sync as referred to the data word is specified by the TFSR bit in the ESAI\_TCR register for the transmitter section and by the RFSR bit in the ESAI\_RCR register for the receive section. The word length frame sync may be generated (or expected) with the first bit of the data word, or with the last bit of the previous word. TFSR and RFSR are ignored when a bit length frame sync is selected.

Polarity of the frame sync signal may be defined as positive (asserted high) or negative (asserted low). The TFSP bit in the ESAI\_TCCR register specifies the polarity of the frame sync for the transmitter section. The RFSP bit in the ESAI\_RCCR register specifies the polarity of the frame sync for the receiver section.

The ESAI receiver looks for a receive frame sync leading edge (trailing edge if RFSP is set) only when the previous frame is completed. If the frame sync goes high before the frame is completed (or before the last bit of the frame is received in the case of a bit frame sync or a word length frame sync with RFSR set), the current frame sync is not recognized, and the receiver is internally disabled until the next frame sync. Frames do not have to be adjacent, that is, a new frame sync does not have to immediately follow the previous frame. Gaps of arbitrary periods can occur between frames. Enabled transmitters are tri-stated during these gaps.

When operating in the synchronous mode (SYN=1), all clocks including the frame sync are generated by the transmitter section.

#### 15.2.1.2.4 Shift Direction Selection

Some data formats, such as those used by codecs, specify MSB first while other data formats, such as the AES-EBU digital audio interface, specify LSB first.

The MSB/LSB first selection is made by programming RSHFD bit in the ESAI\_RCR register for the receiver section and by programming the TSHFD bit in the ESAI\_TCR register for the transmitter section.

### 15.2.2 External Signals

Three to twelve pins are required for operation, depending on the operating mode selected and the number of transmitters and receivers enabled.

The SDO0 and SDO1 pins are used by transmitters 0 and 1 only. The SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins are shared by transmitters 2 to 5 with receivers 0 to 3. The actual mode of operation is selected under software control. All transmitters operate fully synchronized under control of the same transmitter clock signals. All receivers operate fully synchronized under control of the same receiver clock signals.

### 15.2.2.1 Serial Transmit 0 Data Pin

SDO0 is used for transmitting data from the ESAI\_TX0 serial transmit shift register.

SDO0 is an output when data is being transmitted from the ESAI\_TX0 shift register. In the on-demand mode with an internally generated bit clock, the SDO0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO0 may be programmed as a disconnected pin (PC11) when the ESAI SDO0 function is not being used. See [Table 15-12](#).

### 15.2.2.2 Serial Transmit 1 Data Pin

SDO1 is used for transmitting data from the ESAI\_TX1 serial transmit shift register.

SDO1 is an output when data is being transmitted from the ESAI\_TX1 shift register. In the on-demand mode with an internally generated bit clock, the SDO1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO1 may be programmed as a disconnected pin (PC10) when the ESAI SDO1 function is not being used. See [Table 15-12](#).

### 15.2.2.3 Serial Transmit 2/Receive 3 Data Pin

SDO2/SDI3 is used as the SDO2 for transmitting data from the ESAI\_TX2 serial transmit shift register when programmed as a transmitter pin, or as the SDI3 signal for receiving serial data to the ESAI\_RX3 serial receive shift register when programmed as a receiver pin.

SDO2/SDI3 is an input when data is being received by the ESAI\_RX3 shift register. SDO2/SDI3 is an output when data is being transmitted from the ESAI\_TX2 shift register. In the on-demand mode with an internally generated bit clock, the SDO2/SDI3 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO2/SDI3 may be programmed as a disconnected pin (PC9) when the ESAI SDO2 and SDI3 functions are not being used. See [Table 15-12](#).

#### 15.2.2.4 Serial Transmit 3/Receive 2 Data Pin

SDO3/SDI2 is used as the SDO3 signal for transmitting data from the ESAI\_TX3 serial transmit shift register when programmed as a transmitter pin, or as the SDI2 signal for receiving serial data to the ESAI\_RX2 serial receive shift register when programmed as a receiver pin.

SDO3/SDI2 is an input when data is being received by the ESAI\_RX2 shift register. SDO3/SDI2 is an output when data is being transmitted from the ESAI\_TX3 shift register. In the on-demand mode with an internally generated bit clock, the SDO3/SDI2 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO3/SDI2 may be programmed as a disconnected pin (PC8) when the ESAI SDO3 and SDI2 functions are not being used. See [Table 15-12](#).

#### 15.2.2.5 Serial Transmit 4/Receive 1 Data Pin

SDO4/SDI1 is used as the SDO4 signal for transmitting data from the ESAI\_TX4 serial transmit shift register when programmed as transmitter pin, or as the SDI1 signal for receiving serial data to the RX1 serial receive shift register when programmed as a receiver pin.

SDO4/SDI1 is an input when data is being received by the ESAI\_RX1 shift register. SDO4/SDI1 is an output when data is being transmitted from the ESAI\_TX4 shift register. In the on-demand mode with an internally generated bit clock, the SDO4/SDI1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO4/SDI1 may be programmed as a disconnected pin (PC7) when the ESAI SDO4 and SDI1 functions are not being used. See [Table 15-12](#).

### 15.2.2.6 Serial Transmit 5/Receive 0 Data Pin

SDO5/SDI0 is used as the SDO5 signal for transmitting data from the ESAI\_TX5 serial transmit shift register when programmed as transmitter pin, or as the SDI0 signal for receiving serial data to the ESAI\_RX0 serial shift register when programmed as a receiver pin.

SDO5/SDI0 is an input when data is being received by the ESAI\_RX0 shift register. SDO5/SDI0 is an output when data is being transmitted from the ESAI\_TX5 shift register. In the on-demand mode with an internally generated bit clock, the SDO5/SDI0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO5/SDI0 may be programmed as a disconnected pin (PC6) when the ESAI SDO5 and SDI0 functions are not being used. See [Table 15-12](#).

### 15.2.2.7 Receiver Serial Clock

SCKR is a bidirectional pin providing the receivers serial bit clock for the ESAI interface.

The direction of this pin is determined by the RCKD bit in the ESAI\_RCCR register. The SCKR operates as a clock input or output used by all the enabled receivers in the asynchronous mode (SYN = 0), or as serial flag 0 pin in the synchronous mode (SYN = 1).

When this pin is configured as serial flag pin, its direction is determined by the RCKD bit in the ESAI\_RCCR register. When configured as the output flag OF0, this pin reflects the value of the OF0 bit in the ESAI\_SAICR register, and the data in the OF0 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When this pin is configured as the input flag IF0, the data value at the pin is stored in the IF0 bit in the ESAI\_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

SCKR may be programmed as a disconnected pin (PC0) when the ESAI SCKR function is not being used. See [Table 15-12](#).

**NOTE**

Although the external ESAI serial clocks can be independent of and asynchronous to the internal ESAI system clock, the external ESAI serial clock cannot exceed the internal ESAI system clock divided by 6.

For SCKR pin mode definitions, see [Table 15-9](#).

The table below provides a list of asynchronous-mode receiver clock sources. For more information about EXTAL/ESAI clocking control bits (ERI, ERO), refer to [ESAI Control Register \(ESAI\\_ECR\)](#).

**Table 15-1. Receiver Clock Sources (Asynchronous Mode Only)**

RHCKD	RFSD	RCKD	ERI	ERO	Receiver Bit Clock Source	OUTPUTS		
0	0	0	N/A	N/A	SCKR	-	-	-
0	0	1	N/A	N/A	HCKR	-	-	SCKR
0	1	0	N/A	N/A	SCKR	-	FSR	-
0	1	1	N/A	N/A	HCKR	-	FSR	SCKR

EXTAL is the on-chip clock source other than ipg\_clk\_esai ESAI system clock, and it is from esai\_clk\_root in CCM.

### 15.2.2.8 Transmitter Serial Clock

SCKT is a bidirectional pin providing the transmitters serial bit clock for the ESAI interface.

The direction of this pin is determined by the TCKD bit in the ESAI\_TCCR register. The SCKT is a clock input or output used by all the enabled transmitters in the asynchronous mode (SYN = 0) or by all the enabled transmitters and receivers in the synchronous mode (SYN = 1).

The following table provides a list of asynchronous-mode transmitter clock sources.

**Table 15-2. Transmitter Clock Sources (Asynchronous Mode Only)**

THCKD	TFSD	TCKD	ETI	ETO	Transmitter Bit Clock Source	OUTPUTS		
0	0	0	N/A	N/A	SCKT	-	-	-
0	0	1	N/A	N/A	HCKT	-	-	SCKT
0	1	0	N/A	N/A	SCKT	-	FST	-
0	1	1	N/A	N/A	HCKT	-	FST	SCKT

1	1	1	1	0	EXTAL	HCKT	FST	SCKT
1	1	1	1	1	EXTAL	HCKT	FST	SCKT

EXTAL is the on-chip clock sources other than ipg\_clk\_easi ESAI system clock, and it is from esai\_clk\_root in CCM

SCKT may be programmed as a disconnected pin (PC3) when the ESAI SCKT function is not being used. See [Table 15-12](#).

For more information about EXTAL/ESAI clocking control bits (ETI, ETO), see [ESAI Control Register \(ESAI\\_ECR\)](#).

### NOTE

Although the external ESAI serial clocks can be independent of and asynchronous to the internal ESAI system clock, the external ESAI serial clock cannot exceed the internal ESAI system clock divided by 6.

### 15.2.2.9 Frame Sync for Receiver

FSR is a bidirectional pin providing the receivers frame sync signal for the ESAI interface. The direction of this pin is determined by the RFSD bit in ESAI\_RCR register.

In the asynchronous mode (SYN=0), the FSR pin operates as the frame sync input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as either the serial flag 1 pin (TEBE=0), or as the transmitter external buffer enable control (TEBE=1, RFSD=1). For FSR pin mode definitions, see [Table 15-10](#); for receiver clock signals, see [Table 15-1](#).

When this pin is configured as serial flag pin, its direction is determined by the RFSD bit in the ESAI\_RCCR register. When configured as the output flag OF1, this pin reflects the value of the OF1 bit in the ESAI\_SAICR register, and the data in the OF1 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF1, the data value at the pin is stored in the IF1 bit in the ESAI\_SAIRS register, synchronized by the frame sync in normal mode or the slot in network mode.

FSR may be programmed as a disconnected pin (PC1) when the ESAI FSR function is not being used. See [Table 15-12](#).

### 15.2.2.10 Frame Sync for Transmitter

FST is a bidirectional pin providing the frame sync for both the transmitters and receivers in the synchronous mode (SYN=1) and for the transmitters only in asynchronous mode (SYN=0).

See [Table 15-2](#). The direction of this pin is determined by the TFSD bit in the ESAI\_TCCR register. When configured as an output, this pin is the internally generated frame sync signal. When configured as an input, this pin receives an external frame sync signal for the transmitters (and the receivers in synchronous mode).

FST may be programmed as a disconnected pin (PC4) when the ESAI FST function is not being used. See [Table 15-12](#).

### 15.2.2.11 High Frequency Clock for Transmitter

HCKT is a bidirectional pin providing the transmitters high frequency clock for the ESAI interface.

The direction of this pin is determined by the THCKD bit in the ESAI\_TCCR register. In the asynchronous mode (SYN=0), the HCKT pin operates as the high frequency clock input or output used by all enabled transmitters. In the synchronous mode (SYN=1), it operates as the high frequency clock input or output used by all enabled transmitters and receivers. When programmed as input this pin is used as an alternative high frequency clock source to the ESAI transmitter rather than the ARM Core main clock. When programmed as output it can serve as a high frequency sample clock (to external DACs for example) or as an additional system clock (see [Table 15-2](#)).

HCKT may be programmed as a disconnected pin (PC5) when the ESAI HCKT function is not being used. See [Table 15-12](#).

### 15.2.2.12 High Frequency Clock for Receiver

HCKR is a bidirectional pin providing the receivers high frequency clock for the ESAI interface.

The direction of this pin is determined by the RHCKD bit in the ESAI\_RCCR register. In the asynchronous mode (SYN=0), the HCKR pin operates as the high frequency clock input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as the serial flag 2 pin. For HCKR pin mode definitions, see [Table 15-11](#); for receiver clock signals, see [Table 15-1](#).

When this pin is configured as serial flag pin, its direction is determined by the RHCKD bit in the ESAI\_RCCR register. When configured as the output flag OF2, this pin reflects the value of the OF2 bit in the ESAI\_SAICR register, and the data in the OF2 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF2, the data value at the pin is stored in the IF2 bit in the ESAI\_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

HCKR may be programmed as a disconnected pin (PC2) when the ESAI HCKR function is not being used. See [Table 15-12](#).

### 15.2.2.13 Serial I/O Flags

Three ESAI pins (FSR, SCKR and HCKR) are available as serial I/O flags when the ESAI is operating in the synchronous mode (SYN=1).

Their operation is controlled by RCKD, RFSD, TEBE bits in the ESAI\_RCR, ESAI\_RCCR and ESAI\_SAICR registers. The output data bits (OF2, OF1 and OF0) and the input data bits (IF2, IF1 and IF0) are double buffered to/from the HCKR, FSR and SCKR pins. Double buffering the flags keeps them in sync with the TX and RX data lines.

Each flag can be separately programmed. Flag 0 (SCKR pin) direction is selected by RCKD, RCKD=1 for output and RCKD=0 for input. Flag 1 (FSR pin) is enabled when the pin is not configured as external transmitter buffer enable (TEBE=0) and its direction is selected by RFSD, RFSD=1 for output and RFSD=0 for input. Flag 2 (HCKR pin) direction is selected by RHCKD, RHCKD=1 for output and RHCKD=0 for input.

When programmed as input flags, the SCKR, FSR and HCKR logic values, respectively, are latched at the same time as the first bit of the receive data word is sampled. Because the input was latched, the signal on the input flag pin (SCKR, FSR or HCKR) can change without affecting the input flag until the first bit of the next receive data word. When the received data words are transferred to the receive data registers, the input flag latched values are then transferred to the IF0, IF1 and IF2 bits in the SAISR register, where they may be read by software.

When programmed as output flags, the SCKR, FSR and HCKR logic values are driven by the contents of the OF0, OF1 and OF2 bits in the ESAI\_SAICR register respectively, and they are driven when the transmit data registers are transferred to the transmit shift registers. The value on SCKR, FSR and HCKR is stable from the time the first bit of the transmit data word is transmitted until the first bit of the next transmit data word is transmitted. Software may change the OF0-OF2 values thus controlling the SCKR, FSR and HCKR pin values for each transmitted word. The normal sequence for setting output flags when transmitting data is as follows: wait for TDE (transmitter empty) to be set; first write the flags, and then write the transmit data to the transmit registers. OF0, OF1, and OF2 are double buffered so that the flag states appear on the pins when the transmit data is transferred to the transmit shift register, that is, the flags are synchronous with the data.

### 15.2.3 Functional Description

This section provides a complete functional description of the block.

### 15.2.3.1 ESAI After Reset

Hardware or software reset clears the port control register bits and the port direction control register bits, which configure all ESAI I/O pins as disconnected and both ESAI FIFOs are also in reset state.

The ESAI is in personal reset state while all ESAI pins are programmed as disconnected, and it is active only if at least one of the ESAI I/O pins is programmed as an ESAI pin.

### 15.2.3.2 ESAI Interrupt Requests

The ESAI can generate eight different interrupt requests.

Ordered from the highest to the lowest priority):

#### 1. ESAI Receive Data with Exception Status

Occurs when the receive exception interrupt is enabled (REIE=1 in the RCR register), at least one of the enabled receive data registers is full (RDF=1) and a receiver overrun error has occurred (ROE=1 in the SAISR register). ROE is cleared by first reading the SAISR and then reading all the enabled receive data registers.

#### 2. ESAI Receive Even Data

Occurs when the receive even slot data interrupt is enabled (REDIE=1), at least one of the enabled receive data registers is full (RDF=1), the data is from an even slot (REDF=1) and no exception has occurred (ROE=0 or REIE=0).

Reading all enabled receiver data registers clears RDF and REDF.

#### 3. ESAI Receive Data

Occurs when the receive interrupt is enabled (RIE=1), at least one of the enabled receive data registers is full (RDF=1), no exception has occurred (ROE=0 or REIE=0) and no even slot interrupt has occurred (REDF=0 or REDIE=0). Reading all enabled receiver data registers clears RDF.

#### 4. ESAI Receive Last Slot Interrupt

Occurs, if enabled (RLIE=1), after the last slot of the frame ended (in network mode only) regardless of the receive mask register setting. The receive last slot interrupt may be used for resetting the receive mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the receive last slot interrupt guarantees that the previous frame was serviced with the previous setting and the

new frame is serviced with the new setting without synchronization problems. Note that the maximum receive last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).

### 5. ESAI Transmit Data with Exception Status

Occurs when the transmit exception interrupt is enabled (TEIE=1), at least one transmit data register of the enabled transmitters is empty (TDE=1) and a transmitter underrun error has occurred (TUE=1). TUE is cleared by first reading the SAISR and then writing to all the enabled transmit data registers, or to the TSR register.

### 6. ESAI Transmit Last Slot Interrupt

Occurs, if enabled (TLIE=1), at the start of the last slot of the frame in network mode regardless of the transmit mask register setting. The transmit last slot interrupt may be used for resetting the transmit mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the transmit last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum transmit last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).

### 7. ESAI Transmit Even Data

Occurs when the transmit even slot data interrupt is enabled (TEDIE=1), at least one of the enabled transmit data registers is empty (TDE=1), the slot is an even slot (TEDE=1) and no exception has occurred (TUE=0 or TEIE=0). Writing to all the TX registers of the enabled transmitters or to TSR clears this interrupt request.

### 8. ESAI Transmit Data

Occurs when the transmit interrupt is enabled (TIE=1), at least one of the enabled transmit data registers is empty (TDE=1), no exception has occurred (TUE=0 or TEIE=0) and no even slot interrupt has occurred (TEDE=0 or TEDIE=0). Writing to all the TX registers of the enabled transmitters, or to the TSR clears this interrupt request.

## 15.2.3.3 ESAI DMA Requests from the FIFOs

The ESAI can generate two different DMA requests:

1. ESAI Transmit FIFO Empty - Asserts when the number of empty slots in the ESAI transmit FIFO exceeds the threshold programmed in the ESAI Transmit FIFO Configuration Register (TFCR). Automatically negates when the number of empty

slots is less than the threshold programmed in the ESAI Transmit FIFO Configuration Register.

2. ESAI Receive FIFO Full - Asserts when the number of data words in the ESAI receive FIFO exceeds the threshold programmed in the ESAI Receive FIFO Configuration Register (RFCR). Automatically negates when the number of words is less than the threshold programmed in the ESAI Receive FIFO Configuration Register.

### 15.2.3.4 ESAI Transmit and Receive Shift Registers

#### 15.2.3.4.1 ESAI Transmit Shift Registers

The transmit shift registers contain the data being transmitted.

See [Figure 15-5](#) and [Figure 15-6](#).

Data is shifted out to the serial transmit data pins by the selected (internal/external) bit clock when the associated frame sync I/O is asserted.

The number of bits shifted out before the shift registers are considered empty and may be written to again can be 8, 12, 16, 20, 24 or 32 bits (determined by the slot length control bits in the TCR register). Data is shifted out of these registers MSB first if TSHFD=0 and LSB first if TSHFD=1.

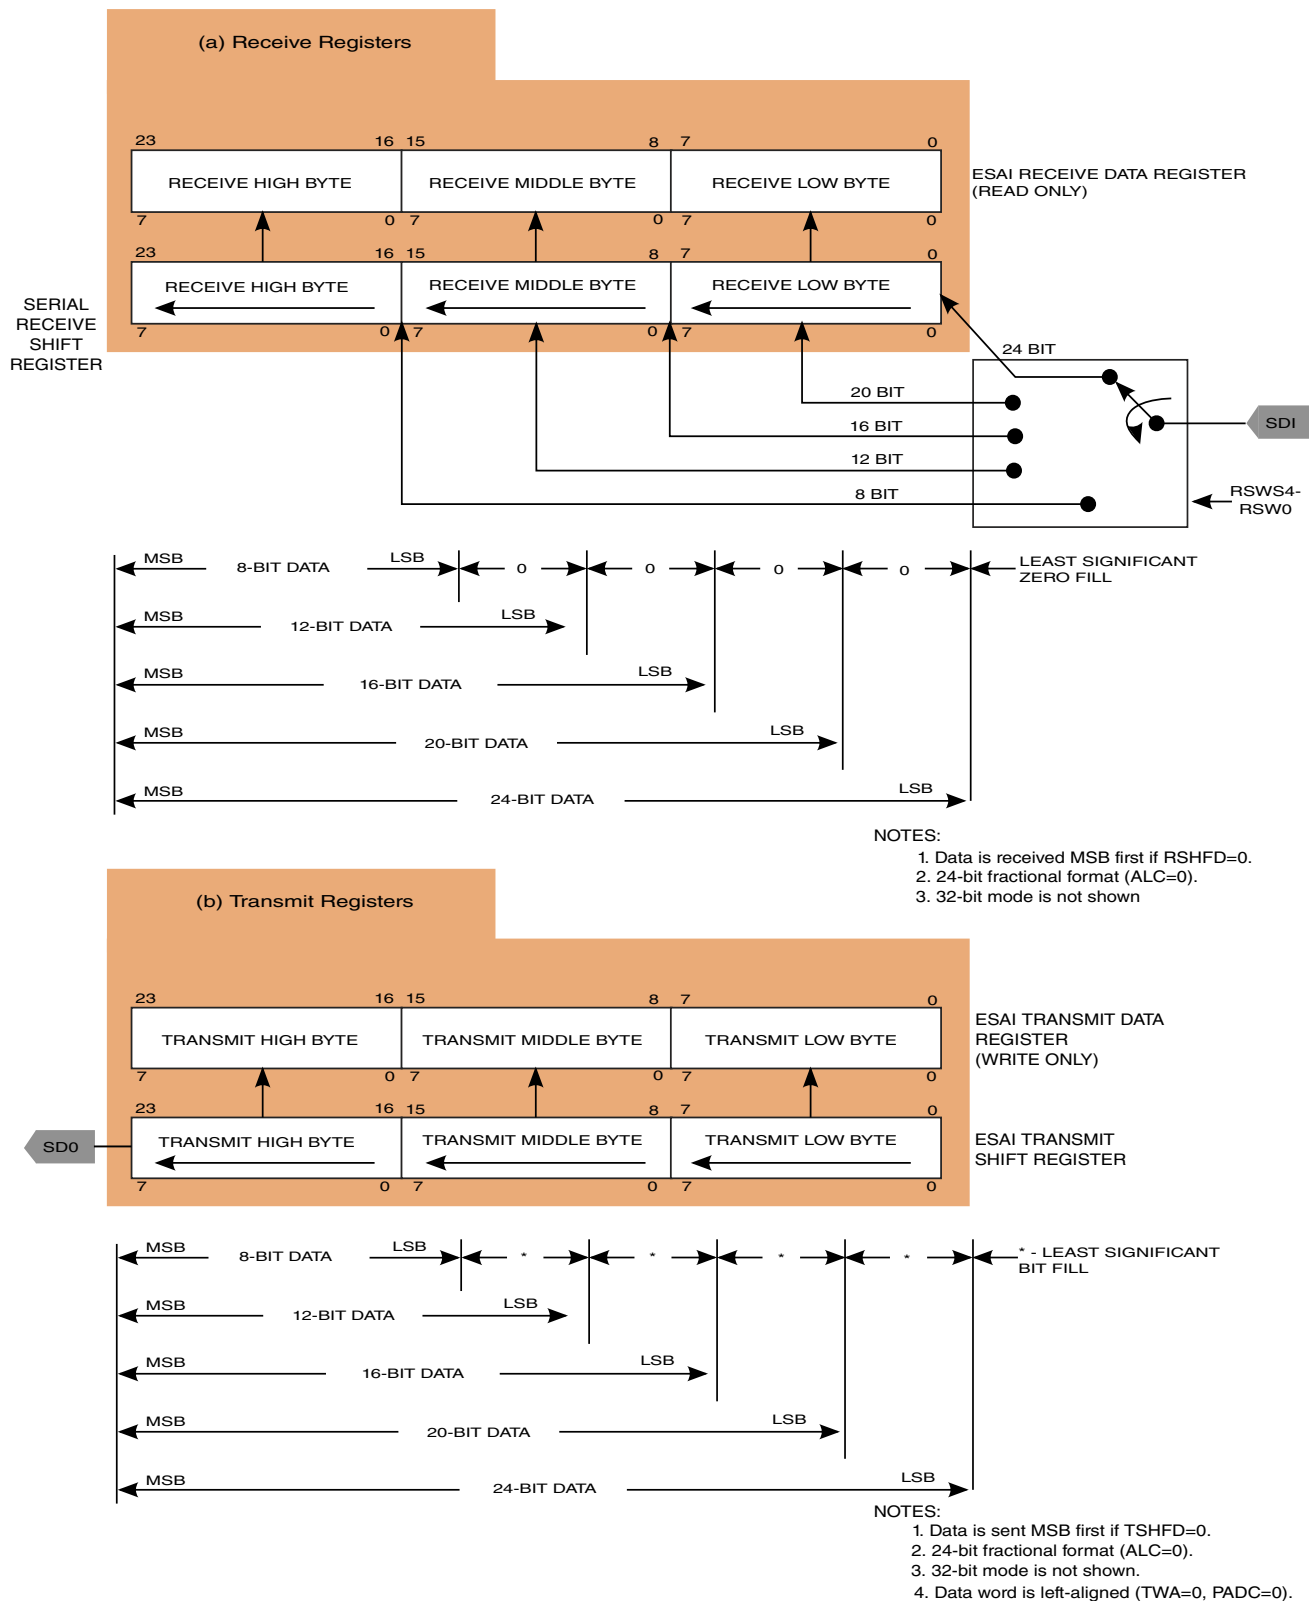

Figure 15-5. ESAI Data Path Programming Model ([R/T]SHFD=0)

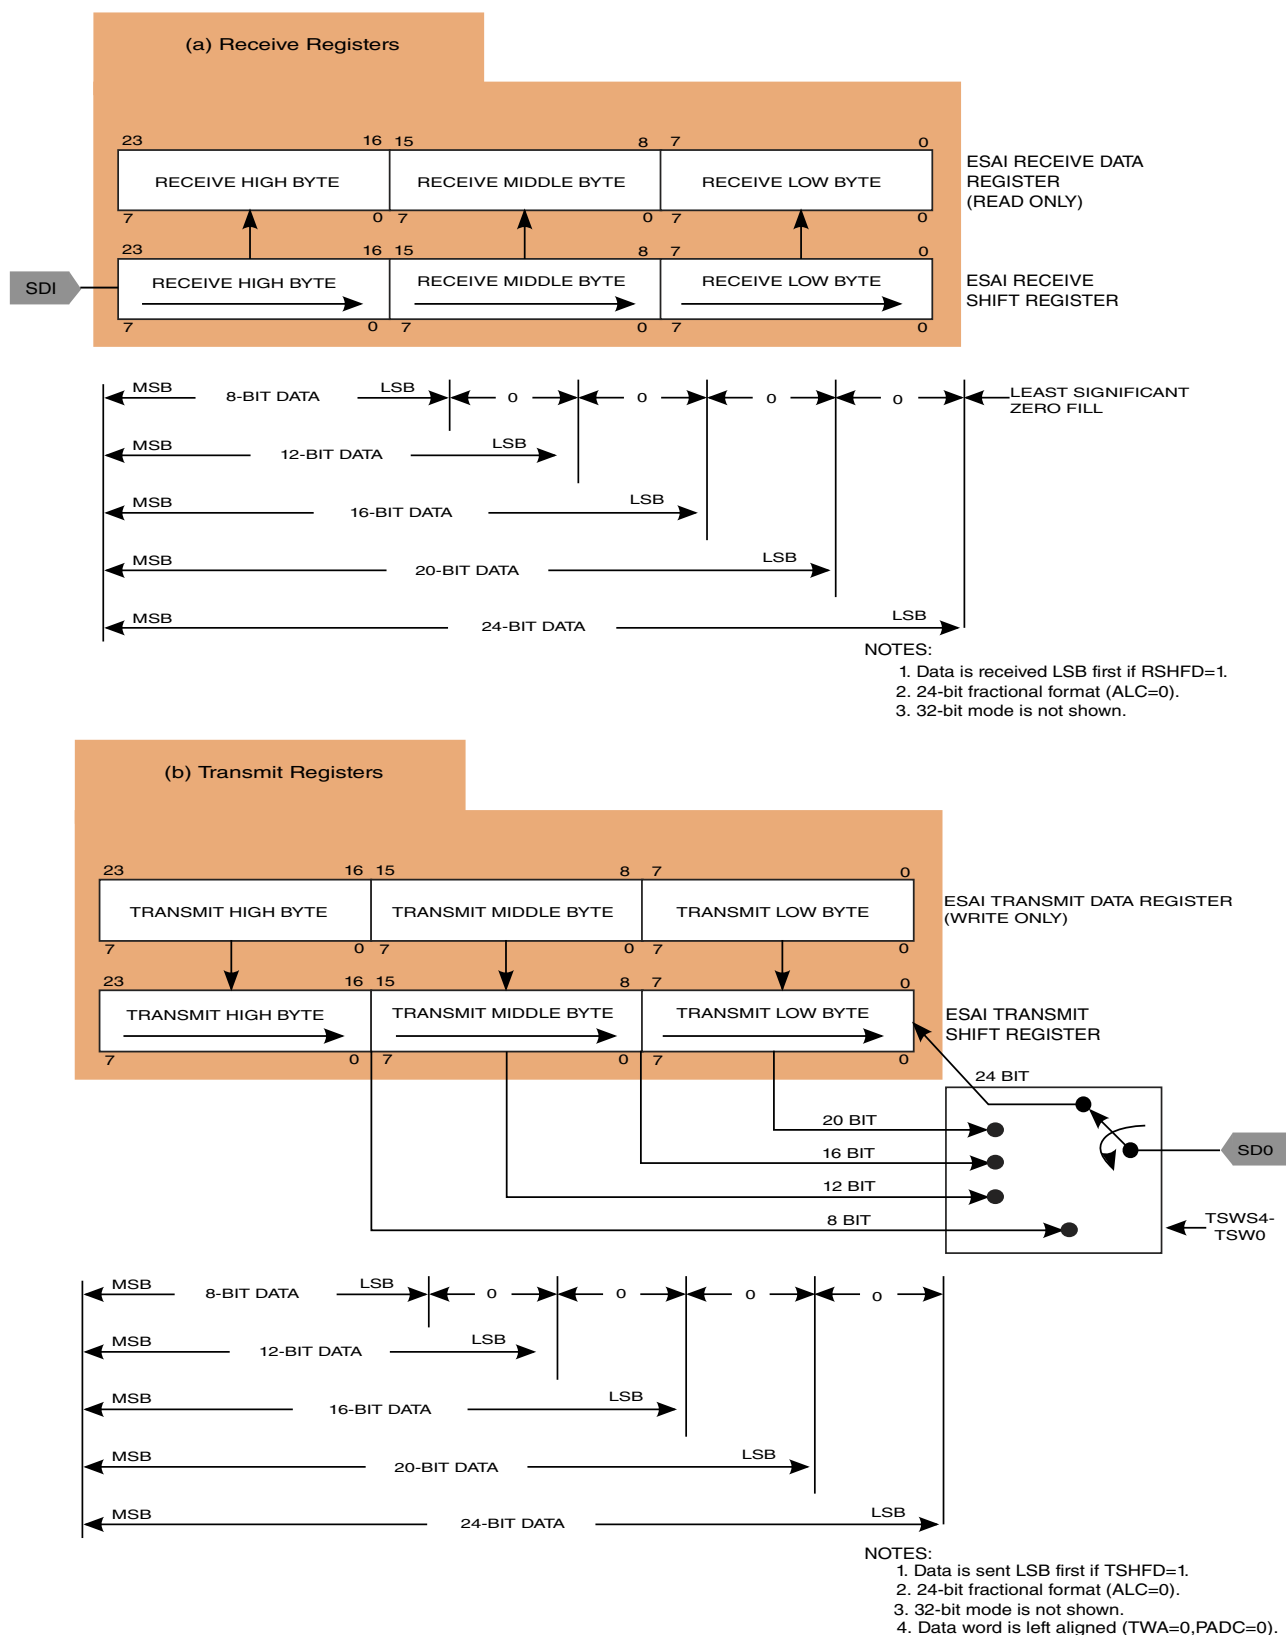

Figure 15-6. ESai Data Path Programming Model ([R/T]SHFD=1)

### 15.2.3.4.2 ESAI Receive Shift Registers

The receive shift registers (Figure 15-5 and Figure 15-6) receive the incoming data from the serial receive data pins. Data is shifted in by the selected (internal/external) bit clock when the associated frame sync I/O is asserted. Data is assumed to be received MSB first if RSHFD=0 and LSB first if RSHFD=1. Data is transferred to the ESAI receive data registers after 8, 12, 16, 20, 24, or 32 serial clock cycles were counted, depending on the slot length control bits in the ESAI\_RCR register.

## 15.2.4 Initialization Information

### 15.2.4.1 ESAI Initialization

The correct way to initialize the ESAI is as follows:

1. Enable the ESAI logic clock by asserting bit 0 of ESAI Control Register (ESAI\_ECR[0]).
2. Hardware, software, ESAI individual reset. Note that asserting bit 1 of ESAI Control Register only reset the ESAI core logic, including configuration registers, but not the ESAI FIFOs.
3. Reset ESAI FIFOs by asserting bit 1 of ESAI\_TFCR and ESAI\_RFCR.
4. Clear the ESAI\_TSMA/ESAI\_TSMB.
5. Program ESAI control registers. (The transmit/receive enable bits of TCR/RCR should not be set.)
6. Program ESAI FIFOs via TFCR and RFCR. (Enable Transmit/Receive FIFO, enable transmitters/receivers, transmit initialization and set Transmit FIFO/Receive FIFO watermark.)
7. Write initial words to ESAI Transmit Data Register (ESAI\_ETDR), at least one word per enabled transmitter slot but as many as desired. For example 4 channels with 2 slot-per-channel are enabled, then 8 words need to be written into ESAI\_ETDR
8. Remove ESAI personal reset by configuring ESAI\_PCRC and ESAI\_PRRC.
9. Enabled Transmitters/Receivers in ESAI\_TCR/ESAI\_RCR.
10. Configure time slot registers, first set ESAI\_TSMB, then ESAI\_TSMA.

During program execution, all ESAI pins may be defined disconnected, causing the ESAI to stop serial activity and enter the individual reset state.

All status bits of the interface are set to their reset state however, the control bits are not affected. This procedure allows the programmer to reset the ESAI separately from the other internal peripherals. During individual reset, internal DMA accesses to the data registers of the ESAI are not valid and data read is undefined.

The programmer must use an individual ESAI reset when changing the ESAI control registers (except for TEIE, REIE, TLIE, RLIE, TIE, RIE, TE0-TE5, RE0-RE3) to ensure proper operation of the interface.

### NOTE

If the ESAI receiver section is already operating with some of the receivers and enabling additional receivers on the fly, that is, without first putting the ESAI receiver in the personal reset state by setting their REx control bits, it will result in erroneous data being received as the first data word for the newly enabled receivers.

## 15.2.4.2 ESAI Initialization Examples

### 15.2.4.2.1 Initializing the ESAI using Personal Reset

1. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register(ESAI\_ECR[0]).
2. The ESAI should be in its personal reset state (ESAI\_PCRC = 0x000 and ESAI\_PRRC = 0x000). In the personal reset state, both the transmitter and receiver sections of the ESAI are simultaneously reset. The TPR bit in the ESAI\_TCR register may be used to reset just the transmitter section. The RPR bit in the ESAI\_RCR register may be used to reset just the receiver section.
3. Clear the ESAI\_TSMA/ESAI\_TSMB and ESAI\_RSMA/ESAI\_RSMB.
4. Configure the control registers (ESAI\_TCCR, ESAI\_TCR, ESAI\_RCCR, ESAI\_RCR) and ESAI FIFOs configuration Registers (ESAI\_TFCR, ESAI\_RFCR) according to the operating mode, but do not enable transmitters (TE5-TE0 = 0x0) or receivers (RE3-RE0 = 0x0). It is possible to set the interrupt enable bits which are in use during the operation (no interrupt occurs).
5. Enable the ESAI by setting the ESAI\_PCRC and ESAI\_PRRC register bits according to pins which are in use during operation.
6. Write initial words to ESAI Transmit Data Register (ESAI\_ETDR), at least one word per enabled transmitter slot but as many as desired. For example 4 channels with 2 slot-per-channel are enabled, then 8 words need to be written into ESAI\_ETDR. This step is needed even if DMA is used to service the transmitters.
7. Enable the transmitters and receivers.
8. Configure time slot registers, first set ESAI\_TSMB, then ESAI\_TSMA, then ESAI\_RSMB, then ESAI\_RSMA.
9. From now on ESAI can be serviced either by polling, interrupts, or DMA.

Operation proceeds as follows:

- For internally generated clock and frame sync, these signals are active immediately after ESAI is enabled (step 4 above).
- Data is received only when one of the receive enable (REx) bits is set and after the occurrence of frame sync signal (either internally or externally generated).
- Data is transmitted only when the transmitter enable (TE<sub>x</sub>) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tri-stated after TE<sub>x</sub> bit is set until the frame sync occurs.

#### 15.2.4.2.2 Initializing the ESAI Transmitter Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register(ESAI\_ECR[0])
3. The transmitter section should be in its individual reset state (TPR = 1) and also reset the ESAI Transmit FIFO (ESAI\_TFCR[1] = 1).
4. Clear the ESAI\_TSMA/ESAI\_TSMB.
5. Configure the control registers ESAI\_TCCR and ESAI\_TCR according to the operating mode, configure the Transmit FIFO Configuration Register (bring transmit FIFO out of reset, enable Transmit FIFO, enable transmitters, transmit initialization and set watermark). Make sure to clear the transmitter enable bits (TE0-TE5). TPR must remain set.
6. Take the transmitter section out of the individual reset state by clearing TPR.
7. Write initial words to ESAI Transmit Data Register (ESAI\_ETDR), at least one word per enabled transmitter slot but as many as desired. For example 4 channels with 2 slot-per-channel are enabled, then 8 words need to be written into ESAI\_ETDR
8. Enable the transmitters by setting their TE bits.
9. Configure time slot registers, first set ESAI\_TSMB, then ESAI\_TSMA.
10. Data is transmitted only when the transmitter enable (TE<sub>x</sub>) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tri-stated after TE<sub>x</sub> bit is set until the frame sync occurs.
11. From now on the transmitters are operating and can be serviced either by polling, interrupts, or DMA.

#### 15.2.4.2.3 Initializing the ESAI Receiver Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register (ESAI\_ECR[0])
3. The receiver section should be in its individual reset state (RPR = 1) and also reset the ESAI Receive FIFO (ESAI\_RFCR[1] = 1).

4. Clear the ESAI\_RSMA/ESAI\_RSMB.
5. Configure the control registers ESAI\_RCCR and ESAI\_RCR according to the operating mode, configure the Receive FIFO Configuration Register (bring receive FIFO out of reset, enable Receive FIFO, receivers, and set watermark). Making sure to clear the receiver enable bits (RE0-RE3). RPR must remain set.
6. Take the receiver section out of the individual reset state by clearing RPR.
7. Enable the receivers by setting their RE bits.
8. Configure time slot registers, first set ESAI\_RSMB, then set ESAI\_RSMA.
9. From now on the receivers are operating and can be serviced either by polling, interrupts, or DMA.

## 15.2.5 ESAI Memory Map/Register Definition

### NOTE

To access ESAI interface registers, CCM\_CACRR [IP\_CLK\_DIV] field in CCM should be greater than or equal to 1 (divider by 2).

#### ESAI\_ETDR field descriptions

Field	Description
ETDR	ESAI Transmit Data Register. Writing to this register stores the data written into the ESAI Transmit FIFO. Writing to this register when the Transmit FIFO is full causes the data written to be lost (the existing data within the FIFO is not overwritten). When multiple ESAI transmitters are enabled, the data for each transmitter must be interleaved from lowest transmitter to highest transmitter (for example, if transmitters 0, 2 and 3 are enabled then data must be written as follows: transmitter #0, transmitter #2, transmitter #3, transmitter #0, transmitter #2, transmitter #3, transmitter #0, etc). Data within the ESAI Transmit FIFO is passed to the ESAI transmit shifter registers as defined by the Transmit Word Alignment configuration bits.

#### 15.2.5.2 ESAI Receive Data Register (ESAI\_ERDR)

Address: 4006\_2000h base + 4h offset = 4006\_2004h

#### ESAI\_ERDR field descriptions

Field	Description
ERDR	ESAI Receive Data Register. Reading this register returns the data within the ESAI Receive FIFO. Reading this register when the Receive FIFO is empty returns the last valid data word. When multiple ESAI receivers are enabled, the data for each receiver is interleaved from lowest receiver to highest receiver (for example, if receivers 0, 2 and 3 are enabled then data is returned as follows: receiver #0,

**ESAI\_ESR field descriptions**

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 TINIT	Transmit Initialization. Indicates that the Transmit FIFO is writing the first word for each enabled transmitter into the Transmit Data Registers. This bit sets when the Transmit FIFO is enabled (provided Transmit Initialization is enabled) and clears after the Transmit Data Registers have been initialized. The Transmit Enable bits in the Transmit Control Register should not be set until this flag has cleared. 0 Transmitter has finished initializing the Transmit Data Registers (or Transmit FIFO is not enabled or Transmit Initialization is not enabled). 1 Transmitter has not finished initializing the Transmit Data Registers.
9 RFF	Receive FIFO Full. Indicates that the number of data words in the Receive FIFO has equaled or exceeded the Receive FIFO Watermark. This flag also drives the ESAI Receiver DMA request line. ESAI FIFO DMA requests see <a href="#">ESAI DMA Requests from the FIFOs</a> . 0 Number of words in Receive FIFO less than Receive FIFO watermark. 1 Number of words in Receive FIFO is equal to or greater than Receive FIFO watermark.

*Table continues on the next page...*

**ESAI\_ESR field descriptions (continued)**

Field	Description
8 TFE	Transmit FIFO Empty. Indicates that the number of empty slots in the Transmit FIFO has met or exceeded the Transmit FIFO Watermark. This flag also drives the ESAI Transmitter DMA request line. ESAI FIFO DMA request see <a href="#">ESAI DMA Requests from the FIFOs</a> .  0 Number of empty slots in Transmit FIFO less than Transmit FIFO watermark. 1 Number of empty slots in Transmit FIFO is equal to or greater than Transmit FIFO watermark.
7 TLS	Transmit Last Slot. Reading this register when TLS is set will negate the Transmit Last Slot interrupt.  0 TLS is not the highest priority active interrupt. 1 TLS is the highest priority active interrupt.
6 TDE	Transmit Data Exception.  0 TDE is not the highest priority active interrupt. 1 TDE is the highest priority active interrupt.
5 TED	Transmit Even Data.  0 TED is not the highest priority active interrupt. 1 TED is the highest priority active interrupt.
4 TD	Transmit Data.  0 TD is not the highest priority active interrupt. 1 TD is the highest priority active interrupt.
3 RLS	Receive Last Slot. Reading this register when RLS is set will negate the Receive Last Slot interrupt.  0 RLS is not the highest priority active interrupt. 1 RLS is the highest priority active interrupt.
2 RDE	Receive Data Exception.  0 RDE is not the highest priority active interrupt. 1 RDE is the highest priority active interrupt.
1 RED	Receive Even Data.  0 RED is not the highest priority active interrupt. 1 RED is the highest priority active interrupt.
0 RD	Receive Data.  0 RD is not the highest priority active interrupt. 1 RD is the highest priority active interrupt.

## 15.2.5.5 Transmit FIFO Configuration Register (ESAI\_TFCR)

Address: 4006\_2000h base + 10h offset = 4006\_2010h

### ESAI\_TFCR field descriptions

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. Reserved
20 Reserved	This field is reserved. Reserved
19 TIEN	Transmitter Initialization Enable. Enables the initialization of the Transmit Data Registers when the Transmitter FIFO is enabled. TIEN=1 is recommended.  0 Transmit Data Registers are not initialized from the FIFO once the Transmit FIFO is enabled. Software must manually initialize the Transmit Data Registers separately. 1 Transmit Data Registers are initialized from the FIFO once the Transmit FIFO is enabled.
18–16 TWA	Transmit Word Alignment. Configures the alignment of the data written into the ESAI Transmit Data Register and then passed to the relevant 24 bit Transmit shift register.  000 MSB of data is bit 31. Data bits 7-0 are ignored when passed to transmit shift register. 001 MSB of data is bit 27. Data bits 3-0 are ignored when passed to transmit shift register. 010 MSB of data is bit 23. 011 MSB of data is bit 19. Bottom 4 bits of transmit shift register are zeroed. 100 MSB of data is bit 15. Bottom 8 bits of transmit shift register are zeroed.

Table continues on the next page...

**ESAI\_TFCR field descriptions (continued)**

Field	Description
	101 MSB of data is bit 11. Bottom 12 bits of transmit shift register are zeroed. 110 MSB of data is bit 7. Bottom 16 bits of transmit shift register are zeroed. 111 MSB of data is bit 3. Bottom 20 bits of transmit shift register are zeroed.
15–8 TFWM	Transmit FIFO Watermark. These bits configure the threshold at which the Transmit FIFO Empty flag will set. The TFE is set when the number of empty slots in the Transmit FIFO equal or exceed the selected threshold.
7 TE5	Transmitter #5 FIFO Enable. This bit enables transmitter #5 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled.  0 Transmitter #5 is not using the Transmit FIFO. 1 Transmitter #5 is using the Transmit FIFO.
6 TE4	Transmitter #4 FIFO Enable. This bit enables transmitter #4 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled.  0 Transmitter #4 is not using the Transmit FIFO. 1 Transmitter #4 is using the Transmit FIFO.
5 TE3	Transmitter #3 FIFO Enable. This bit enables transmitter #3 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled.  0 Transmitter #3 is not using the Transmit FIFO. 1 Transmitter #3 is using the Transmit FIFO.
4 TE2	Transmitter #2 FIFO Enable. This bit enables transmitter #2 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled.  0 Transmitter #2 is not using the Transmit FIFO. 1 Transmitter #2 is using the Transmit FIFO.
3 TE1	Transmitter #1 FIFO Enable. This bit enables transmitter #1 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled.  0 Transmitter #1 is not using the Transmit FIFO. 1 Transmitter #1 is using the Transmit FIFO.
2 TE0	Transmitter #0 FIFO Enable. This bit enables transmitter #0 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled.  0 Transmitter #0 is not using the Transmit FIFO. 1 Transmitter #0 is using the Transmit FIFO.
1 TFR	Transmit FIFO Reset. This bit resets the Transmit FIFO pointers.  0 Transmit FIFO not reset. 1 Transmit FIFO reset.
0 TFE	Transmit FIFO Enable. This bit enables the use of the Transmit FIFO.  0 Transmit FIFO disabled. 1 Transmit FIFO enabled.

## 15.2.5.6 Transmit FIFO Status Register (ESAI\_TFSR)

Address: 4006\_2000h base + 14h offset = 4006\_2014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0	NTFO			0	NTFI			TFCNT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ESAI\_TFSR field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–12 NTFO	Next Transmitter FIFO Out. Indicates which Transmit Data Register receives the top word of the Transmit FIFO. This will usually equal the lowest enabled transmitter, unless the transmit FIFO is empty.  000 Transmitter #0 receives next word from the Transmit FIFO. 001 Transmitter #1 receives next word from the Transmit FIFO. 010 Transmitter #2 receives next word from the Transmit FIFO. 011 Transmitter #3 receives next word from the Transmit FIFO. 100 Transmitter #4 receives next word from the Transmit FIFO. 101 Transmitter #5 receives next word from the Transmit FIFO. 110 Reserved. 111 Reserved.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 NTFI	Next Transmitter FIFO In. Indicates which transmitter receives the next word written to the FIFO.  000 Transmitter #0 receives next word written to the Transmit FIFO. 001 Transmitter #1 receives next word written to the Transmit FIFO. 010 Transmitter #2 receives next word written to the Transmit FIFO. 011 Transmitter #3 receives next word written to the Transmit FIFO. 100 Transmitter #4 receives next word written to the Transmit FIFO. 101 Transmitter #5 receives next word written to the Transmit FIFO. 110 Reserved. 111 Reserved.
TFCNT	Transmit FIFO Counter. These bits indicate the number of data words stored in the Transmit FIFO.

## 15.2.5.7 Receive FIFO Configuration Register (ESAI\_RFCR)

Address: 4006\_2000h base + 18h offset = 4006\_2018h

**ESAI\_RFCR field descriptions**

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. Reserved
20 Reserved	This field is reserved. Reserved
19 REXT	Receive Extension. Enables the receive data to be returned sign extended when the Receive Word Alignment is configured to return data where the MSB is not aligned with bit 31.  0 Receive data is zero extended. 1 Receive data is sign extended.
18–16 RWA	Receive Word Alignment. Configures the alignment of the data passed from the relevant 24 bit Receive shift register and read out the ESAI Receive Data Register.  000 MSB of data is at bit 31. Data bits 7-0 are zeroed. 001 MSB of data is at bit 27. Data bits 3-0 are zeroed. 010 MSB of data is at bit 23. 011 MSB of data is at bit 19. Data bits 3-0 from receive shift register are ignored. 100 MSB of data is at bit 15. Data bits 7-0 from receive shift register are ignored. 101 MSB of data is at bit 11. Data bits 11-0 from receive shift register are ignored.

*Table continues on the next page...*

**ESAI\_RFCR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
	110 MSB of data is at bit 7. Data bits 15-0 from receive shift register are ignored. 111 MSB of data is at bit 3. Data bits 19-0 from receive shift register are ignored.
15–8 RFBM	Receive FIFO Watermark. These bits configure the threshold at which the Receive FIFO Full flag will set. The RFF is set when the number of words in the Receive FIFO equal or exceed the selected threshold. It can be set to a non-zero value.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 RE3	Receiver #3 FIFO Enable. This bit enables receiver #3 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled.  0 Receiver #3 is not using the Receive FIFO. 1 Receiver #3 is using the Receive FIFO.
4 RE2	Receiver #2 FIFO Enable. This bit enables receiver #2 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled.  0 Receiver #2 is not using the Receive FIFO. 1 Receiver #2 is using the Receive FIFO.
3 RE1	Receiver #1 FIFO Enable. This bit enables receiver #1 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled.  0 Receiver #1 is not using the Receive FIFO. 1 Receiver #1 is using the Receive FIFO.
2 RE0	Receiver #0 FIFO Enable. This bit enables receiver #0 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled.  0 Receiver #0 is not using the Receive FIFO. 1 Receiver #0 is using the Receive FIFO.
1 RFR	Receive FIFO Reset. This bit resets the Receive FIFO pointers.  0 Receive FIFO not reset. 1 Receive FIFO reset.
0 RFE	Receive FIFO Enable. This bit enables the use of the Receive FIFO.  0 Receive FIFO disabled. 1 Receive FIFO enabled.

### 15.2.5.8 Receive FIFO Status Register (ESAI\_RFSR)

Address: 4006\_2000h base + 1Ch offset = 4006\_201Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### ESAI\_RFSR field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–12 NRFI	Next Receiver FIFO In. Indicates which Receiver Data Register the Receive FIFO will load next. This will usually equal the lowest enabled receiver, unless the receive FIFO is full.  00 Receiver #0 returns next word to the Receive FIFO. 01 Receiver #1 returns next word to the Receive FIFO. 10 Receiver #2 returns next word to the Receive FIFO. 11 Receiver #3 returns next word to the Receive FIFO.
11–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 NRFO	Next Receiver FIFO Out. Indicates which receiver returns the top word of the Receive FIFO.  00 Receiver #0 returns next word from the Receive FIFO. 01 Receiver #1 returns next word from the Receive FIFO. 10 Receiver #2 returns next word from the Receive FIFO. 11 Receiver #3 returns next word from the Receive FIFO.
RFCNT	Receive FIFO Counter. These bits indicate the number of data words stored in the Receive FIFO.

### 15.2.5.9 Transmit Data Register n (ESAI\_TXn)

ESAI\_TX5, ESAI\_TX4, ESAI\_TX3, ESAI\_TX2, ESAI\_TX1 and ESAI\_TX0 are 32-bit write-only registers. Data to be transmitted is written into these registers and is automatically transferred to the transmit shift registers (Figure 15-5 and Figure 15-6). The data written (8, 12, 16, 20, or 24 bits) should occupy the most significant portion of the TXn according to the ALC control bit setting. The unused bits (least significant portion and the 8 most significant bits when ALC=1) of the TXn are don't care bits. The Core is interrupted whenever the TXn becomes empty if the transmit data register empty interrupt has been enabled.

Address: 4006\_2000h base + 80h offset + (4d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W									TXn																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ESAI\_TXn field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXn	Stores the data to be transmitted and is automatically transferred to the transmit shift registers. See <a href="#">ESAI Transmit Shift Registers</a> .

### 15.2.5.10 ESAI Transmit Slot Register (ESAI\_TSR)

Address: 4006\_2000h base + 98h offset = 4006\_2098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								0																							
W									TSR																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ESAI\_TSR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TSR	The write-only Transmit Slot Register (ESAI_TSR) is effectively a null data register that is used when the data is not to be transmitted in the available transmit time slot. The transmit data pins of all the enabled

*Table continues on the next page...*

ESAI\_TSR field descriptions (continued)

Field	Description
	transmitters are in the high-impedance state for the respective time slot where TSR has been written. The Transmitter External Buffer Enable pin (FSR pin when SYN=1, TEBE=1, RFSD=1) disables the external buffers during the slot when the ESAI_TSR register has been written.

15.2.5.11 Receive Data Register n (ESAI\_RXn)

ESAI\_RX3, ESAI\_RX2, ESAI\_RX1, and ESAI\_RX0 are 32-bit read-only registers that accept data from the receive shift registers when they become full (Figure 15-5 and Figure 15-6). The data occupies the most significant portion of the receive data registers, according to the ALC control bit setting. The unused bits (least significant portion and 8 most significant bits when ALC=1) read as zeros. The Core is interrupted whenever RXn becomes full if the associated interrupt is enabled.

Address: 4006\_2000h base + A0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ESAI\_SAISR field descriptions**

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 TODFE	ESAI_SAISR Transmit Odd-Data Register Empty. When set, TODFE indicates that the enabled transmitter data registers became empty at the beginning of an odd time slot. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TODFE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TODFE is cleared when the Core writes to all the transmit data registers of the

*Table continues on the next page...*

**ESAI\_SAISR field descriptions (continued)**

Field	Description
	enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TODFE is set. Hardware, software, ESAI individual reset clear TODFE.
16 TEDE	ESAI_SAISR Transmit Even-Data Register Empty. When set, TEDE indicates that the enabled transmitter data registers became empty at the beginning of an even time slot. Even time slots are all even-numbered slots (0, 2, 4, 6, etc.). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TEDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TEDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TEDE is set. Hardware, software, ESAI individual reset clear TEDE.
15 TDE	ESAI_SAISR Transmit Data Register Empty. TDE is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TDE is set. Hardware, software, ESAI individual reset clear TDE.
14 TUE	ESAI_SAISR Transmit Underrun Error Flag. TUE is set when at least one of the enabled serial transmit shift registers is empty (no new data to be transmitted) and a transmit time slot occurs. When a transmit underrun error occurs, the previous data (which is still present in the TX registers that were not written) is retransmitted. If TEIE is set, an ESAI transmit data with exception (underrun error) interrupt request is issued when TUE is set. Hardware, software, ESAI individual reset clear TUE. TUE is also cleared by reading the ESAI_SAISR with TUE set, followed by writing to all the enabled transmit data registers or to ESAI_TSR.
13 TFS	ESAI_SAISR Transmit Frame Sync Flag. When set, TFS indicates that a transmit frame sync occurred in the current time slot. TFS is set at the start of the first time slot in the frame and cleared during all other time slots. Data written to a transmit data register during the time slot when TFS is set is transmitted (in network mode), if the transmitter is enabled, during the second time slot in the frame. TFS is useful in network mode to identify the start of a frame. TFS is cleared by hardware, software, ESAI individual reset. TFS is valid only if at least one transmitter is enabled, that is, one or more of TE0, TE1, TE2, TE3, TE4 and TE5 are set. (In normal mode, TFS always reads as a one when transmitting data because there is only one time slot per frame - the "frame sync" time slot)
12–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 RODF	ESAI_SAISR Receive Odd-Data Register Full. When set, RODF indicates that the received data in the receive data registers of the enabled receivers have arrived during an odd time slot when operating in the network mode. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. RODF is set when the contents of the receive shift registers are transferred to the receive data registers. RODF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets.
9 REDF	ESAI_SAISR Receive Even-Data Register Full. When set, REDF indicates that the received data in the receive data registers of the enabled receivers have arrived during an even time slot when operating in the network mode. Even time slots are all even-numbered slots (0, 2, 4, 6, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. REDF is set when the contents of the receive shift registers are transferred to the receive data registers. REDF is cleared when the Core reads all the enabled receive data registers or

*Table continues on the next page...*

**ESAI\_SAISR field descriptions (continued)**

Field	Description
	cleared by hardware, software, ESAI individual resets. If REDIE is set, an ESAI receive even slot data interrupt request is issued when REDF is set.
8 RDF	ESAI_SAISR Receive Data Register Full. RDF is set when the contents of the receive shift register of an enabled receiver is transferred to the respective receive data register. RDF is cleared when the Core reads the receive data register of all enabled receivers or cleared by hardware, software, ESAI individual reset. If RIE is set, an ESAI receive data interrupt request is issued when RDF is set.
7 ROE	ESAI_SAISR Receive Overrun Error Flag. The ROE flag is set when the serial receive shift register of an enabled receiver is full and ready to transfer to its receiver data register (RXn) and the register is already full (RDF=1). If REIE is set, an ESAI receive data with exception (overrun error) interrupt request is issued when ROE is set. Hardware, software, ESAI individual reset clear ROE. ROE is also cleared by reading the SAISR with ROE set, followed by reading all the enabled receive data registers.
6 RFS	ESAI_SAISR Receive Frame Sync Flag. When set, RFS indicates that a receive frame sync occurred during reception of the words in the receiver data registers. This indicates that the data words are from the first slot in the frame. When RFS is clear and a word is received, it indicates (only in the network mode) that the frame sync did not occur during reception of that word. RFS is cleared by hardware, software, ESAI individual reset. RFS is valid only if at least one of the receivers is enabled (REx=1). (In normal mode, RFS always reads as a one when reading data because there is only one time slot per frame - the "frame sync" time slot)
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 IF2	ESAI_SAISR Serial Input Flag 2. The IF2 bit is enabled only when the HCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RHCKD=0, indicating that HCKR is an input flag and the synchronous mode is selected. Data present on the HCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF2 bit is updated with this data when the receive shift registers are transferred into the receiver data registers. IF2 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF2.
1 IF1	ESAI_SAISR Serial Input Flag 1. The IF1 bit is enabled only when the FSR pin is defined as ESAI in the Port Control Register, SYN=1, RFSD=0 and TEBE=0, indicating that FSR is an input flag and the synchronous mode is selected. Data present on the FSR pin is latched during reception of the first received data bit after frame sync is detected. The IF1 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF1 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF1.
0 IF0	ESAI_SAISR Serial Input Flag 0. The IF0 bit is enabled only when the SCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RCKD=0, indicating that SCKR is an input flag and the synchronous mode is selected. Data present on the SCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF0 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF0 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF0.

**15.2.5.13 Serial Audio Interface Control Register (ESAI\_SAICR)**

The read/write Common Control Register (ESAI\_SAICR) contains control bits for functions that affect both the receive and transmit sections of the ESAI.

**ESAI\_SAICR field descriptions**

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 ALC	ESAI_SAICR Alignment Control. The ESAI is designed for 24-bit fractional data, thus shorter data words are left aligned to the MSB (bit 23). Some applications use 16-bit fractional data. In those cases, shorter data words may be left aligned to bit 15. The Alignment Control (ALC) bit supports these applications.  If ALC is set, transmitted and received words are left aligned to bit 15 in the transmit and receive shift registers. If ALC is cleared, transmitted and received word are left aligned to bit 23 in the transmit and receive shift registers.  While ALC is set, 20-bit and 24-bit words may not be used, and word length control should specify 8-, 12-, or 16-bit words; otherwise, results are unpredictable.
7 TEBE	ESAI_SAICR Transmit External Buffer Enable. The Transmitter External Buffer Enable (TEBE) bit controls the function of the FSR pin when in the synchronous mode. If the ESAI is configured for operation in the synchronous mode (SYN=1), and TEBE is set while FSR pin is configured as an output (RFSD=1), the FSR pin functions as the transmitter external buffer enable control to enable the use of an external buffers on the transmitter outputs. If TEBE is cleared, the FSR pin functions as the serial I/O flag 1. See <a href="#">Port C Control Register</a> for a summary of the effects of TEBE on the FSR pin.
6 SYN	ESAI_SAICR Synchronous Mode Selection. The Synchronous Mode Selection (SYN) bit controls whether the receiver and transmitter sections of the ESAI operate synchronously or asynchronously with respect to each other (see <a href="#">Port C Control Register</a> ). When SYN is cleared, the asynchronous mode is chosen and independent clock and frame sync signals are used for the transmit and receive sections. When SYN is set, the synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals.  When in the synchronous mode (SYN=1), the transmit and receive sections use the transmitter section clock generator as the source of the clock and frame sync for both sections. Also, the receiver clock pins SCKR, FSR and HCKR now operate as I/O flags. Refer to <a href="#">Table 15-9</a> , <a href="#">Table 15-10</a> , and <a href="#">Table 15-11</a> for the effects of SYN on the receiver clock pins.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 OF2	ESAI_SAICR Serial Output Flag 2. The Serial Output Flag 2 (OF2) is a data bit used to hold data to be send to the OF2 pin. When the ESAI is in the synchronous clock mode (SYN=1), the HCKR pin is configured as the ESAI flag 2. If the receiver high frequency clock direction bit (RHCKD) is set, the HCKR pin is the output flag OF2, and data present in the OF2 bit is written to the OF2 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.
1 OF1	ESAI_SAICR Serial Output Flag 1. The Serial Output Flag 1 (OF1) is a data bit used to hold data to be send to the OF1 pin. When the ESAI is in the synchronous clock mode (SYN=1), the FSR pin is configured as the ESAI flag 1. If the receiver frame sync direction bit (RFSD) is set and the TEBE bit is cleared, the FSR pin is the output flag OF1, and data present in the OF1 bit is written to the OF1 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.

*Table continues on the next page...*

**ESAI\_SAICR field descriptions (continued)**

Field	Description
0 OF0	ESAI_SAICR Serial Output Flag 0. The Serial Output Flag 0 (OF0) is a data bit used to hold data to be send to the OF0 pin. When the ESAI is in the synchronous clock mode (SYN=1), the SCKR pin is configured as the ESAI flag 0. If the receiver serial clock direction bit (RCKD) is set, the SCKR pin is the output flag OF0, and data present in the OF0 bit is written to the OF0 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.

**15.2.5.14 Transmit Control Register (ESAI\_TCR)**

The read/write Transmit Control Register (ESAI\_TCR) controls the ESAI transmitter section. Interrupt enable bits for the transmitter section are provided in this control register. Operating modes are also selected in this register.

### ESAI\_TCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 TLIE	ESAI_TCR Transmit Last Slot Interrupt Enable. TLIE enables an interrupt at the beginning of last slot of a frame in network mode. When TLIE is set the Core is interrupted at the start of the last slot in a frame in network mode regardless of the transmit mask register setting. When TLIE is cleared the transmit last slot interrupt is disabled. TLIE is disabled when TDC=0x00000 (on-demand mode). The use of the transmit last slot interrupt is described in <a href="#">ESAI Interrupt Requests</a> .
22 TIE	ESAI_TCR Transmit Interrupt Enable. The Core is interrupted when TIE and the TDE flag in the ESAI_SAISR status register are set. When TIE is cleared, this interrupt is disabled. Writing data to all the data registers of the enabled transmitters or to ESAI_TSR clears TDE, thus clearing the interrupt.  Transmit interrupts with exception have higher priority than normal transmit data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
21 TEDIE	ESAI_TCR Transmit Even Slot Data Interrupt Enable. The TEDIE control bit is used to enable the transmit even slot data interrupts. If TEDIE is set, the transmit even slot data interrupts are enabled. If TEDIE is cleared, the transmit even slot data interrupts are disabled. A transmit even slot data interrupt request is generated if TEDIE is set and the TEDE status flag in the ESAI_SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot in the frame is marked by the frame sync signal and is considered to be even. Writing data to all the data registers of the enabled transmitters or to ESAI_TSR clears the TEDE flag, thus servicing the interrupt.  Transmit interrupts with exception have higher priority than transmit even slot data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
20 TEIE	ESAI_TCR Transmit Exception Interrupt Enable. When TEIE is set, the Core is interrupted when both TDE and TUE in the ESAI_SAISR status register are set. When TEIE is cleared, this interrupt is disabled. Reading the ESAI_SAISR status register followed by writing to all the data registers of the enabled transmitters clears TUE, thus clearing the pending interrupt.
19 TPR	ESAI_TCR Transmit Section Personal Reset. The TPR control bit is used to put the transmitter section of the ESAI in the personal reset state. The receiver section is not affected. When TPR is cleared, the transmitter section may operate normally. When TPR is set, the transmitter section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset. The control bits are not affected by the personal reset state. The transmitter data pins are tri-stated while in the personal reset state; if a stable logic level is desired, the transmitter data pins should be defined as GPIO outputs, or external pull-up or pull-down resistors should be used. The

Table continues on the next page...

## ESAI\_TCR field descriptions (continued)

Field	Description
	transmitter clock outputs drive zeroes while in the personal reset state. Note that to leave the personal reset state by clearing TPR, the procedure described in <a href="#">ESAI Initialization Examples</a> should be followed.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 PADC	ESAI_TCR Transmit Zero Padding Control. When PADC is cleared, zero padding is disabled. When PADC is set, zero padding is enabled. PADC, in conjunction with the TWA control bit, determines the way that padding is done for operating modes where the word length is less than the slot length. See the TWA bit description in bit 7 for more details.  Because the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule:  If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted.  If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.
16 TFSR	ESAI_TCR Transmit Frame Sync Relative Timing. TFSR determines the relative timing of the transmit frame sync signal as referred to the serial data lines, for a word length frame sync only (TFSL=0). When TFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When TFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 TFSL	ESAI_TCR Transmit Frame Sync Length. The TFSL bit selects the length of frame sync to be generated or recognized. If TFSL is cleared, a word-length frame sync is selected. If TFSL is set, a 1-bit clock period frame sync is selected. See Figure 1-21 for examples of frame length selection.
14–10 TSWS	ESAI_TCR Tx Slot and Word Length Select (TSWS4-TSWS0). The TSWS4-TSWS0 bits are used to select the length of the slot and the length of the data words being transferred through the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in <a href="#">Table 15-4</a> . See also the ESAI data path programming model in <a href="#">Figure 15-5</a> and <a href="#">Figure 15-6</a> .
9–8 TMOD	ESAI_TCR Transmit Network Mode Control (TMOD1-TMOD0). The TMOD1 and TMOD0 bits are used to define the network mode of ESAI transmitters, as shown in <a href="#">Table 15-4</a> . In the normal mode, the frame rate divider determines the word transfer rate - one word is transferred per frame sync during the frame sync time slot, as shown in <a href="#">Figure 15-8</a> . In network mode, it is possible to transfer a word for every time slot, as shown in <a href="#">Figure 15-8</a> . For further details, refer to <a href="#">Modes of Operation</a>  In order to comply with AC-97 specifications, TSWS4-TSWS0 should be set to 00011 (20-bit slot, 20-bit word length), TFSL and TFSR should be cleared, and TDC4-TDC0 should be set to 0x0C (13 words in frame). If TMOD=0b11 and the above recommendations are followed, the first slot and word will be 16 bits long, and the next 12 slots and words will be 20 bits long, as required by the AC97 protocol.
7 TWA	ESAI_TCR Transmit Word Alignment Control. The Transmitter Word Alignment Control (TWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If TWA is cleared, the data word is left-aligned in the slot frame during transmission. If TWA is set, the data word is right-aligned in the slot frame during transmission.  Because the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule:  If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted.  If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.

Table continues on the next page...

## ESAI\_TCR field descriptions (continued)

Field	Description
6 TSHFD	ESAI_TCR Transmit Shift Direction. The TSHFD bit causes the transmit shift registers to shift data out MSB first when TSHFD equals zero or LSB first when TSHFD equals one (see <a href="#">Figure 15-5</a> and <a href="#">Figure 15-6</a> ).
5 TE5	<p>ESAI_TCR ESAI Transmit 5 Enable. TE5 enables the transfer of data from ESAI_TX5 to the transmit shift register #5. When TE5 is set and a frame sync is detected, the transmit #5 portion of the ESAI is enabled for that frame. When TE5 is cleared, the transmitter #5 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX5 when TE5 is cleared but the data is not transferred to the transmit shift register #5.</p> <p>The SDO5/SDI0 pin is the data input pin for ESAI_RX0 if TE5 is cleared and RE0 in the ESAI_RCR register is set. If both RE0 and TE5 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE0 and TE5 should not be set at the same time.</p> <p>The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one.</p> <p>In the network mode, the operation of clearing TE5 and setting it again disables the transmitter #5 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO5/SDI0 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE5 can be left enabled.</p>
4 TE4	<p>ESAI_TCR ESAI Transmit 4 Enable. TE4 enables the transfer of data from ESAI_TX4 to the transmit shift register #4. When TE4 is set and a frame sync is detected, the transmit #4 portion of the ESAI is enabled for that frame. When TE4 is cleared, the transmitter #4 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX4 when TE4 is cleared but the data is not transferred to the transmit shift register #4.</p> <p>The SDO4/SDI1 pin is the data input pin for ESAI_RX1 if TE4 is cleared and RE1 in the RCR register is set. If both RE1 and TE4 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE1 and TE4 should not be set at the same time.</p> <p>The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one.</p> <p>In the network mode, the operation of clearing TE4 and setting it again disables the transmitter #4 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO4/SDI1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE4 can be left enabled.</p>
3 TE3	<p>ESAI_TCR ESAI Transmit 3 Enable. TE3 enables the transfer of data from ESAI_TX3 to the transmit shift register #3. When TE3 is set and a frame sync is detected, the transmit #3 portion of the ESAI is enabled for that frame. When TE3 is cleared, the transmitter #3 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX3 when TE3 is cleared but the data is not transferred to the transmit shift register #3.</p> <p>The SDO3/SDI2 pin is the data input pin for ESAI_RX2 if TE3 is cleared and RE2 in the ESAI_RCR register is set. If both RE2 and TE3 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE2 and TE3 should not be set at the same time.</p> <p>The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one.</p> <p>In the network mode, the operation of clearing TE3 and setting it again disables the transmitter #3 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO3/SDI2 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE3 can be left enabled.</p>
2 TE2	ESAI_TCR ESAI Transmit 2 Enable. TE2 enables the transfer of data from ESAI_TX2 to the transmit shift register #2. When TE2 is set and a frame sync is detected, the transmit #2 portion of the ESAI is enabled for that frame. When TE2 is cleared, the transmitter #2 is disabled after completing transmission of data

*Table continues on the next page...*

**ESAI\_TCR field descriptions (continued)**

Field	Description
	<p>currently in the ESAI transmit shift register. Data can be written to ESAI_TX2 when TE2 is cleared but the data is not transferred to the transmit shift register #2.</p> <p>The SDO2/SDI3 pin is the data input pin for ESAI_RX3 if TE2 is cleared and RE3 in the ESAI_RCR register is set. If both RE3 and TE2 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE3 and TE2 should not be set at the same time.</p> <p>The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one.</p> <p>In the network mode, the operation of clearing TE2 and setting it again disables the transmitter #2 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO2/SDI3 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE2 can be left enabled.</p>
1 TE1	<p>ESAI_TCR ESAI Transmit 1 Enable. TE1 enables the transfer of data from TX1 to the transmit shift register #1. When TE1 is set and a frame sync is detected, the transmit #1 portion of the ESAI is enabled for that frame. When TE1 is cleared, the transmitter #1 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO1 output is tri-stated, and any data present in TX1 is not transmitted, that is, data can be written to TX1 with TE1 cleared, but data is not transferred to the transmit shift register #1.</p> <p>The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one.</p> <p>In the network mode, the operation of clearing TE1 and setting it again disables the transmitter #1 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE1 can be left enabled.</p>
0 TE0	<p>ESAI_TCR ESAI Transmit 0 Enable. TE0 enables the transfer of data from ESAI_TX0 to the transmit shift register #0. When TE0 is set and a frame sync is detected, the transmit #0 portion of the ESAI is enabled for that frame. When TE0 is cleared, the transmitter #0 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO0 output is tri-stated, and any data present in ESAI_TX0 is not transmitted, that is, data can be written to ESAI_TX0 with TE0 cleared, but data is not transferred to the transmit shift register #0.</p> <p>The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one.</p> <p>In the network mode, the operation of clearing TE0 and setting it again disables the transmitter #0 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO0 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE0 can be left enabled.</p>

**15.2.5.15 Transmit Clock Control Register (ESAI\_TCCR)**

The read/write Transmitter Clock Control Register (ESAI\_TCCR) controls the ESAI transmitter clock generator bit and frame sync rates, the bit clock and high frequency clock sources and the directions of the HCKT, FST and SCKT signals. In the synchronous mode (SYN=1), the bit clock defined for the transmitter determines the receiver bit clock as well. ESAI\_TCCR also controls the number of words per frame for the serial data. Hardware and software reset clear all the bits of the ESAI\_TCCR register.

Care should be taken in asynchronous mode whenever the frame sync clock (FSR, FST) is not sourced directly from its associated bit clock (SCKR, SCKT). Proper phase relationships must be maintained between these clocks in order to guarantee proper operation of the ESAI.

### NOTE

ARM Core clock is ipg\_clk\_esai in block ESAI which is from CCM's ahb\_clk\_root.

**Figure 15-10. ESAI Clock Generator Functional Block Diagram**

### NOTE

1. ETI, ETO, ERI and ERO bit descriptions are covered in [ESAI Control Register \(ESAI\\_ECR\)](#). 2. Fsys is the ESAI system 133 MHz clock. 3. EXTAL is the on-chip clock sources other than ESAI system 133MHz clock.

### ESAI\_TCCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 THCKD	ESAI_TCCR Transmit High Frequency Clock Direction. THCKD controls the direction of the HCKT pin. When THCKD is cleared, HCKT is an input; when THCKD is set, HCKT is an output (see <a href="#">Table 15-2</a> ).
22 TFSD	ESAI_TCCR Transmit Frame Sync Signal Direction. TFSD controls the direction of the FST pin. When TFSD is cleared, FST is an input; when TFSD is set, FST is an output (see <a href="#">Table 15-2</a> ).
21 TCKD	ESAI_TCCR Transmit Clock Source Direction. The Transmitter Clock Source Direction (TCKD) bit selects the source of the clock signal used to clock the transmit shift registers in the asynchronous mode (SYN=0) and the transmit shift registers and the receive shift registers in the synchronous mode (SYN=1). When TCKD is set, the internal clock source becomes the bit clock for the transmit shift registers and word length divider and is the output on the SCKT pin. When TCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKT pin, and an external clock source may drive this pin (see <a href="#">Table 15-2</a> ).
20 THCKP	ESAI_TCCR Transmit High Frequency Clock Polarity The Transmitter High Frequency Clock Polarity (THCKP) bit controls the polarity of the HCKT. 0 - Normal polarity 1 - Inverted polarity
19 TFSP	ESAI_TCCR Transmit Frame Sync Polarity. The Transmitter Frame Sync Polarity (TFSP) bit determines the polarity of the transmit frame sync signal. When TFSP is cleared, the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When TFSP is set, the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 TCKP	ESAI_TCCR Transmit Clock Polarity. The Transmitter Clock Polarity (TCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If TCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit bit clock and latched in on the falling edge of the transmit bit clock. If TCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.
17–14 TFP	ESAI_TCCR Tx High Frequency Clock Divider. The TFP3-TFP0 bits control the divide ratio of the transmitter high frequency clock to the transmitter serial bit clock when the source of the high frequency clock and the bit clock is the internal ARM Core clock. When the HCKT input is being driven from an external high frequency clock, the TFP3-TFP0 bits specify an additional division ratio in the clock divider chain. <a href="#">Table 15-5</a> shows the specification for the divide ratio. <a href="#">Figure 15-10</a> shows the ESAI high frequency clock generator functional diagram.

Table continues on the next page...

## ESAI\_TCCR field descriptions (continued)

Field	Description
13–9 TDC	<p>ESAI_TCCR Tx Frame Rate Divider Control. The TDC4-TDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the transmitter frame clocks.</p> <p>In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (TDC=0x00001 to 0x11111) for network mode. A divide ratio of one (TDC=0x00000) in network mode is a special case (on-demand mode).</p> <p>In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (TDC=0x00000 to 0x11111) for normal mode. In normal mode, a divide ratio of 1 (TDC=0x00000) provides continuous periodic data word transfers. A bit-length frame sync (TFSL=1) must be used in this case.</p> <p>The ESAI frame sync generator functional diagram is shown in <a href="#">Figure 15-11</a></p>
8 TPSR	<p>ESAI_TCCR Transmit Prescaler Range. The TPSR bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When TPSR is set, the fixed prescaler is bypassed. When TPSR is cleared, the fixed divide-by-eight prescaler is operational (see <a href="#">Figure 15-10</a>). The maximum internally generated bit clock frequency is <math>F_{sys}/6</math>; the minimum internally generated bit clock frequency is <math>F_{sys}/(2 \times 8 \times 256 \times 16) = F_{sys}/65536</math>.</p> <p><b>NOTE:</b> Do not use the combination TPSR = 1 and TPM7-RPM0 = 0x00, which causes synchronization problems when using the internal core clock as source (THCKD = 1 or TCKD = 1).</p>
TPM	<p>ESAI_TCCR Transmit Prescale Modulus Select. The TPM7-TPM0 bits specify the divide ratio of the prescale divider in the ESAI transmitter clock generator. A divide ratio from 1 to 256 (TPM=0x00 to 0xFF) may be selected. The bit clock output is available at the transmit serial bit clock (SCKT) pin. The bit clock output is also available internally for use as the bit clock to shift the transmit and receive shift registers.</p> <p>The ESAI transmit clock generator functional diagram is shown in <a href="#">Figure 15-10</a>.</p>

## 15.2.5.16 Receive Control Register (ESAI\_RCR)

The read/write Receive Control Register (ESAI\_RCR) controls the ESAI receiver section. Interrupt enable bits for the receivers are provided in this control register. The receivers are enabled in this register (0,1,2 or 3 receivers can be enabled) if the input data pin is not used by a transmitter. Operating modes are also selected in this register.

**ESAI\_RCR field descriptions**

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RLIE	ESAI_RCR Receive Last Slot Interrupt Enable. RLIE enables an interrupt after the last slot of a frame ended in network mode only. When RLIE is set the Core is interrupted after the last slot in a frame ended regardless of the receive mask register setting. When RLIE is cleared the receive last slot interrupt is disabled. Hardware and software reset clear RLIE. RLIE is disabled when RDC=00000 (on-demand mode). The use of the receive last slot interrupt is described in <a href="#">ESAI Interrupt Requests</a> .
22 RIE	ESAI_RCR Receive Interrupt Enable. The Core is interrupted when RIE and the RDF flag in the ESAI_SAISR status register are set. When RIE is cleared, this interrupt is disabled. Reading the receive data registers of the enabled receivers clears RDF, thus clearing the interrupt.  Receive interrupts with exception have higher priority than normal receive data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
21 REDIE	ESAI_RCR Receive Even Slot Data Interrupt Enable. The REDIE control bit is used to enable the receive even slot data interrupts. If REDIE is set, the receive even slot data interrupts are enabled. If REDIE is cleared, the receive even slot data interrupts are disabled. A receive even slot data interrupt request is generated if REDIE is set and the REDF status flag in the ESAI_SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot is marked by the frame sync signal and is considered to be even. Reading all the data registers of the enabled receivers clears the REDF flag, thus servicing the interrupt.  Receive interrupts with exception have higher priority than receive even slot data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
20 REIE	ESAI_RCR Receive Exception Interrupt Enable. When REIE is set, the Core is interrupted when both RDF and ROE in the ESAI_SAISR status register are set. When REIE is cleared, this interrupt is disabled. Reading the ESAI_SAISR status register followed by reading the enabled receivers data registers clears ROE, thus clearing the pending interrupt.
19 RPR	ESAI_RCR Receiver Section Personal Reset. The RPR control bit is used to put the receiver section of the ESAI in the personal reset state. The transmitter section is not affected. When RPR is cleared, the receiver section may operate normally. When RPR is set, the receiver section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset. The control bits are not affected by the personal reset state. The receiver data pins are disconnected while in the personal reset state.

*Table continues on the next page...*

## ESAI\_RCR field descriptions (continued)

Field	Description
	<b>NOTE:</b> To leave the personal reset state by clearing RPR, the procedure described in <a href="#">ESAI Initialization Examples</a> should be followed.
18–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 RFSR	ESAI_RCR Receiver Frame Sync Relative Timing. RFSR determines the relative timing of the receive frame sync signal as referred to the serial data lines, for a word length frame sync only. When RFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When RFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 RFSL	ESAI_RCR Receiver Frame Sync Length. The RFSL bit selects the length of the receive frame sync to be generated or recognized. If RFSL is cleared, a word-length frame sync is selected. If RFSL is set, a 1-bit clock period frame sync is selected. Refer to <a href="#">Figure 15-9</a> for examples of frame length selection.
14–10 RSWS	ESAI_RCR Receiver Slot and Word Select. The RSWS4-RSWS0 bits are used to select the length of the slot and the length of the data words being received through the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in <a href="#">Table 15-7</a> . See also the ESAI data path programming model in <a href="#">Figure 15-5</a> and <a href="#">Figure 15-6</a> .
9–8 RMOD	ESAI_RCR Receiver Network Mode Control. The RMOD1 and RMOD0 bits are used to define the network mode of the ESAI receivers, as shown in <a href="#">Table 15-6</a> . In the normal mode, the frame rate divider determines the word transfer rate - one word is transferred per frame sync during the frame sync time slot, as shown in <a href="#">Figure 15-8</a> . In network mode, it is possible to transfer a word for every time slot, as shown in <a href="#">Figure 15-8</a> . For more details, see <a href="#">Modes of Operation</a> .  In order to comply with AC-97 specifications, RSWS4-RSWS0 should be set to 0x00011 (20-bit slot, 20-bit word); RFSL and RFSR should be cleared, and RDC4-RDC0 should be set to 0x0C (13 words in frame).
7 RWA	ESAI_RCR Receiver Word Alignment Control. The Receiver Word Alignment Control (RWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If RWA is cleared, the data word is assumed to be left-aligned in the slot frame. If RWA is set, the data word is assumed to be right-aligned in the slot frame.  If the data word is shorter than the slot length, the data bits which are not in the data word field are ignored.  For data word lengths of less than 24 bits, the data word is right-extended with zeroes before being stored in the receive data registers.
6 RSHFD	ESAI_RCR Receiver Shift Direction. The RSHFD bit causes the receiver shift registers to shift data in MSB first when RSHFD is cleared or LSB first when RSHFD is set (see <a href="#">Figure 15-5</a> and <a href="#">Figure 15-6</a> ).
5–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 RE3	ESAI_RCR ESAI Receiver 3 Enable. When RE3 is set and TE2 is cleared, the ESAI receiver 3 is enabled and samples data at the SDO2/SDI3 pin. ESAI_TX2 and ESAI_RX3 should not be enabled at the same time (RE3=1 and TE2=1). When RE3 is cleared, receiver 3 is disabled by inhibiting data transfer into ESAI_RX3. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX3 data register.  If RE3 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX3 will be invalid and must be discarded.
2 RE2	ESAI_RCR ESAI Receiver 2 Enable. When RE2 is set and TE3 is cleared, the ESAI receiver 2 is enabled and samples data at the SDO3/SDI2 pin. ESAI_TX3 and ESAI_RX2 should not be enabled at the same time (RE2=1 and TE3=1). When RE2 is cleared, receiver 2 is disabled by inhibiting data transfer into ESAI_RX2. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX2 data register.  If RE2 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX2 will be invalid and must be discarded.

Table continues on the next page...

**ESAI\_RCR field descriptions (continued)**

Field	Description
1 RE1	<p>ESAI_RCR ESAI Receiver 1 Enable. When RE1 is set and TE4 is cleared, the ESAI receiver 1 is enabled and samples data at the SDO4/SDI1 pin. ESAI_TX4 and ESAI_RX1 should not be enabled at the same time (RE1=1 and TE4=1). When RE1 is cleared, receiver 1 is disabled by inhibiting data transfer into ESAI_RX1. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX1 data register.</p> <p>If RE1 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX1 will be invalid and must be discarded.</p>
0 RE0	<p>ESAI_RCR ESAI Receiver 0 Enable. When RE0 is set and TE5 is cleared, the ESAI receiver 0 is enabled and samples data at the SDO5/SDI0 pin. ESAI_TX5 and ESAI_RX0 should not be enabled at the same time (RE0=1 and TE5=1). When RE0 is cleared, receiver 0 is disabled by inhibiting data transfer into ESAI_RX0. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX0 data register.</p> <p>If RE0 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX0 will be invalid and must be discarded.</p>

**15.2.5.17 Receive Clock Control Register (ESAI\_RCCR)**

The read/write Receiver Clock Control Register (ESAI\_RCCR) controls the ESAI receiver clock generator bit and frame sync rates, word length, and number of words per frame for the serial data. The ESAI\_RCCR control bits are described in the following paragraphs.

**NOTE**

ARM Core clock is ipg\_clk\_esai in block ESAI which is from CCM's ahb\_clk\_root.

## ESAI\_RCCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RHCKD	<p>ESAI_RCCR Receiver High Frequency Clock Direction. The Receiver High Frequency Clock Direction (RHCKD) bit selects the source of the receiver high frequency clock when in the asynchronous mode (SYN=0) and the IF2/OF2 flag direction in the synchronous mode (SYN=1).</p> <p>In the asynchronous mode, when RHCKD is set, the internal clock generator becomes the source of the receiver high frequency clock and is the output on the HCKR pin. In the asynchronous mode, when RHCKD is cleared, the receiver high frequency clock source is external; the internal clock generator is disconnected from the HCKR pin, and an external clock source may drive this pin.</p> <p>When RHCKD is cleared, HCKR is an input; when RHCKD is set, HCKR is an output.</p> <p>In the synchronous mode when RHCKD is set, the HCKR pin becomes the OF2 output flag. If RHCKD is cleared, the HCKR pin becomes the IF2 input flag. Refer to <a href="#">Table 15-1</a> and <a href="#">Table 15-11</a>.</p>
22 RFSD	<p>ESAI_RCCR Receiver Frame Sync Signal Direction. The Receiver Frame Sync Signal Direction (RFSD) bit selects the source of the receiver frame sync signal when in the asynchronous mode (SYN=0) and the IF1/OF1/Transmitter Buffer Enable flag direction in the synchronous mode (SYN=1).</p> <p>In the asynchronous mode, when RFSD is set, the internal clock generator becomes the source of the receiver frame sync and is the output on the FSR pin. In the asynchronous mode, when RFSD is cleared, the receiver frame sync source is external; the internal clock generator is disconnected from the FSR pin, and an external clock source may drive this pin.</p> <p>In the synchronous mode when RFSD is set, the FSR pin becomes the OF1 output flag or the Transmitter Buffer Enable, according to the TEBE control bit. If RFSD is cleared, the FSR pin becomes the IF1 input flag. Refer to <a href="#">Table 15-1</a> and <a href="#">Table 15-10</a>.</p>
21 RCKD	<p>ESAI_RCCR Receiver Clock Source Direction. The Receiver Clock Source Direction (RCKD) bit selects the source of the clock signal used to clock the receive shift register in the asynchronous mode (SYN=0) and the IF0/OF0 flag direction in the synchronous mode (SYN=1).</p> <p>In the asynchronous mode, when RCKD is set, the internal clock source becomes the bit clock for the receive shift registers and word length divider and is the output on the SCKR pin. In the asynchronous mode when RCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKR pin, and an external clock source may drive this pin.</p> <p>In the synchronous mode when RCKD is set, the SCKR pin becomes the OF0 output flag. If RCKD is cleared, the SCKR pin becomes the IF0 input flag. Refer to <a href="#">Table 15-1</a> and <a href="#">Table 15-9</a>.</p>
20 RHCKP	ESAI_RCCR Receiver High Frequency Clock Polarity. The Receiver High Frequency Clock Polarity (RHCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RHCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive high frequency bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RHCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
19 RFSP	ESAI_RCCR Receiver Frame Sync Polarity. The Receiver Frame Sync Polarity (RFSP) determines the polarity of the receive frame sync signal. When RFSP is cleared the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When RFSP is set the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 RCKP	The Receiver Clock Polarity (RCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
17–14 RFP	ESAI_RCCR Rx High Frequency Clock Divider. The RFP3-RFP0 bits control the divide ratio of the receiver high frequency clock to the receiver serial bit clock when the source of the receiver high frequency clock and the bit clock is the internal Arm Core clock. When the HCKR input is being driven

*Table continues on the next page...*

## ESAI\_RCCR field descriptions (continued)

Field	Description
	from an external high frequency clock, the RFP3-RFP0 bits specify an additional division ration in the clock divider chain. <a href="#">Table 15-8</a> provides the specification of the divide ratio. <a href="#">Figure 15-10</a> shows the ESAI high frequency generator functional diagram.
13–9 RDC	<p>ESAI_RCCR Rx Frame Rate Divider Control. The RDC4-RDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the receiver frame clocks.</p> <p>In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (RDC=0x00001 to 0x11111) for network mode. A divide ratio of one (RDC=0x00000) in network mode is a special case (on-demand mode).</p> <p>In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (RDC=0x00000 to 0x11111) for normal mode. In normal mode, a divide ratio of one (RDC=0x00000) provides continuous periodic data word transfers. A bit-length frame sync (RFSL=1) must be used in this case.</p> <p>The ESAI frame sync generator functional diagram is shown in <a href="#">Figure 15-11</a>.</p>
8 RPSR	ESAI_RCCR Receiver Prescaler Range. The RPSR controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When RPSR is set, the fixed prescaler is bypassed. When RPSR is cleared, the fixed divide-by-eight prescaler is operational (see <a href="#">Figure 15-10</a> ). The maximum internally generated bit clock frequency is $F_{sys}/6$ , the minimum internally generated bit clock frequency is $F_{sys}/(2 \times 8 \times 256 \times 16) = F_{sys}/65536$ . (Do not use the combination RPSR=1 and RPM7-RPM0 =0x00, which causes synchronization problems when using the internal Core clock as source (RHCKD=1 or RCKD=1))
RPM	ESAI_RCCR Receiver Prescale Modulus Select. The RPM7-RPM0 bits specify the divide ratio of the prescale divider in the ESAI receiver clock generator. A divide ratio from 1 to 256 (RPM=0x00 to 0xFF) may be selected. The bit clock output is available at the receiver serial bit clock (SCKR) pin. The bit clock output is also available internally for use as the bit clock to shift the receive shift registers. The ESAI receive clock generator functional diagram is shown in <a href="#">Figure 15-10</a> .

## 15.2.5.18 Transmit Slot Mask Register A (ESAI\_TSMA)

The Transmit Slot Mask Register A together with Transmit Slot Mask Register B (ESAI\_TSMA and ESAI\_TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tri-state the transmitter data pins. Fields ESAI\_TSMA[TS] and ESAI\_TSMB[TS] are concatenated to form the 32-bit field TS[31:0]. Bit number n in TS is the enable/disable control bit for transmission in slot number n.

Address: 4006\_2000h base + E4h offset = 4006\_20E4h

## 15.3 Asynchronous Sample Rate Converter (ASRC)

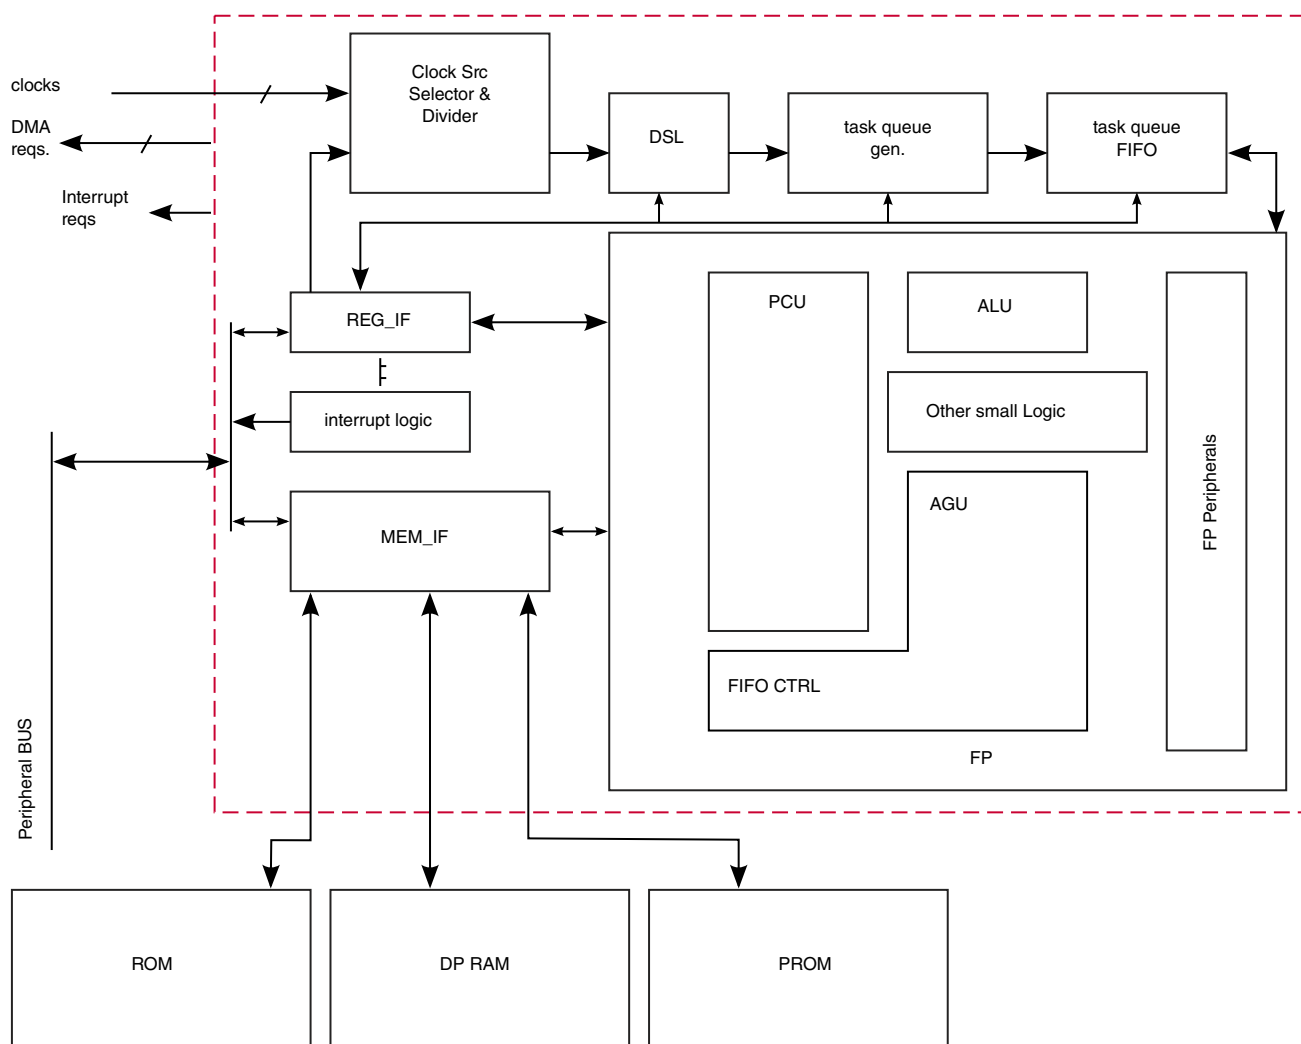

### 15.3.1 Introduction

The figure below is a system view of the connection between the ASRC block and other blocks.

**Figure 15-12. System Overview**

The following figure is the ASRC block diagram.

**Figure 15-13. ASRC block diagram**

### 15.3.1.1 Overview

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated with an input clock into a signal associated with a different output clock. The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The ASRC supports up to three sampling rate pairs.

The incoming audio data to this chip may be received from various sources at different sampling rates. The outgoing audio data of this chip may have different sampling rates and it can also be associated with output clocks that are asynchronous to the input clocks.

The ASRC is implemented as a co-processor in hardware, with minimal ARM Platform intervention required.

### 15.3.1.2 Features

Features:

- Support user-programmable threshold for the input/output FIFOs.
- Support flexible 8/16/24 bit width of input data, and 16/24 bit width of output data.
- Designed for rate conversion between 44.1kHz, 32kHz, 48kHz, 96kHz, and 192kHz. The useful signal bandwidth is below 24kHz.
- Other input sampling rates in the range of 8kHz to 200kHz is also supported, but possibly with less desirable bandwidth.
- Other output sampling rates in the range of 30kHz to 200kHz is also supported, but possibly with less desirable bandwidth.
- Automatic accommodation to slow variations in the incoming and outgoing sampling rates.
- Linear phase
- Tolerant to sample clock jitter

Clock/Data Connections

- The sampling rate clocks are directly connected to the ASRC block, the ratio estimation of the input clocks with output clocks are done in ASRC hardware.
- The clock signals come from the following blocks, for example:
  - ESAI, receiving bit clock and transmitting bit clock
  - SAI, receiving bit clock and transmitting bit clock
  - SPDIF, receiving bit clock and transmitting bit clock
  - other audio peripherals etc.
- The exchange of audio data is done by the processor accessing ASRC block through registers defined on shared peripheral bus.

### 15.3.1.3 Modes of Operation

See the Programmable Registers section for a definition of the registers and parameters used in ASRC.

#### 15.3.1.3.1 Data Transfer Schemes

##### 15.3.1.3.1.1 Data Input Modes

The input mode for each of the three channel sets may be set independently. Three modes of supplying data to the ASRC input FIFOs are available:

- Polling
- Interrupt
- DMA

In all input-data transfer schemes, the ASRC fetches data from each enabled FIFO and processes the data sample-by-sample after each rising edge of the associated input sampling clock until the FIFO level reaches a threshold.

After the threshold is reached, the ASRC requests data. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x=A, B or C.

If the ASRC attempts to fetch data from an empty FIFO, an error is generated and the ASRSTR\_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIER\_AOLIE bit is set), an interrupt is generated.

When writing data to an input FIFO, you must ensure that it is in a predefined sequence. For example, when writing to an input FIFO, the sequence should be: channel\_0, channel\_1, channel\_2,..., channel\_n, channel\_0, channel\_1, channel\_2, etc. Here channel\_n stands for the data intended for the n-th channel. The hardware will re-allocate each data to its corresponding channel FIFO. The channel being re-allocated is shown by ASRCCR\_ACIA.

### Mode 1 (Polling Mode)

Polling mode is the default mode following power-on or individual reset, and is selected by clearing the associated channel set A, B, or C data-input interrupt enable bit (ASRIER\_ADIE<sub>x</sub>, where x=A, B or C). In this mode, data-input interrupts are disabled. When the FIFO level is below the threshold, the associated status bit (ASRSTR\_AIDEx, where x=A, B, or C) is set. To clear the status bit, the FIFO must be written with enough data to raise the level above the threshold.

### Mode 2 (Interrupt Mode)

The ASRC input FIFOs can also be serviced by interrupts. To enable interrupts, the corresponding data-input interrupt enable bits (ASRIER\_ADIE<sub>x</sub>, where x=A, B, or C) should be set. An interrupt is automatically generated any time the input FIFO level is below the threshold. The interrupt is cleared when enough data is written to the FIFO to raise the level above the threshold.

### Mode 3 (DMA Mode)

The ASRC input FIFOs can also be filled using DMA. In this mode, the data-input interrupt-enable bits (ASRIER\_ADIE<sub>x</sub>, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

### 15.3.1.3.1.2 Data Output Modes

The output mode for each of the 3 channel sets (A, B, and C) may be set independently.

Three modes of retrieving data from the ASRC output FIFOs are available:

- Polling
- Interrupt
- DMA

In all output-data transfer schemes, the ASRC places a processed sample into the associated output FIFO. After a threshold is reached, the ASRC requests that data be transferred out of the FIFO.

The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x=A, B or C.

If the ASRC attempts to place data into a FIFO that is already full, an error is generated and the ASRSTR\_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIER\_AOLIE bit is set), an interrupt is generated.

Each output FIFO is organized in the same channel order in which the associated input FIFO was written.

Two transfer modes are supported by Interface Block.

#### Mode 1 (Polling Mode)

The ASRC output FIFOs can be serviced by polling. In this mode, ensure the associated output-data interrupt enable bit (ASRIER\_ADOEx, where x=A, B, or C) is cleared. In this mode, all output-data interrupts are disabled. Any time the output FIFO exceeds the threshold the associated status bit (ASRSTR\_AODFx, where x=A, B, or C) is set. To clear the status bit, enough data must be read from the associated output FIFO to lower the level below the threshold.

#### Mode 2 (Interrupt Mode)

The ASRC output FIFOs may also be serviced using interrupts. To enable this mode, the corresponding output-data interrupt-enable bits (ASRIER\_ADOEx, where x=A, B, or C) should be set. Any time the output FIFO level exceeds the threshold, an interrupt is automatically generated. The interrupt is cleared when enough data is read from the FIFO to lower the level below the threshold.

#### Mode 3 (DMA Mode)

The ASRC output FIFOs can also be read using DMA. In this mode, the output-data interrupt-enable bits (ASRIER\_ADOEx, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

### 15.3.1.3.2 Word Alignment Supported

#### 15.3.1.3.2.1 Input Data Alignment Modes

The position and length of input data word to the input data FIFOs ASRDIA, ASRDIB, ASRDIC are programmable. The control bits are defined in ASRMCR1x {x=A, B, or C}. It supports the following modes.

**Table 15-13. Input Data Alignment**

Format	Bit Number

3	ASRC Pair A output data ready
4	ASRC Pair B output data ready
5	ASRC Pair C output data ready

## 15.3.4 Programmable Registers

All useful registers are listed in the memory map below. The access of undefined registers will behave as normal registers.

All the interface registers are LSB aligned except the input FIFOs and the output FIFOs, and each register has only 24 effective bits.

The input FIFO and output FIFO word alignment can be defined using ASRMCR1{A,B,C} registers in 32-bit interface system.

**ASRC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

### 15.3.4.1 ASRC Control Register (ASRC\_ASRCTR)

The ASRC control register (ASRCTR) is a 24-bit read/write register that controls the ASRC operations.

Address: 4006\_0000h base + 0h offset = 4006\_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## ASRC\_ASRCCTR field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented.  This field is reserved.
23 -	This field is reserved. Reserved. Should be written as zero for compatibility.
22 ATSC	ASRC Pair C Automatic Selection For Processing Options  When this bit is 1, pair C will automatic update its pre-processing and post-processing options (ASRCFG:PREMODC, ASRCFG:POSTMODC) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly.  When this bit is 0, the user needs to choose the proper processing options for pair C.  This bit should be disabled when {USRC, IDRC}={1,1}.
21 ATSB	ASRC Pair B Automatic Selection For Processing Options  When this bit is 1, pair B will automatic update its pre-processing and post-processing options (ASRCFG:PREMODB, ASRCFG:POSTMODB) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly.  When this bit is 0, the user is responsible for choosing the proper processing options for pair B.  This bit should be disabled when {USRB, IDRB}={1,1}.
20 ATSA	ASRC Pair A Automatic Selection For Processing Options  When this bit is 1, pair A will automatic update its pre-processing and post-processing options (ASRCFG:PREMODA, ASRCFG:POSTMODA)based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly.  When this bit is 0, the user needs to choose the proper processing options for pair A.  This bit should be disabled when {USRA, IDRA}={1,1}.
19 -	This field is reserved. Reserved. Should be written as zero for compatibility.
18 USRC	Use Ratio for Pair C  Use ratio as the input to ASRC. This bit is used in conjunction with IDRC control bit.
17 IDRC	Use Ideal Ratio for Pair C  When USRC=0, this bit has no usage.  When USRC=1 and IDRC=0, ASRC internal measured ratio will be used.  When USRC=1 and IDRC=1, the idea ratio from the interface register ASRIDRHC, ASRIDRLC will be used. It is suggested to manually set ASRCFG:POSTMODC, ASRCFG:PREMODC.
16 USRB	Use Ratio for Pair B  Use ratio as the input to ASRC. This bit is used in conjunction with IDRB control bit.
15 IDRB	Use Ideal Ratio for Pair B  When USRB=0, this bit has no usage.  When USRB=1 and IDRB=0, ASRC internal measured ratio will be used.  When USRB=1 and IDRB=1, the idea ratio from the interface register ASRIDRHB, ASRIDRLB will be used. It is suggested to manually set ASRCFG:POSTMODB, ASRCFG:PREMODB.
14 USRA	Use Ratio for Pair A  Use ratio as the input to ASRC. This bit is used in conjunction with IDRA control bit.

Table continues on the next page...

### ASRC\_ASRCCTR field descriptions (continued)

Field	Description
13 IDRA	Use Ideal Ratio for Pair A When USRA=0, this bit has no usage. When USRA=1 and IDRA=0, ASRC internal measured ratio will be used. When USRA=1 and IDRA=1, the idea ratio from the interface register ASRIDRHA, ASRIDRLA will be used. It is suggested to manually set ASRCFG:POSTMODA, ASRCFG:PREMODA.
12–5 -	This field is reserved. Reserved. Should be written as zero for compatibility.
4 SRST	Software Reset This bit is self-clear bit. Once it is been written as 1, it will generate a software reset signal inside ASRC. After 9 cycles of the ASRC processing clock, this reset process will stop, and this bit will be cleared automatically.
3 ASREC	ASRC Enable C Enable the operation of the conversion C of ASRC. When ASREC is cleared, operation of conversion C is disabled.
2 ASREB	ASRC Enable B Enable the operation of the conversion B of ASRC. When ASREB is cleared, operation of conversion B is disabled.
1 ASREA	ASRC Enable A Enable the operation of the conversion A of ASRC. When ASREA is cleared, operation of conversion A is disabled.
0 ASRCEN	ASRC Enable Enable the operation of ASRC.

### 15.3.4.2 ASRC Interrupt Enable Register (ASRC\_ASRIER)

Address: 4006\_0000h base + 4h offset = 4006\_0004h

**ASRC\_ASRIER field descriptions**

<b>Field</b>	<b>Description</b>
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented.  This field is reserved.
23–8 -	This field is reserved. Reserved. Should be written as zero for compatibility.
7 AFPWE	FP in Wait State Interrupt Enable Enables the FP in wait state interrupt.  1 interrupt enabled 0 interrupt disabled
6 AOLIE	Overload Interrupt Enable Enables the overload interrupt.  1 interrupt enabled 0 interrupt disabled
5 ADOEC	Data Output C Interrupt Enable Enables the data output C interrupt.  1 interrupt enabled 0 interrupt disabled
4 ADOEB	Data Output B Interrupt Enable Enables the data output B interrupt.  1 interrupt enabled 0 interrupt disabled
3 ADOEA	Data Output A Interrupt Enable Enables the data output A interrupt.  1 interrupt enabled 0 interrupt disabled
2 ADIEC	Data Input C Interrupt Enable Enables the data input C interrupt.  1 interrupt enabled 0 interrupt disabled
1 ADIEB	Data Input B Interrupt Enable Enables the data input B interrupt.  1 interrupt enabled 0 interrupt disabled
0 ADIEA	Data Input A Interrupt Enable Enables the data input A Interrupt.  1 interrupt enabled 0 interrupt disabled

### 15.3.4.3 ASRC Channel Number Configuration Register (ASRC\_ASRCNCR)

The ASRC channel number configuration register (ASRCNCR) is a 24-bit read/write register that sets the number of channels used by each ASRC conversion pair.

There are 10 channels available for distribution among 3 conversion pairs, they are ordered as 0,1,...,9. The bottom [0, ANCA-1] channels are used for pair A, the top [10-ANCC, 9] channels are used for pair C, and the [ANCA, ANCA+ANCB-1] channels are allocated for pair B. In case that ANCA=0, then the [0, ANCB-1] channels are assigned for pair B.

Address: 4006\_0000h base + Ch offset = 4006\_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ASRC\_ASRCNCR field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–12 -	This field is reserved. Reserved. Should be written as zero for compatibility.
11–8 ANCC	Number of C Channels <sup>1</sup>  0000      0 channels in C (Pair C is disabled) 0001      1 channel in C 0010      2 channels in C 0011      3 channels in C 0100      4 channels in C 0101      5 channels in C 0110      6 channels in C 0111      7 channels in C 1000      8 channels in C 1001      9 channels in C 1010      10 channels in C 1011-1111      Should not be used.
7–4 ANCB	Number of B Channels  0000      0 channels in B (Pair B is disabled) 0001      1 channel in B 0010      2 channels in B 0011      3 channels in B 0100      4 channels in B 0101      5 channels in B

Table continues on the next page...

**ASRC\_ASRCNCR field descriptions (continued)**

Field	Description
	0110 6 channels in B 0111 7 channels in B 1000 8 channels in B 1001 9 channels in B 1010 10 channels in B 1011-1111 Should not be used.
ANCA	Number of A Channels  0000 0 channels in A (Pair A is disabled) 0001 1 channel in A 0010 2 channels in A 0011 3 channels in A 0100 4 channels in A 0101 5 channels in A 0110 6 channels in A 0111 7 channels in A 1000 8 channels in A 1001 9 channels in A 1010 10 channels in A 1011-1111 Should not be used.

1.  $ANCC + ANCB + ANCA \leq 10$ . Hardware is not checking the constraint. Programmer should take the responsibility to ensure the constraint is satisfied.

15.3.4.4 ASRC Filter Configuration Status Register (ASRC\_ASRCFG)

The ASRC configuration status register (ASRCFG) is a 24-bit read/write register that sets and/or automatically senses the ASRC operations.

Address: 4006\_0000h base + 10h offset = 4006\_0010h

ASRC\_ASRCFG field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.

Table continues on the next page...

## ASRC\_ASRCFG field descriptions (continued)

Field	Description
23 INIRQC	Initialization for Conversion Pair C is served When this bit is 1, it means the initialization for conversion pair C is served. This bit is cleared by disabling the ASRC conversion pair (ASRCTR:ASREC=0 or ASRCTR:ASRCEN=0).
22 INIRQB	Initialization for Conversion Pair B is served When this bit is 1, it means the initialization for conversion pair B is served. This bit is cleared by disabling the ASRC conversion pair (ASRCTR:ASREB=0 or ASRCTR:ASRCEN=0).
21 INIRQA	Initialization for Conversion Pair A is served When this bit is 1, it means the initialization for conversion pair A is served. This bit is cleared by disabling the ASRC conversion pair (ASRCTR:ASREA=0 or ASRCTR:ASRCEN=0).
20 NDPRC	Not Use Default Parameters for RAM-stored Parameters For Conversion Pair C 0 Use default parameters for RAM-stored parameters. Override any parameters already in RAM. 1 Don't use default parameters for RAM-stored parameters. Use the parameters already stored in RAM.
19 NDPRB	Not Use Default Parameters for RAM-stored Parameters For Conversion Pair B 0 Use default parameters for RAM-stored parameters. Override any parameters already in RAM. 1 Don't use default parameters for RAM-stored parameter. Use the parameters already stored in RAM.
18 NDPRA	Not Use Default Parameters for RAM-stored Parameters For Conversion Pair A 0 Use default parameters for RAM-stored parameters. Override any parameters already in RAM. 1 Don't use default parameters for RAM-stored parameters. Use the parameters already stored in RAM.
17–16 POSTMODC[1-0]	Post-Processing Configuration for Conversion Pair C These bits will be read/write by user if ASRCTR:ATSC=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSC=1. These bits set the selection of the post-processing configuration.  00 Select Upsampling-by-2 as defined in Signal Processing Flow. 01 Select Direct-Connection as defined in Signal Processing Flow. 10 Select Downsampling-by-2 as defined in Signal Processing Flow.
15–14 PREMODC[1-0]	Pre-Processing Configuration for Conversion Pair C These bits will be read/write by user if ASRCTR:ATSC=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSC=1. These bits set the selection of the pre-processing configuration.  00 Select Upsampling-by-2 01 Select Direct-Connection 10 Select Downsampling-by-2 11 Select passthrough mode. In this case, POSTMODC[1-0] have no use.
13–12 POSTMODB[1-0]	Post-Processing Configuration for Conversion Pair B These bits will be read/write by user if ASRCTR:ATSB=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSB=1. These bits set the selection of the post-processing configuration.  00 Select Upsampling-by-2

*Table continues on the next page...*

### ASRC\_ASRCFG field descriptions (continued)

Field	Description
	01 Select Direct-Connection 10 Select Downsampling-by-2
11–10 PREMODB[1-0]	Pre-Processing Configuration for Conversion Pair B These bits will be read/write by user if ASRCTR:ATSB=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSB=1. These bits set the selection of the pre-processing configuration.  00 Select Upsampling-by-2 01 Select Direct-Connection 10 Select Downsampling-by-2 11 Select passthrough mode. In this case, POSTMODB[1-0] have no use.
9–8 POSTMODA[1-0]	Post-Processing Configuration for Conversion Pair A These bits will be read/write by user if ASRCTR:ATSA=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSA=1. These bits set the selection of the post-processing configuration.  00 Select Upsampling-by-2 01 Select Direct-Connection 10 Select Downsampling-by-2
7–6 PREMODA[1-0]	Pre-Processing Configuration for Conversion Pair A These bits will be read/write by user if ASRCTR:ATSA=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSA=1. These bits set the selection of the pre-processing configuration.  00 Select Upsampling-by-2 01 Select Direct-Connection 10 Select Downsampling-by-2 11 Select passthrough mode. In this case, POSTMODA[1-0] have no use.
-	This field is reserved. Reserved. Should be written as zero for compatibility.

### 15.3.4.5 ASRC Clock Source Register (ASRC\_ASRCSCR)

The ASRC clock source register (ASRCSCR) is a 24-bit read/write register that controls the sources of the input and output clocks of the ASRC.

#### ASRC\_ASRCDR1 field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 AOCDB	Output Clock Divider B Specify the divide ratio of the output clock divider B. The divide ratio may range from 1 to 8 (AOCDB[2:0] = 000 to 111).
20–18 AOCPB	Output Clock Prescaler B Specify the prescaling factor of the output prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
17–15 AOCDA	Output Clock Divider A Specify the divide ratio of the output clock divider A. The divide ratio may range from 1 to 8 (AOCDA[2:0] = 000 to 111).
14–12 AOCPA	Output Clock Prescaler A Specify the prescaling factor of the output prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.
11–9 AICDB	Input Clock Divider B Specify the divide ratio of the input clock divider B. The divide ratio may range from 1 to 8 (AICDB[2:0] = 000 to 111).
8–6 AICPB	Input Clock Prescaler B Specify the prescaling factor of the input prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
5–3 AICDA	Input Clock Divider A Specify the divide ratio of the input clock divider A. The divide ratio may range from 1 to 8 (AICDA[2:0] = 000 to 111).
AICPA	Input Clock Prescaler A Specify the prescaling factor of the input prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.

### 15.3.4.7 ASRC Clock Divider Register 2 (ASRC\_ASRCDR2)

The ASRC clock divider register (ASRCDR2) is a two 24-bit read/write register that controls the division factors of the ASRC input and output clock sources.

Address: 4006\_0000h base + 1Ch offset = 4006\_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ASRC\_ASRCDR2 field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–12 -	This field is reserved. Reserved. Should be written as zero for compatibility.
11–9 AOCDC	Output Clock Divider C Specify the divide ratio of the output clock divider C. The divide ratio may range from 1 to 8 (AOCDC[2:0] = 000 to 111).
8–6 AOCPC	Output Clock Prescaler C Specify the prescaling factor of the output prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.
5–3 AICDC	Input Clock Divider C Specify the divide ratio of the input clock divider C. The divide ratio may range from 1 to 8 (AICDC[2:0] = 000 to 111).
AICPC	Input Clock Prescaler C Specify the prescaling factor of the input prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.

15.3.4.8 ASRC Status Register (ASRC\_ASRSTR)

The ASRC status register (ASRSTR) is a 24-bit read-write register used by the processor core to examine the status of the ASRC block and clear the overload interrupt request and AOLE flag bit. Read the status register will return the current state of ASRC.

Address: 4006\_0000h base + 20h offset = 4006\_0020h

ASRC\_ASRSTR field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.

Table continues on the next page...

**ASRC\_ASRSTR field descriptions (continued)**

Field	Description
23–22 -	This field is reserved. Reserved. Should be written as zero for compatibility.
21 DSL CNT	DSL Counter Input to FIFO ready When set, this bit indicates that new DSL counter information is stored in the internal ASRC FIFO. When clear, this bit indicates that new DSL counter information is in the process of storage into the internal ASRC FIFO. When ASRIER:AFPWE=1, the rising edge of this signal will propose an interrupt request. Writing any value with this bit set will clear the interrupt request proposed by the rising edge of this bit.
20 ATQOL	Task Queue FIFO overload When set, this bit indicates that task queue FIFO logic is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
19 AOOLC	Pair C Output Task Overload When set, this bit indicates that pair C output task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
18 AOOLB	Pair B Output Task Overload When set, this bit indicates that pair B output task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
17 AOOLA	Pair A Output Task Overload When set, this bit indicates that pair A output task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
16 AIOLC	Pair C Input Task Overload When set, this bit indicates that pair C input task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
15 AIOLB	Pair B Input Task Overload When set, this bit indicates that pair B input task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
14 AIOLA	Pair A Input Task Overload When set, this bit indicates that pair A input task is overloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
13 AODOC	Output Data Buffer C has overflowed When set, this bit indicates that output data buffer C has overflowed. When clear, this bit indicates that output data buffer C has not overflowed
12 AODOB	Output Data Buffer B has overflowed When set, this bit indicates that output data buffer B has overflowed. When clear, this bit indicates that output data buffer B has not overflowed

*Table continues on the next page...*

### ASRC\_ASRSTR field descriptions (continued)

Field	Description
11 AODOA	Output Data Buffer A has overflowed When set, this bit indicates that output data buffer A has overflowed. When clear, this bit indicates that output data buffer A has not overflowed
10 AIDUC	Input Data Buffer C has underflowed When set, this bit indicates that input data buffer C has underflowed. When clear, this bit indicates that input data buffer C has not underflowed.
9 AIDUB	Input Data Buffer B has underflowed When set, this bit indicates that input data buffer B has underflowed. When clear, this bit indicates that input data buffer B has not underflowed.
8 AIDUA	Input Data Buffer A has underflowed When set, this bit indicates that input data buffer A has underflowed. When clear, this bit indicates that input data buffer A has not underflowed.
7 FPWT	FP is in wait states This bit is for debug only. When set, this bit indicates that ASRC is in wait states. When clear, this bit indicates that ASRC is not in wait states. If ASRCTR:AFPWE=1 and ASRCTR:ASDBG=1, an interrupt will be proposed when this bit is set.
6 AOLE	Overload Error Flag When set, this bit indicates that the task rate is too high for the ASRC to handle. The reasons for overload may be: <ul style="list-style-type: none"> <li>- too high input clock frequency,</li> <li>- too high output clock frequency,</li> <li>- incorrect selection of the pre-filter,</li> <li>- low ASRC processing clock,</li> <li>- too many channels,</li> <li>- underrun,</li> <li>- or any combination of the reasons above.</li> </ul> Since the ASRC uses the same hardware resources to perform various tasks, the real reason for the overload is not straight forward, and it should be carefully analyzed by the programmer. If ASRCTR:AOLIE=1, an interrupt will be proposed when this bit is set. Write any value with this bit set as one into the status register will clear this bit and the interrupt request proposed by this bit.
5 AODFC	Number of data in Output Data Buffer C is greater than threshold When set, this bit indicates that number of data already existing in ASRDORC is greater than threshold and the processor can read data from ASRDORC. When AODFC is set, the ASRC generates data output C interrupt request to the processor, if enabled (that is, ASRCTR:ADOEC = 1). A DMA request is always generated when the AODFC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
4 AODFB	Number of data in Output Data Buffer B is greater than threshold

Table continues on the next page...

**ASRC\_ASRSTR field descriptions (continued)**

Field	Description
	When set, this bit indicates that number of data already existing in ASRDORB is greater than threshold and the processor can read data from ASRDORB. When AODFB is set, the ASRC generates data output B interrupt request to the processor, if enabled (that is, ASRCTR:ADOEB = 1). A DMA request is always generated when the AODFB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
3 AODFA	Number of data in Output Data Buffer A is greater than threshold  When set, this bit indicates that number of data already existing in ASRDORA is greater than threshold and the processor can read data from ASRDORA. When AODFA is set, the ASRC generates data output A interrupt request to the processor, if enabled (that is, ASRCTR:ADOEA = 1). A DMA request is always generated when the AODFA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
2 AIDEC	Number of data in Input Data Buffer C is less than threshold  When set, this bit indicates that number of data still available in ASRDIRC is less than threshold and the processor can write data to ASRDIRC. When AIDEC is set, the ASRC generates data input C interrupt request to the processor, if enabled (that is, ASRCTR:ADIEC = 1). A DMA request is always generated when the AIDEC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
1 AIDEB	Number of data in Input Data Buffer B is less than threshold  When set, this bit indicates that number of data still available in ASRDIRB is less than threshold and the processor can write data to ASRDIRB. When AIDEB is set, the ASRC generates data input B interrupt request to the processor, if enabled (that is, ASRCTR:ADIEB = 1). A DMA request is always generated when the AIDEB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
0 AIDEA	Number of data in Input Data Buffer A is less than threshold  When set, this bit indicates that number of data still available in ASRDIRA is less than threshold and the processor can write data to ASRDIRA. When AIDEA is set, the ASRC generates data input A interrupt request to the processor, if enabled (that is, ASRCTR:ADIEA = 1). A DMA request is always generated when the AIDEA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.

**15.3.4.9 ASRC Parameter Register (ASRC\_ASRPM<sub>n</sub>)**

Parameter registers determine the performance of ASRC.

The parameter registers must be initialized by software before ASRC is enabled.

**Table 15-17. ASRC Parameter Registers (ASRPM1~ASRPM5)**

Register	Offset	Access	Reset Value	Recommend Value
asrcpm1	0x40	R/W	0x00_0000	0x7fffff

#### ASRC\_ASRCCR field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–20 ACOC	The channel counter for Pair C's output FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair C's output FIFO's usage. The value can be any value between [0, ANCC-1]
19–16 ACOB	The channel counter for Pair B's output FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair B's output FIFO's usage. The value can be any value between [0, ANCB-1]
15–12 ACOA	The channel counter for Pair A's output FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair A's output FIFO's usage. The value can be any value between [0, ANCA-1]
11–8 ACIC	The channel counter for Pair C's input FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair C's input FIFO's usage. The value can be any value between [0, ANCC-1]
7–4 ACIB	The channel counter for Pair B's input FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair B's input FIFO's usage. The value can be any value between [0, ANCB-1]
ACIA	The channel counter for Pair A's input FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair A's input FIFO's usage. The value can be any value between [0, ANCA-1]

15.3.4.12 ASRC Data Input Register for Pair x (ASRC\_ASRDIn)

These registers are the interface registers for the audio data input of  $x$ =pair A, B, or C. They are backed by FIFOs.

Address: 4006\_0000h base + 60h offset + (8d × i), where i=0d to 2d

ASRC\_ASRDIn field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
DATA	Audio data input

15.3.4.13 ASRC Data Output Register for Pair x (ASRC\_ASRDOx)

These registers are the interface registers for the audio data output of pair  $x$ =A, B, or C. They are backed by FIFOs.

Address: 4006\_0000h base + 64h offset + (8d × i), where i=0d to 2d

ASRC\_ASRDOx field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
DATA	Audio data output

### 15.3.4.14 ASRC Ideal Ratio for Pair A-High Part (ASRC\_ASRIDRHA)

The ideal ratio registers (ASRIDRHA, ASRIDRLA) hold the ratio value IDRATIOA.  $IDRATIOA = F_{s_{inA}} / F_{s_{outA}} = T_{s_{outA}} / T_{s_{inA}}$  is a 32-bit fixed point value with 26 fractional bits. This value is only useful when  $ASRC_{CTR}:\{USRA, IDRA\}=2'b11$ .

Address: 4006\_0000h base + 80h offset = 4006\_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ASRC\_ASRIDRHC field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–8 -	This field is reserved. Reserved
IDRATIOC[31:24]	IDRATIOC[31:24]. High part of ideal ratio value for pair C.

### 15.3.4.19 ASRC Ideal Ratio for Pair C-Low Part (ASRC\_ASRIDRLC)

The ideal ratio registers (ASRIDRHC, ASRIDRLC) hold the ratio value IDRATIOC.  $IDRATIOC = F_{s_{inC}} / F_{s_{outC}} = T_{s_{outC}} / T_{s_{inC}}$  is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCRTR:{USRC, IDRC}=2'b11.

Address: 4006\_0000h base + 94h offset = 4006\_0094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ASRC\_ASRIDRLC field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
IDRATIOC[23:0]	IDRATIOC[23:0]. Low part of ideal ratio value for pair C.

15.3.4.20 ASRC 76kHz Period in terms of ASRC processing clock (ASRC\_ASR76K)

The register (ASR76K) holds the period of the 76 KHz sampling clock in terms of the ASRC processing clock with frequency  $F_{s\ ASRC}$ .

$ASR76K = F_{s\ ASRC} / F_{s\ 76k}$

Reset value is 0x0A47 which assumes that  $F_{s\ ASRC} = 200\text{ MHz}$ .

This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically. In a system when  $F_{s\ ASRC} = 133\text{MHz}$ , the value should be assigned explicitly as 0x06D6 in user application code.

Address: 4006\_0000h base + 98h offset = 4006\_0098h

ASRC\_ASR76K field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–17 -	This field is reserved. Reserved
ASR76K	Value for the period of the 76kHz sampling clock.

15.3.4.21 ASRC 56kHz Period in terms of ASRC processing clock (ASRC\_ASR56K)

The register (ASR56K) holds the period of the 56kHz sampling clock in terms of the ASRC processing clock with frequency  $F_{s\ ASRC}$ .

$ASR56K = F_{s\ ASRC} / F_{s\ 56k}$

Reset value is 0x0DF3 which assumes that  $F_{s\ ASRC} = 200\text{ MHz}$ .

This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically. In a system when  $F_{s\ ASRC} = 133\text{MHz}$ , the value should be assigned explicitly as 0x0947 in user application code.

Address: 4006\_0000h base + 9Ch offset = 4006\_009Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### ASRC\_ASRMCRA field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 ZEROBUFA	Initialize buf of Pair A when pair A is enabled. Always clear option. This bit is used to control whether the buffer is to be zeroized when pair A is enabled.

Table continues on the next page...

## ASRC\_ASRMCRA field descriptions (continued)

Field	Description
	1 Do not reset the buffer 0 Reset the buffer
22 EXTTHRSA	Use external thresholds for FIFO control of Pair A This bit will determine whether the FIFO thresholds externally defined in this register is used to control ASRC internal FIFO logic for pair A. 1 Use external defined thresholds. 0 Use default thresholds.
21 BUFSTALLA	Stall Pair A conversion in case of Buffer Near Empty/Full Condition This bit will determine whether the near empty/full FIFO condition will stall the rate conversion for pair A. This option can only work when external ratio is used. Near empty condition is the condition when input FIFO has less than 4 useful samples per channel. Near full condition is the condition when the output FIFO has less than 4 vacant sample words to fill per channel. 1 Stall Pair A conversion in case of near empty/full FIFO conditions. 0 Don't stall Pair A conversion even in case of near empty/full FIFO conditions.
20 BYPASSPOLYA	Bypass Polyphase Filtering for Pair A This bit will determine whether the polyphase filtering part of Pair A conversion will be bypassed. 1 Bypass polyphase filtering. 0 Don't bypass polyphase filtering.
19–18 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
17–12 OUTFIFO_ THRESHOLDA[5:0]	The threshold for Pair A's output FIFO per channel These bits stand for the threshold for Pair A's output FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of output FIFO fillings of the pair is greater than n samples per channel, the output data ready flag is set; when the number of output FIFO fillings of the pair is less than or equal to n samples per channel, the output data ready flag is automatically cleared.
11 RSYNIFA	Re-sync Input FIFO Channel Counter If bit set, force ASRCCR:ACIA=0. If bit clear, untouch ASRCCR:ACIA.
10 RSYNOFA	Re-sync Output FIFO Channel Counter If bit set, force ASRCCR:ACOA=0. If bit clear, untouch ASRCCR:ACOA.
9–6 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
INFIFO_ THRESHOLDA[5:0]	The threshold for Pair A's input FIFO per channel These bits stand for the threshold for Pair A's input FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of input FIFO fillings of the pair is less than n samples per channel, the input data needed flag is set; when the number of input FIFO fillings of the pair is greater than or equal to n samples per channel, the input data needed flag is automatically cleared.

## 15.3.5 Functional Description

### 15.3.5.1 Algorithm Description

#### 15.3.5.1.1 Signal Processing Flow

The figure below shows the possible configurations of the ASRC. Each configuration consists of 2 to 4 stages.

### Figure 15-14. Signal processing configurations

- x2 up-sampling rate expander (zero insertion only) (Input Branch 1), or direct connection (Input Branch 2), or low-pass pre decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Input Branch 3),
- low-pass pre-filter, the low-pass bandwidth is at most  $0.25 \times F_s$ , where  $F_s$  is the sampling rate of the input signal to this low-pass pre-filter,
- polyphase filter
- x2 post upsampling filter (consisting of a x2 up-sampling rate expander (zero insertion only) with low-pass half-band FIR filter) (Output Branch 1), or direct connection (Output Branch 2), or low-pass post decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Output Branch 3).

By flowing through different processing branches, and different setup of the pre-filter, this ASRC scheme can be used to handle different requirement of rate conversion.

Configuration (a): Input Branch 1+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = Fs_{in}/2$ . The signal sampling rate of the polyphase filter output is  $Fs_{ppout} = Fs_{out}/2$ .

Configuration (b): Input Branch 1+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/2$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = F_{s_{out}}$ .

Configuration (c): Input Branch 1+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/2$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = 2F_{s_{out}}$ .

Configuration (d): Input Branch 2+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/4$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = F_{s_{out}}/2$ .

Configuration (e): Input Branch 2+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/4$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = F_{s_{out}}$ .

Configuration (f): Input Branch 2+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/4$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = 2F_{s_{out}}$ .

Configuration (g): Input Branch 3+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/8$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = F_{s_{out}}/2$ .

Configuration (h): Input Branch 3+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/8$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = F_{s_{out}}$ .

Configuration (i): Input Branch 3+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most  $BW_{in} = F_{s_{in}}/8$ . The signal sampling rate of the polyphase filter output is  $F_{s_{ppout}} = 2F_{s_{out}}$ .

**Table 15-18. Pre-Processing, Post-Processing options**

Table continues on the next page...

**Table 15-18. Pre-Processing, Post-Processing options (continued)**

	88.2	NA	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	96	NA	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	128	NA	{1,2}	{1,2}	{1,2}	{1,1}	{1,1}	{1,1}	{1,1}	{1,1}
	192	NA	{2,2}	{2,2}	{2,2}	{2,1}	{2,1}	{2,1}	{2,1}	{2,1}

Comments:

In the {Pre\_Proc, Post\_Proc} pair, the meaning of the values are:

Pre\_Proc:

- 0 --- Pre-processing Branch 1
- 1 --- Pre-processing Branch 2
- 2 --- Pre-processing Branch 3 decimation-by-2

Post\_Proc:

- 0 --- Post-processing Branch 1
- 1 --- Post-processing Branch 2
- 2 --- Post-processing Branch 3

The latencies of the different option can be calculated as follows:

- For Preproc = 0, Postproc = 1 : min latency = constant\_A / input-sample-rate + constant\_B / output-sample-rate
- For Preproc = 0, Postproc = 0 : min latency = constant\_A / input-sample-rate + constant\_C / output-sample-rate
- For Preproc = 1, Postproc = 1 : min latency = constant\_D / input-sample-rate + constant\_B / output-sample-rate

The constants are only influenced by the PreProc/PostProc and (input/output) sampling rate to which they are connected. Input latencies have no relationship with the output latencies, but both elements add together to form the total latencies. For a rough estimation, the constants can be set as:

- Constant for Preproc = 0: 39
- Constant for Preproc = 1: 78.5
- Constant for Preproc = 2: 235
- Constant for Postproc = 0: 42.5
- Constant for Postproc = 1: 8.5
- Constant for Postproc = 2: 172

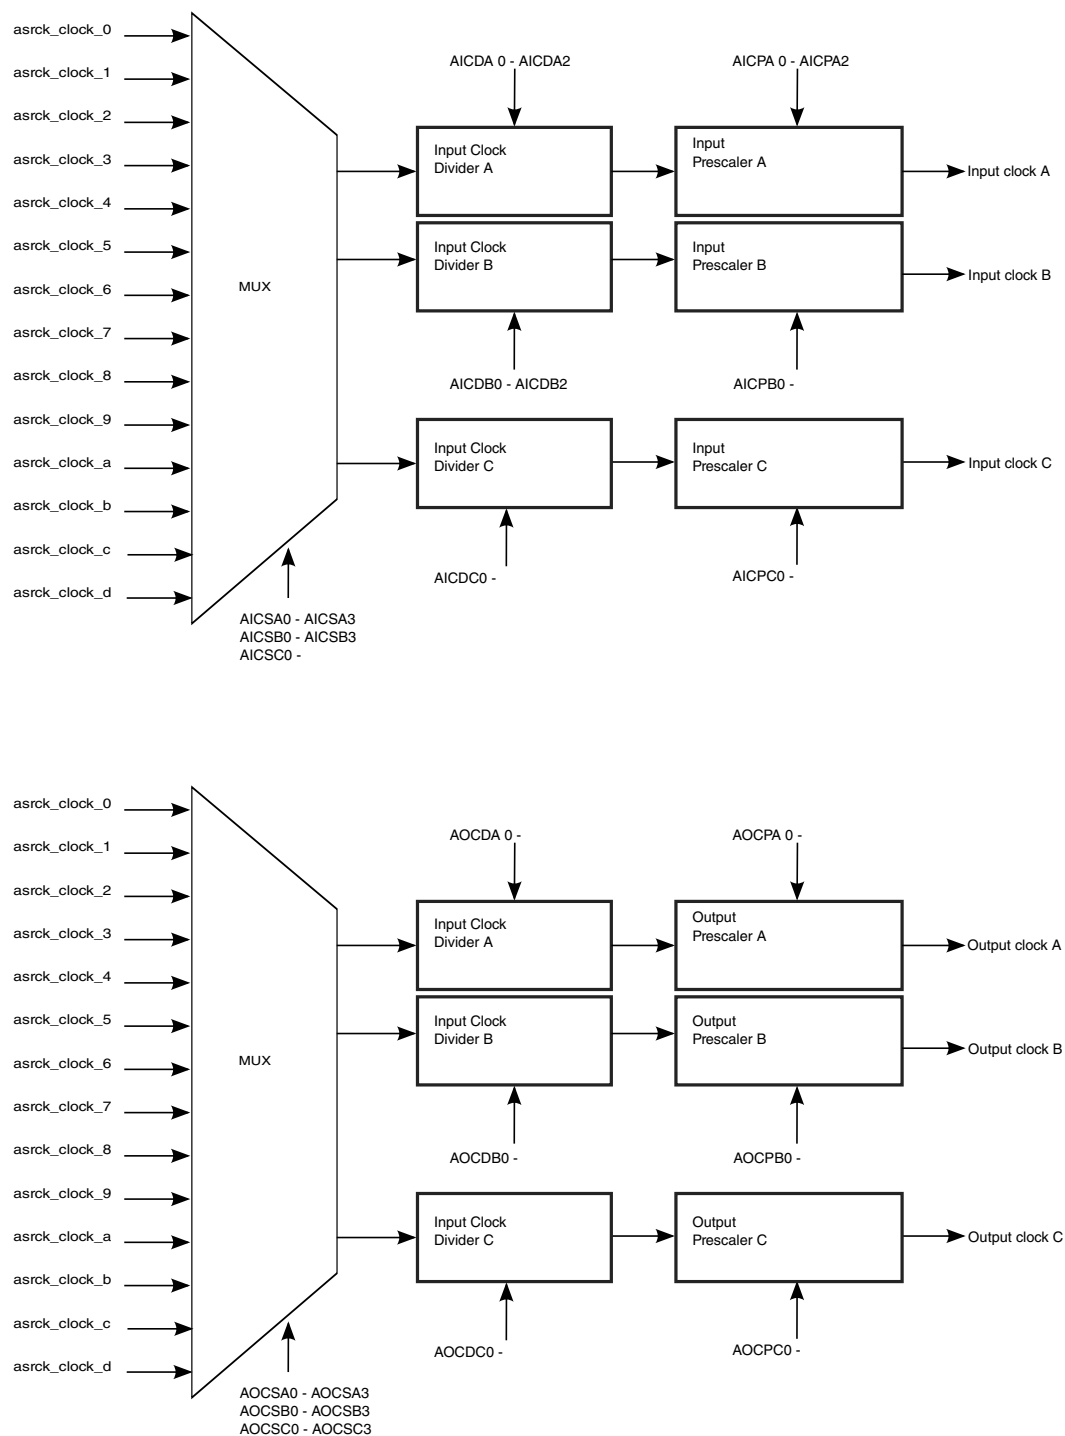

The max latency can be derived from this value by using the following formula (where 32 means the input/output FIFO depth that will arouse data transfer):

- max latency = min latency + 32 / input-sample-rate + 32 / output-sample-rate

### 15.3.5.1.2 Operation of the Filter

#### **15.3.5.1.2.1 Support of Physical Clocks**

This design supports physical sampling clocks. The clocks can be provided by Sony/Phillips digital interface (SPDIF), Synchronus Audio Interface, Enhanced Serial Audio Interface (ESAI)media local bus controller (MLB), Core master clock derivative as ASRCK1 .

**Figure 15-15. Clock Source Selector & Divider**

Software can set the ASRC Clock Source Register (ASRC SR) and the Clock Divider Register to select the desired clock source and divide it to the needed sample rate clock for use by the ASRC. The clocks have the following restriction. If the prescaler is set to 1, the clock divider can only be set to 1 and the clock source must have a 50% duty cycle.

## 15.3.6 Startup Procedure

The following example shows the normal setup procedure for the ASRC block.

```
#include "asrc_common.h"

#include "stdio.h"

#include "soc_api.h"

## 15.4 Sony/Philips Digital Interface (SPDIF)

### 15.4.1 Introduction

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio. The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal and external components in the system such as ESAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

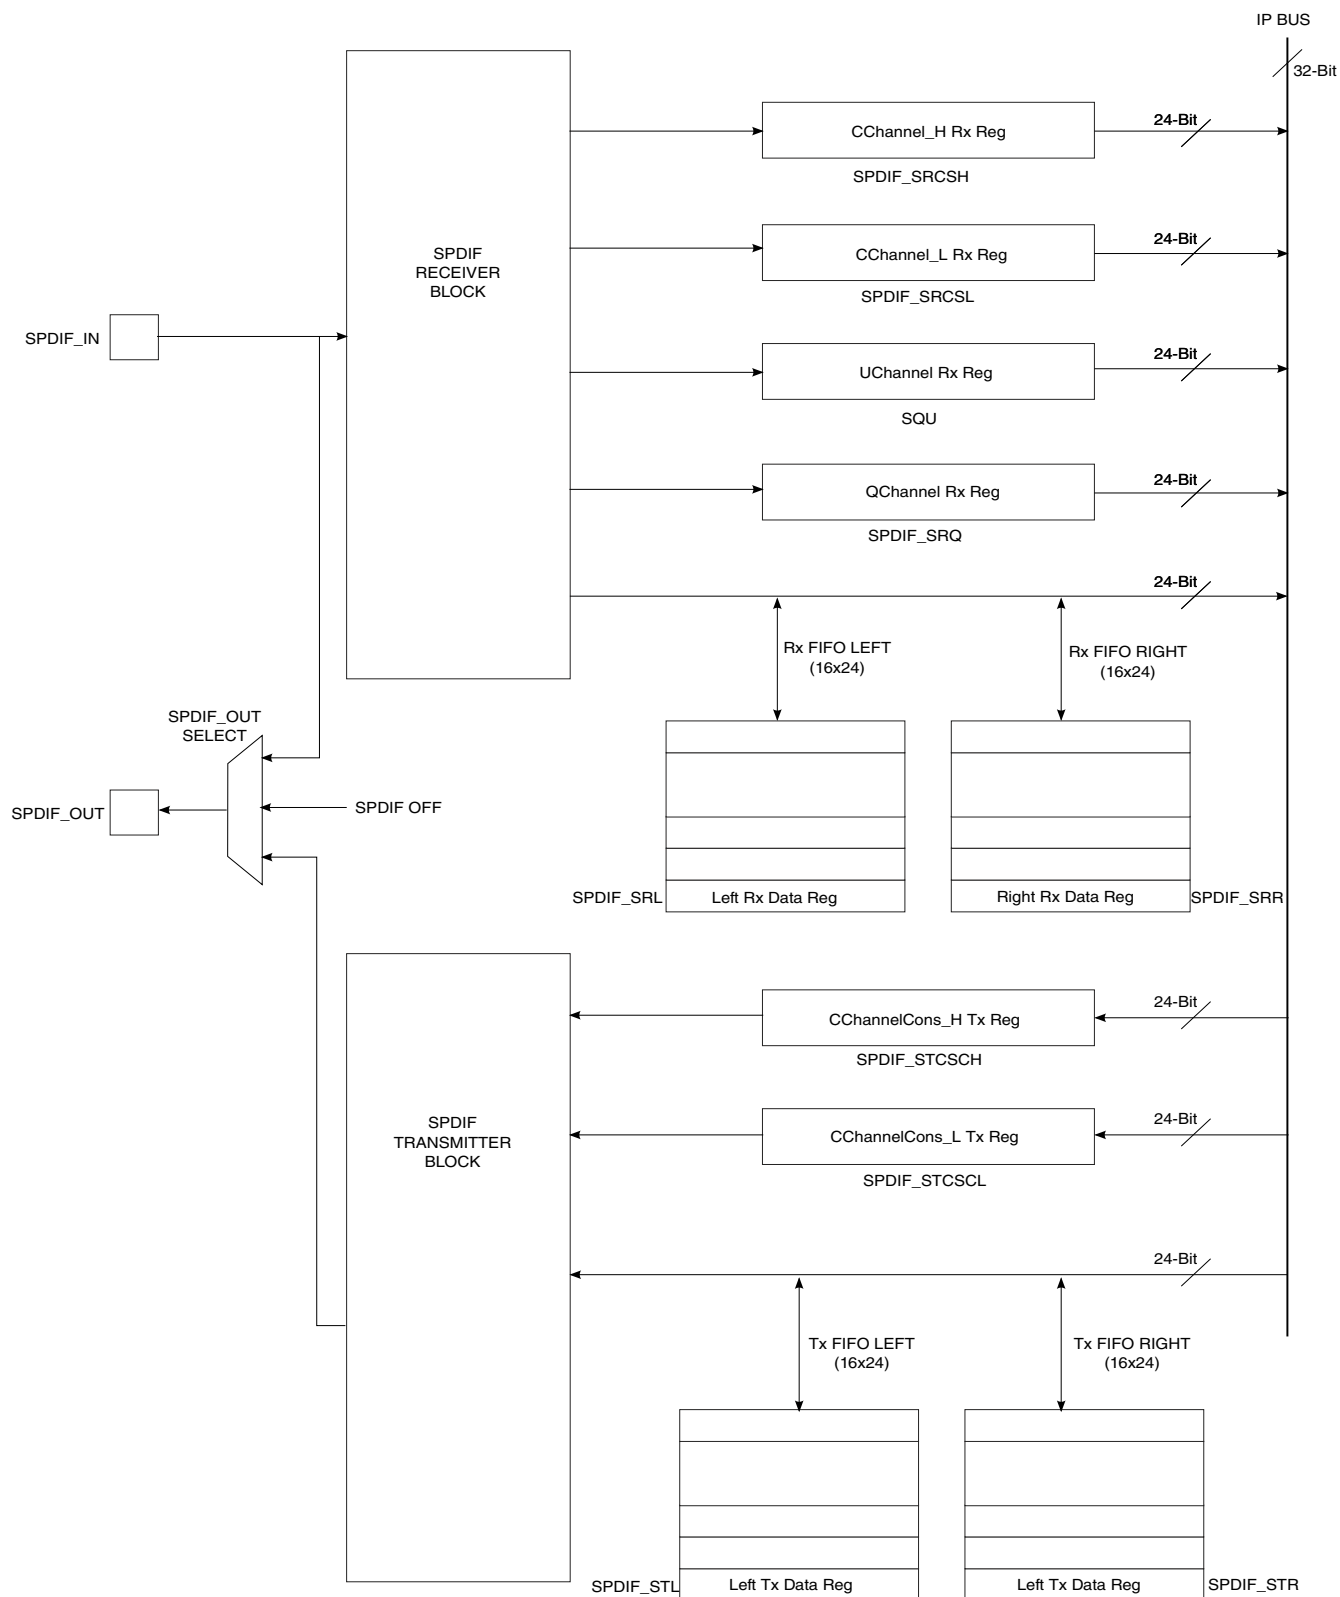

Figure 15-16. SPDIF Transceiver Data Interface Block Diagram

### 15.4.1.1 Overview

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphas mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphas bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generation block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. Both the Rx clock and Tx clock are sent to the ASRC.

## 15.4.2 External Signal Description

**Table 15-19. Signal Properties**

Signal Name	Signal Type	Description
SPDIFIN	input	SPDIF Input Line IEC60958 data in biphas mark format.
SPDIFOUT	output	SPDIF Output Line IEC60958 data in biphas mark format. (Consumer C channel).

## 15.4.3 Functional Description

### 15.4.3.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception
- Channel Status bits Reception
- U Channel bits Reception
- Validity Flag Reception
- SPDIF Receiver Exception support
- SPDIF Lock Detection

#### 15.4.3.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight. Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

##### 15.4.3.1.1.1 SPDIF receiver data registers - Behavior on overrun, underrun

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device with two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Ddata Rx FIFO overrun occurs on ,for example, the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

### 15.4.3.1.1.2 SPDIF receiver data registers - Automatic resynchronization of FIFOs

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

**Figure 15-17. FIFO Auto-resync Controller State Machine**

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state the FIFO resynchronization disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

### 15.4.3.1.1.3 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules:

- When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (For example, if sample frequency is 44 Khz, approximately 10 micro-seconds. For 88 Khz, approximately 5 micro-seconds.)
- Write/read data to FIFO s at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

#### 15.4.3.1.1.3.1 SPDIF receiver - Additional features

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overflow
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overflow occurs. When "full" is set, and the FIFO contains, for example, 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overflow" are set when one of the FIFOs do underrun or do overflow. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIF Configuration Register

#### 15.4.3.1.1.3.2 Rx FIFO on and Rx FIFO reset

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

#### 15.4.3.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCCChannel\_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCCChannel\_l.

#### NOTE

Single DMA channel cannot service SPDIF Tx or Rx.  
Therefore, two DMA channels linked to each another are required to service SPDIF Rx request.

##### 15.4.3.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptClear Register (SPDIF\_SIC).

#### 15.4.3.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD which is selected by SPDIF\_SRCD[USyncMode].

##### 15.4.3.1.3.1 Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver

This mode is selected if SPDIF\_SRCD[USyncMode]=1.

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

**Table 15-20. Sync Control Bits**

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-44	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q

channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.

- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

#### 15.4.3.1.3.2 Behavior of U Channel receive interface on incoming non-CD data

This mode is selected if SPDIF\_SRCD[USyncMode]=0.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

#### 15.4.3.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

#### 15.4.3.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxCCChannel1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.<sup>2</sup>
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overflow. Set when there is a underrun/overflow on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overflow. Set when Q channel buffer overflow.
- Receive U Channel buffer overflow. Set on U channel buffer overflow.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

#### 15.4.3.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

---

2. The SPDIF input is a biphasemark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

Supported input frequency range is 12 KHz up to 96 KHz. (fully compliant) and 96 KHz up to 176 KHz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

#### 15.4.3.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin PLOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 KHZ input sampling frequency, the average pulse rate = 128 x 44.1 KHZ.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

#### 15.4.3.1.8 Measuring Frequency of SPDIF\_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS\_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS\_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS\_CLK.

$$\text{FreqMeas}[23:0] = \text{FreqMeas\_CLK} / (\text{BUS\_CLK} * (2^{10}) * \text{GAIN})$$

For example, if the GAIN is selected as  $8 * 2^{10}$  (PhaseConfig[5:3] = 3'b011), the actual result

$$\text{FreqMeas\_CLK} / \text{BUS\_CLK} \text{ is equal to } \text{FreqMeas}[23:0] / 2^{23}.$$

### 15.4.3.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is from either the osc\_audio, ipg\_baud\_spdif\_clk, hckt, or spdif\_extclk, mlbclk or frequency divided ipg\_clk. A multiplexer is used to choose the clock source. The SPDIF transmitter clock source can be divided down as needed using Txclk\_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphas mark format, consisting of audio data, channel status.

#### 15.4.3.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See [Audio Data Reception](#).

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty

- under/overflow
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

### 15.4.3.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCCChannelCons\_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCCChannelCons\_l.

### 15.4.3.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF\_SCR register.

**SPDIF\_SIS field descriptions**

Field	Description
31–21 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error

Table continues on the next page...

**SPDIF\_SIS field descriptions (continued)**

Field	Description
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	This field is reserved. Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxFIFOEmpty	Tx FIFO Empty Sets the Tx FIFO Empty flag.
0 RxFIFOFull	Rx FIFO full flag Sets the Rx FIFO full flag.

### 15.4.4.6 InterruptClear Register (SPDIF\_SIC)

The InterruptClear (SPDIF\_SIC) register is a write only register and is used to clear interrupts.

Address: 4006\_1000h base + 10h offset = 4006\_1010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## SPDIF\_SIC field descriptions

Field	Description
31–21 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	This field is reserved. Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overflow
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
-	This field is reserved. Reserved.

### 15.4.4.7 SPDIFRxLeft Register (SPDIF\_SRL)

SPDIFRxLeft register is an audio data reception register.

Address: 4006\_1000h base + 14h offset = 4006\_1014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								RxDataLeft																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_SRL field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataLeft	Processor receive SPDIF data left

### 15.4.4.8 SPDIFRxRight Register (SPDIF\_SRR)

SPDIFRxRight register is an audio data reception register.

Address: 4006\_1000h base + 18h offset = 4006\_1018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								RxDataRight																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_SRR field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataRight	Processor receive SPDIF data right

### 15.4.4.9 SPDIFRxChannel\_h Register (SPDIF\_SRC SH)

SPDIFRxChannel\_h register is a channel status reception register.

Address: 4006\_1000h base + 1Ch offset = 4006\_101Ch

#### SPDIF\_SRC SH field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxChannel_h	SPDIF receive C channel register, contains first 24 bits of C channel without interpretation

### 15.4.4.10 SPDIFRxChannel\_l Register (SPDIF\_SRC SL)

SPDIFRxChannel\_l register is a channel status reception register.

Address: 4006\_1000h base + 20h offset = 4006\_1020h

#### SPDIF\_SRC SL field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxChannel_l	SPDIF receive C channel register, contains next 24 bits of C channel without interpretation

15.4.4.11 UchannelRx Register (SPDIF\_SRU)

UChannelRx register is a user bits reception register.

Address: 4006\_1000h base + 24h offset = 4006\_1024h

SPDIF\_SRU field descriptions

Field	Description
31–24 unimplemented	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
RxUChannel	SPDIF receive U channel register, contains next 3 U channel bytes

15.4.4.12 QchannelRx Register (SPDIF\_SRQ)

QChannelRx register is a user bits reception register.

Address: 4006\_1000h base + 28h offset = 4006\_1028h

SPDIF\_SRQ field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxQChannel	SPDIF receive Q channel register, contains next 3 Q channel bytes

### 15.4.4.13 SPDIFTxLeft Register (SPDIF\_STL)

SPDIFTxLeft register is an audio data transmission register.

Address: 4006\_1000h base + 2Ch offset = 4006\_102Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																															
W									TxDataLeft																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_STL field descriptions

Field	Description
31–24 unimplemented	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataLeft	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

### 15.4.4.14 SPDIFTxRight Register (SPDIF\_STR)

SPDIFTxRight register is an audio data transmission register.

Address: 4006\_1000h base + 30h offset = 4006\_1030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																															
W									TxDataRight																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_STR field descriptions

Field	Description
31–24 unimplemented	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataRight	SPDIF transmit right channel data. It is write-only, and always returns zeros when read

### 15.4.4.15 SPDIFTxChannelCons\_h Register (SPDIF\_STCSCH)

SPDIFTxChannelCons\_h register is a channel status transmission register.

Address: 4006\_1000h base + 34h offset = 4006\_1034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W	Reserved								TxChannelCons_h																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_STCSCH field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
TxChannelCons_h	SPDIF transmit Cons. C channel data, contains first 24 bits without interpretation. When read, it returns the latest data written by the processor

### 15.4.4.16 SPDIFTxChannelCons\_l Register (SPDIF\_STCSCL)

SPDIFTxChannelCons\_l register is a channel status transmission register.

Address: 4006\_1000h base + 38h offset = 4006\_1038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TxCCChannelCons_I																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_STCSCL field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
TxChannelCons_l	SPDIF transmit Cons. C channel data, contains next 24 bits without interpretation. When read, it returns the latest data written by the processor

### 15.4.4.17 FreqMeas Register (SPDIF\_SRFM)

Address: 4006\_1000h base + 44h offset = 4006\_1044h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								FreqMeas																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### SPDIF\_SRFM field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
FreqMeas	Frequency measurement data

### 15.4.4.18 SPDIFTxClk Register (SPDIF\_STC)

The SPDIFTxClk Control register includes the means to select the transmit clock and frequency division.

Address: 4006\_1000h base + 50h offset = 4006\_1050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								0				SYSCLK_DF			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SYSCLK_DF					TxClk_Source			tx_all_clk_en	TxClk_DF						
W																
Reset	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0

### SPDIF\_STC field descriptions

Field	Description
31–24 unimplemented	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–20 Reserved	This read-only field is reserved and always has the value 0.
19–11 SYSCLK_DF	system clock divider factor, 2~512. 0 no clock signal 1 divider factor is 2 511 divider factor is 512
10–8 TxClk_Source	Defines the transmit clock source 000 SPDIF EXTAL (EXTAL_CLK from PAD 79 ALT mode 5) 001 PLL4 DIV CLK 010 AUDIO EXTAL (AUD_EXT_CLK from PAD3 ALT2/PAD5 ALT2 /PAD40 ALT2) 011 MLB CLK IN (MLB CLOCK from PAD1 ALT7/PAD54 ALT6) 100 ESAI HCKT (ESAI High speed Transmitter Clock from PAD78 ALT3) 101 SYS CLK (SPDIF BUS CLOCK) 110 SAI0 TX BCLK (SAI0TX_BCLK Clock PAD93 ALT1) 111 SAI3 TX BCLK (SAI3 TX_BCLK clock PAD16 ALT2)
7 tx_all_clk_en	Spdif transfer clock enable. When data is going to be transfered, this bit should be set to 1. 0 disable transfer clock. 1 enable transfer clock.
TxClk_DF	Divider factor (1-128) 0 divider factor is 1 1 divider factor is 2 127 divider factor is 128

# Chapter 16

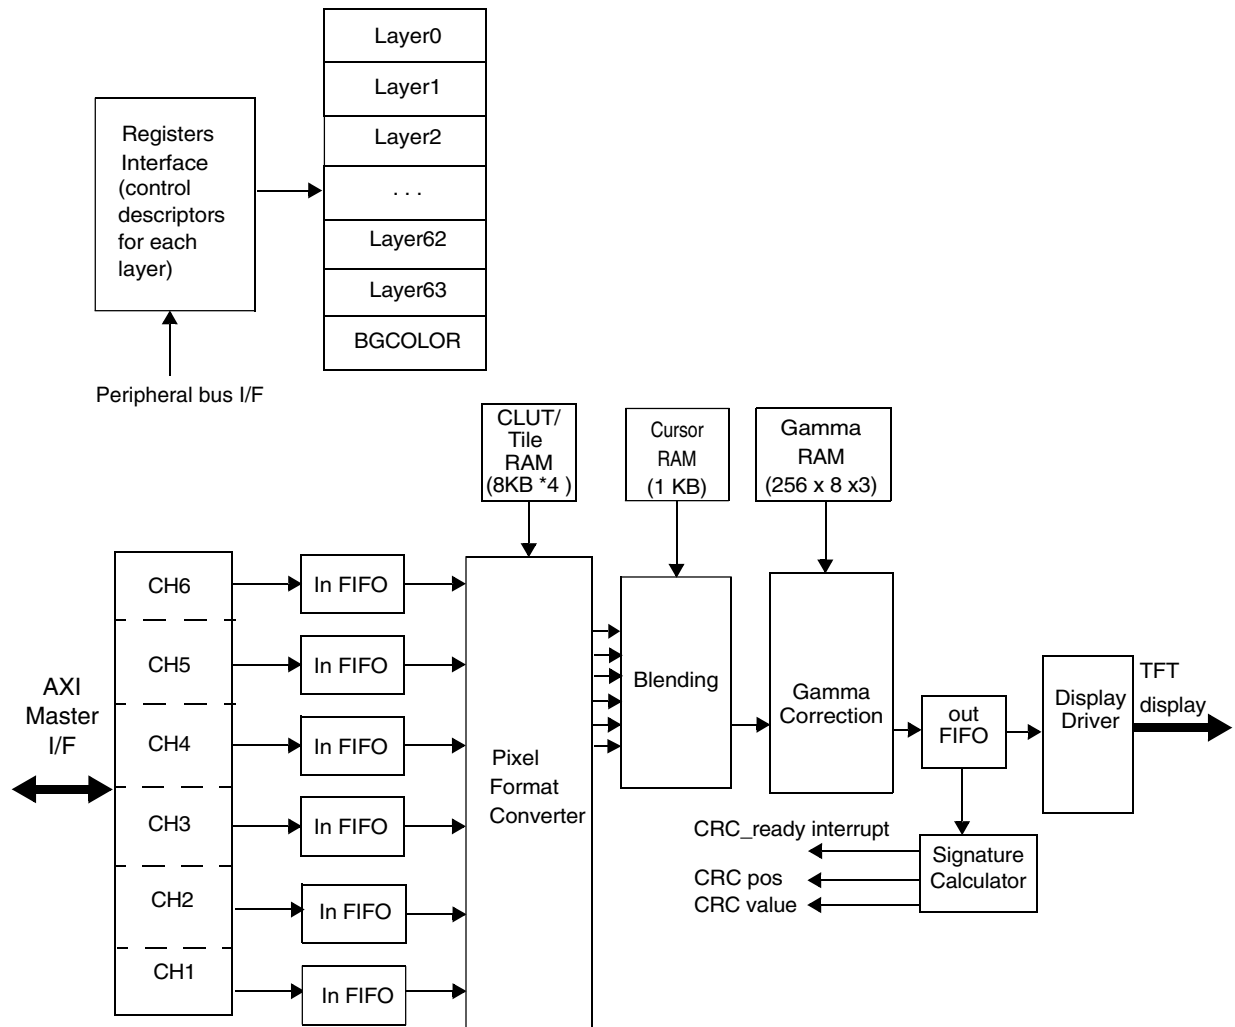

## Display

### 16.1 Display Control Unit (DCU)

#### 16.1.1 Introduction

The Display Controller Unit (DCU4) module (2D-ACE functionality) is a system master that fetches graphics stored in internal or external memory and displays them on a TFT LCD panel. A wide range of panel sizes is supported and the timing of the interface signals is highly configurable. Graphics are read directly from memory and then blended in real-time, which allows for dynamic content creation with minimal CPU intervention. Graphics may be encoded in a variety of formats to optimise memory usage.

### 16.1.1.1 Overview

**Figure 16-1. Display control unit block diagram**

Figure 16-1 shows the DCU4 architecture. This comprises two distinct sections. The lower section shows the functional blocks of the DCU4 that fetch the graphic and video content and drive the TFT LCD panel. The upper section describes the user interface through which the user configures the graphical content of the TFT LCD panel.

The configuration of the lower section is dependent on the specific TFT LCD panel that is attached to the DCU4 output. In most cases, this is configured once for the hardware in use before the DCU4 is enabled. When active, this section automatically:

- Calculates the relevant graphical content for each pixel
- Fetches the source graphics from memory using its internal DMA channels (labelled CH1 to CH6) and stores the data in dedicated FIFO buffers

- Converts the graphic value of each fetched pixel into full quality color format (if required)
- Calculates the required pixel value by blending the values of up to six separate graphics
- Performs a gamma correction on the pixel value (if required)
- Sends the pixel value to the TFT LCD display over its data bus
- Sets flags to indicate end of frame, FIFO buffer threshold, and other status changes

The upper section describes the characteristics of the graphics to be displayed on the panel and how they are blended together. The DCU4 manages the graphical content of the panel through sets of registers called layers. There are 64 layers available in the DCU4 and each contains the following information:

- Horizontal and vertical size of graphic
- Position of graphic on the panel
- Address of graphic in memory
- Color encoding format and color palettes (if required)
- Type and depth of blending
- Range of colors identified for chroma blending
- Tile size
- Foreground and background colors for transparency encoded graphics

The values in these registers may be changed at any time, but register updates are always processed during the vertical sync gap, i.e. between two refreshes of the display.

There are two modes:

- Automatic: they become active in the next VSync
- Manual: they become active in the Vsync just after the updates are committed by SW.

The layers are set to a fixed priority, and this is used by the lower section to define which layers are blended, in which order, on the panel.

The upper section also contains configuration registers for a cursor graphic, the default background color, interrupt enables, test graphic, and simple register protection settings.

### 16.1.1.2 Features

The DCU4 has these features:

- Full RGB888 output to TFT LCD panel
- 64 graphics layers, a default background color layer and a cursor layer with integrated blinking option
- Blending of each pixel using up to 6 source layers dependent on size of panel
- Programmable panel size up to a maximum of XGA (1008x768) and a typical operating configuration of SVGA (800 x 600)
- Gamma correction with 8-bit resolution on each color component
- Safety mode for tagging pixels on highest priority layers
- Dedicated memory blocks to store a cursor and Color Look Up Tables (CLUTs)
- Temporal Dithering.

Each graphic layer has the following attributes:

- Can be placed with one pixel resolution in either axis
- Can also be placed in negative X and Y directions
- Supports multiple color-encoding formats including:
  - 1, 2, 4 and 8 bits per pixel indexed colors with alpha channel in look-up table
  - APAL8 indexed colors with alpha channel in each pixel
  - RGB565 and RGB888 direct colors without alpha channel
  - ARGB1555, ARGB4444, and BGRA8888 direct colors with an alpha channel
  - YCbCr422 format
- Alpha blending with 8-bit resolution
- Chroma-key blending for anti-mask encoding
- Multiple combined alpha and chroma-key blending modes
- Transparency modes for anti-aliased text and graphics
- Luminance mode for highlighting content
- Tile mode for efficient creation of textured background content
- Support for Run Length Encoding (RLE) compression
- Optimized mode for use with DDR memory

### 16.1.1.3 Modes of Operation

The DCU4 has three modes of operation:

- **DCU\_OFF**: When in this mode, the DCU4 is turned off. All the logic in the design is put in reset state to reduce power.
- **NORMAL\_MODE**: The DCU4 displays and blends the graphics specified by the layer descriptors.
- **COLBAR\_MODE**: Color bar generation for testing purposes.

### NOTE

The DCU does not have a valid display configuration after reset as the display characteristics are application specific. Because of this the controller may generate error flags/interrupts until it is configured with a valid display configuration.

## 16.1.2 External Signal Description

This section covers the DCU interface signals.

### 16.1.2.1 Overview

The choice of signals used depends on the configuration of the DCU4. All active signals must be selected by configuring the appropriate IOMUX registers.

### 16.1.2.2 Detailed Signal Descriptions

**Table 16-1. Detailed Signal Descriptions**

Signal	Direction	Description
Display Interface		
DCU_PCLK	OUT	Pixel clock used to drive the display panel
DCU_VSYNC	OUT	Vertical sync signal, indicating the beginning of a new frame
DCU_HSYNC	OUT	Horizontal sync signal, indicating the beginning of a new line
DCU_TAG	OUT	When high, this signal indicates that the pixel is tagged and an application can calculate CRC externally on this pixel.
DCU_DE	OUT	Data Enable. Qualifies the data output (dcu_ld)
DCU_R[7:0] DCU_G[7:0] DCU_B[7:0]	OUT	Red, green and blue data output.

## 16.1.3 DCU4 Memory Map

Table 16-2. DCU4 memory map

Parameter	Address Range
Register address space	0x0000 – 0x1FFF
Palette/Tile address space	0x2000 – 0x3FFF
Gamma_R address space	0x4000 – 0x43FF
Gamma_G address space	0x4400 – 0x47FF
Gamma_B address space	0x4800 – 0x4BFF
Cursor address space	0x4C00 – 0x4FFF

## 16.1.4 Memory Map and Registers

DCU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_8000	Control Descriptor Cursor 1 Register (DCU0_CTRLDESCCURSOR1)	32	R/W	0000_0000h	<a href="#">16.1.4.1/3352</a>

**DCUx\_DCU\_MODE field descriptions**

Field	Description
31 DCU_SW_RESET	Puts the DCU4 internal configuration into its reset state. This has the effect of stopping all display activity except the PCLK; graphics are not fetched and sent to the panel.

*Table continues on the next page...*

**DCUx\_DCU\_MODE field descriptions (continued)**

Field	Description
	0 No action 1 All DCU4 internal registers are forced into their reset state. User registers are not affected
30 EN_DITHER	Enable dithering mode.  0 Disabled 1 Enabled
29–28 ADDB	Two-bit value to be added to pixel blue component for dithering.
27–26 ADDG	Two bit Value to be added with pixel green component for dithering.
25–24 ADDR	Two-bit value to be added to pixel red component for dithering.
23 DDR_MODE	Enables Special DDR Mode (see Section 54.6.9 Special DDR Mode"). Select BLEND_ITER = 1106 when enabled.  0 Special DDR mode is disabled 1 Special DDR mode is enabled
22–20 BLEND_ITER	Defines the maximum number of pixels which are blended in the pixel blend stack.  000 Reserved 001 Reserved 010 Two pixel blending (default) 011 Three pixel blending 100 Four pixel blending 101 Five pixel blending 110 Six plane blending 111 Reserved
19–16 RESERVED	This field is reserved.
15 RESERVED	This field is reserved.
14 RASTER_EN	Enables raster scanning of pixel data including the VSYNC and HSYNC signals and the pixel data. This bit takes effect immediately and does not require a transfer to the frame timing logic.  0 Disabled 1 Enabled
13 RESERVED	This field is reserved.
12 RESERVED	This field is reserved.

10 RESERVED	This field is reserved.
9–8 RESERVED	This field is reserved.
7 RESERVED	This field is reserved.

*Table continues on the next page...*

**DCUx\_DCU\_MODE field descriptions (continued)**

Field	Description
6 TAG_EN	Enables the calculation of CRC only on the safety layers. 0 CRC calculated over the whole area of interest (area of interest given by SIG_DESC registers) 1 Calculates CRC only on safety enabled layers
5 SIG_EN	Enables the signature calculator block. 0 Signature calculator is disabled 1 Signature calculator is enabled
4 RESERVED	This field is reserved.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 EN_GAMMA	Enables/Disables the Gamma Correction. 0 Gamma correction is disabled 1 Gamma Correction is enabled
DCU_MODE	DCU operating mode. 00 DCU off (pixel clock active if enabled by I/O). 01 Normal mode. Panel content controlled by layer configuration. 10 Test mode. DCU disables all DMA fetches and all the pixels of an enabled layer take the value in the CLUT RAM selected by the respective LUOFFS field of control descriptor 4. 11 Color Bar Generation. Panel content controlled by color bar registers.

**16.1.4.6 Background Register (DCUx\_BGND)****NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								BGND_R								BGND_G								BGND_B							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DCUx\_BGND field descriptions**

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**DCUx\_BGND field descriptions (continued)**

Field	Description
23–16 BGND_R	Red component of the default color displayed in the sectors where no layer is active.
15–8 BGND_G	Green component of the default color displayed in the sectors where no layer is active.
BGND_B	Blue component of the default color displayed in the sectors where no layer is active.

**16.1.4.7 Display Size Register (DCUx\_DISP\_SIZE)****NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#).

**NOTE**

The device supports the panel size up to XGA (1008 x 768) only.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					DELTA_Y											0					DELTA_X										
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DCUx\_DISP\_SIZE field descriptions**

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 DELTA_Y	Sets the display size vertical resolution (in pixels).
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DELTA_X	Sets the display size horizontal resolution (in multiples of 16 pixels).

**16.1.4.8 Horizontal Sync Parameter Register (DCUx\_HSYN\_PARA)**

HSYN\_PARA register sets timing parameters related to the horizontal synchronization signal generation. The fields FP\_H, BP\_H, and PW\_H stand for HSYNC signal front-porch, back-porch, and active pulse width, respectively.

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	BP_H										0	PW_H

W																
Reset	0	0	0	1	1	0	0	0	0	0	0	0	0	0	1	1

**DCUx\_HSYN\_PARA field descriptions**

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 BP_H	HSYNC back-porch pulse width (in pixel clock cycles). Pulse width has a minimum value of 1.
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–11 PW_H	HSYNC active pulse width (in pixel clock cycles).
10–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FP_H	HSYNC front-porch pulse width (in pixel clock cycles). Pulse width has a minimum value of 1.

**16.1.4.9 Vertical Sync Parameter Register (DCUx\_VSYN\_PARA)**

VSYN\_PARA register sets timing parameters related to the vertical synchronization signal generation. The fields FP\_V, BP\_V, and PW\_V stand for VSYNC signal front-porch, back-porch, and active pulse width, respectively.

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Memory Map and Registers

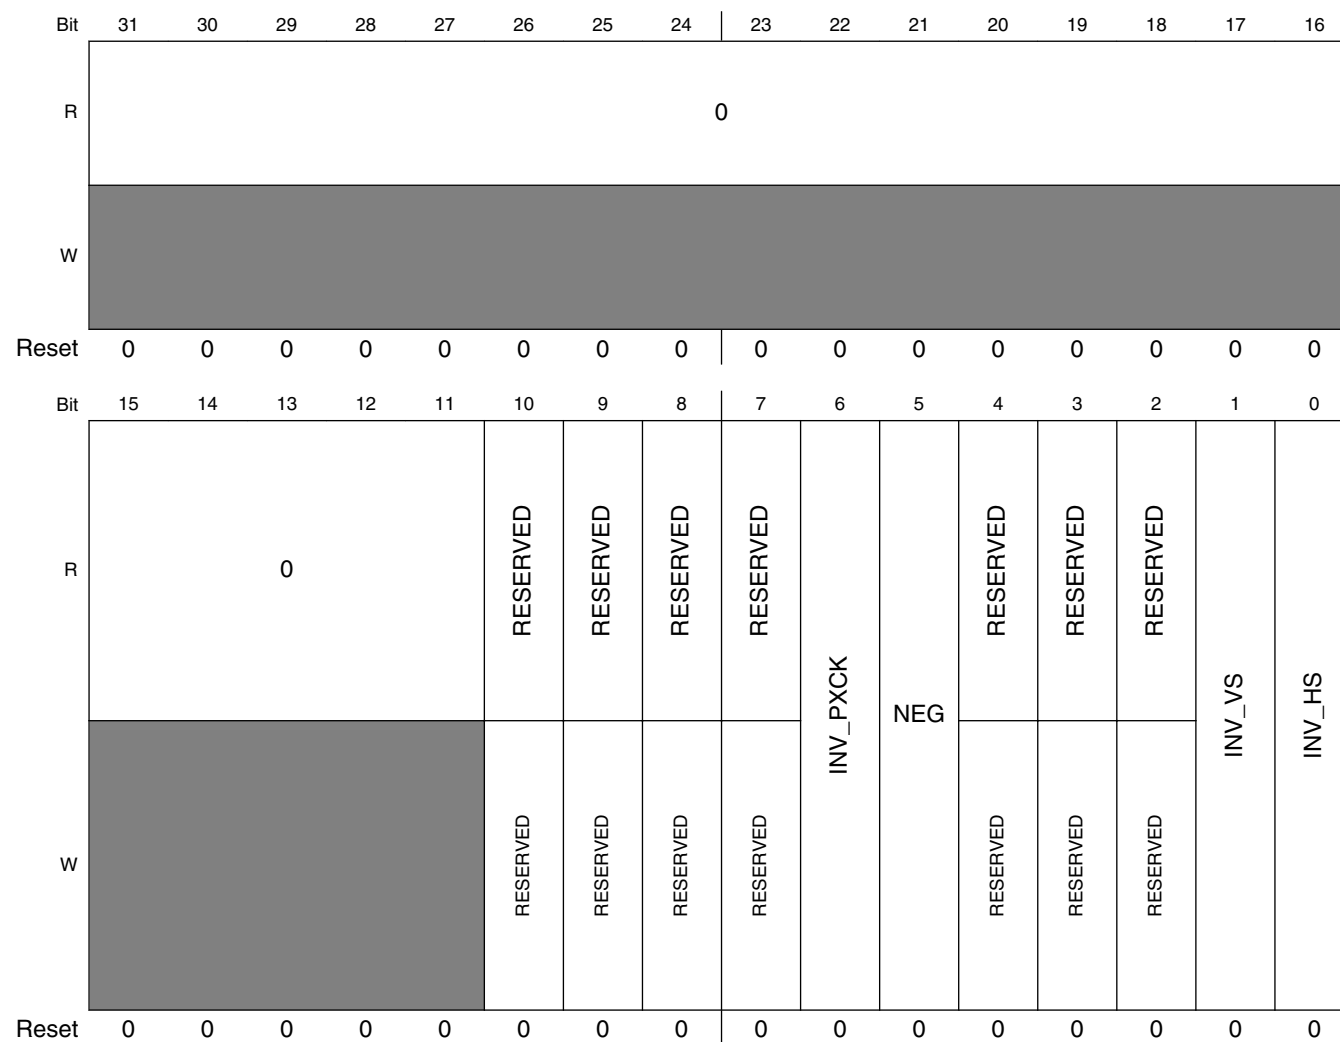

DCUx\_VSYN\_PARA field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 BP_V	VSYNC back-porch pulse width (in horizontal line cycles). Pulse width has a minimum value of 1.
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–11 PW_V	VSYNC active pulse width (in horizontal line cycles).
10–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FP_V	VSYNC front-porch pulse width (in horizontal line cycles). Pulse width has a minimum value of 1.

### 16.1.4.10 Synchronize Polarity Register (DCUx\_SYNPOL)

The SYNPOL register selects the polarity for the DCU synchronisation signals (HSYNC and VSYNC).

Address: Base address + 24h offset

**DCUx\_SYNPOL field descriptions**

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 RESERVED	This field is reserved.
9 RESERVED	This field is reserved.

*Table continues on the next page...*

## DCUx\_SYNPOL field descriptions (continued)

Field	Description
8 RESERVED	This field is reserved.
7 RESERVED	This field is reserved.
6 INV_PXCK	Polarity change of Pixel Clock. 0 Display samples data on the falling edge 1 Display samples data on the rising edge
5 NEG	Indicates if value at the output (pixel data output) needs to be negated. 0 Output is to remain same 1 Output to be negated
4 RESERVED	This field is reserved.
3 RESERVED	This field is reserved.
2 RESERVED	This field is reserved.
1 INV_VS	Invert Vertical synchronization signal. 0 VSYNC signal not inverted (active HIGH). 1 Invert VSYNC signal (active LOW).
0 INV_HS	Invert Horizontal synchronization signal. 0 HSYNC signal not inverted (active HIGH). 1 Invert HSYNC signal (active LOW).

## 16.1.4.11 Threshold Register (DCUx\_THRESHOLD)

## NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					LS_BF_VS											OUT_BUF_HIGH								OUT_BUF_LOW							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	1	0	1	0

## DCUx\_THRESHOLD field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 LS_BF_VS	Lines before VS_BLANK threshold value. The LS_BF_VS status flag (in INT_STATUS) is set this number of lines before the VS_BLANK signal is asserted.
15–8 OUT_BUF_HIGH	Output buffer high threshold (in pixels). When the output buffer exceeds this value the datapath clock is suspended.
OUT_BUF_LOW	Output buffer filling low Threshold (in pixels). This value is used to generate the underrun exception (UNDRUN in INT_STATUS).

## 16.1.4.12 Interrupt Status Register (DCUx\_INT\_STATUS)

See [Interrupt generation](#) for a description of how the DCU4 collects interrupt events into different source groups.

Unless stated otherwise, the flags in this register are cleared by writing 1 to the relevant bit.

Address: Base address + 2Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	P6_EMPTY	P5_EMPTY	P4_EMPTY	P3_EMPTY	P2_EMPTY	P1_EMPTY	0		P6_FIFO_HI_FLAG	P6_FIFO_LO_FLAG	P5_FIFO_HI_FLAG	P5_FIFO_LO_FLAG	P4_FIFO_HI_FLAG	P4_FIFO_LO_FLAG	P3_FIFO_HI_FLAG	P3_FIFO_LO_FLAG
W

R	0	DMA_TRANS_FINISH	0	LYR_TRANS_FINISH	IPM_ERROR	PROG_END	P2_FIFO_HI_FLAG	P2_FIFO_LO_FLAG	P1_FIFO_HI_FLAG	P1_FIFO_LO_FLAG	CRC_OVERFLOW	CRC_READY	VS_BLANK	LS_BUF_FINISH	UNDRUN	VSNC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## DCUx\_INT\_STATUS field descriptions

Field	Description
31 P6_EMPTY	Interrupt flag to indicate that the FIFO in position 6 in the pixel blend stack underflowed.
30 P5_EMPTY	Interrupt flag to indicate that the FIFO in position 5 in the pixel blend stack underflowed.
29 P4_EMPTY	Interrupt flag to indicate that the FIFO in position 4 in the pixel blend stack underflowed.

Table continues on the next page...

**DCUx\_INT\_STATUS field descriptions (continued)**

Field	Description
28 P3_EMPTY	Interrupt flag to indicate that the FIFO in position 3 in the pixel blend stack underflowed.
27 P2_EMPTY	Interrupt flag to indicate that the FIFO in position 2 in the pixel blend stack underflowed.
26 P1_EMPTY	Interrupt flag to indicate that the FIFO in position 1 (lowest) in the pixel blend stack underflowed.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 P6_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 6 in the pixel blend stack.
22 P6_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 6 in the pixel blend stack.
21 P5_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 5 in the pixel blend stack.
20 P5_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 5 in the pixel blend stack.
19 P4_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 4 in the pixel blend stack.
18 P4_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 4 in the pixel blend stack.
17 P3_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 3 in the pixel blend stack.
16 P3_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 3 in the pixel blend stack.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DMA_TRANS_FINISH	Interrupt flag, which indicates that the DCU4 DMA has fetched the last pixel of data from the memory.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LYR_TRANS_FINISH	Interrupt flag, which indicates that an error response has been received by the DCU from the AXI bus on a read transaction.
11 IPM_ERROR	Interrupt flag, which indicates that an error has occurred in the Magenta line transaction.
10 PROG_END	Interrupt flag which indicates that the DCU4 has begun to transfer layer configuration from the layer control descriptor registers into the DCU4 functional block. Any register modification after this time and before LYR_TRANS_FINISH is asserted may or may not be included in this transfer.

*Table continues on the next page...*

**DCUx\_INT\_STATUS field descriptions (continued)**

Field	Description
9 P2_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 2 in the pixel blend stack.
8 P2_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 2 in the pixel blend stack.
7 P1_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 1 (lowest) in the pixel blend stack.
6 P1_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 1 (lowest) in the pixel blend stack.
5 CRC_OVERFLOW	Interrupt signal to indicate that CRC_ready has not been serviced and CRC has been calculated for the next frame
4 CRC_READY	Interrupt flag to indicate CRC calculation is done and ready to be compared with precomputed CRC value by the software.
3 VS_BLANK	Interrupt signal to indicate vertical blanking period. This is the period in which all the registers that affect the visible state of the layers need to be latched. This is needed so that CPU writes to the register while the display is being updated does not cause any errors. Interrupt can be cleared by writing 1 to this bit..
2 LS_BF_VS	Interrupt flag to indicate the Lines Before VS_BLANK event has been reached. The LS_BF_VS field in the Threshold register defines the timing of the event.
1 UNDRUN	Interrupt flag to indicate the output buffer underrun condition. Asserted when the panel needs data and the output buffer level is lower than or equal to the OUT_BUF_LOW threshold. Flag is cleared when the data in the output buffer is greater than threshold and CPU writes 1 to this bit.
0 VSYNC	Interrupt flag to indicate that the vertical synchronization phase has begun. If enabled, an interrupt is generated at the beginning of a frame.

**16.1.4.13 Interrupt Mask Register (DCUx\_INT\_MASK)**

This register enables or masks the corresponding interrupt.

For each individual interrupt bit:

0 Not masked

1 Interrupt is masked

## Memory Map and Registers

### DCUx\_INT\_MASK field descriptions

Field	Description
31 M_P6_EMPTY	Mask for P6_EMPTY interrupt flag.
30 M_P5_EMPTY	Mask for P5_EMPTY interrupt flag.
29 M_P4_EMPTY	Mask for P4_EMPTY interrupt flag.
28 M_P3_EMPTY	Mask for P3_EMPTY interrupt flag.
27 M_P2_EMPTY	Mask for P2_EMPTY interrupt flag.
26 M_P1_EMPTY	Mask for P1_EMPTY interrupt flag.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 M_P6_FIFO_HI_FLAG	Mask for P6_FIFO_HI_FLAG interrupt flag.
22 M_P6_FIFO_LO_FLAG	Mask for P6_FIFO_LO_FLAG interrupt flag.
21 M_P5_FIFO_HI_FLAG	Mask for P5_FIFO_HI_FLAG interrupt flag.
20 M_P5_FIFO_LO_FLAG	Mask for P5_FIFO_LO_FLAG interrupt flag.

Table continues on the next page...

**DCUx\_INT\_MASK field descriptions (continued)**

<b>Field</b>	<b>Description</b>
19 M_P4_FIFO_HI_FLAG	Mask for P4_FIFO_HI_FLAG interrupt flag.
18 M_P4_FIFO_LO_FLAG	Mask for P4_FIFO_LO_FLAG interrupt flag.
17 M_P3_FIFO_HI_FLAG	Mask for P3_FIFO_HI_FLAG interrupt flag.
16 M_P3_FIFO_LO_FLAG	Mask for P6_FIFO_LO_FLAG interrupt flag.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 M_DMA_TRANS_FINISH	Mask for DMA_TRANS_FINISH interrupt flag.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 M_LYR_TRANS_FINISH	Mask for SHDW_CMPLT interrupt flag.
11 M_IPM_ERROR	Mask for IPM_ERROR interrupt flag.
10 M_PROG_END	Mask for PROG_END interrupt flag.
9 M_P2_FIFO_HI_FLAG	Mask for P2_FIFO_HI_FLAG interrupt flag.
8 M_P2_FIFO_LO_FLAG	Mask for P2_FIFO_LO_FLAG interrupt flag.
7 M_P1_FIFO_HI_FLAG	Mask for P1_FIFO_HI_FLAG interrupt flag.
6 M_P1_FIFO_LO_FLAG	Mask for P1_FIFO_LO_FLAG interrupt flag.
5 M_CRC_OVERFLOW	Mask for CRC_OVERFLOW interrupt flag.
4 M_CRC_READY	Mask for CRC_READY interrupt flag.
3 M_VS_BLANK	Mask for VS_BLANK interrupt flag. rrupt can be cleared by writing 1 to this bit..
2 M_LS_BF_VS	Mask for LS_BF_VS interrupt flag.

*Table continues on the next page...*

## DCUx\_INT\_MASK field descriptions (continued)

Field	Description
1 M_UNDRUN	Mask for M_UNDRUN interrupt flag.
0 M_VSYNC	Mask for VSYNC interrupt flag.

## 16.1.4.14 COLBAR\_1 Register (DCUx\_COLBAR\_1)

## NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## DCUx\_COLBAR\_3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_3_R	Red component value.
15–8 COLBAR_3_G	Green component value.
COLBAR_3_B	Blue component value.

## 16.1.4.17 COLBAR\_4 Register (DCUx\_COLBAR\_4)

## NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	1								COLBAR_4_R								COLBAR_4_G								COLBAR_4_B							
W																																
Reset	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0

## DCUx\_COLBAR\_4 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_4_R	Red component value.
15–8 COLBAR_4_G	Green component value.
COLBAR_4_B	Blue component value.

### 16.1.4.18 COLBAR\_5 Register (DCUx\_COLBAR\_5)

#### NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 44h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### DCUx\_COLBAR\_5 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_5_R	Red component value.
15–8 COLBAR_5_G	Green component value.
COLBAR_5_B	Blue component value.

### 16.1.4.19 COLBAR\_6 Register (DCUx\_COLBAR\_6)

#### NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 48h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	1								COLBAR_6_R								COLBAR_6_G								COLBAR_6_B							
W																																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## DCUx\_COLBAR\_6 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_6_R	Red component value.
15–8 COLBAR_6_G	Green component value.
COLBAR_6_B	Blue component value.

## 16.1.4.20 COLBAR\_7 Register (DCUx\_COLBAR\_7)

## NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 4Ch offset

#### DCUx\_COLBAR\_8 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_8_R	Red component value.
15–8 COLBAR_8_G	Green component value.
COLBAR_8_B	Blue component value.

### 16.1.4.22 Divide Ratio Register (DCUx\_DIV\_RATIO)

This register for vertical/horizontal size of the area for CRC calculation.

#### NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 54h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DCUx\_DIV\_RATIO field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV_RATIO	Specifies the divide value for the input clock. Used to generate the pixel clock to support different types of displays. To divide by N, set the DIV_RATIO to (N – 1).

**16.1.4.23 Sign Calculation 1 Register (DCUx\_SIGN\_CALC\_1)**

This register specifies the vertical/horizontal size of the area for the CRC calculation.

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DCUx\_SIGN\_CALC\_1 field descriptions**

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 SIG_VER_SIZE	Vertical size of the window of interest of pixels for CRC calculation (in pixels).
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SIG_HOR_SIZE	Horizontal size of window of interest of pixels for CRC calculations (in pixels).

**16.1.4.24 Sign Calculation 2 Register (DCUx\_SIGN\_CALC\_2)**

This register specifies the position of the window of interest for the CRC calculation

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 5Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DCUx\_SIGN\_CALC\_2 field descriptions**

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 SIG_VER_POS	Vertical position of the window of interest of pixels for CRC calculation (in pixels).
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SIG_HOR_POS	Horizontal position of window of interest of pixels for CRC calculation (in pixels).

**16.1.4.25 CRC Value Register (DCUx\_CRC\_VAL)**

This register contains the result of the CRC calculation for the value of the pixels on the safety layers.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DCUx\_CRC\_VAL field descriptions**

Field	Description
CRC_VAL	The result of the CRC calculation for the value of the pixels on the safety layers

**16.1.4.26 Parameter Error Status 1 Register (DCUx\_PARR\_ERR\_STATUS1)**

An error in a layer can occur under the following conditions:

- Number of pixels in a tile > maximum tile memory size when internal tile memory mode is in use.
- There is a non-valid horizontal size and color format combination. See [Layer size and positioning](#) for details.

## Memory Map and Registers

These errors are grouped into a single bit error for each layer. The parameter error specific to each layer is signalled only when the layer is enabled.

Address: Base address + 6Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### DCUx\_PARR\_ERR\_STATUS1 field descriptions

Field	Description
L[31:0]	For each individual interrupt: 0 Parameter error is not set 1 Parameter error is set

## 16.1.4.27 Parameter Error Status 2 Register (DCUx\_PARR\_ERR\_STATUS2)

An error in a layer can occur under the following conditions:

- Number of pixels in a tile > maximum tile memory size when internal tile memory mode is in use.
- There is a non-valid horizontal size and color format combination. See [Layer size and positioning](#) for details.

These errors are grouped into a single bit error for each layer. The parameter error specific to each layer is signalled only when the layer is enabled.

For each individual interrupt:

0 Parameter error is not set

1 Parameter error is set

Address: Base address + 70h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	L[63:32]																															
W

### DCUx\_PARR\_ERR\_STATUS2 field descriptions

Field	Description
L[63:32]	For each individual interrupt: 0 Parameter error is not set

**DCUx\_PARR\_ERR\_STATUS2 field descriptions (continued)**

Field	Description
	1 Parameter error is set

**16.1.4.28 Parameter Error Status 3 Register (DCUx\_PARR\_ERR\_STATUS3)**

DISP\_ERR occurs when the size of display (height or width) is set to zero or when the pulse width of hsync/vsync is programmed as zero.

SIG\_ERR occurs when the area of interest for calculating CRC value is programmed with values which are outside the display.

HWC\_ERR occurs if size of cursor programmed is greater than memory size (256 x 32). See [Hardware cursor](#) for further details on how cursor can be programmed.

RLE\_ERR occurs when more than one layer has its RLE\_EN bit set (Control Descriptor 4).

Address: Base address + 7Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DCUx\_PARR\_ERR\_STATUS3 field descriptions**

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 RLE_ERR	Error signal to indicate that more than one layer has RLE mode enabled.
2 HWC_ERR	Interrupt signal to indicate HWC error. This can occur if HWC position is out of display area or cursor memory is bigger than the HWC size. When this occurs, the HWC is disabled.
1 SIG_ERR	Interrupt occurs whenever the area of interest specified by SIG_CALC register is outside the display size.

Table continues on the next page...

**DCUx\_PARR\_ERR\_STATUS3 field descriptions (continued)**

Field	Description
0 DISP_ERR	Interrupt occurs whenever width and height of display, pulse width (both vertical and horizontal sync) value is 0.

**16.1.4.29 Mask Parameter Error Status 1 Register (DCUx\_MASK\_PARR\_ERR\_STATUS1)**

This register enables or masks the corresponding interrupt.

For each individual interrupt bit:

0 Not masked

1 Interrupt is masked

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DCUx\_MASK\_PARR\_ERR\_STATUS3 field descriptions**

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 M_RLE_ERR	Mask for RLE_ERR interrupt flag.
2 M_HWC_ERR	Mask for HWC_ERR interrupt flag.
1 M_SIG_ERR	Mask for SIG_ERR interrupt flag.
0 M_DISP_ERR	Mask for DISP_ERR interrupt flag.

### 16.1.4.32 Threshold Input 1 Register (DCUx\_THRESHOLD\_INP\_BUF\_1)

This is the threshold configuration register for FIFO buffers 1 and 2. Note: A write to this register does not take effect until the value is transferred to the frame timing logic - see 43.5.4.2 Transfer of DCU Configuration.

#### NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#).

Address: Base address + 94h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### DCUx\_THRESHOLD\_INP\_BUF\_1 field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–24 INP_BUF_P2_HI	High threshold for the FIFO in position 2 in the pixel blend stack.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 INP_BUF_P2_LO	Low threshold for the FIFO in position 2 in the pixel blend stack.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 INP_BUF_P1_HI	High threshold for the FIFO in position 1 (lowest) in the pixel blend stack.
7 Reserved	This field is reserved.
INP_BUF_P1_LO	Low threshold for the FIFO in position 1 (lowest) in the pixel blend stack.

### 16.1.4.33 Threshold Input 2 Register (DCUx\_THRESHOLD\_INP\_BUF\_2)

This is the threshold configuration register for FIFO buffers 3 and 4.

#### NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#).

Address: Base address + 98h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### DCUx\_THRESHOLD\_INP\_BUF\_2 field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–24 INP_BUF_P4_HI	High threshold for the FIFO in position 4 in the pixel blend stack.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 INP_BUF_P4_LO	Low threshold for the FIFO in position 4 in the pixel blend stack.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 INP_BUF_P3_HI	High threshold for the FIFO in position 3 in the pixel blend stack.
7 Reserved	This field is reserved.
INP_BUF_P3_LO	Low threshold for the FIFO in position 3 in the pixel blend stack.

16.1.4.34 Threshold Input 3 Register  
(DCUx\_THRESHOLD\_INP\_BUF\_3)

This is the threshold configuration register for FIFO buffers 5 and 6.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 9Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCUx\_LYR\_INTPOL\_EN field descriptions

Field	Description
31 EN	Interpolation Enable bit for DCU4 Layer coded in YCbCr422 format.  This bit controls whether the chroma value for eac h pixel in the conversion from YCbCr 4:2:2 to 4:4:4 should use interpolation or the same value for both pixels.

Table continues on the next page...

**DCUx\_LYR\_INTPOL\_EN field descriptions (continued)**

Field	Description
0	Chroma value is same for two pixels
1	Interpolation is enabled
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**16.1.4.41 Layer Luminance Component Register (DCUx\_LYR\_LUMA\_COMP)****NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + B8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Y_RED										0	Y_GREEN

**DCUx\_LYR\_CHRM\_BLUE field descriptions**

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 Cr_BLUE	Cr coefficient for calculation of blue component.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Cb_BLUE	Cb coefficient for calculation of blue component.

16.1.4.45 Compression Image Size Register (DCUx\_COMP\_IMSIZE)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + C8h offset

DCUx\_COMP\_IMSIZE field descriptions

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COMP_IMSIZE	Compressed Image size in bytes for RLE coded layer.

16.1.4.46 Update Mode Register (DCUx\_UPDATE\_MODE)

Address: Base address + CCh offset

DCUx\_UPDATE\_MODE field descriptions

Field	Description
31 MODE	Do not set the MODE bit while the READREG is also set as this will block automatic updates. Do not set the MODE bit and the READREG register in the same write operation.

Table continues on the next page...

**DCUx\_UPDATE\_MODE field descriptions (continued)**

Field	Description
	<p>The first frame transfer must be initiated manually using the READREG bit. Subsequent transfers can be performed automatically or manually.</p> <p>0 Transfer of register values during vertical blanking period only when READREG is set</p> <p>1 Automatic transfer of register values during vertical blanking period</p>
30 READREG	<p>When the MODE bit is clear this bit is a control bit which can be written to initiate a transfer of register value during the next vertical blanking period. 1'b1: (MODE=0) Transfer register values on next vertical blanking period.</p> <p><b>NOTE:</b> If a transfer is underway, it is possible that changes to layer control descriptor values may be included in the transfer.</p> <p>0 (MODE=0) No transfer scheduled. When the MODE bit is set, this bit is a status bit which indicates when a register transfer is underway. (MODE=1) No transfer is underway.</p> <p>1 (MODE=0) Transfer register values on next vertical blanking period. (MODE=1) Register value transfer is underway.</p>
Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

**16.1.4.47 Underrun Register (DCUx\_UNDERRUN)**

Address: Base address + D0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## DCUx\_SFT\_LCK\_L1\_TRANSP field descriptions

Field	Description
31 WEN_L1_FC FCOLOR	Write Enable for Soft Lock Bit SLB_L1_FC 0 SLB is not modified 1 Value is written to SLB
30 WEN_L1_BC BCOLOR	Write Enable for Soft Lock Bit SLB_L1_BC 0 SLB is not modified 1 Value is written to SLB
29–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SLB_L1_FC FCOLOR	Soft Lock Bit for L1_FC Register. 0 Associated protected register is not locked and writeable 1 Associated protected register is locked for write access
26 SLB_L1_BC BCOLOR	Soft Lock Bit for L1_BC Register. 0 Associated protected register is not locked and writeable 1 Associated protected register is locked for write access
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 16.1.4.56 Control Descriptor Ln\_0 Register (DCUx\_CTRLDESCLn\_1)

This register sets the height and width of the layer associated with the register.

## NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 200h offset + (64d × i), where i=0d to 63d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																0

## DCUx\_CTRLDESCLn\_1 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 HEIGHT	Height of the layer in pixels.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

**DCUx\_CTRLDESCLn\_1 field descriptions (continued)**

Field	Description
WIDTH	Width of the layer (in pixels).  The layer width must be in multiples of the number of pixels that can be stored in 32 bits, and therefore differs depending on color encoding. For example, if 2 bits per pixel format is used, then the layer width must be configured in multiples of 16. See <a href="#">Layer size and positioning</a> .

**16.1.4.57 Control Descriptor Ln\_1 Register (DCUx\_CTRLDESCLn\_2)**

This register sets the origin (top/left) of the layer associated with the register.

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 204h offset + (64d × i), where i=0d to 63d

**DCUx\_CTRLDESCLn\_2 field descriptions**

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–16 POSY	Two's complement signed value setting the vertical position of top row of the layer, where 0 is the top row of the panel. Positive values are below and negative values are above the top row of the panel. See <a href="#">Run Length Encoding (RLE) Mode</a> .
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
POSX	Two's complement signed value setting the horizontal position of left hand column of the layer, where 0 is the left-hand column of the panel. Positive values are to the right and negative values are to the left the left-hand column of the panel.

**16.1.4.58 Control Descriptor Ln\_2 Register (DCUx\_CTRLDESCLn\_3)**

This register sets the beginning address of layer data.

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

## Memory Map and Registers

Address: Base address + 208h offset + (64d × i), where i=0d to 63d

### DCUx\_CTRLDESCLn\_3 field descriptions

Field	Description
ADDR	Address of layer data in the memory. The address programmed should be 64-bit aligned.

## 16.1.4.59 Control Descriptor Ln\_3 Register (DCUx\_CTRLDESCLn\_4)

This register controls various graphics options and whether the layer is enabled.

### NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

Address: Base address + 20Ch offset + (64d × i), where i=0d to 63d

### DCUx\_CTRLDESCLn\_4 field descriptions

Field	Description
31 EN	Enable the layer.  0 Layer is disabled 1 Layer is enabled
30 TILE_EN	Enable the Tile Mode. Cannot be used when POSY is a negative value.  This bit is available only for layer numbers 0 through 7 and 56 through 63. For the rest of the layers this bit is reserved and returns zero.

Table continues on the next page...

**DCUx\_CTRLDESCLn\_4 field descriptions (continued)**

Field	Description
	0 OFF 1 ON
29 DATA_SEL	Selects the Tile data either from MCU memory or CLUT.  This bit is available only for layer numbers 0 through 7 and 56 through 63. For the rest of the layers this bit is reserved and returns zero.  0 Tile Mode data resides in the MCU memory 1 Tile mode data resides in the CLUT
28 SAFETY_EN	Safety Mode Enable Bit. Valid only for layer 0 and layer 1. For registers of all other layers, this should be set to 0.  0 Safety Mode is disabled 1 Safety Mode is enabled for this layer
27–20 TRANS	Transparency Level. Specifies the alpha value for the layer. This value may be used by the blending engine to blend pixels on this layer. Value can vary between 0-255 iwhere 0 is completely transparent adn 255 is completely opaque.
19–16 BPP	Layer encoding format (bit per pixel)  0000 1 bpp 0001 2 bpp 0010 4 bpp 0011 8 bpp 100 16 bpp (RGB565) 0101 24 bpp 0110 32 bpp (ARGB8888) 0111 Transparency mode 4 bpp 1000 Transparency mode 8bpp 1001 Luminance offset mode 4 bpp 1010 Luminance offset mode 8 bpp 1011 16 bpp (ARGB1555) 1100 16 bpp (ARGB4444) 1101 16 bpp (APAL8 mode) 1110 YCbCr422 (the blend engine allows only a single YCbCr layer in any blend operation) 1111 Reserved
15 RLE_EN	Enable RLE mode for layer.  0 Disabled 1 Enabled
14–4 LUOFFS	Look Up Table offset.  Value gives the offset to the start address of the CLUT or tile (when used in internal tile mode) in the CLUT/TILE RAM.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 BB	Chroma Keying.  0 OFF 1 ON

*Table continues on the next page...*

**DCUx\_CTRLDESCLn\_4 field descriptions (continued)**

Field	Description
AB	Alpha Blending.  00 No alpha Blending 01 Blend only the pixels selected by chroma keying in case BB=1'b1 10 Blend the whole frame 11 Same functionality as 2'b00

**16.1.4.60 Control Descriptor Ln\_4 Register (DCUx\_CTRLDESCLn\_5)**

This register sets the maximum Chroma Keying values for RGB.

Refer to [Layer size and positioning](#) for a description of Chroma Keying.

**NOTE**

A write to this register does not take effect until the value is transferred to the frame timing logic - see [Transfer of DCU Configuration](#) .

## 16.1.5 Functional Description

The DCU4 is a master on the NIC; it fetches graphic source information directly from memory and dynamically performs blending and bit-bliting operations before delivering data to a TFT LCD panel.

### 16.1.5.1 Graphic sources

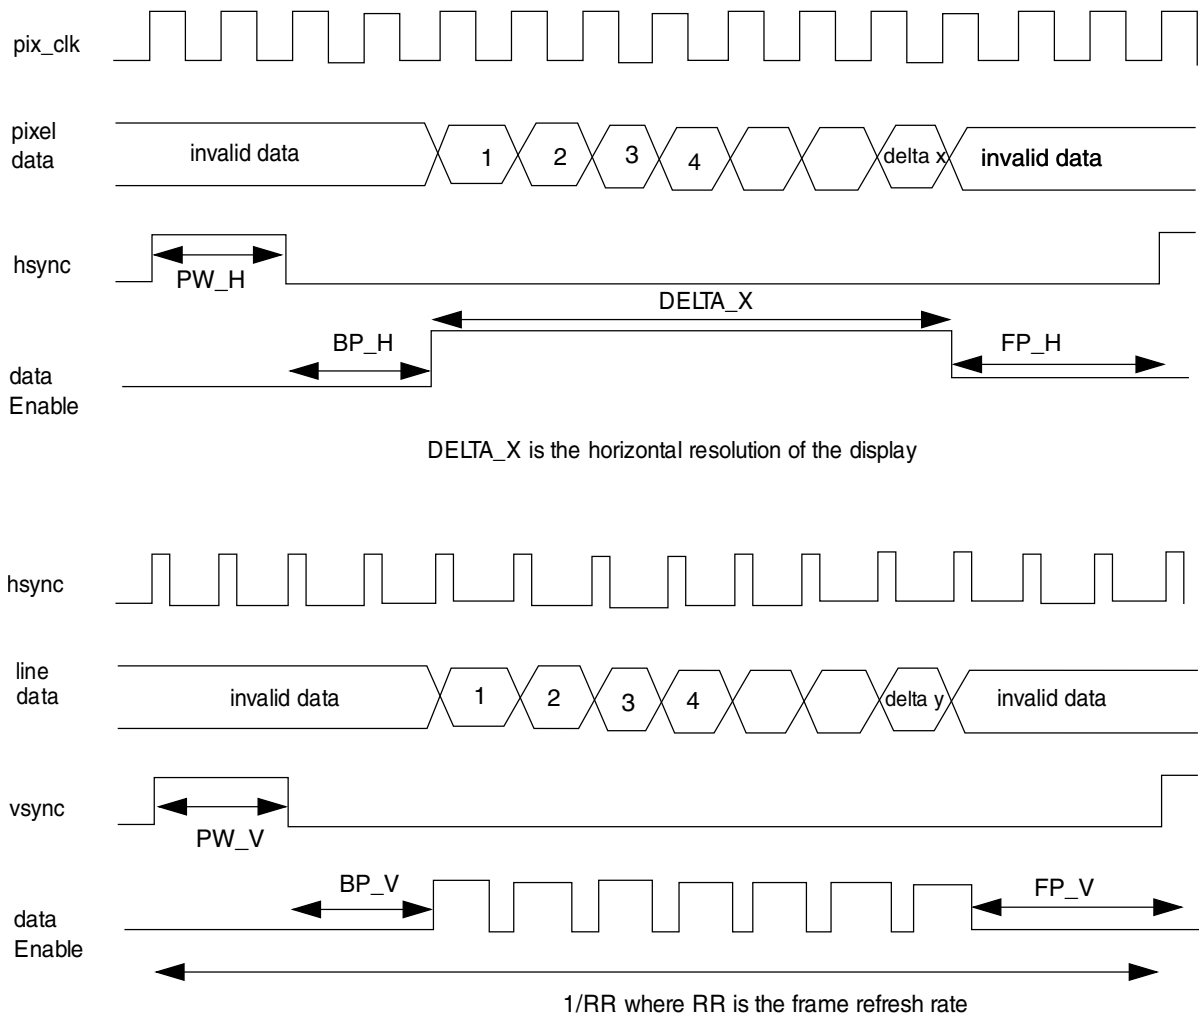

As the DCU4 is a master on the NIC, it can access directly any memory or device connected to the NIC as a slave. This includes all on-chip RAM, and any slave capable of providing high enough data rates, such as, for example an expanded bus interface or a QuadSPI module. Therefore, any compatible graphic stored anywhere on-chip or in an accessible interface can be displayed on the connected TFT LCD panel with no further intervention from the CPU, except to program the DCU4 to fetch and place it. The DCU4 also includes a dedicated memory to store the graphic for its cursor layer.

### 16.1.5.2 TFT LCD panel configuration

The nature and timing of the signals required by TFT LCD panels vary greatly between manufacturers. Therefore, the DCU4 allows highly flexible and detailed configuration of these signals.

Timing diagrams for TFT LCD panels are typically divided into a horizontal timing chart and a vertical timing chart. See [Figure 16-2](#) for details.

## Memory Map and Registers

**Figure 16-2. HSYNC and VSYNC timing diagram**

The number of pixel data slots in the horizontal timing diagram is defined by the width of the panel. The number of line data slots is defined by the height of the panel. Both of these values are defined in the DISP\_SIZE register (DELTA\_X, DELTA\_Y). The width of the panel must always be defined as a multiple of 16.

The timing of the pixel clock is defined by the DIV\_RATIO register and the frequency of the clock supplied to the DCU4.

In addition to defining the number and timing of pixels in each line and the number of lines, it is normal for TFT LCD panel manufacturers to define other timing signals in terms of pixel clock periods or of the number of horizontal lines. The DCU4 also follows this convention.

If the TFT LCD panel requires a horizontal synchronizing signal (HSYNC) and/or a data enable signal, then these can be configured using the fields in the HSYN\_PARA register. HSYNC provides a pulse to give the panel notice that the next line of pixel data is about to start, and the data enable signal indicates when that data is present. The PW\_H bit field

indicates the width of the HSYNC pulse, in pixel data clock periods. The BP\_H bit field defines the delay between the end of the HSYNC pulse and the start of the data enable signal (and pixel data delivery), in pixel clock periods. The FP\_H bit field defines the delay between the end of the data enable signal (and pixel data delivery) and the next HSYNC pulse, in pixel clock periods. FP\_H and BP\_H have minimum values of 1.

The TFT LCD panel's vertical synchronizing signal (VSYNC) can be configured using the fields in the VSYN\_PARA register. VSYNC provides a pulse to give the panel notice that the next frame of pixel data lines is about to start, and the panel defines delays before and after this pulse, in terms of pixel clock periods. The PW\_V bit field indicates the width of the VSYNC pulse in horizontal line periods. The BP\_V bit field defines the delay between the end of the VSYNC pulse and the start of the next pixel data (data enable signal), in horizontal line periods. The FP\_V bit field defines the delay between the end of the last pixel data (data enable signal) and the next VSYNC pulse, in horizontal line periods. FP\_V and BP\_V have minimum values of 1.

The polarity of all these signals, including the pixel data itself, may be inverted by using the control bits in the SYN\_POL register.

The refresh rate for the panel can be calculated using the Pixel Clock calculation below:

$$RR = \frac{\text{pix\_clk}}{(\text{DELTA\_X} + \text{FP\_H} + \text{PW\_H} + \text{BP\_H}) \times (\text{DELTA\_Y} + \text{FP\_V} + \text{PW\_V} + \text{BP\_V})}$$

- pix\_clk is the pixel clock
- DELTA\_X is the horizontal resolution (in pixels)
- DELTA\_Y is the vertical resolution (in pixels)
- FP\_H is the hsync front porch pulse width (in pixel clock cycles)
- BP\_H is the hsync back porch pulse width (in pixel clock cycles)
- PW\_H is the hsync active pulse width (in pixel clock cycles)
- FP\_V is the vsync front porch pulse width (in number of horizontal lines)
- BP\_V is the vsync back porch pulse width (in number of horizontal lines)
- PW\_V is the vsync active pulse width (in number of horizontal lines)

pix\_clk = DCU4 Clock / (DIV\_RATIO – 1), where DIV\_RATIO is an integer value in the DIV\_RATIO register that can range from 1 to 128.

The configuration values in these registers are "locked-in" for the panel when a frame refresh cycle is initiated. For more information about this process see [Transfer of DCU Configuration](#).

### 16.1.5.3 DCU4 Mode selection and background color

Once the DCU4 is configured for use with a particular TFT LCD panel, it can be enabled for use. There are three modes to choose from, as shown in the following table.

**Table 16-3. List of DCU operating modes**

Mode	DCU_MODE[1:0]	Description
Off	00	DCU4 disabled; the TFT LCD panel is not driven.
Color bar	11	DCU4 displays a test pattern consisting of vertical bands of programmable color.
Normal	01	DCU4 blends layers and displays result on TFT LCD panel.

The DCU\_MODE control bits are in the DCU\_MODE register. The DCU4 has an interface enable bit for the TFT LCD panel interface called RASTER\_EN, also in the DCU\_MODE register. When RASTER\_EN is 0, the raster scanning of pixels to the panel is disabled, but the pixel clock continues to run if enabled on the I/O pin.

Color bar mode is intended for testing the interface between the DCU4 and the TFT LCD panel. In this mode, the panel is divided into eight vertical strips of equal width, and the strips display a single color whose RGB value is specified in the COLBAR\_1 to COLBAR\_8 registers. At reset, the colors are set to black, blue, cyan, green, yellow, red, magenta, and white, where positive logic for the RGB values is assumed. The mode can be used to verify correct connection of the interface to the DCU4 and correct timing configuration of the interface. In this mode, any layer configuration settings are ignored.

In Normal mode, the DCU4 operates according to the timings specified in [TFT LCD panel configuration](#) and displays graphics according to the configuration of its layers. The BGND register sets the RGB color of the background shown when no other layers are present. This background color is included in the layer blending process but, since it is always the background, it does not include any layer blending settings.

### 16.1.5.4 Layer configuration and blending

Users control the graphical content of the TFT panel by manipulating the configuration of elements in the DCU4 called layers. Each layer has control descriptors that define the size, position, memory encoding, blending, and memory location of the graphic to be displayed. The DCU4 provides 64 independent layers that all display graphics with a fixed priority, and this affects how individual pixels are blended when layers overlap. The blending setting on each layer allows the pixels on that layer to be opaque, partially transparent, or fully transparent, which allows them to combine with pixels on other layers that they overlap.

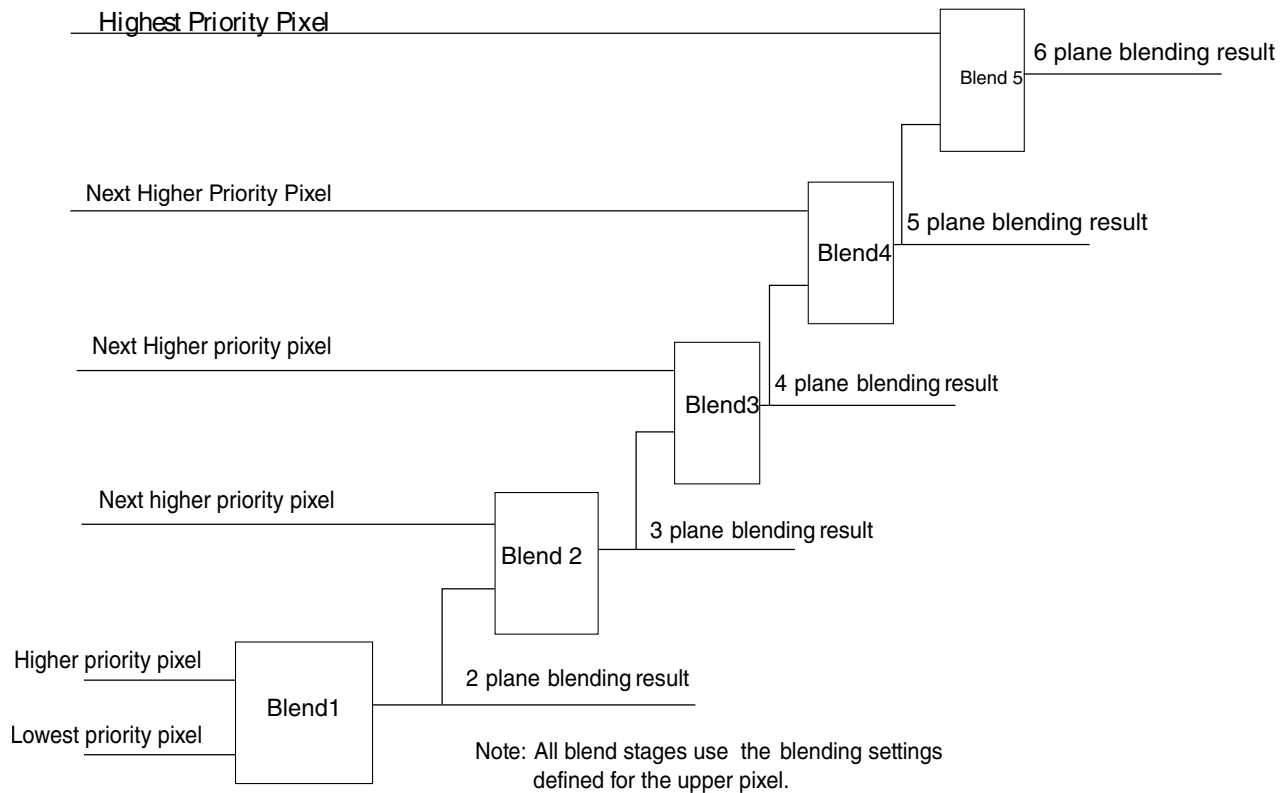

#### 16.1.5.4.1 Blending priority of layers

The 64 layers available in the DCU4 are each fixed in priority order, with layer 0 being the highest priority, layer 1 being the second highest priority, and so on until layer 63, which is the lowest priority. The priority is used by the DCU4 to define how to blend individual pixels within the layers. For example, if layer 0 is defined as not being blended with other layers and a pixel on layer 0 overlaps a pixel on layer 1 then the pixel on layer 0 will be visible on the panel unchanged by the pixel on layer 1. However, if layer 0 is defined as being partially transparent, then the DCU4 will blend the overlapping pixel such that the result is a combination of the pixel on layer 0 and the pixel on layer 1. It is possible to blend up to six layers at each pixel position.

As there is a maximum number of layers that can be blended together, the hardware arbitrates automatically, for every pixel individually, the 6 layers with the highest priority to be used for the blend. If a pixel is on a layer that has the lowest priority in any blending scheme, then the blending settings for that pixel are ignored and the pixel is treated as a background pixel. This means that a lower priority layer may have some pixels completely obscured by those on higher priority layers on one part of the panel, and some other pixels visible or blended on other parts of the panel.

[Figure 16-3](#) shows how the pixel blend takes place inside the DCU4. The priority of the layers determines at which stage of the blend the pixel enters. Any pixels lower than the threshold priority are ignored and, as can be seen, the blend settings for the lowest priority pixel is also ignored. The maximum number of pixels in the blend is configured by the `BLEND_ITER` bit field in the `DCU_MODE` register. As can be seen in the figure, the blending process is iterative so that six-pixel blending takes more DCU4 clock cycles than five-pixel blending, and three-pixel blending takes more DCU4 clock cycles than two-pixel blending.

**Figure 16-3. Pixel blending stack**

The number of pixels in each blend depends on two factors: The `BLEND_ITER` setting which defines the maximum and the actual number of layers present at the particular location on the panel. If fewer layers are present than the value in `BLEND_ITER` then only the number of blend stages required will occur. If more layers are present than the value in `BLEND_ITER` then the pixels below the lowest priority pixel are ignored. Note that the blend stack always operates from the lowest to highest such that a two layer blend will always use CH1 and CH2 to produce the 2 pixel blending result whereas a five layer blend will use CH1, CH2, CH3, CH4 and CH5 to produce the 5 pixel blending result.

This priority concept is illustrated in [Figure 16-4](#) and [Figure 16-5](#). In this case, there are five layers enabled, and each contains a graphic that is a solid rectangular block of a single color. The size and shape of each layer is different. The background color of the panel is set to grey and layers have been placed such that they overlap each other.

[Figure 16-4](#) shows the individual source graphics and the case where no layer has any blending enabled. Here, the highest priority layer (in this case layer 0) is fully visible. Layer 1 is visible where layer 0 does not overlap it. Layer 2 is visible where layer 1 does not overlap it. Layer 3 is overlapped by layers 0 and 1 and so is only partially visible. Layer 4 is partially obscured by all of the other layers. Note that layer 4 is higher priority than the background color.

**Figure 16-4. Example of layer placement with no blending**

Figure 16-5 shows the same layer configuration except that, in this case, the layers have been made 50% transparent and the depth of the pixel blend is set to 3. The pixels in layer 0 are now blended with pixels in the underlying layers. In particular, note region A where layer 0 is blended with layer 4 and the background color. This blending effect is repeated across all of the layers; however, note the pixels in region B. In this region the pixels from layer 0 are blended with those on layer 1 and layer 2; however, the pixels from layer 4 and the background color are not included in this blend. This is because the DCU4 is configured to blend three layers only, and so the blend setting for layer 2 is ignored for those pixels in region B.

**Figure 16-5. Example of layer placement with 3-layer blending**

All blending is performed using full 8-bits-per-component colors. The DCU4 automatically performs a color promotion on source data that is stored in less than RGB888 color.

#### **16.1.5.4.2 Transfer of DCU Configuration**

The configuration of the DCU occurs in two stages. Firstly the configuration values are written into the appropriate register by the user software. Secondly, these values are transferred into the frame timing logic for use on the next frame refresh. This means that the values written into the registers do not take effect until the transfer completes. Similarly, error conditions will not be detected until the transfer occurs and so error flags will not be set until the transfer is complete. Refer to the register descriptions for details of which registers require this transfer operation.

The transfer itself always occurs at a fixed time in relation to the vertical blanking period. The time at which the control descriptors are updated and ready to transfer is under user control and there are two control bits in the UPDATE\_MODE register that determine how the DCU behaves. The READREG bit causes a single transfer to begin at the next frame blanking period. This bit is cleared when the transfer is complete. The MODE bit forces the transfer to occur on every frame blanking period. This means that any changes to the affected registers must be complete before the transfer is ready to begin otherwise coherency issues can occur. The DCU provides a status flag called PROG\_END bit in the INT\_STATUS register which is asserted when the transfer is beginning and a status flag called LYR\_TRANS\_FINISH which indicates when the transfer is complete. Both of these status flags can generate an interrupt.

Changes to register contents before the transfer is complete may be copied as part of the transfer.

### NOTE

Every transfer must be performed using the READREG bit until the DCU\_MODE[DCU\_MODE] bit field is set to non-zero. All subsequent transfers may be performed using either the READREG or the MODE bit method.

#### 16.1.5.4.3 Control Descriptors

The control descriptor for each layer consists of nine registers, and all 64 control descriptors have common features that allow the display and blending of a graphic in the frame. In addition, the top two layers (0 and 1) have additional control bits for the safety mode. The top and bottom eight layers (0 to 7 and 56 to 63) also have support for tile mode.

The control descriptors contain the configuration that will be used for a future frame. The current frame configuration will remain the same until all of the control descriptor contents are updated by the user and subsequently transferred to the frame timing logic. Once this transfer is complete the control descriptors can be modified for the next frame.

#### 16.1.5.4.4 Layer size and positioning

The size of each layer is defined by register 1 in the control descriptor for the layer (CTRLDESCLn\_1, where n is the layer number). The register contains two bit fields, HEIGHT and WIDTH, which determine the size and shape of the layer. Both fields are expressed in terms of the number of pixels in each dimension.

The HEIGHT bit field may take any value.

The WIDTH field has a restriction on the value it can take, depending on the data format of the graphic specified by the layer. This field must always be an integer multiple of the number of pixels that are represented by a 32-bit word except in the special case of 1 bit per pixel where the multiple is 16. The data format can range from 1 bit per pixel to 32 bits per pixel and so there is a range of multiples from 1 to 32. [Table 16-4](#) shows the multiples for the WIDTH bit field and some correct values.

**Table 16-4. Example of WIDTH multiples for different graphic data formats**

Data format	WIDTH multiples	Example values
1 bpp	16	16, 32, 48, 64, ...
2 bpp	16	16, 32, 48, 64, ...
4 bpp	8	8, 16, 24, 32, ...

*Table continues on the next page...*

**Table 16-4. Example of WIDTH multiples for different graphic data formats (continued)**

Data format	WIDTH multiples	Example values
8 bpp	4	4, 8, 12, 16, ...
16 bpp	2	2, 4, 6, 8, ...
24 bpp	4 (= 3 whole 32-bit words)	4, 8, 12, 16
32 bpp	1	1, 2, 3, 4, ...
YUV422	4	4, 8, 12, 16, ...

If the WIDTH bit field is set to an invalid multiple, then the layer configuration is invalid, the layer cannot be made visible, and an error flag is set in the layer parameter error register (PARR\_ERR\_STATUS1 and PARR\_ERR\_STATUS2).

The position of each layer on the panel is defined by register 2 in the control descriptor for the layer (CTRLDESCLn\_2, where n is the layer number). The register contains two bit fields, POSY and POSX, which determine the location of the upper left pixel of the layer in the x and y axes. Both fields are expressed in terms of the number of pixels in each axis.

There are no restrictions on layer placement. Any layer can be placed and moved to any panel position. If a layer is placed so that pixels would appear beyond the dimensions of the panel, then the DCU4 displays the pixels on the panel and ignores the pixels off the panel.

There is one restriction for YPOS in Tile Layers: Negative values for YPOS is not supported (only in Tile Layers). Use of negative YPOS will result in corrupted tiled image. This should be handled by SW. However, negative values for XPOS are supported.

For RLE encoded graphic data, negative XPOS and YPOS values are discouraged as this quickly leads to underrun situations.

#### 16.1.5.4.5 Graphics and data format

The memory location of the graphic that is displayed on the layer is defined by register 3 in the control descriptor for the layer (CTRLDESCLn\_3, where n is the layer number). This 32-bit value can contain the address of any memory location in the memory map of the MCU.

The format of the data that describes the graphic is defined by the BPP bit field in register 4 in the control descriptor for the layer (CTRLDESCLn\_4, where n is the layer number). This value also influences the range of values for the width of the layer (see [Layer size and positioning](#)). By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

There are five modes where the RGB values of the pixels are stored directly in the graphic. In these modes, the DCU4 treats the data as describing a true RGB color. The modes are:

- ARGB8888, where the data defines 8-bit values for the red, green, blue, and alpha components of the image. This blends as ARGB, however, in this format the order of the bytes is reversed compared to other formats.
- RGB888, where the data defines 8-bit values for the red, green, and blue components of the image.
- RGB565 where the data defines 5-bit values for the red and blue components, and 6-bit values for the green component of the image.
- ARGB1555 where the data defines 5-bit values for the red, green, and blue components, and a 1-bit value for the alpha channel of the image.
- ARGB4444, where the data defines 4-bit values for the red, green, blue, and alpha components of the image.

The three 16-bit formats (RGB565, ARGB1555, and ARGB4444) are promoted to full 8 bit per component format by shifting the bits left so that the MSB of the component in the 16-bit format becomes the MSB of the 24/32 bpp (bit per pixel) format, and the LSB is filled with the value of the MSBs. For example, an RGB565 value of 10000:010000:11011 becomes 10000100:01000001:11011110. An RGB4444 value of 1010:0011:1100:0101 becomes 10101010:00110011:11001100:01010101. An RGB1555 value of 1:10100:01000:11011 becomes 11111111:10100101:01000010:11011110.

There are five indexed color formats (1/2/4/8 bpp & APAL8) where the data in the graphic does not define the RGB color to display. Instead, the data defines the entry in a color look-up table (CLUT) that contains a palette of ARGB colors. The maximum number of colors in the CLUT is defined by the size of the data stored in the graphic. For 1 bpp graphics, there is a maximum of two colors in the CLUT. For 2 bpp, there is a maximum of four colors. For 4 bpp and 8 bpp data, the maximums are 16 and 256 colors, respectively. In APAL8 mode(16 bpp), the upper 8 bits define the alpha component of the pixel and the lower 8 bits define the offset in the CLUT (the alpha component in the CLUT color is ignored).

The address of the first value in the CLUT is defined in the LUOFFS bit field of register 4 and the CLUT is the RAM block dedicated to the DCU4 which is described in [CLUT/ Tile RAM](#)". Since the RGB values stored in the CLUT are 32-bit RGB, there is no need for further adjustment before blending.

The DCU4 also supports graphics encoded using luminance and chrominance format. This format is generically known as YUV and stores the luminance (brightness, Y) of a pixel separate from its chrominance (color information, U and V). This format is used by the DCU4 when stored in memory for display on a layer. The specific implementation used by the DCU4 is more accurately described as YCbCr422 which uses twice as many bits to describe the luminance as to describe the blue (Cb) and red (Cr) difference of the chrominance.

The DCU4 takes these pixels and converts them to RGB format using equations configured using its LYR\_LUMA\_COMP, LYR\_CHROMA\_RED, LYR\_CHROMA\_GREEN, and LYR\_CHROMA\_BLUE registers. The YCbCr format specifies a common chroma setting for two pixels; however, it is possible to interpolate the chroma for the pixels rather than setting both to the same value. This feature is enabled by the LYR\_INTPOL\_EN[EN] field. Due to the additional conversion step required, the DCU4 is able to blend a maximum of one layer encoded in YCbCr for each pixel.

There are four additional modes defined by the BPP bit field. These configure the graphic in transparency mode and luminance mode (see [Transparency mode and blending](#)" and [Luminance mode](#)" respectively).

There is a set storage format for each data format provided by the DCU4. These formats can be seen in the following tables.

**Table 16-5. Data Layout for ARGB8888**

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	A0	R0	G0	B0	A1	R1	G1	B1
0x08	A2	R2	G2	B2	A3	R3	G3	B3

In the following table, the YCbCr422 format encodes chroma information across two pixels. Therefore, the chroma values apply to the even pixel denoted in the table and its adjacent odd pixel.

**Table 16-6. Data layout for YCbCr422 format**

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	Y1	Cr0	Y0	Cb0	Y3	Cr2	Y2	Cb2
0x08	Y5	Cr4	Y4	Cb4	Y7	Cr6	Y6	Cb6

**Table 16-7. Data Layout for 24 bpp**

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	B1	R0	G0	B0	G2	B2	R1	G1
0x08	R3	G3	B3	R2	B5	R4	G4	B4

For 16 bpp, data expected is in the form of RGB565, ARGB1555 or ARGB4444, or APAL8.

The DCU4 includes a flag that indicates when it has completed fetching graphics from memory for the current frame refresh. If required, this flag (DMA\_TRANS\_FINISH in the INT\_STATUS register) can be used to determine when changes can be made to the source graphic content.

#### 16.1.5.4.6 Alpha and Chroma-key blending

The blending configuration of each layer is defined by the BB, AB, and TRANS bit fields in register 4 in the control descriptor for the layer (CTRLDESCLn\_4, where n is the layer number). The pixels affected by the blending configuration can be further selected by registers 5 and 6 in the control descriptor (CTRLDESCLn\_4 and CTRLDESCLn\_5). Depending on the priority and placement of the layer (see [Blending priority of layers](#)"), these bit fields and registers define how pixels from different layers are blended together.

The AB and BB bit fields define whether blending is active and whether the whole graphic or a selected portion is blended. Registers 5 and 6 specify the range of RGB colors that define the selected pixels. The TRANS bit field defines the transparency of the selected pixels.

The BB bit field defines whether the whole graphic, or only certain pixels, should be blended. When this bit is set, pixels that have an RGB value that falls into the range defined by registers 5 and 6 are considered to be selected and treated differently to the non-selected pixels in the graphic. This is a process known as chroma-keying since it is the color of the pixel that defines the selection. The selected pixels must be within the range defined by each color component of registers 5 and 6. See [Table 16-17](#) for examples of pixels that are selected and not selected when the given range is defined as 0x0080C0 to 0x0FB0FF.

**Table 16-17. Example of how chroma-key range selects pixels**

Source pixel	Red 00–0F	Green 80–B0	Blue C0–FF	Comment
0x000000	P	X	X	Not selected
0x08C0C0	P	X	P	Not selected
0x08A0C0	P	P	P	Pixel is selected

The AB bit field defines how any selected and non-selected pixels are blended. By combining this control with the BB bit field it is possible to define 11 unique ways of blending the pixels on a layer dependent on the type of layer. Depending on the configuration defined by the AB and BB bit fields, the TRANS bit field combines the two pixels in every blend stage using the alpha value of the upper pixel (which has the effect of making this pixel more or less transparent and revealing more or less of the lower pixel).

The result of each blend stage is calculated for all three color components as shown in [Figure 16-6](#).

$$A = (\text{BGPixel} * (255 - \text{alpha})) + (\text{FGPixel} * \text{alpha})$$

**Figure 16-6. Blend Calculation**

The result of the calculation must then be divided by 255 to normalize the result. This calculation is performed as follows:

1. First Division  $\text{output\_val} = A + (A \gg 8)$
2. Rounding off first addition & division if  $((A \gg 7) \& 0x1) == 0x1$   $\text{output\_val}++$
3. Second Division with rounding  $\text{output\_val} = \text{output\_val} \gg 7$ ; if  $((\text{output\_val} \& 0x1) == 0x1)$   $\text{output\_val} = \text{output\_val} + 0x2$ ;  $\text{output\_val} = \text{output\_val} \gg 1$

The blend can apply to pixels with no alpha channel (RGB) or with an alpha channel (ARGB) in different ways.

Table 16-18 defines how the settings of the BB and AB bit fields affect the pixels in the layer; RGB modes are 1 bpp, 2 bpp, 4 bpp, 8 bpp, RGB565, and RGB888; ARGB modes are ARGB1555, ARGB4444, and BGRA8888.

**Table 16-18. Blend options for BB and AB configurations**

Case	BB	AB[1:0]	Mode	Function
1	0	00	RGB	No blending, underlying pixels are obscured
2	1	00	RGB	Selected pixels are completely removed
3	0	01	RGB	The value in TRANS becomes the alpha channel of all pixels on the layer
4	1	01	RGB	The value in TRANS becomes the alpha channel of the selected pixels on the layer
5	0	10	RGB	Same as case 3
6	1	10	RGB	Selected pixels are completely removed and the value in TRANS becomes the alpha channel of the non-selected pixels on the layer
7	0	11	RGB	Reserved
8	1	11	RGB	Reserved
9	0	00	ARGB	No blending, pixel alpha is ignored and underlying pixels are obscured
10	1	00	ARGB	Selected pixels are completely removed, pixel alpha is ignored
11	0	01	ARGB	Pixel alpha is used to blend layer with underlying pixels. Value in TRANS is ignored.
12	1	01	ARGB	Uses the pixel alpha of the selected pixels only to blend layer with underlying pixels. Value in TRANS is ignored.
13	0	10	ARGB	The value in TRANS is multiplied with the pixel alpha value and the resultant alpha is used to blend all the pixels
14	1	10	ARGB	Selected pixels are completely removed, the value in TRANS is multiplied with the pixel alpha value and the resultant alpha is used to blend the non-selected pixels on the layer
15	0	11	ARGB	Reserved
16	1	11	ARGB	Reserved

Figure 16-7 to Figure 16-15 illustrate the effect of the cases identified in Table 16-18. In all cases there is a single active layer and a white background color.

**Figure 16-7. Case 1 example (no blend)**

**Figure 16-15. Case 14 example (selected pixels removed, pixel and layer alpha used in blend)**

#### 16.1.5.4.7 Transparency mode and blending

Transparency mode is a special case for the graphic data format and is defined by the BPP bit field in register 4 in the control descriptor for the layer (CTRLDESCLn\_4, where n is the layer number). This value also influences the range of values for the width of the layer (see [Layer size and positioning](#)). By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

In transparency mode, the source graphic does not contain any direct or indexed color information. Instead, the graphic data represents the alpha channel of the graphic. The DCU4 creates the final graphic by pre-blending a foreground color and background color using the alpha value of each pixel. The result of this pre-blend can then be blended with pixels on other layers using the normal blending process. Each layer has dedicated registers to contain the foreground and background colors for this mode within the control descriptor. These are registers CTRLDESCLn\_8 and CTRLDESCLn\_9, where n is the layer number. See Figure 11-76.

Transparency mode is typically used when a graphic must blend smoothly into the underlying layers, but where a rich color palette is not required. Examples include text where this mode allows the text to blend smoothly with any background — this is known as anti-aliasing.

There are two transparency modes available: 4 bpp and 8 bpp. The 4 bit data is translated to 8 bit by concatenating the 4 bits. The result of the pre-blend can be treated as an RGB888 graphic and blended in a similar way to previously described, or it can be treated as a special case of ARGB with only the foreground color visible in the final blend. Table 16-19 describes the blend options for transparency mode.

**Table 16-19. Blend options for transparency mode**

Case	BB	AB[1:0]	Mode	Function
1	0	00	Transpare ncy	No blending, underlying pixels are obscured
2	1	00	Transpare ncy	Reserved
3	0	01	Transpare ncy	The value in TRANS becomes the alpha channel of all pixels on the layer
4	1	01	Transpare ncy	The value in TRANS becomes the alpha channel of the selected pixels on the layer
5	0	10	Transpare ncy	Same as case 3
6	1	10	Transpare ncy	Background color is ignored, selected pixels are completely removed, the value in TRANS is multiplied with the graphic data value (alpha) and the resultant alpha is used to blend the non-selected pixels on the layer
7	0	11	Transpare ncy	Reserved
8	1	11	Transpare ncy	Reserved

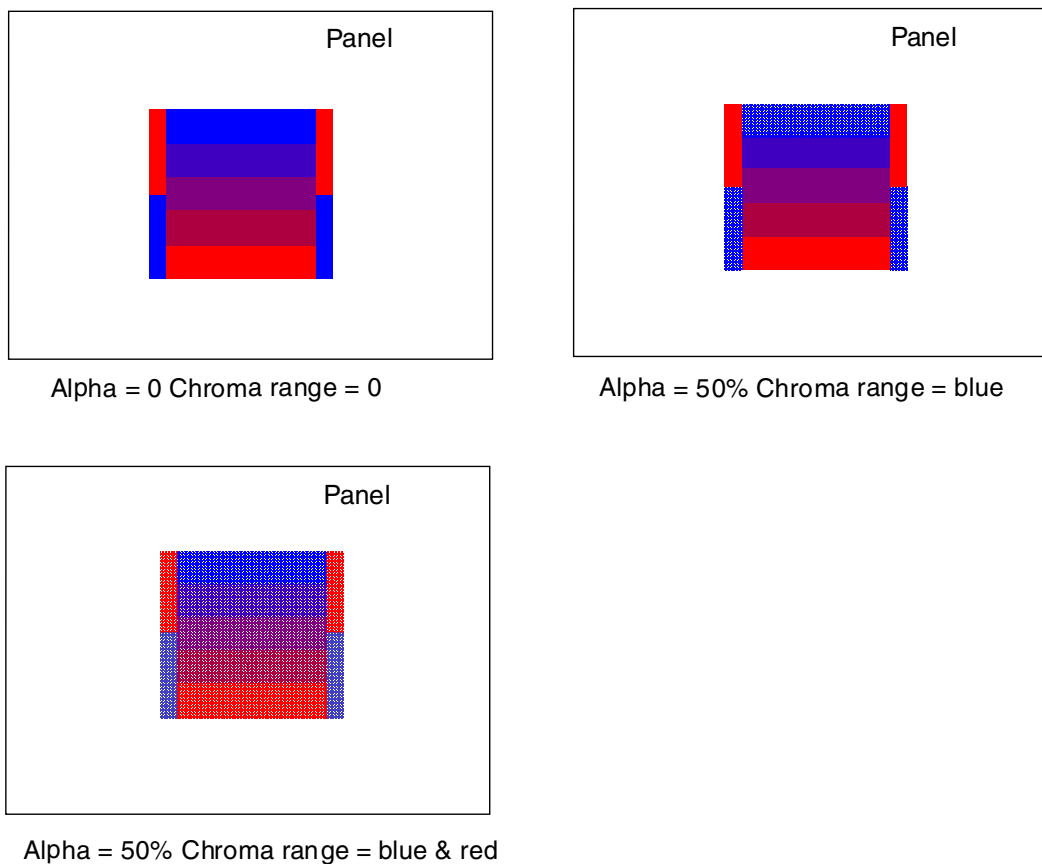

Figure 16-16 –Figure 16-19 illustrate the effect of the cases identified in Table 16-19. In all cases there is a single active transparency layer and a white background color.

**Figure 16-16. Case 1 example (no blend)**

**Figure 16-17. Case 3 example (all pixels transparent)**

**Figure 16-18. Case 4 example (selected pixels transparent)**

Figure 16-19. Case 6 example (only foreground color blended)

16.1.5.4.8 Luminance mode

Luminance mode is a special case for the graphic data format and is defined by the BPP bit field in register 4 in the control descriptor for the layer (CTRLDESCLn\_4, where n is the layer number). This value also influences the range of values for the width of the layer (see [Layer size and positioning](#)"). By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

In luminance mode, the data in the source graphic does not contain any direct or indexed color information or alpha information. The data values in a layer in luminance mode modify the values of the pixels on underlying layers only. There are two luminance modes available: 4 bpp and 8 bpp. In both cases, the data values behave as signed integers that are added to each component of the underlying pixel. The 4 bpp mode is left-shifted with the 4 bits concatenated to form a signed 8 bpp integer. The results of the addition are prevented from overflowing, so that any result greater than 0xFF is set to 0xFF and any result less than 0x00 is set to 0x00.

The result of a blend with a luminance layer is that the intensity of the underlying pixel's color will be increased or decreased. In this way, luminance mode can be used to highlight or dim pixels on the panel without having to modify the source graphic data. [Table 16-20](#) describes the effect of luminance blends on an underlying pixel.

Table 16-20. Example of a blend with a luminance mode layer

Pixel value	Luminance value	Resultant pixel
0xFF8040	0x40	0xFFC080
0xFF8040	0xC0	0x3F0000

#### 16.1.5.4.9 Tile mode

Tile mode is a special case for the layer and is enabled by the TILE\_EN bit field in register 4 in the control descriptor for the layer (CTRLDESCLn\_4, where n is the layer number). Tile mode is only available on layers 0 to 7 and 56 to 63.

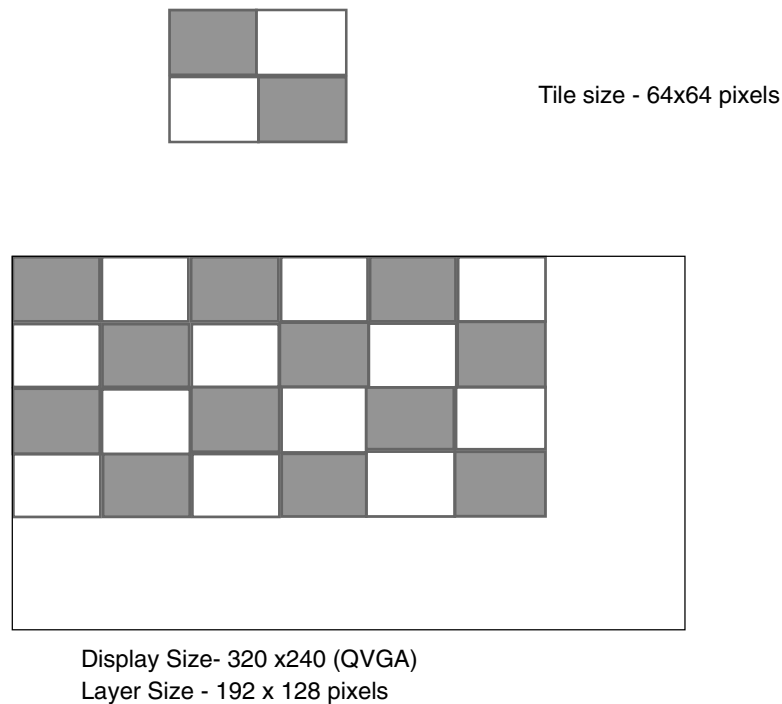

#### NOTE

Tile mode cannot be used with RLE mode on the same layer. In addition it cannot be used when the POSY parameter CTRLDESCLn\_2 register is negative. Neither of these conditions set the parameter error flag.

In this mode the layer size register (CTRLDESCLn\_1, where n is the layer number) defines the size of the layer; however, the size of the graphic is defined in control register 7 (CTRLDESCLn\_7, where n is the 64layer number). The size of the graphic must be less than or equal to the size of the layer. When tiled mode is enabled, the graphic is repeated horizontally and vertically until it fills the whole layer. The horizontal size of the tile is defined by the TILE\_HOR\_SIZE bit field and is restricted to be a multiple of 16 pixels. The vertical size of the tile is defined by the TILE\_VER\_SIZE bit field.

The graphic data for the Tile Mode can be fetched either from the system memory or from the internal CLUT/Tile memory. This is defined by the DATA\_SEL bit field in register 4 in the control descriptor for the layer. If the graphic is fetched from CLUT/tile memory then it must be in the CLUT/tile RAM direct color format. Otherwise the graphic can be in any previously described data format. See [Figure 16-20](#) for an example of a layer in tile mode.

When DATA\_SEL is set (to use CLUT/TILE RAM) the LUOFFS bit-field defines the start address of the tile graphic. Tile mode is not permitted when RLE mode is active on a layer.

**Figure 16-20. Tile Mode**

### 16.1.5.5 Hardware cursor

In addition to the 64 layers, the DCU4 also provides a special layer intended for use as a cursor. This cursor operates in 1 bpp mode and includes its own RAM area to store the graphic. The cursor may be placed at any location on the panel and includes an automatic blink option. The hardware cursor is configured using a dedicated control descriptor.

The size of the cursor is defined by register 1 in the control descriptor for the cursor (CTRLDESCCURSOR\_1). The register contains two bit fields, HEIGHT and WIDTH, which determine the size and shape of the layer. Both fields are expressed in terms of the number of pixels in each dimension. The HEIGHT is limited to a maximum of 256 pixels, and the total number of pixels cannot exceed the number of bits in the cursor RAM (8192 bits).

Bits in the cursor RAM that are 0 become transparent on the panel. Bits that are 1 become fully opaque in the color defined in register 3 in the control descriptor for the cursor (CTRLDESCCURSOR\_3). The DEFAULT\_CURSOR\_COLOR bit field is in RGB888 format.

There are restrictions on the arrangement of bits in the cursor RAM depending on how the HEIGHT and WIDTH bit fields are configured.

- When the cursor width is an integer multiple of 32 bits, the pixels in each row roll from one word in the RAM to the next one. The rightmost bit in the first word in the

RAM is the top leftmost pixel on the display. The leftmost bit in the word represents a pixel that is adjacent to the rightmost bit in the next word (in the same row). The leftmost pixel on the next row is the rightmost bit in the first word after  $n$  words that describe the first row.

- When the width of the cursor is greater than 32 bits but not an integer multiple of 32, the pixels in each row roll from one word into the next one such that the rightmost bit in the first word of the row is the leftmost bit on the display. In the final word of the row there are unused bits.

The position of the cursor on the panel is defined by register 2 in the control descriptor for the cursor (CTRLDESCCURSOR\_2). The register contains two bit fields, POSY and POSX, which determine the location of the upper left pixel of the cursor in the x and y axes. Both fields are expressed in terms of the number of pixels in each axis. Placing the cursor beyond the panel area is not allowed.

The cursor can be configured to blink at a particular rate when it is enabled. The EN\_BLINK, HWC\_BLINK\_ON, and HWC\_BLINK\_OFF bit fields define the blink behavior. These are in register 4 in the control descriptor for the cursor (CTRLDESCCURSOR\_4). EN\_BLINK enables blinking. The blinking time is based on the frame rate, and the on and off times are independently configurable. HWC\_BLINK\_ON configures the number of frame refresh cycles for which the cursor is visible. HWC\_BLINK\_OFF configures the number of frame refresh cycles for which the cursor is not visible. For a frame refresh rate of 64 Hz, the HWC\_BLINK\_ON and HWC\_BLINK\_OFF counters give a range of on/off times up to 4 seconds.

The cursor is enabled by setting the CUR\_EN bit field in register 3 in the control descriptor for the cursor (CTRLDESCCURSOR\_3).

If the DCU4 detects an invalid configuration in the cursor control descriptor, then the cursor configuration is invalid and it cannot be made visible. In addition, the error flag HWC\_ERR is set in the layer parameter error register (PARR\_ERR\_STATUS3).

The cursor RAM may be written at any time when the TFT LCD panel is not being driven with data. This means that the RAM can be modified when the DCU4 is not enabled and during the vertical blanking period.

### 16.1.5.6 CLUT/Tile RAM

The internal tile memory and color look up table (CLUT) memory share a common block of RAM internal to the DCU4. Color information in this RAM is always stored as aligned 32-bit words where the most-significant byte is the alpha component, the next byte contains the red component, the next the green component and the least significant byte the blue component (0xAARRGGBB).

This memory block can be used to store either color look-up tables or graphics for use as a tile on a layer. The content of the RAM at a specific address is defined by the control descriptor of a layer. The LUOFFS bit field in the layer control descriptor defines the starting address of the area, and the BPP and TILE\_EN bit fields define what type of use the RAM area has.

In [Figure 16-21](#) three areas of the RAM are defined for different purposes. Area A is used by layer 1 as a CLUT for its 4 bpp graphic. Area B is used by layer 5 as a store for its tile graphic. Area C is used by layers 2, 7, and 9 as a CLUT for their 8 bpp graphics.

**Figure 16-21. An example of use for the CLUT/Tile RAM**

The CLUT/Tile RAM is mapped in the DCU4 32K memory space from address 0x2000 to 0x3FFF. This gives 2048 entries, which provides up to eight full CLUTs for 8 bpp layers.

The CLUT/Tile RAM may be written at any time when the TFT LCD panel is not being driven with data. This means that the RAM can be modified when the DCU4 is not enabled and during the vertical blanking period.

### 16.1.5.7 Gamma correction

The gamma table allows the user to define an arbitrary transfer function at the output of each color component. The function ([Gamma correction](#)) is applied to each pixel after all blending is complete and before the data is driven to the TFT LCD panel. Gamma

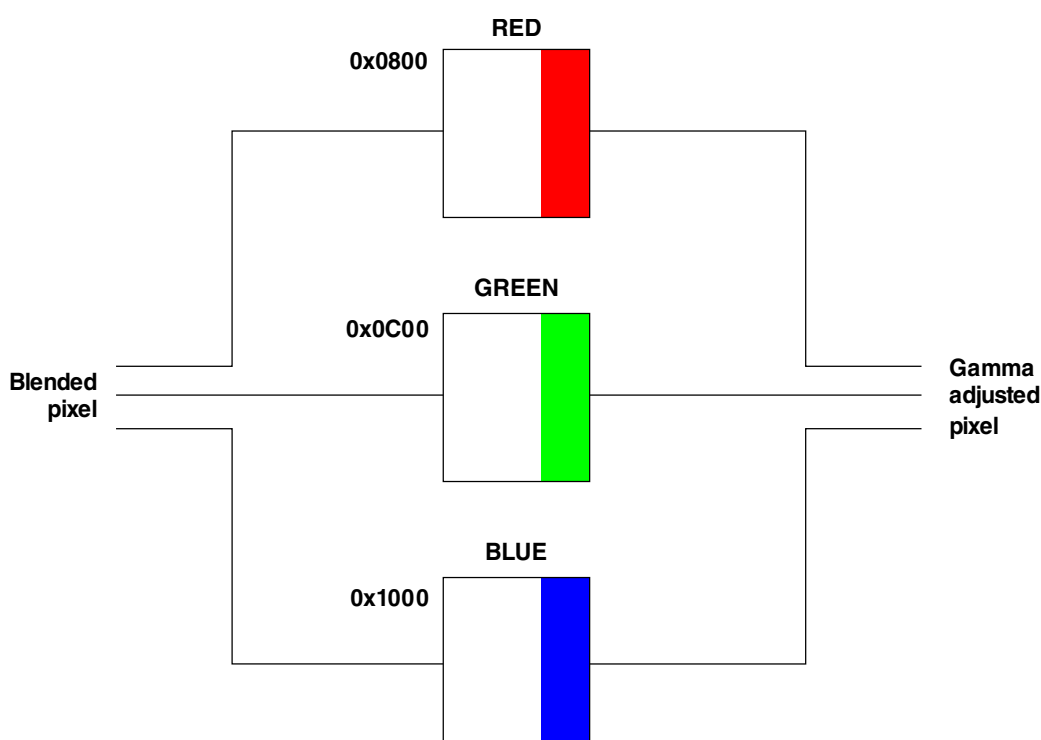

correction is optional and can be used to adjust the color output values to match the gamut of a particular TFT LCD panel, or to perform data inversion or data length reduction on each component.

$$\text{output\_color\_component} = \text{gamma\_table}[\text{input\_color\_component}]$$

### Equation 2

The table is arranged as three separate memory blocks within the DCU4 memory map; one for each of the three color components. Each memory block has one entry for every possible 8-bit value and the entries are stored at 32-bit aligned addresses. This means that the upper 24 bits are not used while reading/writing the gamma memories. See [Figure 16-22](#) for details of the memory arrangement.

**Figure 16-22. Gamma Correction Table Organization**

The gamma table can only be read or written when the DCU4 is not enabled or during the vertical blanking period.

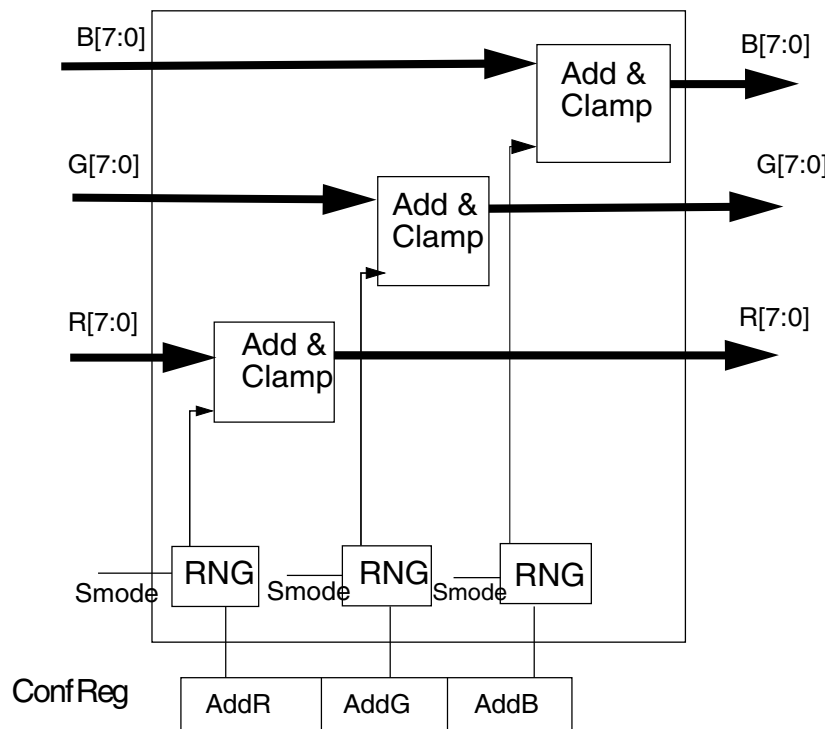

### 16.1.5.8 Temporal Dithering

This is a technique that allows the emulation of a color resolution higher than the resolution supported by the display. It is done by changing the intensity values over time sent to the display. The averaging done by the human eye gives the impression of the intensity of such alternating pixels as an interim value between the two supported intensity values. Temporal dithering is enabled by the DCU\_MODE[DITHER\_EN] bit.

The key features of the dithering block are:

- Temporal dithering increases the optically perceived depth of a limited TFT display.
- Supports display with 5-8 bits resolution per color component.
- Independent dither control parameters per color component.
- Support for safety mode.

Temporal dithering is enabled and controlled by the EN\_DITHER, ADDB, ADDG, and ADDR bits in the DCU\_MODE register. The ADDx fields are each 2 bits wide and select how many bits to add to each color component. The typical setting is 8 minus the number of bits in each component required by the display.

**Figure 16-23. Dithering block diagram**

The Random Number Generator (RNG) provides a random number of up to 3 bits. The number of bits provided is selected by the values of each component's ADDx field.

When pixels from a safety layer are encountered the RNG output is forced to 0 which effectively disables the temporal dithering block and these pixels are passed to the display unmodified.

The Add & Clamp block adds the eight bit pixel value to the three bit number generated by the RNG. The result is then clamped to the range of 0..255.

### 16.1.5.9 Special DDR Mode

Special DDR mode is a special configuration that optimizes the use of an SDRAM memory by the DCU4 by forcing the DCU4 to fetch data in optimal chunks. In this special mode only the six highest priority layers (0:5) are available in the DCU4. This mode is enabled using the DCU\_MODE[DDR\_MODE] bit.

When this mode is enabled the DCU4 will fetch data in 32-byte chunks if the layer is encoded in 8, 16 or 32 bpp formats, thus optimizing the SDRAM throughput. Any layers in 1, 2, 4 or 24 bpp formats will be fetched using normal access thus they will not benefit from any optimization and may disrupt optimal access for any 8-, 16- and 32-bit formatted layers if both are in the SDRAM. Therefore it is highly recommended to store any 1, 2, 4 or 24 bpp layers in non-SDRAM memory such as on-chip SRAM.

Depending on the layer configuration in use this mode may also benefit other synchronous memory interfaces such as QuadSPI.

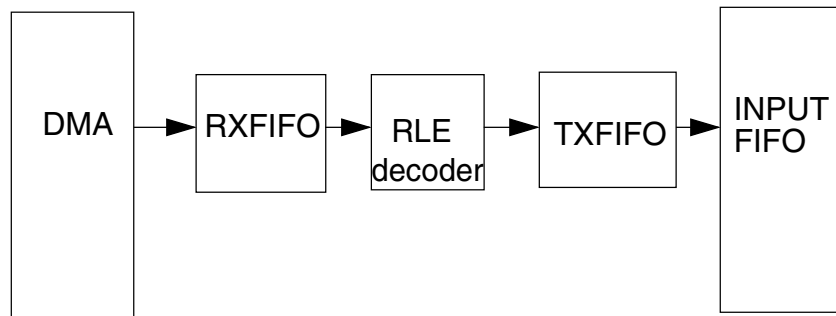

This mode causes a fixed assignment of DCU layers to the planes (i.e. 6 fetch pipelines). As a result: in DDR mode only 6 layers can be used. There is a maximum 6 layer blend. Therefore, the DCU\_MODE[BLEND\_ITER] field must be set to 6.

### 16.1.5.10 Run Length Encoding (RLE) Mode

RLE mode is available on all the layers and allows the DCU4 to load RLE compressed data from memory and directly decode it for use on the panel. The mode is enabled using the RLE\_EN bit in the control descriptor 4 register CTRLDESCLn\_4. This mode is only available when Special DDR mode is enabled and can only be used on layers equal to a number of RLE layers at a time. Maximum value of number of RLE layers can be 6. In addition the mode only supports 8 bpp, 16 bpp (RGB565, ARGB1555, ARGB4444, APAL8), 24 bpp and 32 bpp BGRA8888 formats.

When enabled, the DCU4 fetches encoded data on start of arbitration and provides the decompressed data according to the new arbitration scheme to the normal DCU blend process.

The following figure shows the dataflow for the RLE decoded data.

**Figure 16-24. RLE Decoding in DCU4**

The decoded data is read by the input FIFO once at least 8 bytes are available in the TXFIFO. The size of RXFIFO is 64x8 bits while the size of TXFIFO is 16x8 bits.

If more than the number of rle layers have RLE\_EN set, then the error flag RLE\_ERR is asserted.

#### **NOTE**

It is not recommended to use RLE mode together with negative offset on y axis especially on large images. Due to bandwidth limitation and latency RLE engine cannot fetch first valid pixel from RLE image fast enough.

#### **16.1.5.10.1 RLE Decoding Scheme**

Before enabling an RLE encoded layer configure the COMP\_IMSIZE register with the size of the compressed image. The decoder expects to read COMP\_IMSIZE bytes from the image and produce from that the number of pixels specified in the layer Control Descriptor 11 register.

The format of RLE encoded layers is as follows:

- The first data byte read at the image address (Layer Control Descriptor 3) is a command byte (CMD[7:0]).
- The ms bit (CMD[7]) indicates if the following bytes are raw or compressed pixels. One pixel can be 8-bit, 16-bit, 24-bit or 32-bit wide, depending on the BPP bit field in the Layer Control Descriptor 4 register.
- The remaining 7 command bits (CMD[6:0]) specify the number of raw or compressed pixels that follow the command byte. This count is offset by 1 such that a value of 0 means one pixel follows.
- For compressed pixels (CMD[7] = 1), only one pixel follows the command byte. This pixel is repeated count+1 times on the layer. The pixel size may be 8, 16, 24 and 32 bits.

- For raw pixels (CMD[7] = 0) count + 1 pixels follow the command byte and these are included on the layer as is. The pixel size may be 8, 16, 24 and 32 bits.
- If there is more data to decode, a new command follows after CMD+(1\*{Pixel width}) bytes. This encoding is repeated until the whole image is decoded.

## 16.1.6 Timing, Error and Interrupt Management

The DCU4 can detect and raise status and error flags when the status of the system changes and when configuration or operational errors are detected.

### 16.1.6.1 Synchronizing to panel frame rate

Since the DCU4 fetches data directly from memory independently of the CPU, there is the possibility that changes to the DCU4 layer configuration or content can create incoherent content on the panel. To help avoid this situation there are five timing control flags that define when the DCU4 recognizes and locks changes to its configuration. These can be used to manage changes to control descriptors, CLUT or tile memory, or source graphics and so avoid coherency problems on the panel. All the timing flags are in the INT\_STATUS register and can be used to generate interrupts from the DCU4.

The VS\_BLANK and LS\_BF\_VS flags give indication of the start of the vertical blanking period. The VS\_BLANK flag is set at the beginning of the vertical blanking period. The LS\_BF\_VS flag is set a given number of horizontal lines before the start of the vertical blanking period; the given number of lines is defined by the LS\_BF\_VS bit field in the THRESHOLD register.

The PROG\_END flag indicates that the DCU4 has begun a new panel refresh period. Further changes to the layer control descriptors should not occur until the transfer is complete.

The DMA\_TRANS\_FINISH flag indicates that the DCU4 has completed fetching all data from memory in the current panel refresh cycle. This normally precedes the vertical blanking period and indicates that it is possible to change the contents of a memory that contains graphics used by the DCU4.

The VSYNC flag indicates that the DCU4 has begun the next panel refresh period.

An additional flag called LVR\_TRANS\_FINISH is available to indicate when the DCU4 has completed transferring the layer configuration for this refresh cycle. This operates as a functional interrupt rather than a timing interrupt but can also help to ensure data coherency.

### 16.1.6.2 Managing the DCU4 FIFOs and DMA activity

The DCU4 fetches graphic data directly from internal and external memory using a dedicated DMA system and manages the output of data to the TFT LCD panel such that the panel always receives the pixel information when expected. Since the panel is sharing access to memory with the system DMA and CPU it cannot depend on the required data always being available at all times. It therefore it uses input and output FIFOs to temporarily store incoming and outgoing data until required and thus reduces the opportunity for the panel to be starved of pixel data.

The DCU4 manages the supply of graphic data to its format conversion and blending stages using input FIFO buffers that are 256 x 64 bits in size. The data that is driven to panel is managed using an output FIFO buffer that is 128 pixels in size. See [Figure 16-1](#) for a diagram of the input FIFO and output FIFO operation in the DCU4

The input FIFOs are not accessible to the user but it is possible to set thresholds that control the DCU4 behavior when the FIFOs are becoming full or empty and observe when the lower and higher thresholds are reached. The DCU4 also provides information on those conditions where data is expected from an input FIFO but is not available. This can help detect and avert situations where the DCU4 is running out of data to send to the panel.

The FIFO thresholds are set in the THRESHOLD\_INPUT\_BUF\_1/2/3 registers. The upper thresholds are set by the INP\_BUF\_Pm\_HI bit fields (where m is the position of the pixel in the blend stack) and these set the point at which the DCU pauses fetching data from memory. The maximum size of any DMA burst is fixed to 16 pixels and so is dependent on the graphic encoding. The lower thresholds are set by the INP\_BUF\_Pm\_LO bit fields.

Each of the six input FIFOs has two flags that indicate whether the FIFO has reached its upper or lower threshold. The Pm\_FIFO\_HI\_FLAG flags (where m is the position of the pixel in the blend stack) indicates that the input FIFO has reached the upper threshold. The Pm\_FIFO\_LO\_FLAG indicates that the input FIFO has less data than its low threshold. Depending on when the low threshold is reached this may indicate a number of scenarios

- The expected graphical data is not available for the DCU4 to load
- The DCU4 is reaching the end of a frame and does not need to load any more data
- The blend stack does not need pixels of this priority

In the situation where the data is not available to the DCU4 then there may or may not be an impact to the data visible on the panel. The DCU4 provides additional information in this case via the Pm\_EMPTY flags in the INT\_STATUS register and the LINE and PIXEL values in the UNDERRUN register. The Pm\_EMPTY flags indicate which position in the blend stack that the latest problem occurred and the LINE and PIXEL entries indicate approximately where on the panel the condition occurred. Taken together this information should allow identification of the source graphic/layer which was too slow to be loaded.

In the situation where the output FIFO is full then it is possible for the DCU4 to accept a delay before it requires to use the incoming data.

The output FIFO is not accessible to the user but it is possible to set thresholds that control the DCU4 behavior when the FIFO is becoming full or empty and observe the lower threshold. This can help detect and avert situations where the DCU4 is running out of data to send to the panel.

The buffer thresholds are set in the THRESHOLD register. The upper threshold is set by the OUT\_BUF\_HIGH bit field and this indicates that sufficient data exists in the output buffer and processing should stop until the DCU4 uses some of the values in the FIFO. If this value is set too low then the possibility of the DCU4 running out of data to drive the panel is increased. The lower threshold is set by the OUT\_BUF\_LOW bit field.

When the output FIFO has emptied below its low threshold (OUT\_BUF\_LOW bit field) it sets the UNDRUN bit. In an under run situation there may or may not be an impact to the data visible on the panel. The impact depends on whether the DCU4 is reaching the end of a frame and how close to running out the threshold is set.

The best guide to indicate whether the DCU4 is able to supply the required pixel information to the panel is the output buffer. If the output is indicating that it is running out of data, the input FIFOs and UNDERRUN register may help identify the areas of memory that are restricting the supply of data. Using these indicators can help to set the DCU4 thresholds and ensure that the data throughput on the MCU is balanced correctly for all master devices.

Finally, note that the number of DCU4 clock cycles to fetch and blend each pixel increases with the depth of the blend stack. However, the time taken to process the pixel data is fixed by the timing requirements of the panel. Therefore, for full performance across all color encodings the ratio between the DCU4 clock and the pixel clock must increase as the blend stack depth increases:

- For two pixel blend, maximum supported pixel clock is DCU4 clock/2.
- For three pixel blend, maximum supported pixel clock is DCU4 clock/3.
- For four pixel blend, maximum supported pixel clock is DCU4 clock/4.

- For five pixel blend, maximum supported pixel clock is DCU4 clock/5.
- For six pixel blend, maximum supported pixel clock is DCU4 clock/6.

### 16.1.6.3 Error detection

The DCU4 asserts error flags when errors are detected in its configuration or when the user attempts to modify the configuration at an invalid point in the panel refresh period or when it is unable to access the required source data. The error flags may raise an interrupt if enabled to do so by the related mask bit in the corresponding mask register.

Error flags are stored in the PARR\_ERR\_STATUS1, PARR\_ERR\_STATUS2, PARR\_ERR\_STATUS3, and INT\_STATUS registers.

Errors in the DCU4 layer configuration are collected in the PARR\_ERR\_STATUS1 and PARR\_ERR\_STATUS2 registers.

The flags Ln (where n is the layer number) indicate an error in the configuration of the layer which can be either an invalid tile mode size or a layer with a horizontal dimension that is smaller than the minimum size defined by the layer encoding (see [Layer size and positioning](#)).

Reads of CLUT/Tile RAM during the period when the TFT LCD panel is being updated do not return the CLUT/Tile RAM content.

Errors caused when the DCU is unable to access its required source data are collected in the INT\_STATUS register. These errors are indicated by the UNDRUN flag, the Pm\_EMPTY flags, and the Pm\_FIFO\_LO\_FLAG flags (where m is the position in the blend stack)

### 16.1.6.4 Interrupt generation

The DCU4 generates interrupt through four lines that are controlled by the contents of the following registers:

- INT\_STATUS
- INT\_MASK
- PARR\_ERR STATUS1
- PARR\_ERR STATUS2
- PARR\_ERR STATUS3
- MASK\_PARR\_ERR STATUS1

- MASK\_PARR\_ERR STATUS2
- MASK\_PARR\_ERR STATUS3

There are three interrupt status lines defined. These lines are grouped as follows

- Timing based interrupts:
  - VSYNC
  - LS\_BF\_VS
  - VS\_BLANK
  - PROG\_END
  - DMA\_TRANS\_FINISH
- Functional interrupts:
  - UNDRUN
  - LYR\_TRANS\_FINISH
  - CRC\_READY
  - CRC\_OVERFLOW
  - P1\_FIFO\_HI\_FLAG
  - P1\_FIFO\_LOW\_FLAG
  - P1\_EMPTY
  - P2\_FIFO\_HI\_FLAG
  - P2\_FIFO\_LOW\_FLAG
  - P2\_EMPTY
  - P3\_FIFO\_HI\_FLAG
  - P3\_FIFO\_LOW\_FLAG
  - P3\_EMPTY
  - P4\_FIFO\_HI\_FLAG
  - P4\_FIFO\_LOW\_FLAG
  - P4\_EMPTY
  - P5\_FIFO\_HI\_FLAG
  - P5\_FIFO\_LOW\_FLAG
  - P5\_EMPTY
  - P6\_FIFO\_HI\_FLAG
  - P6\_FIFO\_LOW\_FLAG

- P6\_EMPTY
- IPM\_ERROR
- Parameter error interrupts
  - Layer Error
  - Signature Calculator Error
  - Display Error
  - HWC\_error

When any interrupt occurs, the host can identify which type of interrupt has occurred by reading the interrupt status register and PARR\_ERR status registers.

## **16.1.7 Register protection**

There is a customized register protection scheme on the DCU4. The scheme provides a mechanism to protect certain registers in the DCU4 from being written.

### **16.1.7.1 Operation of scheme**

The register protection scheme provides a two-step protection scheme for the protected register.

Firstly, each register has an associated soft lock bit (SLB) that prevents further writes to the register when it is set. Each SLB has a corresponding write enable (WEN) bit that must be set in the same write operation as the SLB. The SLB can be set or cleared by writing a '1' or '0' to it while its WEN bit is set. The SLB bits are in the Soft Lock Registers L0 and L1, DISP\_SIZE, HSYNC/VSYSN\_PARA, POL, L0\_TRANSP and L1\_TRANSP registers.

Secondly, there is a hard lock bit (HLB) in the Global Protection Register which prevents all changes to soft lock bits. The HLB can only be cleared by a system reset.

If a write is made to a register whose SLB is set then a transfer error occurs that generates a data abort on the CPU. Similarly if the HLB is set then any write to the SLB registers causes a transfer error.

### **16.1.7.2 List of protected registers**

The register protection scheme applies to the following registers:

- All Layer 0 control descriptors CTRLDESCLO\_1 to CTRLDESCLO\_9
- All Layer 1 control descriptors CTRLDESCL1\_1 to CTRLDESCL1\_9
- DISP\_SIZE
- HSYNC\_PARA
- VSYNC\_PARA
- SYNPOL

### 16.1.8 Safety Mode

Safety layers are used in a multi-layer DCU4 environment for the purpose of guaranteeing that the content is driven to the display regardless of the setting of remaining layers and the pixel manipulation algorithms of the DCU4. Features such as this are a requirement from qualification institutes to be able to reach a safety level of SIL2 or ASILB. The DCU4 has two safety layers (Layer 0 and Layer 1) which also have the highest priority. When Safety Mode is active the safety layers can use chroma keying for complex area description, however alpha blending for the layer is always ignored. Additionally, if a layer has safety mode enabled then a layer format of 32 bpp or luminance is not allowed. Using these formats causes the layer to be disabled.

Safety Mode is implemented using a signature calculator module implemented inside the DCU4 that calculates two signatures (pixel value and pixel position) for a predefined area of the frame. The user makes layer 0 and/or layer 1 active as a safety layer, defines the window/area of the pixels for which the signature is to be calculated, and enables safety mode. When enabled, the signature calculator starts to calculate the signature after the first pixel in the selected area is available and after the start of the next frame (VSYNC). It is also possible to calculate the signature value for all pixels if `DCU_MODE[TAG_EN] = 0`.

As the pixels in the selected area become available they are "tagged" by the DCU4, except for those removed by chroma-keying. These tags identify the pixels to be included in the signature calculation. The signature calculation itself is an industry-standard CRC.

The DCU4 asserts the `CRC_READY` flag at the end of any frame which has Safety Mode enabled. This can be used to indicate the completed signature calculations for each full frame of pixels after the mode is enabled. The completed signature can then be compared against a pre-calculated value with any difference indicating that the pixels displayed did not match what was expected. The signature calculator then continues to calculate the CRC for the next frame. If the `CRC_READY` flag is not processed within one frame time period, then the `CRC_OVERFLOW` interrupt is issued and the latest calculation

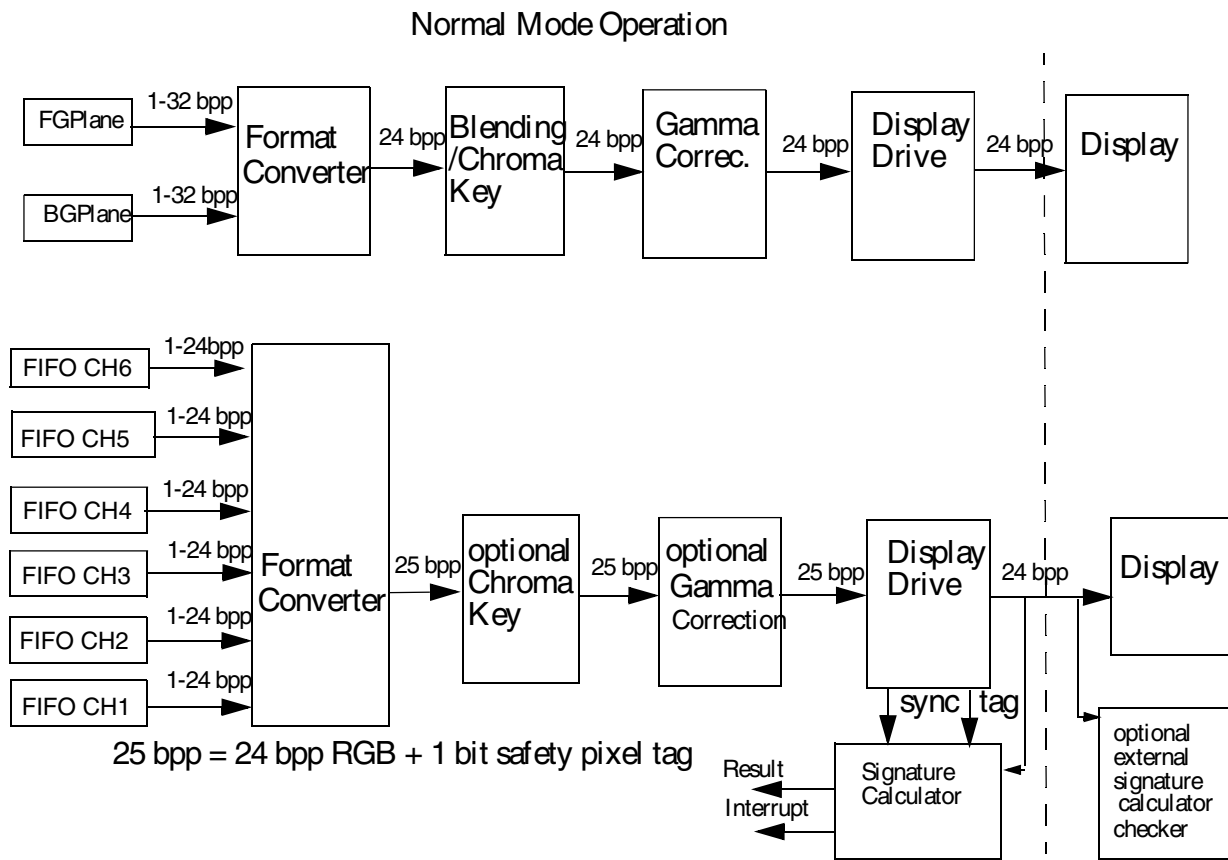

overwrites the previous value. Since the CRC\_READY flag is set at the end of any frame with Safety Mode enabled, it is possible that a full frame has not yet been completed and therefore no signature calculation exists for the frame that set the flag.

If the user has set the NEG bit for the DCU4 which indicates that the pixels fed to the display are inverted, then the value CRC is calculated on non-inverted values. The position CRC, however, remains as is.

Normal arbitration takes place only when a pixel has content on layer 0 and layer 1 but where Safety Mode is enabled in layer 1.

The polynomial used for CRC calculation is  $(x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1)$ .

For the value CRC, the 24-bit value of each output pixel (after decoding) is sent to the polynomial. For the position CRC, the value sent is  $(\text{pixel\_delta\_y} * \text{display.delta\_x}) + (\text{pixel\_delta\_x} + 1)$ .

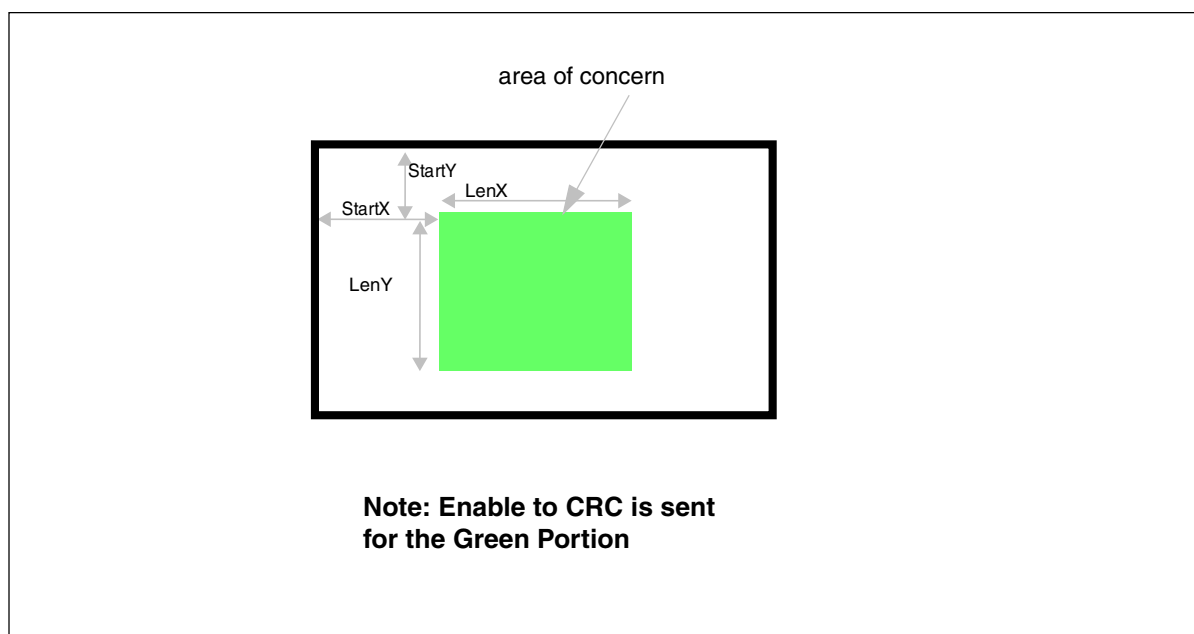

**Figure 16-25. Safety Mode Block Diagram**

## 16.1.8.1 CRC Area Description

### 16.1.8.1.1 Relationship between various input signals

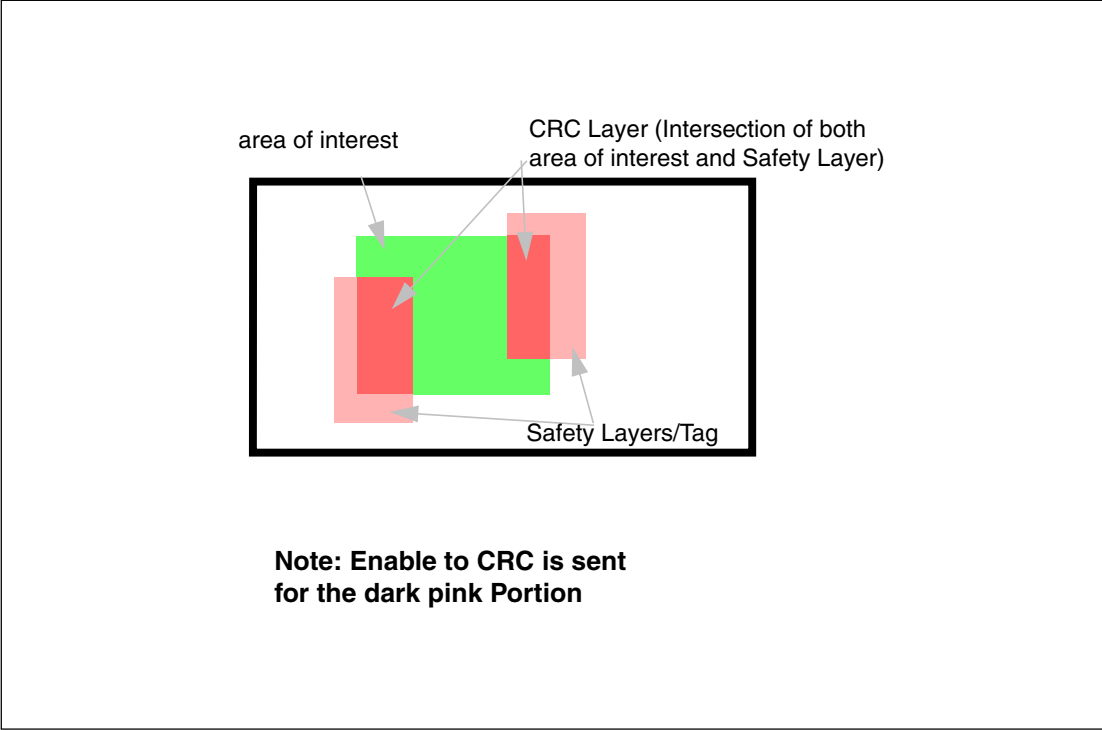

To configure the CRC calculation:

1. CRC\_VAL and CRC\_POS are calculated when Safety Mode is enabled using DCU\_MODE[SIG\_EN].
2. The CRC can be calculated for part of the panel as shown in the following figure. The green portion on the panel is identified using the SIGN\_CALC\_1 and SIGN\_CALC\_2 registers which defined the size of the area and the location of the area respectively. If SIGN\_CALC\_1 and SIGN\_CALC\_2 are configured appropriately this calculation will cover the whole panel.

**Figure 16-26. Safety Mode enabled for part of the screen**

3. The CRC can be calculated exclusively for layers 0 and 1 by setting DCU\_MODE[TAG\_EN] and enabling the SAFETY\_EN bit in control descriptor 4 of each of the layers. In this configuration the CRC is calculated using values from the layers only where they intersect the area of interest defined in SIGN\_CALC\_1 and SIG\_CALC\_2. An example is shown (in dark pink) in the following figure.

**Figure 16-27. Safety Mode with tag bit high**

4. Layer 0 and 1 (i.e., safety layer) in safety mode does not supports blending or luminance offset.

**16.1.8.1.2 Features**

- SC support area modes mentioned in [Table 16-21](#)
- Supports calculation of CRC on the pixel value only
- CRC is calculated with the initial value as 32'h000000000
- CRC does not support:
  - Any modification of input bytes
  - Any modification of the output CRC value before reporting.

**Table 16-21. Supported Area**

Area	Tag Value	Note
Full	1'b0	StartX = 0 StartY = 0 LenX = Screen Size LenY = Screen Height
Part	1'b0	All the parameter have value other the one mentioned above as shown in <a href="#">Figure 16-26</a> .

Table continues on the next page...

**Table 16-21. Supported Area (continued)**

Area	Tag Value	Note
Safety Layer (Layer 0 and 1 only)	1'b1	Part of the safety Layer would depend on <ul style="list-style-type: none"> <li>• Part lying within the area of concern defined by the StartX startY LenX LenY</li> <li>• Part deleted by the chroma keying functionality</li> </ul>

### 16.1.8.1.3 Summary of Operation

The area included in the CRC calculation is summarized in the following table. The initial value on all CRC calculations is 0x00000000.

**Table 16-22. CRC calculation area**

Area	DCU_MODE[TAG_EN]	Note
Full	0	SIGN_CALC_2[SIG_HOR_POS] = 0 SIGN_CALC_2[SIG_VER_POS] = 0 SIGN_CALC_1[SIG_HOR_POS] = Panel Width SIGN_CALC_1[SIG_VER_POS] = Panel Height
Part	0	The SIGN_CALC parameters have values other than those mentioned above. See figure 11-86.
Safety Layer (Layer 0 and 1 only)	1	The included portion of the safety layers depends on: <ul style="list-style-type: none"> <li>– The portion lying in the area defined by SIGN_CALC1 and SIGN_CALC12</li> <li>– The pixels removed by chroma keying functionality</li> </ul>

## 16.1.9 DCU4 Initialization

The following steps describe a typical approach to initializing the DCU4 for use in an application.

1. After reset, configure the DCU4 peripheral to be active and configure the DCU4 clock source.
2. If using a panel with an integrated TCON module, disable the TCON signals by setting the TCON\_BYPASS bit in the TCON CTRL1 register. Due to the configuration of the TCON module, the DCU4 pixel clock signal will be output as soon as it is selected by the related IOMUX register. This is independent of the DCU4 operating mode.
3. Configure the output ports in the IOMUX registers as required.

4. Configure the timing registers to match the TFT LCD panel in use (see [TFT LCD panel configuration](#)).
5. Initialize/disable all layer descriptors
6. Set the background color as required.
7. Load the initial tile or palette colors into the CLUT/Tile memory.
8. Initiate a manual refresh of the frame by setting the READREG bit in the UPDATE\_MODE register.
9. If Automatic transfer is required, wait until the READREG bit is cleared before setting the MODE bit in the UPDATE\_MODE register

## 16.2 LCD Driver (LCD)

### 16.2.1 Introduction

This section introduces the LCD driver module.

#### NOTE

For the chip-specific implementation details of this module's instances see the chip configuration chapter.

#### 16.2.1.1 Overview

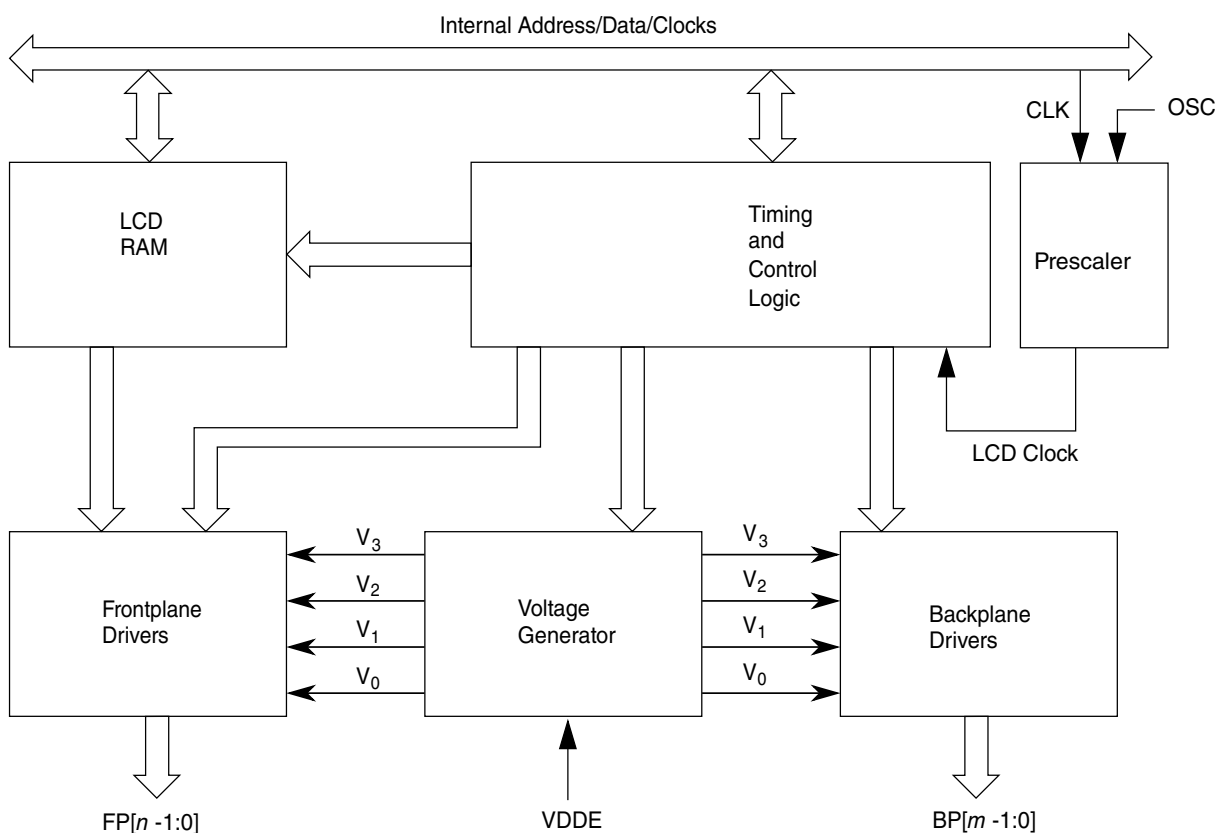

The LCD driver module has up to 64 frontplane drivers ( $n$ ) and up to 8 backplane drivers ( $m$ ) so that a maximum of 512 LCD segments are controllable. The actual implementation ( $n,m$ ) depends on the device specification. Each segment is controlled by a corresponding bit in the LCD RAM.  $m$  multiplex modes ( $1/1, 1/2, \dots 1/m$  duty), and three bias ( $1/1, 1/2, 1/3$ ) methods are available. The  $V_0$  voltage is the lowest level of the output waveform and  $V_3$  becomes the highest level. All frontplane and backplane pins can be multiplexed with other Port functions.

The LCD driver system consists of five major sub-modules:

- Timing and Control – consists of registers and control logic for frame clock generation, bias voltage level select, frame duty select, contrast adjustment, backplane select and frontplane select/enable, remapping of backplane drivers to produce the required frame frequency and voltage waveforms.
- LCD RAM – contains the data to be displayed on the LCD. Data can be read from or written to the display RAM at any time.

- Frontplane Drivers – consists of  $n$  frontplane drivers.
- Backplane Drivers – consists of  $m$  backplane drivers.
- Voltage Generator – Based on reference voltage VDDE. It generates the voltage levels for the timing and control logic to produce the frontplane and backplane waveforms.

**Figure 16-28. Block Diagram**

### 16.2.1.2 Features

The LCD64F6B includes these distinctive features:

- Up to 64 frontplane drivers
  - Each frontplane has an individual enable bit
- Up to 8 backplane drivers
- Remapping of backplane drivers
- Programmable frame clock generator

- Programmable bias voltage level selector
- Programmable output current
- Selectable output current boost during transitions.
- Selectable LCD frame frequency interrupt event
- On-chip generation of four different output voltage levels
- Contrast adjustment by using Contrast adjustment phases
- Selectable continuous drive of LCD while in power down mode

### 16.2.1.3 Modes of Operation

The LCD64F6B module supports up to seven operation modes with different numbers of backplanes and different biasing levels. During power saving mode the LCD operation can be suspended under software control. Depending on the state of internal bits, the LCD can operate normally with source clock applied, or the LCD clock generation can be turned off and the LCD64F6B module enters a power conservation state.

This is a high level description only, detailed descriptions of operating modes are contained in later sections.

### 16.2.2 External Signal Description

**Table 16-23. Signal Properties**

Name	Port	Function	Reset	Pull Up
$m$ Backplane Waveforms	BP[ $m-1:0$ ]	Backplane waveform signals that connect directly to the pads	high impedance	
$n$ Frontplane Waveforms	FP[ $n-1:0$ ]	Frontplane waveform signals that connect directly to the pads	high impedance	
VDD33 Voltage	VDD33	LCD supply and reference voltage		
VSSE Voltage	VSSE	LCD ground voltage		

## 16.2.2.1 Detailed Signal Descriptions

**Table 16-24. Interface A—Detailed Signal Descriptions**

Signal	Description
BP[m-1:0]	This output signal vector represents the analog backplane waveforms of the LCD64F6B module and is connected directly to the corresponding pads.
FP[n-1:0]	This output signal vector represents the analog frontplane waveforms of the LCD64F6B module and is connected directly to the corresponding pads.
VDDE	Positive supply and reference voltage for the LCD waveform generation.
VSSE	Ground supply voltage for the LCD waveform generation.

## 16.2.3 Memory Map and Registers

This section describes the Memory map table and the register descriptions in address order.

**LCD memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400B_E000	LCD Control Register (LCD_LCDCR)	32	R/W	0000_0000h	<a href="#">16.2.3.1/3456</a>
400B_E004	LCD Prescaler Control Register (LCD_LCDPCR)	32	R/W	0000_0000h	<a href="#">16.2.3.2/3458</a>
400B_E008	LCD Contrast Control Register (LCD_LCDCCR)	32	R/W	0000_0000h	<a href="#">16.2.3.3/3459</a>
400B_E010	LCD Frontplane Enable Register 0 (LCD_ENFPR0)	32	R/W	0000_0000h	<a href="#">16.2.3.4/3459</a>
400B_E014	LCD Frontplane Enable Register 1 (LCD_ENFPR1)	32	R/W	0000_0000h	<a href="#">16.2.3.5/3460</a>
400B_E020	LCDRAM (Location 0) (LCD_LCDRAM0)	32	R/W	0000_0000h	<a href="#">16.2.3.6/3460</a>
400B_E024	LCDRAM Location 1 (LCD_LCDRAM1)	32	R/W	0000_0000h	<a href="#">16.2.3.7/3461</a>
400B_E028	LCDRAM Location 2 (LCD_LCDRAM2)	32	R/W	0000_0000h	<a href="#">16.2.3.8/3462</a>
400B_E02C	LCDRAM Location 3 (LCD_LCDRAM3)	32	R/W	0000_0000h	<a href="#">16.2.3.9/3462</a>
400B_E030	LCDRAM Location 4 (LCD_LCDRAM4)	32	R/W	0000_0000h	<a href="#">16.2.3.10/3463</a>
400B_E034	LCDRAM Location 5 (LCD_LCDRAM5)	32	R/W	0000_0000h	<a href="#">16.2.3.11/3464</a>

*Table continues on the next page...*

## 16.2.3.1 LCD Control Register (LCD\_LCDCR)

Address: 400B\_E000h base + 0h offset = 400B\_E000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LCDEN	LCDRST	LCDRCS	DUTY			BIAS	VLCDs	PWR		BSTEN	BSTSEL	BSTAO	LCDOCS	LCDINT	EOFI
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	NOF								0	0	LCDBPA		0	LCDBPS		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## LCD\_LCDCR field descriptions

Field	Description
31 LCDEN	LCD Driver System Enable.  0 All frontplane and backplane pins are disabled. In addition, the LCD Driver is disabled and all LCD waveform generation clocks are stopped. 1 LCD Driver System is enabled. All FP[n-1:0] pins with ENFP[n-1] set, will output an LCD driver waveform. The BP[m-1:0] pins will output an LCD Driver waveform based on the settings of DUTY.
30 LCDRST	Continue to drive LCD display while stop/standby requested.Can be written only when LCDEN is cleared. See Section “Operation in Power Saving Modes” for details.  0 Stop LCD64F6B display driver system while stop/standby requested. 1 LCD display driver system operates normally while stop/standby requested.
29 LCDRCS	LCD Reference Clock Select.Can be written only when LCDEN is cleared.It controls the selection between oscillator clock and system clock.

Table continues on the next page...

## LCD\_LCDCR field descriptions (continued)

Field	Description
	0 System clock is selected. 1 scillator clock selected based on LCDOCS.
28–26 DUTY	LCD Duty Select. The DUTY bits select the duty (multiplex mode) of the LCD Driver system as shown in <a href="#">Table 16-27</a> . The multiplex mode should be changed only when LCD Driver is disabled, LCDEN is not set.
25 BIAS	BIAS Voltage Select. This bit selects the bias voltage levels during various LCD operating modes, as shown in <a href="#">Table 16-27</a>
24 VLCD5	Reserved Can be written only when LCDEN is cleared. See <a href="#">Operation in Power Saving Modes</a> 0 No effect. 1 No effect.
23–22 PWR	LCD Power mode The PWR bits select the output current and have a direct impact on the power consumption and drive capability of the LCD64F6B module. <a href="#">Table 16-28</a> lists the possible selections.
21 BSTEN	LCD output current boost enable Since the LCD appears like a capacitance to the driver it is sometimes useful to boost the output current during transitions to increase the slew rate of the driver. 0 No output current boost available. 1 Output current boost during transitions according to the BSTSEL bit.
20 BSTSEL	LCD output current boost select The BSTSEL bit sets the multiplier for the output current boost. If the BSTEN bit is set, the output current is boosted during transitions in the following way: 0 Current boosting by a factor of 8. 1 Current boosting by a factor of 16.
19 BSTAO	LCD Boost always on. If set, the selected by BST and enabled by BSTEN boost current is always on and not only during the time frame generated by the state machine 0 The Boost always on feature is disabled. 1 The Boost always on feature is enabled.
18 LCDOCS	LCD OSC Clock Select. Can be written only when LCDEN is cleared..It selects between oscillator clocks. 0 128Khz Slow Internal RC Oscillator Clock is selected. 1 32Khz External Oscillator clock is selected.
17 LCDINT	LCD interrupt enable. 0 Interrupt request is disabled. 1 Interrupt will be requested whenever EOFIF is set.
16 EOFIF	End of frame interrupt flag. End of frame interrupt flag bit is set every time when LCD is enabled or when NOF frames have been executed while LCDEN is set. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LCDINT = 1), EOFIF causes an interrupt request. 0 Defined via NOF bits frames have not been executed yet. 1 Defined via NOF bits frames have been executed.
15–8 NOF	Number of frames. The number of frames bits determine how many frames are counted until an interrupt will be requested. The possible number of frames are: 0x00 An interrupt is requested at the end of every frame 0x01 An interrupt is requested at the end of every second frame. .... and so on up to 0xFF An interrupt is requested at the end of every 256th frame

Table continues on the next page...

## LCD\_LCDCR field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 LCDBPA	Backplane Adding. If set, the backplanes, which are not available in standard configuration, will be mapped on frontplanes as shown in <a href="#">Table 16-26</a> . Hence, up to 8 backplanes can be used to drive LCD displays.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
LCDBPS	Backplane Shifting. Using these bits, backplanes will be swapped with frontplanes as shown in <a href="#">Table 16-26</a> .

## 16.2.3.2 LCD Prescaler Control Register (LCD\_LCDPCR)

Address: 400B\_E000h base + 4h offset = 400B\_E004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## LCD\_LCDPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 LCLK	LCD Clock Prescaler. The LCD Clock Prescaler bits determine the clock divider value to produce the LCD Clock Frequency. For detailed description of the correlation between LCD Clock Prescaler bits and the divider value please refer to <a href="#">Table 16-25</a> . LCD Clock Prescaler bits should be changed only when LCD Driver is disabled, LCDEN is not set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 16.2.3.3 LCD Contrast Control Register (LCD\_LCDCCR)

Address: 400B\_E000h base + 8h offset = 400B\_E008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CCEN	0					LCC									
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### LCD\_LCDCCR field descriptions

Field	Description
31 CCEN	LCD Contrast Control Enable. 0 The Contrast Control is disabled. 1 The Contrast Control is enabled. The length of the contrast phase depends on the bits LCC.
30–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 LCC	LCD Contrast Control. The Contrast Control bits determine the width of the contrast phase. 0x7FF=Contrast Phase lasts the whole duty cycle. 0x000=Contrast Phase has no duration which results in highest contrast.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 16.2.3.4 LCD Frontplane Enable Register 0 (LCD\_ENFPR0)

Address: 400B\_E000h base + 10h offset = 400B\_E010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ENFP																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## LCD\_ENFPR0 field descriptions

Field	Description
ENFP	<p>Frontplane Output Enable.</p> <p>The ENFP[31:0] bits enable the frontplane driver outputs. If LCDEN = 0, these bits have no effect on the state of the I/O pins. It is recommended to set ENFP[31:0] bits before LCDEN is set.</p> <p>1 Frontplane driver output enabled on FP[31:0].  0 Frontplane driver output disabled on FP[31:0].</p>

## 16.2.3.5 LCD Frontplane Enable Register 1 (LCD\_ENFPR1)

Address: 400B\_E000h base + 14h offset = 400B\_E014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## LCD\_ENFPR1 field descriptions

Field	Description
ENFP	<p>Frontplane Output Enable.</p> <p>The ENFP[63:32] bits enable the frontplane driver outputs. If LCDEN = 0, these bits have no effect on the state of the I/O pins. It is recommended to set ENFP[63:32] bits before LCDEN is set.</p> <p>1 Frontplane driver output enabled on FP[63:32].  0 Frontplane driver output disabled on FP[63:32].</p> <p><b>NOTE:</b> The implemented ENFP[n-1] bits depend on the number of implemented frontplanes.</p>

## 16.2.3.6 LCDRAM (Location 0) (LCD\_LCDRAM0)

Address: 400B\_E000h base + 20h offset = 400B\_E020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## LCD\_LCDRAM9 field descriptions

Field	Description
31–24 FP36_BP	LCD segment ON. The FP36BP[7:0] bit displays (turns on) the LCD segment connected between FP36 and BP[7:0].  1 LCD segment ON 0 LCD segment OFF
23–16 FP37_BP	LCD segment ON. The FP37 BP[7:0] bit displays (turns on) the LCD segment connected between FP37 and BP[7:0].  1 LCD segment ON 0 LCD segment OFF
15–8 FP38_BP	LCD segment ON. The FP38BP[7:0] bit displays (turns on) the LCD segment connected between FP38 and BP[7:0].  1 LCD segment ON 0 LCD segment OFF
FP39_BP	LCD segment ON. The FP39 BP[7:0] bit displays (turns on) the LCD segment connected between FP39 and BP[7:0].  1 LCD segment ON 0 LCD segment OFF.

## 16.2.4 Functional Description

This section describes frontplane, backplane, LCD System During Reset, LCD clock and frame frequency, contrast adjustment, LCD driver system enable and frontplane enable sequencing.

### 16.2.4.1 Frontplane, Backplane, and LCD System During Reset

During a reset the following conditions exist:

- All frontplane enable bits, ENFP[ $n-1:0$ ] are cleared and the ON/OFF control for the display, the LCDEN bit is cleared, thereby forcing all frontplane and backplane driver outputs to the high impedance state. The pin state during reset is defined by the port control module.
- The LCD64F6B system is configured in the default mode, 1/1 duty and 1/1 bias, that means only BP0 is used, system clock as reference.

### 16.2.4.2 LCD Clock and Frame Frequency

The frequency of the clock and the clock divider determine the LCD Clock Frequency. The input clock for the prescaler can be selected by LCDRCS bit. The divider is set by the LCD Clock Prescaler bits in the LCD Prescaler Control Register as shown in the following table.

**Table 16-25. Clock Divider**

LCLK	Divider
0000	480
0001	2 * 480
0010	2 <sup>2</sup> * 480
0011	2 <sup>3</sup> * 480
0100	2 <sup>4</sup> * 480
0101	2 <sup>5</sup> * 480
0110	2 <sup>6</sup> * 480
0111	2 <sup>7</sup> * 480
1000	2 <sup>8</sup> * 480
1001	2 <sup>9</sup> * 480
1010	2 <sup>10</sup> * 480
1011	2 <sup>11</sup> * 480
1100	2 <sup>12</sup> * 480
1101	2 <sup>13</sup> * 480
1110	2 <sup>14</sup> * 480
1111	2 <sup>15</sup> * 480

The following formula may be used to calculate the LCD frame frequency:

$$\text{LCDFrameFrequency(Hz)} = \left\lfloor \frac{\text{OSCCLK(Hz)}}{\text{Divider}} \right\rfloor$$

#### Equation 3

Example: Clock = 16 MHz, Prescaler = 1010;

$$\left\lfloor \frac{16 \cdot 10^6}{2^{10} \cdot 480} \right\rfloor \approx 33\text{Hz}$$

#### Equation 4

#### Note

A "Frame" is the full refresh cycle of the display. See [LCD Waveform Examples](#) for waveform illustrations.

### 16.2.4.3 Contrast Adjustment

The LCD Driver module offers two different ways to adjust contrast:

#### 16.2.4.3.1 Adjusting the supply voltage (VDDE)

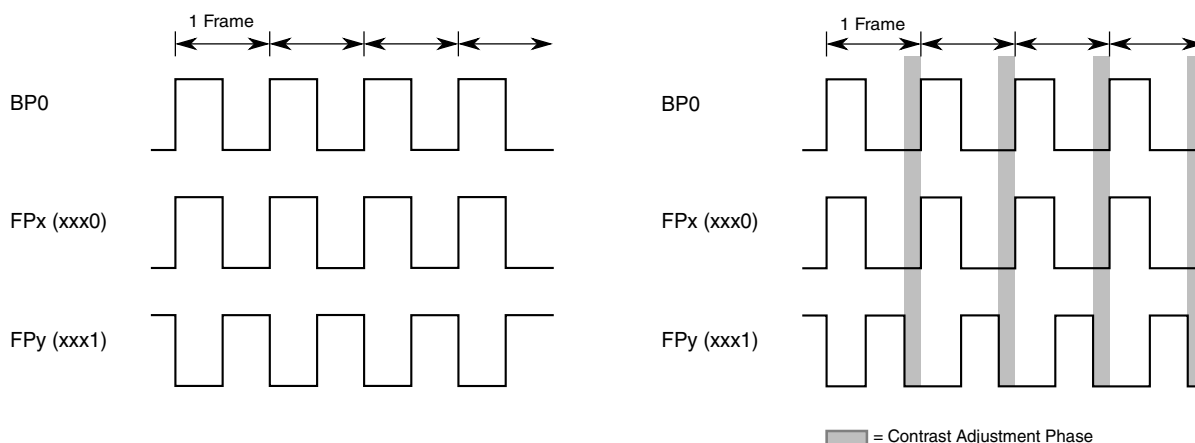

The VDDE voltage is directly used as reference and source to drive the LCD segments. The contrast could be adjusted by altering the voltage VDDE, but be aware that this voltage is used for the padding also.

#### 16.2.4.3.2 Adding Contrast Adjustment Phases

Another way to adjust the contrast is to add another phase to the refresh cycle which keeps the voltage the same on all frontplane and backplane electrodes ( $V_{SS}$  in this case). This will contribute towards lowering the  $V_{ONRMS}$  and  $V_{OFFRMS}$  voltages over the segment. For this reason, the whole frame is divided into steps. The value from the Contrast Control register (LCC) determines how many of these steps are taken by the contrast phase. Whenever the length of the contrast adjustment phase is changed, the length of the other phases is automatically changed to ensure the frame length remains the same.

Example: A value of 256 in the Contrast Control (LCC) register will force the contrast phase to take approximately a 256/2047 of the length of the whole frame.

The figure below shows an example of waveform with 1/1 duty and 1/1 bias ratios with the additional contrast adjustment phases

**Figure 16-29. Contrast Adjustment Phases**

### Note

RMS stands for root mean square and is a statistical measure of the magnitude of a varying quantity. It is calculated with the formula:

$$V_{\text{RMS}} = \sqrt{\frac{\int_0^T V^2 dt}{T}}$$

**Equation 5**

#### 16.2.4.4 LCD RAM

For a segment on the LCD to be displayed, data must be written to the LCD RAM. The bits in the LCD RAM correspond to the segments that are driven by the frontplane and backplane drivers. Writing a '1' to a given location will result in the corresponding display segment being driven with a differential RMS voltage, based on selected reference, necessary to turn the segment ON when the LCDEN bit is set and the corresponding ENFP[*n*-1:0] bit is set. Writing a '0' to a given location will result in the corresponding display segment being driven with a differential RMS voltage necessary to turn the segment OFF. The LCD RAM is a dual port RAM that interfaces with the internal address and data buses of the MCU. It is possible to read from LCD RAM locations for scrolling purposes. Writing or reading of the LCDEN bit does not change the contents of the LCD RAM. After a reset, the LCD RAM contents will be cleared.

#### 16.2.4.5 LCD Driver System Enable and Frontplane Enable Sequencing

If LCDEN = 0 (LCD Driver System disabled) and the frontplane enable bit, ENFP[*n*-1:0], is set, the frontplane driver waveform will not appear on the output until LCDEN is set. If LCDEN = 1 (LCD Driver System enabled), the frontplane driver waveform will appear on the output as soon as the corresponding frontplane enable bit, ENFP[*n*-1:0], in the registers ENFPR0 and ENFPR1 is set.

#### 16.2.4.6 LCD Driver Backplane Remapping

The backplane and frontplane pins can be remapped/swapped using LCDBPS and LCDBPA. While LCDBPA adds the non available backplane waveforms onto FP pins, LCDBPS does a swapping of backplanes waveforms with frontplanes waveforms on

selected pins. The swapping of LCDBPS depends on the availability of Frontplane pins FP[n-1:0]. If the number of frontplanes n implemented is not sufficient no remapping will occur. See the following table for details.

**Table 16-26. Backplane Remapping**

LCDBPS	Condition: FP[n-1:0]	Remapping LCDBPA[1:0]=00 or LCDBPA[1:0]=11 BP[m-1:0]	Remapping LCDBPA[1:0]=01BP[m-1:0]	Remapping LCDBPA[1:0]=10BP[m-1:0]
000		no remapping	FP[5-m:0] <- BP[5:m] if m=6 no remapping	FP[7-m:0] <- BP[7:m] if m=8 no remapping
001		BP[m-1:0] <- FP[m-1+4:4] FP[m-1+4:4] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+4:4] FP[5+4:4] <- BP[5:0]	BP[m-1:0] <- FP[m-1+4:4] FP[7+4:4] <- BP[7:0]
010		BP[m-1:0] <- FP[m-1+12:12] FP[m-1+12:12] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+12:12] FP[5+12:12] <- BP[5:0]	BP[m-1:0] <- FP[m-1+12:12] FP[7+12:12] <- BP[7:0]
011		BP[m-1:0] <- FP[m-1+20:20] FP[m-1+20:20] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+20:20] FP[5+20:20] <- BP[5:0]	BP[m-1:0] <- FP[m-1+20:20] FP[7+20:20] <- BP[7:0]
100	n=36 or n>36	BP[m-1:0] <- FP[m-1+28:28] FP[m-1+28:28] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+28:28] FP[5+28:28] <- BP[5:0]	BP[m-1:0] <- FP[m-1+28:28] FP[7+28:28] <- BP[7:0]
101	n=44 or n>44	BP[m-1:0] <- FP[m-1+36:36] FP[m-1+36:36] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+36:36] FP[5+36:36] <- BP[5:0]	BP[m-1:0] <- FP[m-1+36:36] FP[7+36:36] <- BP[7:0]
110	n=52 or n>52	BP[m-1:0] <- FP[m-1+44:44] FP[m-1+44:44] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+44:44] FP[5+44:44] <- BP[5:0]	BP[m-1:0] <- FP[m-1+44:44] FP[7+44:44] <- BP[7:0]
111	n=60 or n>60	BP[m-1:0] <- FP[m-1+52:52] FP[m-1+52:52] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+52:52] FP[5+52:52] <- BP[5:0]	BP[m-1:0] <- FP[m-1+52:52] FP[7+52:52] <- BP[7:0]

#### Examples:

1. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 000 and LCDBPA is set to 01

Frontplanes FP[39:2] and BP[3:0] will stay the same, but FP[1:0] pins will controlled by BP[5:4] functionality.

2. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 010 and LCDBPA is set to 00

Frontplanes FP[39:16] and FP[11:0] will stay the same, but FP[15:12] pins are swapped with BP[3:0].

3. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 010 and LCDBPA is set to 01

Frontplanes FP[39:18] and FP[11:0] will stay the same. FP[15:12] pins are swapped with BP[3:0]. FP[17:16] is replaced by BP[5:4] functionality.

4. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 101 and LCDBPA is set to 01

No remapping: Frontplanes FP[39:0] and BP[3:0] will stay the same, because condition  $n \geq 44$  is not fulfilled.

### 16.2.4.7 LCD Bias and Modes of Operation

The LCD64F6B driver has seven modes of operation:

- 1/1 Duty (1 backplane), 1/1 Bias (2 voltage levels)
- 1/2 Duty (2 backplanes), 1/2 Bias (3 voltage levels)
- 1/2 Duty (2 backplanes), 1/3 Bias (4 voltage levels)
- 1/3 Duty (3 backplanes), 1/3 Bias (4 voltage levels)
- 1/4 Duty (4 backplanes), 1/3 Bias (4 voltage levels)
- 1/5 Duty (5 backplanes), 1/3 Bias (4 voltage levels)
- 1/6 Duty (6 backplanes), 1/3 Bias (4 voltage levels)
- 1/8 Duty (8 backplanes), 1/3 Bias (4 voltage levels)

The voltage levels required for the different operating modes are generated internally based on selected reference voltage. VDDE is used as reference and supply. Changing VDDE alters the differential RMS voltage across the segments in the ON and OFF states, thereby changing the display contrast. The 1/3 Bias for an 1/8 Duty has more or less identical  $V_{onrms}/V_{offrms}$  ratio like 1/4 Bias. Therefore the 1/3 Bias is supported for 1/8 Duty segment LCDs due to its advantage regarding lower power consumption. Segment LCDs with more than 8 backplanes are not recommended to be used with this driver.

The backplane waveforms are continuous and repetitive every frame. They are fixed within each operating mode and are not affected by the data in the LCD RAM.

The frontplane waveforms generated are dependent on the state (ON or OFF) of the LCD segments as defined in the LCD RAM. The LCD driver hardware uses the data in the LCD RAM to construct the frontplane waveform to create a differential RMS voltage necessary to turn the segment ON or OFF.

The LCD duty is decided by the DUTY bits in the LCD Control Register (LCDCR). The number of bias voltage levels is determined by the BIAS bit in the LCDCR. The following table summarizes the Multiplex modes (duties) and the bias voltage levels that

can be selected for each multiplex mode (duty). The backplane pins have their corresponding backplane waveform output BP[ $m-1:0$ ] in high impedance state when in the OFF state as indicated in the following table. In the OFF state the corresponding pins BP[ $m-1:0$ ] can be used for other functionality.

**Table 16-27. LCD Duty and Bias**

	LCD CR Register	Backplanes								Bias Level	
Dut y	DUTY	BP7	BP6	BP5	BP4	BP3	BP2	BP1	BP0	BIAS=0	BIAS=1
1/1	000	OFF							ON	1/1	
1/2	001	OFF						ON		1/2	1/3
1/3	010	OFF					ON			1/3	
1/4	011	OFF				ON				1/3	
1/5	100	OFF			ON					1/3	
1/6	101	OFF		ON						1/3	
1/6	110	OFF		ON						1/3	
1/8	111	ON								1/3	

## 16.2.4.8 Operation in Power Saving Modes

### 16.2.4.8.1 Operation in STOP mode

The LCD64F6B system operation during STOP mode is controlled by the LCDRST bit in the LCD Control Register (LCD CR).

If the LCD64F6B is requested to enter STOP mode and LCDRST is cleared while LCDEN is set the LCD waveform generation clocks are stopped and the LCD64F6B drivers pull down to ground those frontplane and backplane pins that were enabled before entering STOP mode. The contents of the LCD RAM and the LCD registers retain the values they had prior to entering stop mode.

If LCDRST is set while LCDEN is set and the LCD64F6B is requested to enter STOP mode the LCD waveform generation is continued.

### 16.2.4.8.2 Operation in LPSTOP Mode

The LCD64F6B system operation during LPSTOP Mode is controlled by the LCDRST bit in the LCD Control Register (LCD CR).

If the LCD64F6B is not powered down by the system, and is requested to enter LPSTOP Mode and LCDRST is cleared while LCDEN is set the LCD waveform generation clocks are stopped and the LCD64F6B drivers pull down to ground those frontplane and backplane pins that were enabled before entering LPSTOP Mode. The contents of the LCD RAM and the LCD registers retain the values they had prior to entering LPSTOP Mode.

If the LCD64F6B is not powered down by the system, and is requested to enter LPSTOP Mode and LCDRST is set while LCDEN is set the LCD waveform generation is continued.

### Note

The user needs to take care that the system keeps the clock applied to the running LCD64F6B module during all modes where it is enabled. If no clock is applied while the LCD64F6B module is running the LCD could be damaged.

## 16.2.4.9 Other Power Saving

The LCD64F6B has features to adjust the frontplane & backplane drive strength and to boost the drive strength while the planes are switching.

### 16.2.4.9.1 LCD Reference Clock Select

Using LCDRCS the LCD reference clock can be selected. If LCDRCS is cleared, the system clock is applied as reference clock to the prescaler input. If LCDRCS is set, the source clock for LCD Driver system (prescaler input) is SXOSC clock. Selecting the lower power consuming clock of both as reference clock for the prescaler input can save power consumption.

### 16.2.4.9.2 Boost at Switching

Since the LCD appears like a capacitance to the driver it is sometimes useful to boost the output current during transitions to increase the slew rate of the driver. If boosting is enabled, the drive strength capability is increased a little ahead in time when the planes are switching, and reduced again to normal drive after a certain time. To enable the boosting BSTEN need to be set. If BSTEN is not set, standard drive strength is used.

Using the BST bit if BSTEN is set, LCD output current magnification (boost) can be selected. Available is 8 times boosting, when BST is deasserted and 16 times boosting when BST is asserted.

The selected boost via BST bit can be switched to be always on by setting BSTAO, if BSTEN is set.

### 16.2.4.9.3 Standard Drive Selection

The output current has a direct impact on the power consumption and drive capability of the LCD64F6B module. The PWR bits select the output current height and can be used to influence power consumption and drive strength. The following table lists the possible selections of PWR.

**Table 16-28. Output Current Selection (PWR)**

PWR	Current
00	Standard Current
01	2 * Standard Current
10	3 * Standard Current
11	4 * Standard Current

### 16.2.4.9.4 Usage Recommendation

It is recommended to start with maximum output current and maximum enabled boosting. As long as the LCD is fully functional in all environments a reduction of Output Current and boosting can be done.

When reducing the Output Current (PWR), the power consumption of the LCD module and the maximum switching current of the planes is reduced.

When reducing or disabling the boosting (BST,BSTEN), the output current, while planes are switching, is reduced.

The user can select any combination of PWR, BST, BSTEN, BSTAO to best fit their needs. The following figure gives an overview of the impact when taking advantage of [Boost at Switching](#) and [Standard Drive Selection](#).

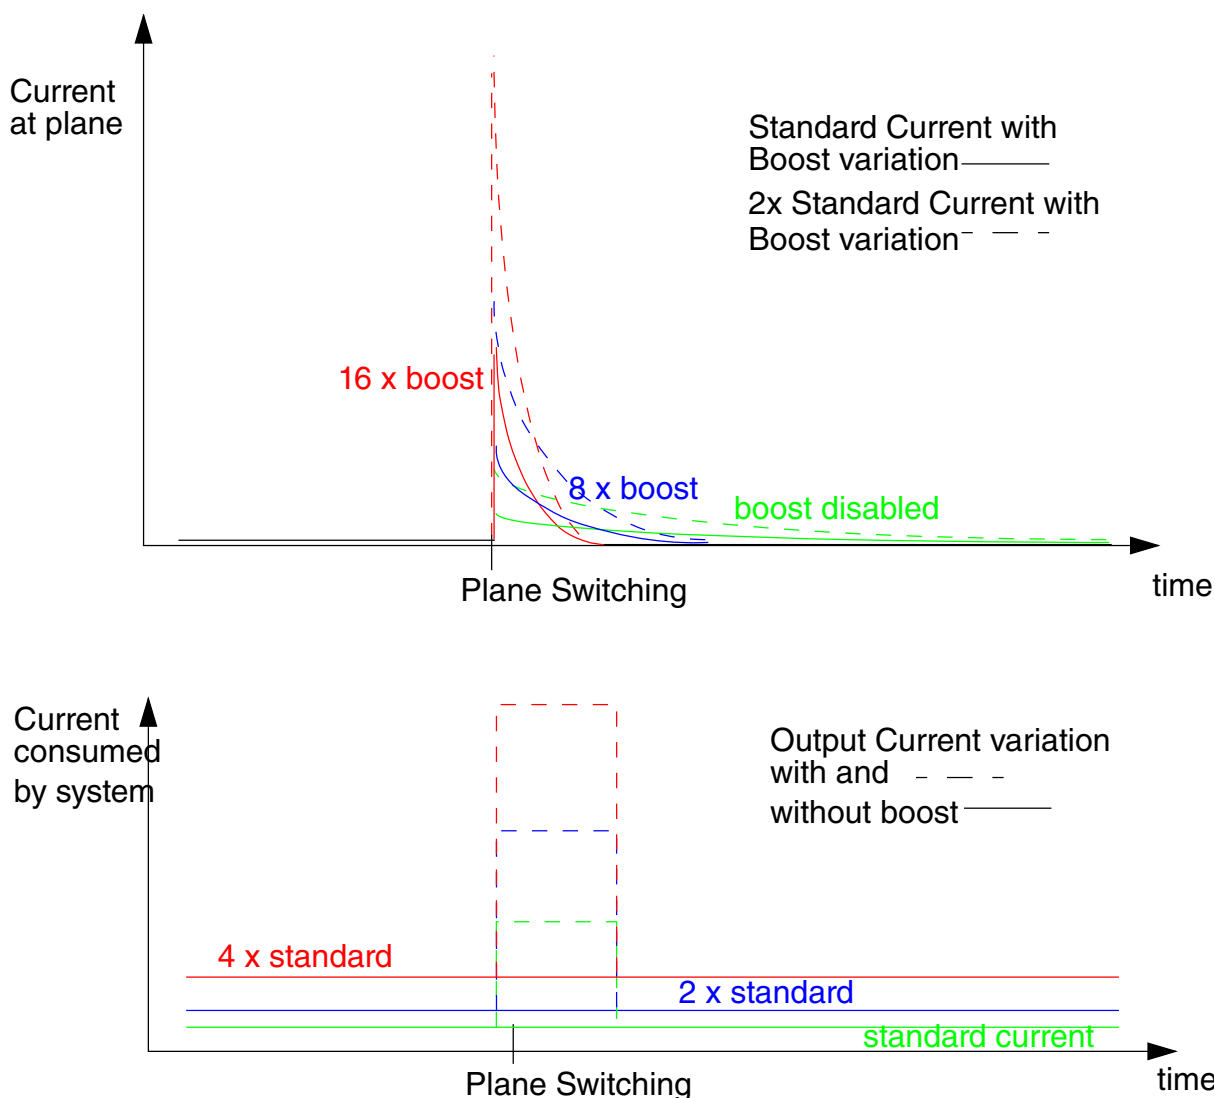

Figure 16-30. PWR, BST, BSTEN Example Diagram

## 16.2.4.10 Interrupts

This section describes all interrupts originated by LCD64F6B.

### 16.2.4.10.1 EOF Interrupt

LCDEN must be set to enable the interrupt at end of frame feature. Every time a frame generation was completed a counter is decremented by 1. If the counter reaches zero End of Frame interrupt Flag (EOFIF) bit is set and the counter is reset to NOF. The counter is reset to request interrupt at the end of every frame, as if NOF would be 0x00, if LCDEN is asserted while the LCD is off.

The EOFIF flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LCDINT = 1), EOFIF causes an interrupt request. The number of frames (NOF) bits determine how many frames are count until EOFIF flag is set. The possible number of frames are:

NOF= 0x00: An interrupt is requested at the end of every frame.

NOF= 0x01: An interrupt is requested at the end of every second frame.

NOF= 0x02: An interrupt is requested at the end of every third frame.

...

NOF= 0xFF: An interrupt is requested at the end of every 256th frame.

## 16.2.5 LCD Waveform Examples

The following figures show the timing examples of the LCD output waveforms for the available modes of operation. The contrast control is disabled in all examples (CCEN = 0 in LCDCCR). Reference voltage is VDDE.

### 16.2.5.1 1/1 Duty Multiplexed with 1/1 Bias Mode

Duty = 1/1:DUTY = 000

Bias = 1/1:BIAS = 0 or BIAS = 1

$V_0 = V_1 = VSSE$   $V_2 = V_3 = VDDE$

- Only BP0 is used, a maximum of 64 segments are displayed.

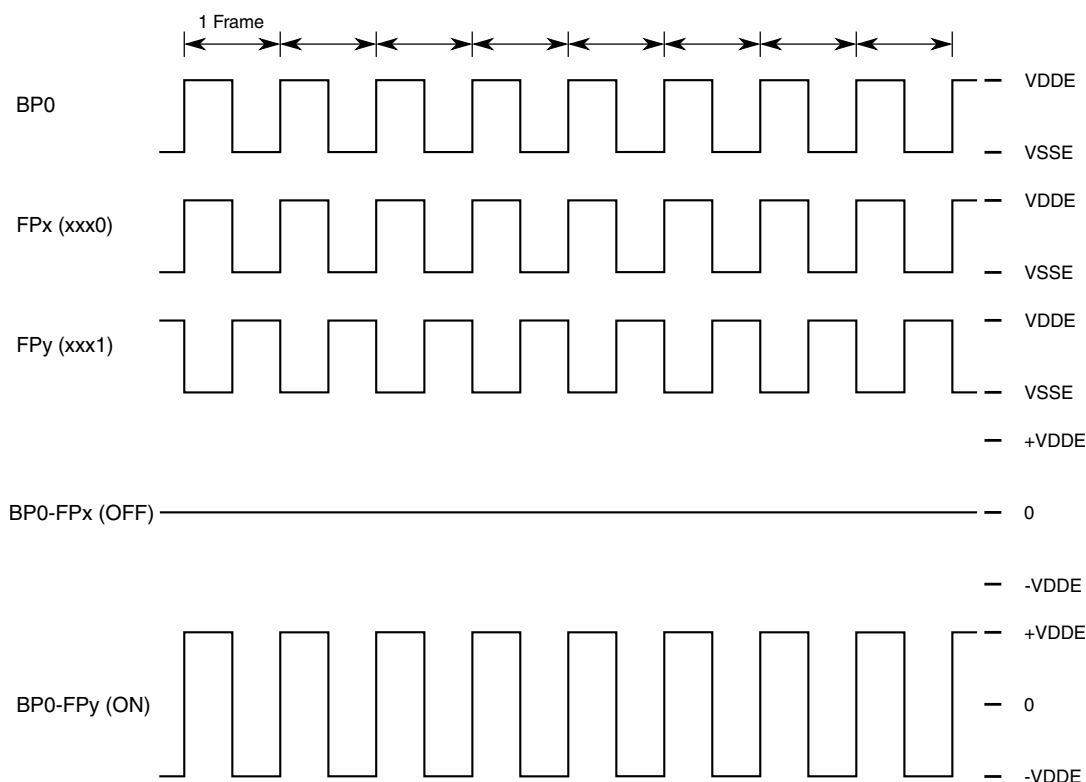

Figure 16-31. 1/1 Duty and 1/1 Bias

### 16.2.5.2 1/2 Duty Multiplexed with 1/2 Bias Mode

Duty = 1/2:DUTY = 001

Bias = 1/2:BIAS = 0

$V_0 = VSSE$ ,  $V_1 = VDDE * 1/3$ ,  $V_2 = VDDE * 2/3$ ,  $V_3 = VDDE$

- Only BP0 and BP1 are used, a maximum of 128 segments are displayed.

Figure 16-32. 1/2 Duty and 1/2 Bias

### 16.2.5.3 1/2 Duty Multiplexed with 1/3 Bias Mode

Duty = 1/2: DUTY = 001

Bias = 1/3: BIAS = 1

$V_0 = VSSE$ ,  $V_1 = VDDE \times 1/3$ ,  $V_2 = VDDE \times 2/3$ ,  $V_3 = VDDE$

- Only BP0 and BP1 are used, a maximum of 128 segments are displayed.

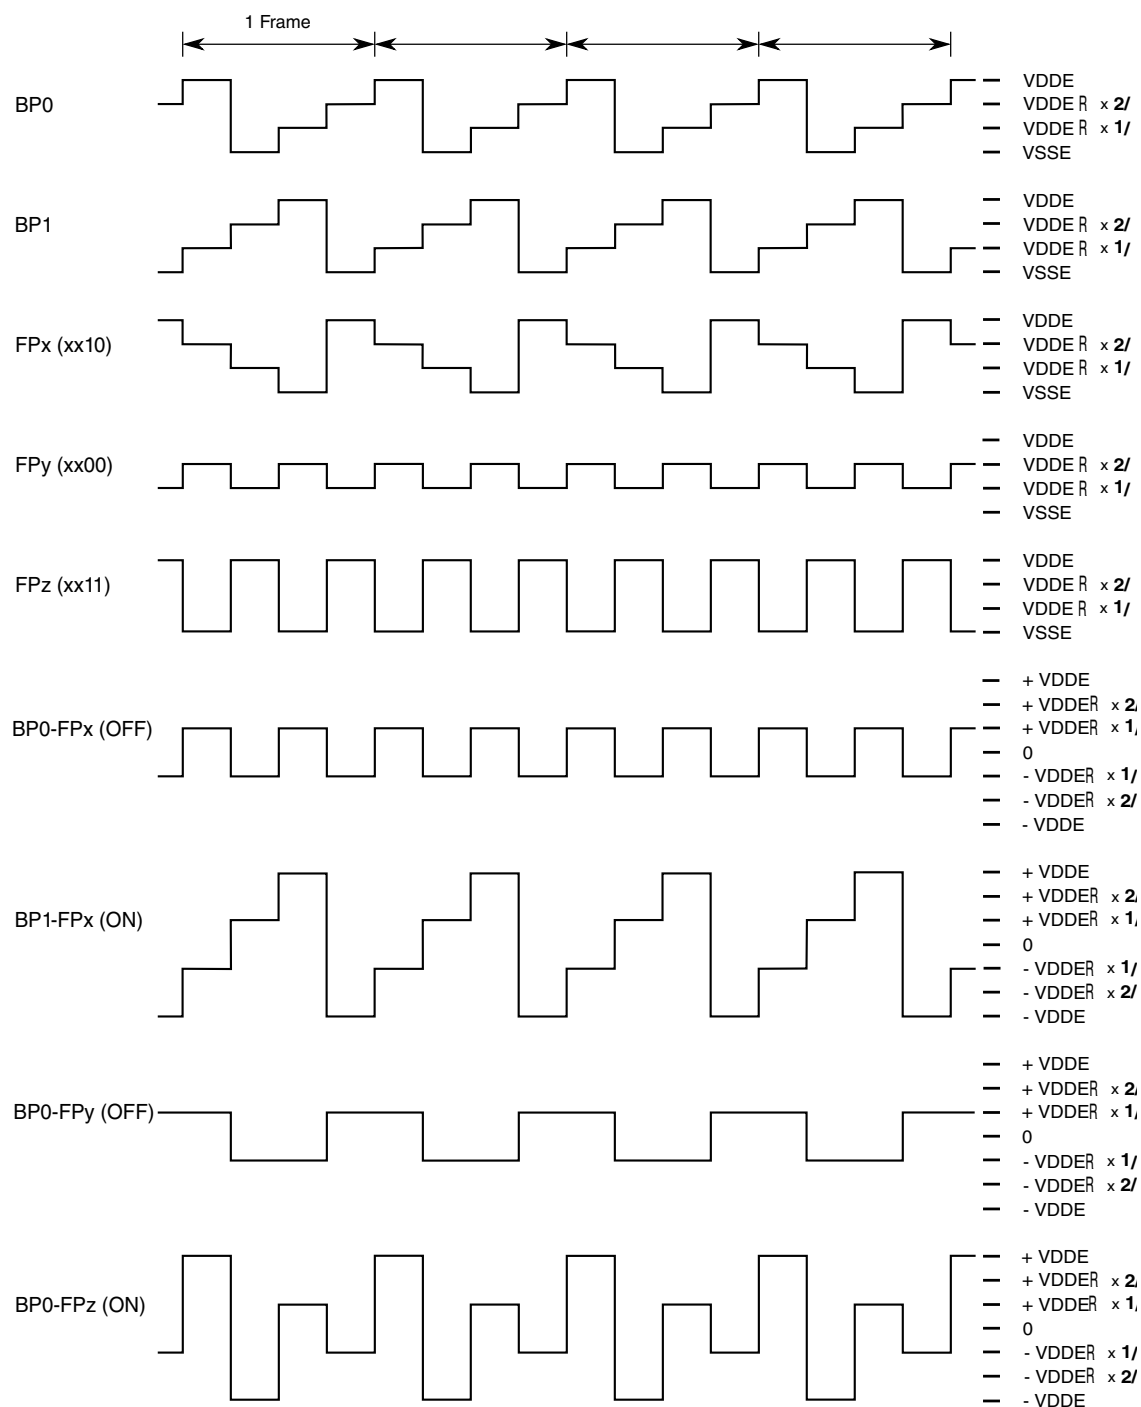

Figure 16-33. 1/2 Duty and 1/3 Bias

#### 16.2.5.4 1/3 Duty multiplexed with 1/3 Bias mode

Duty = 1/3: DUTY = 010

Bias = 1/3: BIAS = 0 or BIAS = 1

$$V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE$$

- Only BP0, BP1 and BP2 are used, a maximum of 192 segments are displayed.

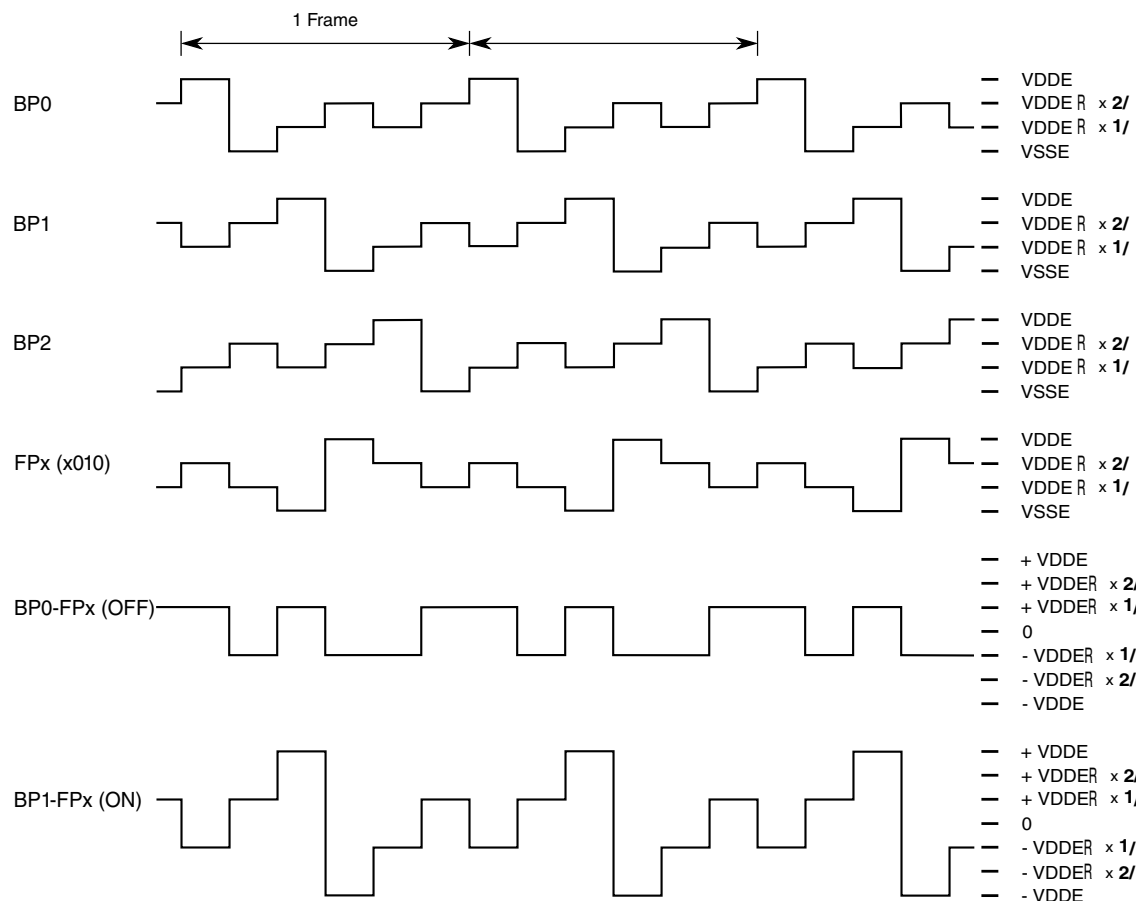

Figure 16-34. 1/3 Duty and 1/3 Bias

### 16.2.5.5 1/4 Duty multiplexed with 1/3 Bias mode

Duty = 1/4: DUTY = 011

Bias = 1/3: BIAS = 0 or BIAS = 1

$$V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE$$

- BP4 and BP5 are not used, a maximum of 256 segments are displayed.

Figure 16-35. 1/4 Duty and 1/3 Bias

### 16.2.5.6 1/5 Duty multiplexed with 1/3 Bias

Duty = 1/5: DUTY = 100

Bias = 1/3: BIAS = 0 or BIAS = 1

$V_0 = VSSE$ ,  $V_1 = VDDE \times 1/3$ ,  $V_2 = VDDE \times 2/3$ ,  $V_3 = VDDE$

- BP5 is not used, a maximum of 320 segments are displayed.

Figure 16-36. 1/5 Duty and 1/3 Bias

### 16.2.5.7 1/6 Duty multiplexed with 1/3 Bias mode

Duty = 1/5:DUTY = 101

Bias = 1/3:BIAS = 0 or BIAS = 1

$V_0 = VSSE$ ,  $V_1 = VDDE * 1/3$ ,  $V_2 = VDDE * 2/3$ ,  $V_3 = VDDE$

- All backplanes are used, a maximum of 384 segments are displayed.

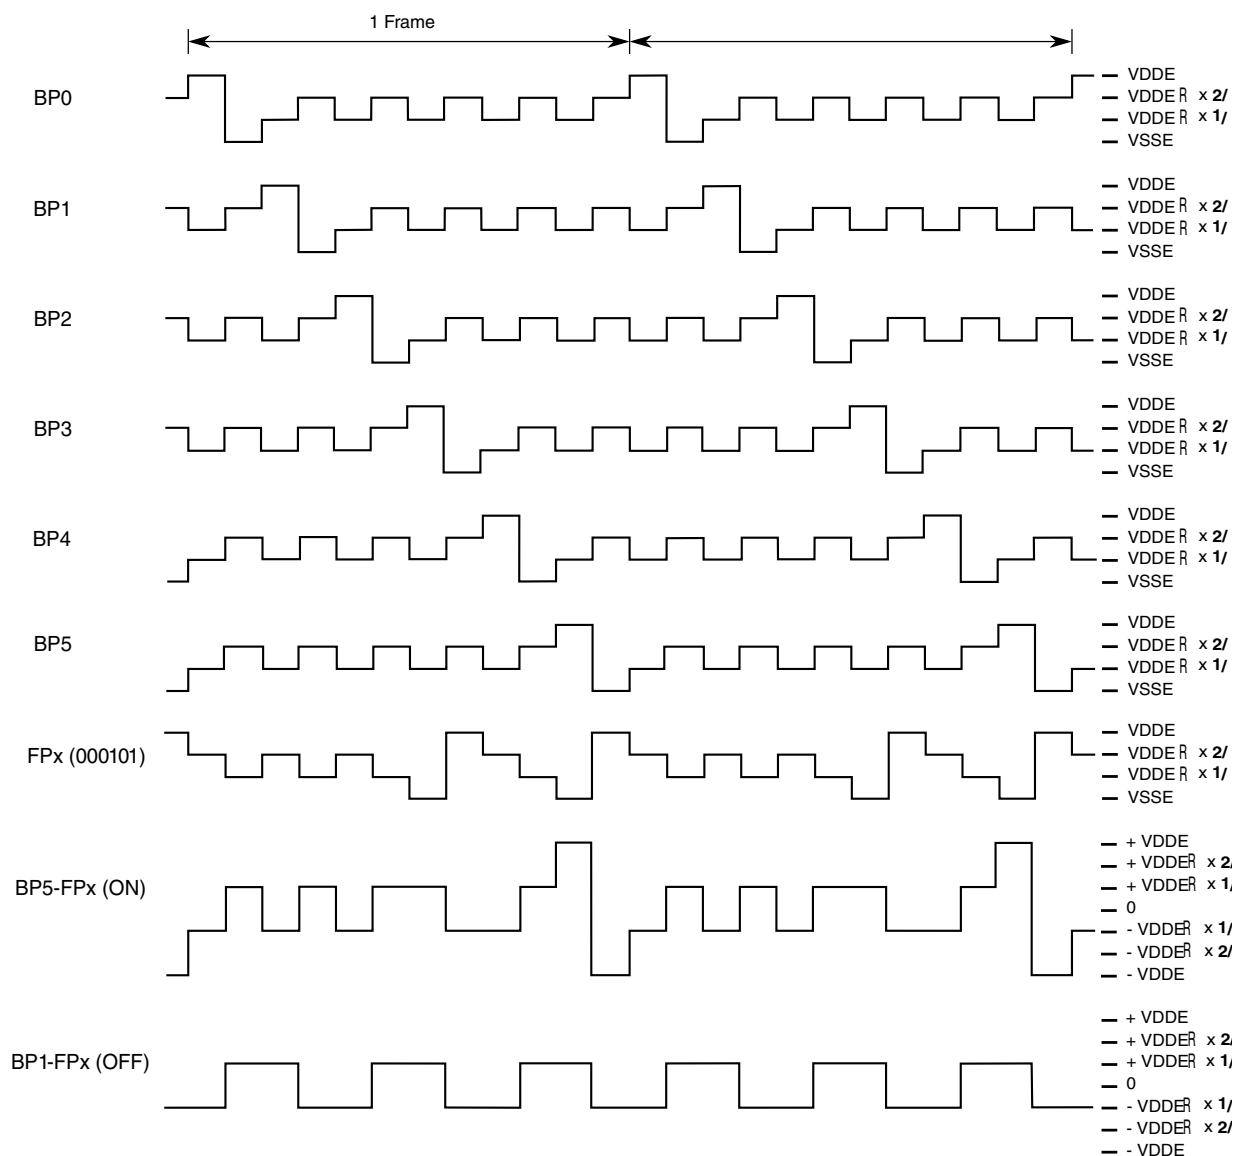

Figure 16-37. 1/6 Duty and 1/3 Bias

## 16.2.6 Initialization Information

This is a step-wise example for initializing the module. The initial values of all registers are the reset values.

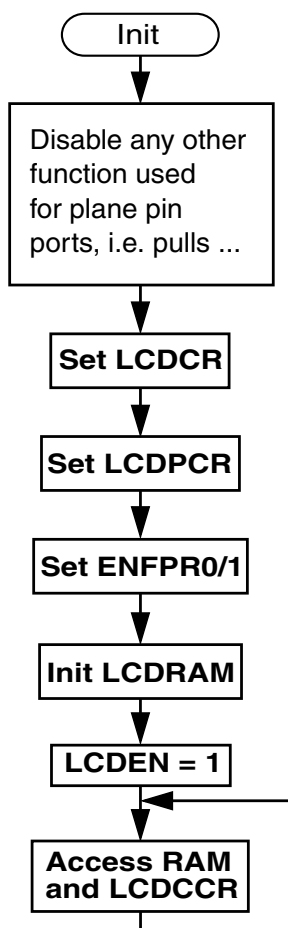

Figure 16-38. Example Initialization Diagram

## 16.3 Timing Controller (TCON)

### 16.3.1 Introduction

The Timing Controller module (TCON) provides an alternative interface for the Display Controller module (DCU4) that provides RGB data and timing signals for "raw" TFT panels which have no embedded TCON.

#### 16.3.1.1 Features

- Flexible timing generation unit supporting 12 timing signal channels
- Support bit mapping of 8-bit or 6-bit color depth
- Blanking of RGB data during inactive period (driven to all "0" or all "1")

### 16.3.1.2 Modes of Operation

The TCON has 2 operation modes:

- Bypass mode: the input signals are passed through, and the TCON is turned off
- TTL mode: the TCON is functional, driving parallel RGB output, and the TCON timing signals

### 16.3.2 Memory map and register definition

The memory map for the TCON module is given below. The total address for each register is the sum of the base address for the TCON module and the address offset for each register.

**TCON memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4003_D000	TCON control1 register (TCON0_CTRL1)	32	R/W	0000_000Ch	<a href="#">16.3.2.1/3491</a>
4003_D004	Bit map control register (TCON0_BMC)	32	R/W	0000_0000h	<a href="#">16.3.2.2/3493</a>
4003_D008	Comparator configure register (TCON0_COMP0)	32	R/W	0000_0FFFh	<a href="#">16.3.2.3/3494</a>
4003_D00C	Comparator configure register (TCON0_COMP1)	32	R/W	0000_0FFFh	<a href="#">16.3.2.3/3494</a>
4003_D010	Comparator configure register (TCON0_COMP2)	32	R/W	0000_0FFFh	<a href="#">16.3.2.3/3494</a>
4003_D014	Comparator configure register (TCON0_COMP3)	32	R/W	0000_0FFFh	<a href="#">16.3.2.3/3494</a>
4003_D018	Comparator compare value mask register (TCON0_COMP0_MSK)	32	R/W	0000_0FFFh	<a href="#">16.3.2.4/3495</a>
4003_D01C	Comparator compare value mask register (TCON0_COMP1_MSK)	32	R/W	0000_0FFFh	<a href="#">16.3.2.4/3495</a>
4003_D020	Comparator compare value mask register (TCON0_COMP2_MSK)	32	R/W	0000_0FFFh	<a href="#">16.3.2.4/3495</a>
4003_D024	Comparator compare value mask register (TCON0_COMP3_MSK)	32	R/W	0000_0FFFh	<a href="#">16.3.2.4/3495</a>
4003_D028	Pulse configure register (TCON0_PULSE0)	32	R/W	0FFF_0FFFh	<a href="#">16.3.2.5/3496</a>
4003_D02C	Pulse configure register (TCON0_PULSE1)	32	R/W	0FFF_0FFFh	<a href="#">16.3.2.5/3496</a>

*Table continues on the next page...*

## TCON memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

R	INIT_DELAY				V_REF_SEL			H_REF_SEL		VLEN		HSYNC_INV	VSYNC_INV	COLOR_DEPTH	RGB_PADDING_EN	RGB_PADDING
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

## TCONx\_CTRL1 field descriptions

Field	Description
31 TCON_EN	

Table continues on the next page...

**TCONx\_CTRL1 field descriptions (continued)**

Field	Description
	<p><b>NOTE:</b> Program the TCON_CTRL1 register to configure the operation mode of TCON and enable TCON (It is recommended to do this in two steps, and set TCON_EN in the second).</p> <p>0 Disable TCON. 1 enable TCON.</p>
30 RESERVED	This field is reserved.
29 TCON_BYPASS	<p>Controls whether TCON is bypassed.</p> <p>0 Not bypass TCON. State of the TCON is decided by TCON_EN. 1 Bypass TCON, both data and timing signals will pass through the TCON unmodified. see the "Bypass Mode" section for pin mapping in that mode.</p>
28 INV_EN	<p>The input pixel (n) is compared with pixel (n-1). If more than half of the RGB data bits toggle, the pixel (n) output will be inverted and the tcon_out[11] flags this data inversion to the gray scale reference. tcon_out[11] =1 -&gt; data_out is inverted, tcon_out[11] =0 -&gt; data_out is not inverted. Intention of this feature is for board level EMI reduction.</p> <p>0 Disable output data inversion 1 Enable output data inversion</p>
27-16 TCONx_INV	<p>TCONx output inversion control</p> <p>0 do not invert tconx 1 invert output tconx</p>
15-13 INIT_DELAY	(INIT_DELAY[2:0]) Initialization delay, set the number of frames before the TCON starts to output timing signals.
12-10 V_REF_SEL	<p>(V_REF_SEL[2:0]) v_ref selector, please refer to the "Toggle generator" section for use of v_ref signal. Note: pulse generated must be vertical based for the toggle generator.</p> <p>000 select tcon_pulse0 output as v_ref 001 select tcon_pulse1 output as v_ref 010 select tcon_pulse2 output as v_ref 011 select tcon_pulse3 output as v_ref 100 select tcon_pulse4 output as v_ref 101 select tcon_pulse5 output as v_ref 110 select tcon_pulse0 output as v_ref, while reset vtgl_counter and vtgl[3] to 0 at rising edge of v_ref. 111 select tcon_pulse0 output as v_ref, while set vtgl_counter to 1 and reset vtgl[3] to 0 at rising edge of v_ref.</p>
9-8 H_REF_SEL	<p>(H_REF_SEL[2:0]) h_ref selector, please refer to the "Toggle generator" section for use of h_ref signal.</p> <p>00 select tcon_comp0 output as h_ref. 01 select tcon_comp1 output as h_ref. 10 select tcon_comp2 output as h_ref. 11 select tcon_comp3 output as h_ref.</p>
7-6 VLEN	(VLEN[1:0]) Maximum counter value for vtgl_counter in the toggle generator. Please refer to to the "Toggle generator" section for detailed functionality of this field.
5 HSYNC_INV	<p>Horizontal sync.</p> <p>0 hsync_in signal is active high 1 hsync_in signal is active low</p>

Table continues on the next page...

**TCONx\_CTRL1 field descriptions (continued)**

Field	Description
4 VSYNC_INV	Vertical sync. 0 vsync_in signal is active high 1 vsync_in signal is active low
3 COLOR_DEPTH	Color depth of each color component 0 6 bits, the 2 LSB's are set to 2'b0 1 8 bits
2 RGB_PADDING_EN	RGB data padding enable 0 disable padding during blanking 1 enable padding during blanking
1 RGB_PADDING	RGB data driven during blanking. 0 all "0" 1 all "1"
0 RESERVED	This field is reserved. Always write the reset value to this field.

**16.3.2.2 Bit map control register (TCONx\_BMC)**

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	Reserved																
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**TCONx\_PULSEn field descriptions**

Field	Description
31–30 FUNC_SEL	(FUNC_SEL[1:0]) Select the type of pulse, horizontal/vertical/or mix 00 SET/RESET value both for horizontal compare 01 SET/RESET value both for vertical compare, signal transition point determined by COMPARATOR_SEL 10 SET/RESET value both for vertical compare, signal transitions at the beginning of the line which is matched. 11 SET value for horizontal compare, RESET value for vertical compare. Signal transition point for RESET determined by COMPARATOR_SEL.
29–28 RESERVED	This field is reserved.
27–16 SET	(SET[11:0]) Set point compare value Note: There will be a two pixel clock cycle delay between the internal pixel counter and the output pixel data in horizontal direction, user should take this two cycle delay into account when programming this field. See the "Pulse generator" section for a detailed explanation.
15–14 COMPARATOR_SEL	(COMPARATOR_SEL[1:0]) When FUNC_SEL is set to 01, 1 of the 4 comparator outputs is selected to define the horizontal change point for both SET/RESET. When FUNC_SEL is set to 11, 1 of the 4 comparator outputs is selected to define the horizontal change point for RESET. Note: when FUNC_SEL set to 01 or 11, user should program the corresponding comparator for horizontal compare to ensure the timing signal is generated as expected. 00 select comparator0 01 select comparator1 10 select comparator2 11 select comparator3

*Table continues on the next page...*

TCONx\_PULSE<sub>n</sub> field descriptions (continued)

Field	Description
13–12 RESERVED	This field is reserved.
RESET	(RESET[11:0]) Reset point compare value  Note: There will be a two pixel clock cycle's delay between the internal pixel count and the output pixel data in horizontal direction, user should take this two cycle delay into account when programming this field. See the "Pulse generator" section for a detailed explanation.

16.3.2.6 Pulse compare value mask register (TCONx\_PULSE<sub>n</sub>\_MSK)

Address: Base address + 40h offset + (4d × i), where i=0d to 5d

#### TCONx\_CTRL2 field descriptions

Field	Description
31–25 RESERVED	This field is reserved.
24–16 CLK_OFFSET	(CLK_OFFSET[8:0]) Output pixel clock offset value in half ipg_clk cycle unit. please refer to the "Clock/Data Skew Adjustment" section for use of this field. The valid range of this field is to 0 to 2N-1 in TTL mode, where N=(DIV_RATIO+1).
15–8 RESERVED	This field is reserved.
DIV_RATIO	(DIV_RATIO[7:0]) TCON pixel clock divide ratio. When DIV_RATIO set to N, pix_clk will be ipg_clk divided by N+1.

## 16.3.3 Functional Description

The major functions of the TCON are to generate timing signals needed to drive the external row drivers and column drivers, and map the RGB data bits to output pins. It accepts RGB data, Horizontal/Vertical synchronization signals from the module, maintains two internal counters (x\_count, and y\_count), and uses these to generate the timing signals. In order to support as many types of panels as possible, the timing generation unit has been designed to be flexible and can be configured freely to generate complicated timing signals. See [Timing signal generator](#) for details about the timing signal generation unit.

The TCON has two operation modes: TTL mode, and bypass mode. In bypass mode the input signals are passed through the TCON unchanged, and in TTL mode the TCON performs signal (the RGB data and pixel clock) bit mapping. For details of the operation modes see [Modes of operation](#), and for the signal bit mapping see [Bit Mapping Control \(BMC\)](#).

### 16.3.3.1 Modes of operation

Various operation modes are discussed below.

### 16.3.3.1.1 TTL mode

In TTL mode the TCON drives the RGB data, pixel clock, and the TCON timing signals all via TTL interface. In this mode simple signal bit mapping is performed, see [Bit mapping in TTL mode](#).

It is also possible to assign the pixel clock to any one of the 25 output pins in TTL mode, see [Clock mapping in TTL mode](#).

To enable the TTL mode, the user shall set the TCON\_CTRL1[TCON\_BYPASS]='0', and TCON\_CTRL1[TCON\_EN]='1'.

### 16.3.3.1.2 Bypass mode

For applications where the TCON is not in use, a bypass mode is provided in which the input signals from the module are passed through the TCON unchanged. See the table below for how the input signals are assigned to the TCON output.

**Table 16-29. input/output signal mapping in bypass mode**

Input	Output
data_in[23:0]	data_out[25:2]
pix_clk	data_out[1]
dcu_tag	tcon_out[0]
hsync_in	tcon_out[1]
vsync_in	tcon_out[2]
data_en_in	tcon_out[3]

To put the TCON in bypass mode set TCON\_CTRL1[TCON\_EN]='0' and TCON\_CTRL1[TCON\_BYPASS]='1'.

### 16.3.3.2 Timing signal generator

The Timing Signal Generator (TSG) is the TCON timing signal generation unit. It accepts the HSYNC/VSYNC signals from the input parallel display interface, and maintains two counters (*hcount*, *vcount*) based on that. All the timing signals are generated based on these two counters.

For every line the *hcount* counts the current pixel number, from 1 to the number of pixels per line (the full line, including inactive period). It restarts from 1 with the HSYNC signal rising edge.

Similarly the *vcount* counts from 1 with the VSYNC signal rising edge (first line), increments by "1" at the end of each line, until the last line in a frame (including inactive lines).

The timing signal generator is composed of 4 comparators ([Comparator](#)), 6 pulse generators ([Pulse generator](#)), 1 toggle generator ([Toggle generator](#)), and a signal mixer or synthesizer ([Signal Mixer \(SMX\)](#)). See the following sections for detailed descriptions.

### 16.3.3.2.1 Comparator

There are 4 comparators in the TCON, each can be configured to compare *hcount* or *vcount* with the value specified in a TCON\_COMPx Register. If desired the user can mask some bits from comparing by setting the corresponding bits in both TCON\_COMPx\_MSK and TCON\_COMPx register to "0". A one-cycle (pixel clock cycle, or line cycle) pulse will be generated when the compare result is match, and the comparison logic is shown below:

```
compare_out = (TCON_COMPx.COMP_VALUE == (TCON_COMPx_MSK.MASK & hcount))
```

or

```
compare_out = (TCON_COMPx.COMP_VALUE == (TCON_COMPx_MSK.MASK & vcount))
```

TCON\_COMPx[FUNC\_SEL] determines which of the above equations is used (i.e. comparison is done on horizontal or vertical direction).

### 16.3.3.2.2 Pulse generator

There are 6 pulse generators in the TCON which can be used to generate pulses which have a *set* point and a *reset* point, and the pulse length is discretionary. The *set* and *reset* point is determined by TCON\_PULSEx[SET] and TCON\_PULSEx[RESET], to which the *hcount* or *vcount* value will be compared. If desired the user can mask some bits from comparing by setting the corresponding bits in both TCON\_PULSEx\_MSK and TCON\_PULSEx register to 0. The equations used to find the *set/clear* point are similar to the equations given in the "Comparator" section above.

TCON\_PULSEx[FUNC\_SEL] controls the type of the pulse, a.k.a. whether the *set/reset* point comparison is performed on horizontal direction (compare with *hcount*) or vertical direction (compare with *vcount*). And when vertical comparison is selected (ie.

FUNC\_SEL = 01 or 11), 1 of the 4 comparator outputs (must be a horizontal pulse) can be selected to further determine the signal transition point on horizontal direction. Or when FUNC\_SEL = 10, the signal transition will happen immediately when the vertical

compare matches (i.e. at the beginning of the line). When needed TCON\_PULSEx[COMPARATOR\_SEL] selects 1 of the 4 comparator outputs as the horizontal reference.

### 16.3.3.2.3 Toggle generator

There is a toggle generator in the TCON that can be used to generate signals which toggles line to line, or frame to frame, or signal which toggles line to line but polarity changes from frame to frame. The toggle generator accepts the 4 comparator outputs (TCON\_COMP[0:3]) and the 6 pulses (TCON\_PULSE[0-5]), and generates 4 toggle signals (vtgl[0-3]) based on that.

The toggle generator uses a counter (vtgl\_counter) and a T flip-flop to generate the 4 toggle signals. The vtgl\_counter takes 1 of the 4 comparator outputs as the clock (*h\_ref*), and 1 of the 6 pulses as the enable signal (*v\_ref*). The *h\_ref/v\_ref* selection is controlled via TCON\_CTRL1[H\_REF\_SEL] and TCON\_CTRL1[V\_REF\_SEL].

TCON\_CTRL1[VLEN] sets the maximum counter value. The vtgl\_counter increments at the rising edge of *h\_ref* when *v\_ref* is high, and it falls back to "0" when the counter value exceeds VLEN. And then the vtgl[0-2] are generated by decoding the counter value via the following equations.

$$vtgl[0] = (vtgl\_counter == 0)$$

$$vtgl[1] = (vtgl\_counter == 1)$$

$$vtgl[2] = (vtgl\_counter == 2)$$

The H\_REF\_SEL and V\_REF\_SEL shall be programmed so that the *h\_ref* is a horizontal pulse (one pixel clock cycle pulse per line) and the *v\_ref* is a vertical pulse (pulse lasts for 1 line or several lines). The following table shows the relationship between vlen, vtgl\_counter sequence and vtgl[2:0].

**Table 16-30. vtgl[0-2] sequence**

INPUT	OUTPUT	vtgl_counter sequence								
vlen	vtgl	0	1	2	3	4	5	6	7	8
0	0	1	1	1	1	1	1	1	1	1
	1	0	0	0	0	0	0	0	0	0
	2	0	0	0	0	0	0	0	0	0
1	0	1	0	1	0	1	0	1	0	1
	1	0	1	0	1	0	1	0	1	0
	2	0	0	0	0	0	0	0	0	0
2	0	1	0	0	1	0	0	1	0	0
	1	0	1	0	0	1	0	0	1	0
	2	0	0	1	0	0	1	0	0	1

A T flip-flop is used to generate  $vtgl[3]$ . T flip-flop is a type of flip-flop whose output toggles (inverts) at the rising edge of the clock input when the enable signal input is high. The T flip-flop in the toggle generator is clocked by  $h\_ref$ , and the enable signal ( $en$ ) is the bit-AND of  $vtgl[0]$  and  $v\_ref$ .

By programming the VLEN, and control the pulse length of  $v\_ref$ , the  $vtgl[3]$  can be used to generate toggle signals whose polarity changes from frame to frame. See the table below for some programming examples.

**Table 16-31.  $vtgl[3]$  programming examples**

$vtgl[3]$	$v\_ref$ pulse length	vlen
toggles every line, polarity inverts frame to frame, steady during vertical blanking (2 frame sequence)	odd (eg. number of active lines + 1)	0
toggles every other line, polarity inverts frame to frame, steady during vertical blanking (2 frame sequence)	odd*2 (eg. number of active lines)	1
toggles every 3rd line, polarity inverts frame to frame, steady during vertical blanking (2 frame sequence)	odd*3 (eg. number of active lines + 3)	2
toggles every other line, walking pattern (4 frame sequence)	odd (eg. number of active lines + 1)	1

To make it easier to understand, the following table shows a simpler example where the number of active lines is 6.

**Table 16-32.  $ctgl[3]$  signal example A**

VLEN	Frame	Active Line Number									$v\_ref$ pulse length
		0	1	2	3	4	5	6	7	8	
0	0	0	1	0	1	0	1	0			7
	1	1	0	1	0	1	0	1			7
1	0	0	1	1	0	0	1				6
	1	1	0	0	1	1	0				6
2	0	0	1	1	1	0	0	0	1	1	9
	1	1	0	0	0	1	1	1	0	0	9
1	0	0	1	1	0	0	1	1			7
	1	0	0	1	1	0	0	1			7
	2	1	0	0	1	1	0	0			7
	3	1	1	0	0	1	1	0			7

### 16.3.3.2.4 Signal Mixer (SMX)

To generate more complicated timing signals, there are 14 Signal Mixer/Synthesizer (SMX) modules in the TCON which can be used to perform logic operations between every two signals. Each SMX module takes 2 signal inputs (X and Y), and generates 1 SMXx output.

The X and Y input of each SMX module can be selected from any two of the 28 signals (4 comparator outputs, 6 pulses, 4 toggle generator outputs, constant 0 or 1, and 12 feedback signals SMX0~11). The X/Y signal selection is configurable via TCON\_SMXx[X\_SEL] and TCON\_SMXx[Y\_SEL]. 12 of the SMXx output (SMX0~11) can be feedback to the SMXx input again in order to generate even more complicated signals (combining information of more than 2 signals),

The SMX module is composed of several logic operation units (AND, OR, XOR or NAND), and a look-up-table (LUT).

The LUT takes 4 inputs, including the current LUT output value and a 4-bit index (index[3:0]), the LUT output is the next cycle SMX output. Function performed by the LUT is determined by the values programmed into TCON\_LUTx. By default the value of TCON\_LUTx is 32'hffff\_005c and the default truth table of the LUT is shown in the following table where SMXx(n-1) is the current SMXx state and SMXx(n) is the next cycle SMXx value. With this setting the LUT emulates the function of a Set/Reset/Toggle/Data flip-flop, where index3 to index0 are the Set/Reset/Toggle enable/Data inputs, "Set" has the highest priority. The user can also reprogram the TCON\_LUTx registers so that the LUT performs different operations (e.g. change the priority order of the Set/Reset/Toggle enable/Data signals).

The index[3:0] input of the LUT is generated by the logic operation units. Each bit of it is a logic operation of X, Y, 0 or 1. The logic operations performed are selected by TCON\_SMXx[INDEX0-3\_SEL].

**Table 16-33. Default TCON LUT Truth Table**

index3	index2	index1	index0	SMXx(n-1)	SMXx(n)
1	x <sup>1</sup>	x	x	x	1
0	1	x	x	x	0
0	0	1	x	0	1
0	0	1	x	1	0
0	0	0	1	x	1
0	0	0	0	x	0

1. Don't care

### 16.3.3.2.5 Output Crossbar Mux

The output crossbar mux is used to select 12 from the generated 20 timing signals as the 12 TCON timing signal outputs. The 20 timing signals include: 6 pulses, 4 toggle generator outputs (vtgl[0:3]), constant "0" and "1", and 8 of the 14 SMXs output (SMX6~13). TCON\_OMUX\_HIGH and TCON\_OMUX\_LOW determines which 12 timing signals are selected as the output.

### 16.3.3.3 Bit Mapping Control (BMC)

The Bit Mapping Control (BMC) module is adopted to remap the color component order, color bit order and output clock position. The following figure shows the diagram of the bit mapping control module.

Figure 16-39. Bit mapping control

#### 16.3.3.3.1 Bit mapping in TTL mode

The default bit mapping in 8-bit color mode is given in the following table.

Table 16-34. TTL mode bit mapping, 8-bit color

data signal	Rising of pix_clk
Remapped RGB[23:16]	{R7,R6,R5,R4,R3,R2,R1,R0}
Remapped RGB[15:8]	{G7,G6,G5,G4,G3,G2,G1,G0}
Remapped RGB[7:0]	{B7,B6,B5,B4,B3,B2,B1,B0}

The default bit mapping in 6-bit colour mode is given in the following table:

Table 16-35. TTL mode bit mapping, 6-bit color

data signal	Rising of pix_clk
Remapped RGB[23:16]	{R7,R6,R5,R4,R3,R2,2'b0}
Remapped RGB[15:8]	{G7,G6,G5,G4,G3,G2,2'b0}
Remapped RGB[7:0]	{B7,B6,B5,B4,B3,B2,2'b0}

Besides the default bit mapping, it is possible to swap the RGB color component order (TCON\_BMC[COLOR\_ORDER]) and the LSB/MSB bit order in each color component (TCON\_BMC[BIT\_ORDER]).

### 16.3.3.3.2 Bit mapping examples

TTL mode; below settings will remap the bit order as given in the following table.

TCON\_BMC[COLOR\_ORDER] = 3'b000; //color order RGB

TCON\_BMC[BIT\_ORDER] = 1; //0 up to MSB7

TCON\_CTRL1[COLOR\_DEPTH] = 1; //6bit per color;

**Table 16-36. Bit mapping example**

Data signal	Rising of pix_clk
Remapped RGB[23:16]	{R2,R3,R4,R5,R6,R7,2'b0}
Remapped RGB[15:8]	{G2,G3,G4,G5,G6,G7,2'b0}
Remapped RGB[7:0]	{B2,B3,B4,B5,B6,B7,2'b0}

### 16.3.3.3.3 Clock mapping in TTL mode

It is possible to assign the pixel clock output to any bit of the data\_out[1:25] in TTL mode, configured via TCON\_BMC[CLK\_POS]. See the table below for details. The data\_out pins are represented on the rows of the table with the number of the pin being in the left hand column. The selected function for that pin is indicated in the row by the CLK\_POS value (0 to 24). For example, if CLK\_POS = 10 then the function on data\_out[11] is clock; if CLK\_POS < 10 then data\_out[11] is RGB[9]; if CLK\_POS > 10 the data\_out[11] is RGB[10]

**Table 16-37. Clock mapping in TTL mode**

2. n stand for remapped rgb[n]

### 16.3.3.4 Clock/Data Skew Adjustment

In order to fulfill different setup/hold timing requirements on the output interface, it is possible to adjust the signal skew between the pixel clock output and the data output (including RGB data and timing signals). The output pixel clock can be flexibly shifted compared to the data signals. It can be shifted over the whole pixel clock period with a granularity of half of the source pixel clock period (the clock from which the pixel clock is derived/divided).

TCON\_CTRL2[DIV\_RATIO] configures the pixel clock divide ratio, and TCON\_CTRL2[CLK\_OFFSET] configures the offset between the internal pixel clock and the output pixel clock.

## 16.3.4 Initialization/Application Information

This section discusses TCON initialization and startup.

### 16.3.4.1 TCON Initialization

The procedure to bring up the TCON out of reset state and start data and timing signal generation:

1. Program TCON\_COMPx and TCON\_COMPx\_MSK registers to configure the comparator.
2. Program TCON\_PULSEx and TCON\_PULSEx\_MSK registers to configure the pulse generator.
3. Program TCON\_SMXx and TCON\_LUTx registers if necessary.
4. Program TCON\_BMC register to configure the bit mapping control.
5. Program the TCON\_CTRL1 register to configure the operation mode of TCON and enable TCON (It is recommended to do this in two steps, and set TCON\_EN in the second).

## 16.4 Run Length Encoding Decoder (RLE\_DEC)

### 16.4.1 Introduction

The RLE\_DEC module is used to decode data that has been compressed using a Run Length Encoding (RLE) scheme. It has input and output FIFO buffers directly connected to the crossbar switch and requires the CPU or DMA to push in the encoded data and then extract the decoded result. The module configuration is optimized for decoding data stored in a two-dimensional image format but can also be used to extract data stored as a linear array.

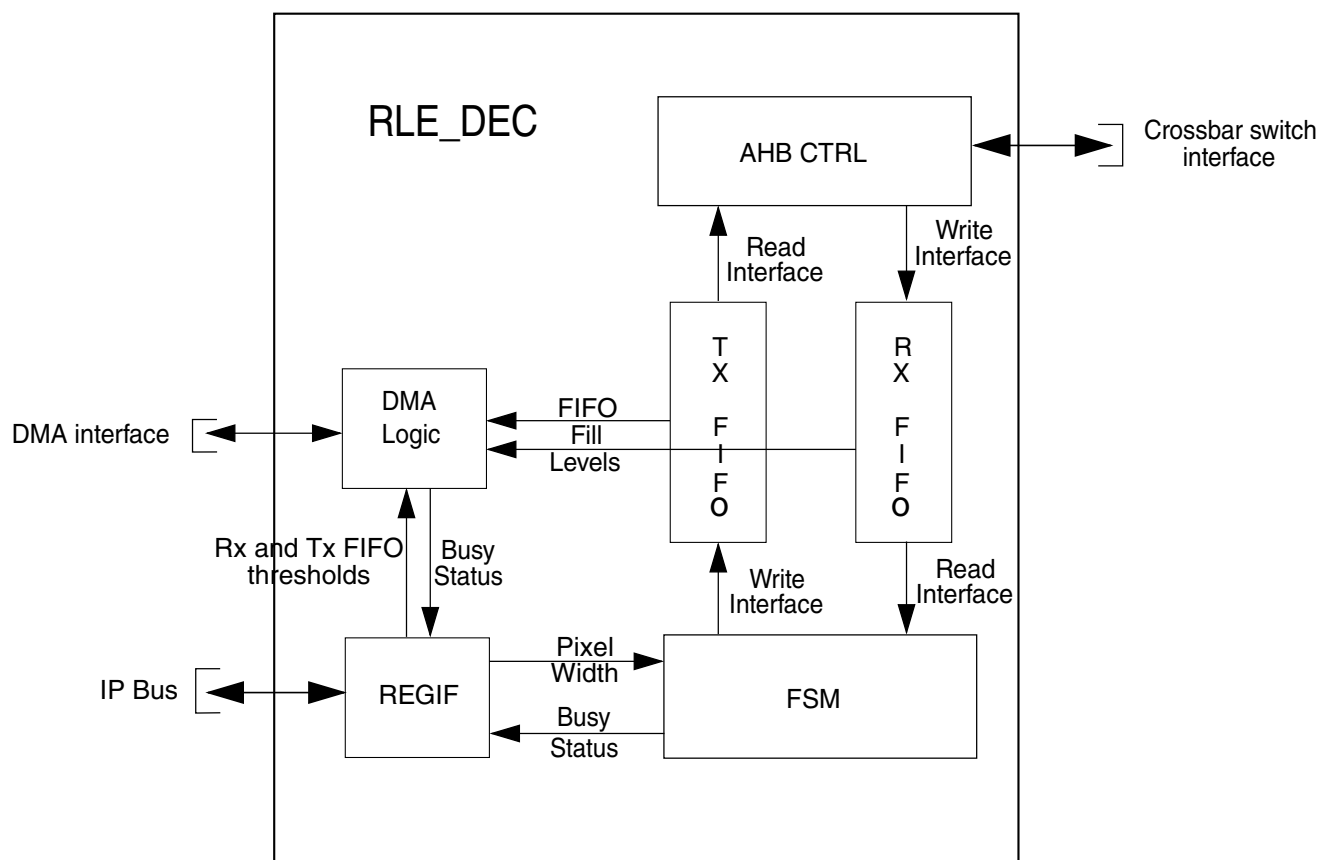

Figure 16-40. RLE\_DEC Block Diagram

### 16.4.1.1 Overview

The above figure is a block diagram of the Run Length Encoding Decoder (RLE\_DEC) module. The module has two independent interfaces that are memory mapped into the device:

- Crossbar switch interface for moving data into and out of the module
- IP bus interface for configuring the module

The crossbar interface appears in the device memory map as two FIFOs. Writes to the Rx FIFO will cause the RLE\_DEC to begin decoding operations. The RLE\_DECs Finite State Machine (FSM) removes data from the Rx FIFO, decodes it and places the output into the Tx FIFO. The decoded data appears in the Tx FIFO and is removed from this FIFO after it is read by a crossbar master such as the CPU or eDMA. The DMA operations require the use of two different DMA channels.

The module is configured and its status monitored using registers on the IP bus that appear as locations in the module register memory area. This configuration includes information on the size of the image (or data set) and the size of the individual pixels (or data elements) in the image. The RLE\_DEC uses this information to determine when an operation is complete. For this reason the RLE\_DEC will typically be reconfigured for each operation since the size of each compressed image will be different.

The module can raise interrupts to indicate errors and when an operation is complete.

### 16.4.1.2 Features

The RLE\_DEC supports the following features:

- Lossless decompression
- Pixel formats supported: 8bpp, 16bpp, 24bpp and 32bpp (Programmable)
- AHB mapped Rx FIFO (8x8 bytes deep) with DMA support.
- AHB mapped Tx FIFO (8x8 bytes deep) with DMA support.
- Programmable fill levels of read and write buffers for initiating burst transfers.
- Partial Image Decode feature, wherein only a portion of the decoded image is given as output.
- Horizontal Gradient Support.
- Support for Stop Mode for power-saving purposes

### 16.4.1.3 RLE\_DEC Modes of Operation

This section describes the modes of operation.

#### 16.4.1.3.1 Normal Mode

In this mode, the RLE\_DEC block performs the normal 'Run Length Encoding' Decode operation. Further details about this mode of operation can be found in chapter [Normal Mode](#).

#### 16.4.1.3.2 Module Disable Mode

The Module Disable Mode is used for power management of the device containing the RLE\_DEC module. It is controlled by signals external to the RLE\_DEC. The clock to the non-memory mapped logic in the RLE\_DEC can be stopped while in the Module Disable Mode. See [Module Disable Mode](#).

#### 16.4.1.3.3 Stop Mode

The Stop Mode is used for power management by the system mode management. When a request is made to enter Stop Mode, the RLE\_DEC block completes the action currently processed. Then the request is acknowledged.

### 16.4.2 External Signal Description

RLE\_DEC has no external signals.

### 16.4.3 Interrupt and DMA Request Signals

The interrupt and DMA request lines of the RLE\_DEC module are mapped to the internal flags in the DEC\_RLE\_ISR register.

### 16.4.4 Memory map and register definition

The memory map for the RLE\_DEC module is given below. The total address for each register is the sum of the base address for the RLE\_DEC module and the address offset for each register. Also, please note that the bit order for each register bit field is [highest:lowest], whereas the overall register bits are numbered [lowest:highest].

## RLE\_DEC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4004_2000	Module Configuration Register (RLE_DEC_MCR)	32	R/W	2020_0009h	<a href="#">16.4.4.1/3516</a>

4004_2020	End Pixel Co-ordinate Register of Image (RLE_DEC_EPCR)	32	R/W	0000_0000h	<a href="#">16.4.4.9/3522</a>

16.4.4.1 Module Configuration Register (RLE\_DEC\_MCR)

The RLE\_DEC\_MCR holds configuration data associated with RLE\_DEC operation. This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004\_2000h base + 0h offset = 4004\_2000h

RLE\_DEC\_MCR field descriptions

Field	Description
31–30 RESERVED	This field is reserved.
29–24 RX_FIFO_THRESHOLD	Rx FIFO threshold: This field determines how much space should be available for writing into the Rx Buffer until the write action is triggered (through DMA). When the number of bytes of available space in RX FIFO exceeds the number given by this field the RLE_DEC_FR[RFFR] flag is asserted.
23–22 RESERVED	This field is reserved.
21–16 TX_FIFO_THRESHOLD	Tx FIFO threshold: This field determines how many entries must be read into the TX FIFO until the readout action is triggered. When the number of valid entries in the TX FIFO exceeds the number given by this field the RLE_DEC_FR[TFDR] flag is asserted.
15–4 RESERVED	This field is reserved.
3 GRLE_EN	Enable Gradient RLE decoding

Table continues on the next page...

**RLE\_DEC\_MCR field descriptions (continued)**

Field	Description
	This bit enables or disables Gradient RLE decoding. Gradient RLE is described in detail in the section, RLE encoding format.  0 Disables the Gradient RLE decoding. Decoding is performed only as traditional RLE. 1 Enables the Gradient RLE decoding. Decoding can be done according to either Gradient RLE or traditional RLE algorithm, based on the decoding of Command Byte.
2 TXFFEN	Tx FIFO Flush Enable. This bit configures the operation of the RLE Decoder in the case when the image decoding is complete and the data remaining in the Tx FIFO is below the value of TX_FIFO_THRESHOLD.  0 Trigger the DMA action only when TxFIFO has more data than TX_FIFO_THRESHOLD. 1 Trigger the DMA action until the Tx FIFO is empty even if it is less than TX_FIFO_THRESHOLD.
1 Reserved	This bit should not be written by the user. Writes to a reserved location can result in unpredictable functionality or behavior.  This field is reserved.
0 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the RLE_DEC to be stopped, putting the RLE_DEC in a software controlled power-saving state. See the "Module Disable Mode" section for more information.  0 Enable RLE_DEC clocks. 1 Allow external logic to disable RLE_DEC clocks.

**16.4.4.2 Image Configuration Register (RLE\_DEC\_ICR)**

The RLE\_DEC\_ICR holds configuration data associated with configuration of image parameters. This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004\_2000h base + 4h offset = 4004\_2004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**RLE\_DEC\_CISR field descriptions**

Field	Description
SIZE	This is the byte-size of compressed image, that will be given as an input to the RLE DEC. This should be programmed before the Module is enabled using MDIS.

**16.4.4.4 Decompressed Image Co-ordinates register (RLE\_DEC\_DICR)**

The RLE\_DEC\_DICR holds the final coordinates of the decompressed image. Decompression is done until this pixel reached. Please refer to section "Image Coordinates' Description". This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004\_2000h base + Ch offset = 4004\_200Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### RLE\_DEC\_DICR field descriptions

Field	Description
31–16 X	This is the X Co-ordinate of the final pixel of the decompressed image, that will be given as the output of the RLE DECODER. This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.
Y	This is the Y Co-ordinate of the final pixel of the decompressed image, that will be given as the output of the RLE DECODER. This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.

#### 16.4.4.5 Status Register (RLE\_DEC\_SR)

The RLE\_DEC\_SR register provides the status information about the TX FIFO and RX FIFO.

Address: 4004\_2000h base + 10h offset = 4004\_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																RXFREE								TXFILL							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	

### RLE\_DEC\_SR field descriptions

Field	Description
31–16 RESERVED	This field is reserved.
15–8 RXFREE	This status gives the amount of free space in bytes, available in Rx FIFO to write.
TXFILL	This status gives the amount of data in bytes, available in Tx FIFO to read.

### 16.4.4.6 Interrupt Request Status Register (RLE\_DEC\_ISR)

The RLE\_DEC\_ISR register is the Interrupt Status Register for RLE DECODER. The interrupts are asserted upon associated events. They are deasserted upon write to this register.

Address: 4004\_2000h base + 14h offset = 4004\_2014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**RLE\_DEC\_ISR field descriptions**

Field	Description
31–8 RESERVED	This field is reserved.
7 RXDIF	Rx Image Done. Is asserted when the amount of received data has equalled the programmed "Compressed Image Size Register"
6 TXDIF	Tx Image Done. Is asserted when coordinates of decompressed image cross End Pixel Coordinates which are defined in "End Pixel Coordinate Register"
5 RXUIF	Rx FIFO has space. Asserted when Rx FIFO has more space than Rx FIFO Threshold. (DMA request for input data.)
4 TXUIF	Tx FIFO has data. Asserted when Tx FIFO has more data than Tx FIFO Threshold. (DMA request for output data.)
3 RXFIF	Rx FIFO Full: Asserted when Rx FIFO has no more space left for data and a write was attempted on it.
2 TXFIF	Tx FIFO Full: Asserted when Tx FIFO has no more space left for data and a write was attempted on it.

*Table continues on the next page...*

**RLE\_DEC\_ISR field descriptions (continued)**

Field	Description
1 RXEIF	Rx FIFO Empty: Asserted when Rx FIFO has no data and a read was attempted from it.
0 TXEIF	Tx FIFO Empty: Asserted when Tx FIFO has no data and a read was attempted from it.

**16.4.4.7 Interrupt Request Enable Register (RLE\_DEC\_RIER)**

The RLE\_DEC\_RIER register provides enables for the interrupts in the RLE\_DEC module.

Address: 4004\_2000h base + 18h offset = 4004\_2018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**RLE\_DEC\_SPCR field descriptions**

Field	Description
31–16 X	This is the X Co-ordinate of the first pixel of the decompressed image, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.
Y	This is the Y Co-ordinate of the final pixel of the decompressed image, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.

**16.4.4.9 End Pixel Co-ordinate Register of Image (RLE\_DEC\_EPCR)**

The RLE\_DEC\_SPCR holds the end co-ordinates of the decompressed image of interest. Please refer to section "Image Coordinates' Description". This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004\_2000h base + 20h offset = 4004\_2020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### RLE\_DEC\_EPCR field descriptions

Field	Description
31–16 X	This is the X Co-ordinate of the last pixel of the decompressed image of interset, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.
Y	This is the Y Co-ordinate of the last pixel of the decompressed image of interset, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.

#### 16.4.4.10 Crossbar Switch Bus Register Memory Map

The table below shows the Rx and Tx FIFOs of the RLE\_DEC mapped to the Crossbar switch (AHB) interface.

**Table 16-38. RLE\_DEC AMBA Bus Memory Map**

Address	Register Name
RLE_DEC-AMBA_BASE + 0x0000_0000 to RLE_DEC-AMBA_BASE + 0x0000_0038	Rx FIFO address range:- The AHB master can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Rx FIFO.
RLE_DEC-AMBA_BASE + 0x0000_0040 to RLE_DEC-AMBA_BASE + 0x0000_0078	Tx FIFO address range:- The AHB master can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Tx FIFO.
RLE_DEC-AMBA_BASE + 0x0000_0080 to RLE_DEC-AMBA_BASE + 0x0000_00B8	Memory Mapped Area for Rx FIFO. AHB can only Write into this address. A write into this address results in a write to the Rx FIFO wherever the write pointer points. If Rx FIFO is full, AHB write request will result in HREADY low, unless space is there for the write operation.  (Please Note: The write(burst or single write) should start from address (RLE_DEC_AMBA_BASE + 0x0000_0080) only.)
RLE_DEC-AMBA_BASE + 0x0000_00C0 to RLE_DEC-AMBA_BASE + 0x0000_00F8	Memory Mapped Area for Tx FIFO. AHB can only Read from this address. A read into this address results in a read from the top of the Tx FIFO. If Tx FIFO is empty, AHB Read request will result in HREADY low, unless some data is available for reading.  (Please Note: The read(burst or single read) should start from address (RLE_DEC_AMBA_BASE + 0x0000_00C0) only.)

#### 16.4.4.11 Crossbar switch memory map descriptions

This section describes the Rx and Tx FIFO address mapping.

#### 16.4.4.11.1 Rx FIFO Address Range

The size Rx FIFO is 8-bytes X 8-bytes. The Rx FIFO address range is (RLE\_DEC\_AMBA\_BASE address + 0x0000) to (RLE\_DEC\_AMBA\_BASE address + 0x0038). A crossbar switch can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Rx FIFO.

#### 16.4.4.11.2 Tx FIFO Address Range

The size Tx FIFO is 8-bytes X 8-bytes. The Tx FIFO address range is (RLE\_DEC\_AMBA\_BASE address + 0x0040) to (RLE\_DEC\_AMBA\_BASE address + 0x0078). A crossbar switch can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Tx FIFO.

#### 16.4.4.11.3 Memory Mapped Rx FIFO

The contents of Rx FIFO are mapped to (RLE\_DEC\_AMBA\_BASE address + 0x0080). Writing RLE compressed data into the Rx FIFO increments the write-pointer based on the size of the written data.

The RLE decode process can be automated by using the eDMA. Each time the free space of Rx FIFO exceeds a certain level (programmable), a (Rx FIFO) DMA request is asserted. When enabled the eDMA can be used to write RLE compressed data into the Rx FIFO.

A read request to Rx FIFO results in an error.

#### 16.4.4.11.4 Memory Mapped Tx FIFO

The contents of Tx FIFO are mapped to (RLE\_DEC\_AMBA\_BASE address + 0x00C0). The RLE\_DEC module writes decompressed data into the Tx FIFO.

The RLE decode process can be automated by using the eDMA. Each time the contents of the Tx FIFO exceeds a certain fill-level (programmable), a (Tx FIFO) DMA request is asserted. When enabled the eDMA can be used to read the decompressed data from the Tx FIFO.

A write request to Tx FIFO results in an error.

## 16.4.5 Functional Description

This section describes the module functions.

### 16.4.5.1 RLE encoding format

In the traditional RLE encoding format, the expected encoding is as follows:

- The first data byte in the encoded image is a command byte (CMD[7:0]).
- The ms bit (CMD[7]) indicates if the following bytes are raw or compressed pixels. One pixel can be 8-bit, 16-bit, 24-bit or 32-bit wide, depending on the PIXEL\_WIDTH configuration.
- The remaining 7 command bits (CMD[6:0]), specify the "count", i.e. the number of raw or compressed pixels that follow the command byte. The count is offset by 1. Value 0 means count is 1. Value 1 means count is 2, and so on.
- For compressed pixels (CMD[7] = 1), only one pixel follows the command byte. This pixel is repeated count+1 times. A new command follows after CMD+(1\*{Pixel width}) pixels.
- For raw pixels (CMD[7] = 0), count+1 number of pixels follow the command byte and these are passed to the Tx FIFO as is.
- If there is more data to decode then a new command follows after CMD+({count + 1}\*{Pixel width}) bytes. This encoding continues until the whole image is decoded.

In the gradient RLE encoding format, the expected encoding is as follows:

- The first data byte in the encoded image is a command byte (CMD[7:0]).
- For raw pixels (CMD[7] = 0), the encoding is same as traditional RLE.
- For compressed pixels (CMD[7] = 1), the remaining 7 command bits (CMD[6:0]) (or the "count") are used to differentiate between traditional and gradient RLE. If the count is non-zero, the encoding is treated as traditional RLE. If the count is zero, the encoded data is in Gradient RLE format.
- If the encoded data is in Gradient RLE format, the second byte represents the decoded sequence length. If the value of second byte is X, then the decoded sequence length is X+3 pixels. (X+3 is the length of the generated output sequence).

- The pixel that follows represents the first pixel of the decoded sequence. And the pixel after that is the delta. The delta bytes are signed 8-bit fixed point numbers. The second pixel of the decoded sequence is calculated by adding adding delta to the first pixel. The third pixel of the decoded sequence is calculated by adding adding delta to the second pixel, and so on.
- The adding of delta to the pixels is done with help of accumulators. The pixel bytes are loaded into 14-bit accumulators at the MSB. The LSB 6-bits of the accumulator are 0s. The delta are added to respective accumulators. The MSB 8-bits of the accumulators form the next pixel.

### **16.4.5.2 RLE decoding process**

The recommended process to decode the data is as follows:

- The RLE\_DEC module is disabled by default (MDIS=1).
- Before enabling the device, program the compressed image size register (RLE\_DEC\_CISR) and decompressed image size register (RLE\_DEC\_DICR) for the image. The decoder expects to read compressed-image-size amount of bytes from the Rx FIFO and expects to decode and write decompressed-image-size amount of bytes into the Tx FIFO.
- When less than the full image is to be decoded then configure the Start Pixel Coordinates Register (RLE\_DEC\_SPCR) and the End Pixel Coordinates Register (RLE\_DEC\_EPCR).
- Configure the WIDTH of the pixels in the image (RLE\_DEC\_ICR).
- Enable the RLE\_DEC DMA Rx and Tx channels in the DMAMUX module and connect these to channels in the eDMA. Configure the selected eDMA channels such that the compressed image is written into the Rx FIFO and the decompressed image is copied from the Tx FIFO.
- Enable the RLE\_DEC by setting MDIS=0.
- When the decoding is complete the TXDIF flag is set (RLE\_DEC\_ISR register). This indicates that the RLE process is complete but depending on the size of the image and the value of the RLE\_DEC\_MCR[TXFFEN] bit there may be some decoded pixels that have not yet been copied from the Tx FIFO because its threshold has not been reached.

- If the TXFFEN bit is not set to automatically flush the Tx FIFO then trigger an eDMA transfer under software control until the Tx FIFO is empty (TXFILL=0 in RLE\_DEC\_SR register).
- Set MDIS=1 to disable the module. The module needs to be disabled at the end of image decompression and enabled again only after the parameters of the new image have been programmed.

### 16.4.5.3 Image coordinates' example

The following figure shows the definition of the coordinates used in RLE\_DEC to define the decompressed image.

Let the decompressed image be of size 10-pixels x 10-pixels. The start coordinate is the coordinate at the top-left corner, (1,1), i.e. X=1 and Y=1. The last coordinate is the bottom-right coordinate, (10,10) in this case. So, we see that the image size can be described by the bottom-right coordinate of the image. This pixel coordinate is described in the register "Decompressed Image Coordinate Register".

If only a part of the complete image is to be given as output, then "Start Pixel Coordinate Register" and "End Pixel Coordinate Register" should be programmed appropriately. For example, in the figure shown below, if the gray area is the image of interest and it is only required to output only that part of the decompressed image, then the "Start Pixel Coordinate Register" should be programmed as (X=3, Y=4) and "End Pixel Coordinate Register" should be programmed as (X=7, Y=7).

If however, the complete decompressed image is to be output, then the "Start Pixel Coordinate Register" should be programmed as (X=1, Y=1) and "End Pixel Coordinate Register" should be programmed as (X=10, Y=10), i.e. equal to "Decompressed Image Coordinate Register".

**Table 16-39. Decompressed 10x10 pixel image**

(1,1)	(2,1)	(3,1)	(4,1)	(5,1)	(6,1)	(7,1)	(8,1)	(9,1)	(10,1)

(1,7)						(7,7)			
(1,8)									
(1,9)									
(1,10)									(10,10)

### 16.4.5.4 Modes of Operation

The possible operational modes of the RLE\_DEC block are:

- Normal Mode: This is used for normal RLE decompression of data received from AHB interface. The module enters this mode by deasserting RLE\_DEC\_MCR[MDIS].
- Stop Mode: The mode used by the system when changing modes if the RLE is no longer required. When the system requests Stop Mode, the RLE\_DEC block completes the execution of the current command and acknowledges the request. The system then removes clocks to the RLE\_DEC block.
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the RLE\_DEC can be stopped while in Module Disable Mode. The module enters the mode by setting RLE\_DEC\_MCR[MDIS].

### 16.4.5.5 Normal Mode

In normal mode, decompression of data is performed using RLE scheme. The module enters this mode by deasserting RLE\_DEC\_MCR[MDIS].

Whenever the Rx FIFO has some data, the state machine is triggered. The decoding operation starts according to the RLE decoding scheme described above. Whenever Tx FIFO is not full and Rx FIFO has got data to transmit, the decoding is done.

After completing the decode of one image, the Normal mode should be exited. For decoding the data of next image, the re-entry to Normal mode should be done only after the new image parameters have been programmed.

### 16.4.5.6 Power Saving Features

The RLE\_DEC supports the following power-saving strategies:

- Stop Mode
- Module Disable Mode

### 16.4.5.6.1 Module Disable Mode

The RLE\_DEC block is in Module Disable Mode by default. It is exited to Normal-Mode by de-asserting the MDIS bit in RLE\_DEC\_MCR register.

Host software can initiate Module Disable Mode by writing a '1' to the MDIS bit. When a request is encountered to enter Module Disable Mode, the RLE\_DEC negates clock-enable when it is ready to enter the Module Disable Mode.

If implemented, the clock-enable signal can stop the clock to the non-memory mapped logic. When clock-enable is negated, the RLE\_DEC is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the RLE\_DEC is in the Module Disable Mode. DMA request signals cannot be cleared while in the Module Disable Mode.

Note that issuing a new AHB request is illegal in Normal Mode during the time starting with raising the request to enter Module Disable Mode and ending with leaving the Module Disable Mode.

## 16.5 2D Graphics Processing Unit (GPU2D) (R-Series only)

### 16.5.1 Overview

The V2D GPU2D module defines a high-performance graphics core designed for hardware acceleration of OpenVG vector graphics display on a variety of consumer devices. Addressable screen sizes range from the smallest cell phones to HD 1080p displays.

The GPU2D cores provide powerful graphics at low power consumption, utilizing the smallest silicon footprints. Dynamic power consumption is minimized by extensive use of localized clock gating.

GPU V2D Hardware acceleration is brought to numerous VG applications including graphical user interfaces (GUI), menu displays, flash animation, and gaming.

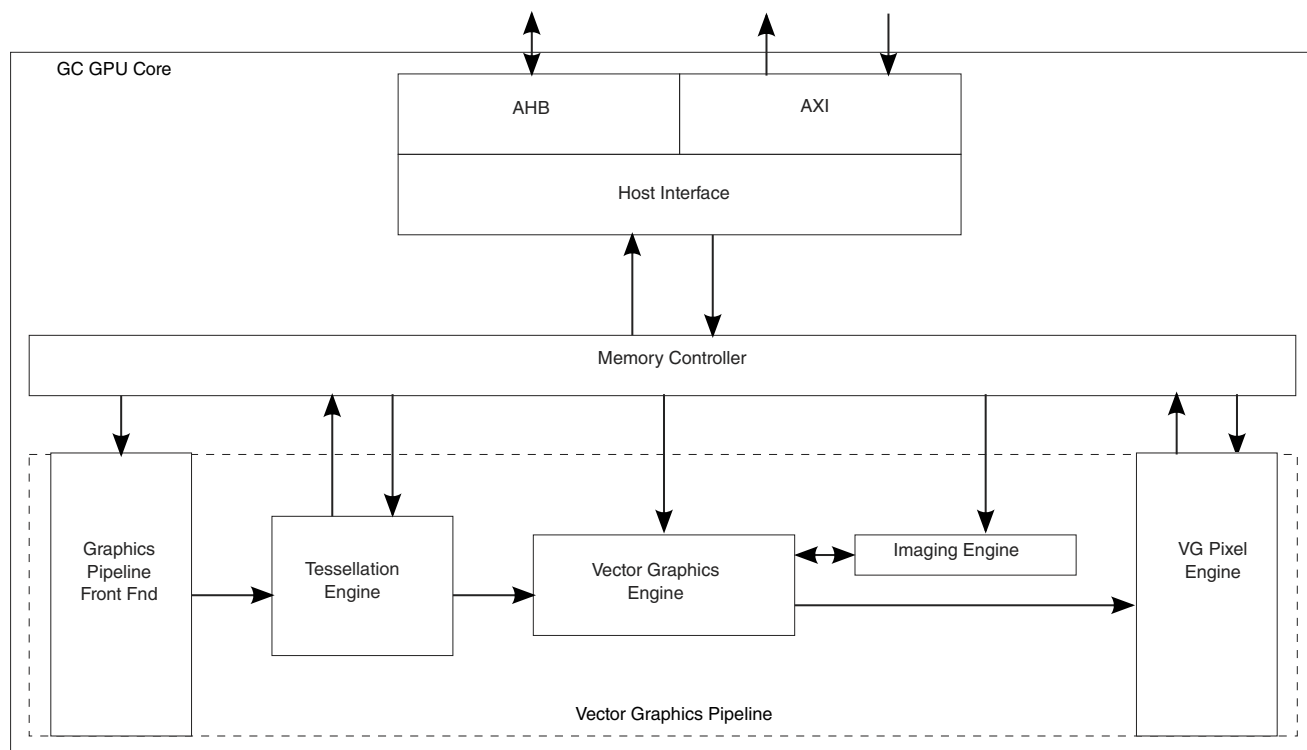

### 16.5.2 GPU2D Block Diagram

### 16.5.2.1 V2D GPU

Vivante GC355 graphics processing unit (GPU) IP defines a high-performance graphics core designed for hardware acceleration of OpenVG vector graphics display. Vivante GPU IP is designed for easy integration onto the SoC.

The module supports the following graphics APIs:

- OpenVG 1.1

**Figure 16-41. Module Block Diagram**

### 16.5.3 GPU2D Features

The following sections describe the functional features of the andV2D GPU.

#### 16.5.3.1 V2D GPU Structure

The main functional blocks of the GC355 GPU IP are described here. A block diagram of the complete graphics pipeline is given in Figure 3.

### **16.5.3.1.1 Host Interface-V2D**

Allows GC355 to communicate with external memory and the CPU through AXI or AHB bus. In this block, data crosses clock domain boundaries.

### **16.5.3.1.2 Memory Controller-V2D**

Internal memory management unit that is the block-to-host memory request interface.

### **16.5.3.1.3 Graphics Pipeline Front End-V2D**

Inserts high level primitives and commands into the graphics pipeline.

### **16.5.3.1.4 Tessellation Engine**

Transforms vertices and control points; tessellates lines, quadratic and cubic Bezier curves.

### **16.5.3.1.5 Vector Graphics Engine**

OpenVG Rasterizer that converts primitives to pixels.

### **16.5.3.1.6 Imaging Engine**

OpenVG paint and image generator that colors each pixel.

### **16.5.3.1.7 VG Pixel Engine**

OpenVG renderer that combines different sources into the final pixel value.

## **16.5.4 GPU2D OPERATIONS**

### **16.5.4.1 V2D GPU Operations**

Information detailing the V2D GPU operations can be found [here](#).

#### **16.5.4.1.1 OPENVG 1.1-API STANDARD for VECTOR GRAPHICS ACCELERATION**

OpenVG is a royalty-free, cross-platform API managed by the member-funded consortium known as Khronos Group. It provides a low-level hardware acceleration interface for vector graphics libraries such as Flash and SVG. OpenVG is used for acceleration of high-quality vector graphics for user interfaces and text on small screen devices.

#### **NOTE**

User can disable GC355 with fuse bit available in the device.  
The fuse index in the device for DISABLE\_OVG is d126.

#### **16.5.4.1.2 Advantages of Using OpenVG**

- Hardware accelerators can reduce power consumption by up to 90% compared to a software engine.
- Scalability with high-quality rendering, including anti-aliasing, to different screen sizes without multiple bitmaps.

#### **16.5.4.1.3 OpenVG Target Applications**

- SVG Viewers
- Portable Mapping Applications
- E-book Readers
- Games
- Scalable User Interface

#### **16.5.4.1.4 OpenVG Features**

##### **16.5.4.1.4.1 Core API**

- Coordinate Systems and Transformations (Image drawing uses a 3x3 perspective transformation matrix)
- Viewport Clipping, Scissoring and Alpha Masking
- Paths
- Images
- Image Filters
- Paint (gradient and pattern)
- Blending
- Dithering

#### **16.5.4.1.4.2 The VGU Utility Library**

- Higher-level Geometric Primitives
- Image Warping

#### **16.5.4.1.4.3 OpenVG Rendering Pipeline**

- Stage 1: Path, Transformation, Stroke, and Paint
- Stage 2: Stroked Path Generation
- Stage 3: Transformation
- Stage 4: Rasterization
- Stage 5: Clipping and Masking
- Stage 6: Paint Generation
- Stage 7: Image Interpolation
- Stage 8: Blending and Anti-aliasing

### **16.5.4.2 V2D GPU Operations**

Information detailing the V2D GPU operations can be found [here](#).

#### **16.5.4.2.1 Memory Master Interfaces**

- 64-bit independent read and write data buses
- Multiple burst length (8 bytes, 16 bytes, 32 bytes, or 64 bytes)
- Supports out-of-order return data for different clients
- Asynchronous interface to the GPU
- Optimized for size while meeting performance requirements
- Designed to support up to 356 MHz

#### **16.5.4.2.2 Slave Interface to CPU or controller interface**

- 256 KB addressable register space
- 32-bit accesses only (no bursts)
- 32-bit data bus
- Handles error response for illegal accesses
- Asynchronous interface to the GPU
- Interrupt support
- Supports up to 500 MHz
- Returns error status for unacceptable read/write access

### 16.5.4.3 Debug Support

The 8-bit debug bus for Lab debugging implemented on this device is not required as the debug bus is tied off internally on the module.

### 16.5.4.4 Interrupt

The module can send interrupt signal to the host processor. Signal XAQ2\_INTR generated after all the IDLE bits goes high and INTR enabled, will be remained high until the Host processor clears the Interrupt by reading the Interrupt Acknowledge register(AQINTRACKnowledge register).

#### NOTE

Module interrupt is connected to 82 line of CA5 Interrupt Vector line and 66 line of CM4 Interrupt Vector line.

#### NOTE

In this device, GPU2D interrupt should not be enabled before its clock. It needs few clocks to initialize itself (app. 124 clocks).

## 16.5.5 GPU2D Memory Map/Register Definition

Host Interface Registers:

The Host Interface is a bridge between the Memory Controller and the AXI interface. It also acts as a bridge between the core and the AHB bus. The Host Interface's register set contain the control settings for the clocks, AXI interface and interrupts. It also contains the identification registers and some counters that are used for debug. Users can access all of the Host Interface registers via the AHB bus.

Memory Controller Registers:

All memory accesses that go to or from the AXI bus pass through the Memory Controller. It connects the Host Interface to the rest of the core. The Memory Controller's register set contains the controls for the memory interface, the settings for the virtual memory page table, and the values of the offset registers. It also contains a variety of debug registers that are set by other blocks within the core. Users can access all of the Memory Controller's registers via the AHB bus.

DMA Unit Registers:

The DMA Unit (also known as the Fetch Engine) has only a few registers that the user can access via the AHB bus. The most important of these control the location and the fetching of the command stream. The register set also contains several debug registers. The rest of the DMA register set must be accessed by state load commands in software.

#### Fetch Engine Registers:

The usage of GPU2D is through software driver. Customers are not supported programming directly through the above registers. As to the software driver, please contact Freescale for the corresponding documents.

### 16.5.5.1 Clock Control Register (GPU2D\_AQHiClockControl)

This register controls the clock used by the module.

Address: 400C\_F000h base + 0h offset = 400C\_F000h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CLK3D_DIS	CLK2D_DIS	FSCALE_VAL							FSCALE_CMD_LOAD	DISABLE_RAM_CLOCK_GATING	DISABLE_DEBUG_REGISTERS	SOFT_RESET	Reserved		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	IDLE3_D	IDLE2_D	IDLE_VG	ISOLATE_GPU	MULTI_PIPE_REG_SELECT				MULTI_PIPE_USE_SINGLE_AXI				Reserved			
W																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

**GPU2D\_AQHiClockControl field descriptions**

Field	Description
0 CLK3D_DIS	Disable 3D clock.
1 CLK2D_DIS	Disable 2D clock.
2–8 FSCALE_VAL	This is used for clock pulse skip.
9 FSCALE_CMD_LOAD	This is used to enable the pulse skip configuration.
10 DISABLE_RAM_CLOCK_GATING	Disables clock gating for rams.
11 DISABLE_DEBUG_REGISTERS	Disable debug registers. If this bit is 1, debug registers are clock gated.
12 SOFT_RESET	Soft resets the IP.
13–15 -	This field is reserved. Reserved

Table continues on the next page...

**GPU2D\_AQHiClockControl field descriptions (continued)**

Field	Description
16 IDLE3_D	3D pipe is idle.
17 IDLE2_D	2D pipe is idle.
18 IDLE_VG	VG pipe is idle.
19 ISOLATE_GPU	Isolate GPU bit
20–23 MULTI_PIPE_ REG_SELECT	Determines which HI/MC to use while reading registers.
24–27 MULTI_PIPE_ USE_SINGLE_ AXI	Force all the transactions to go to one AXI.
28–31 -	This field is reserved. Reserved

### 16.5.5.2 Idle Status Register (GPU2D\_AQHidle)

Provides the status of different modules in the IP.

Address: 400C\_F000h base + 4h offset = 400C\_F004h

**GPU2D\_AQHidle field descriptions**

Field	Description
0 IDLE_FE	Graphics Pipeline Front End (FE) is idle.
1 IDLE_DE	Draw Engine (DE) is idle.
2 IDLE_PE	Pixel Engine (PE) is idle.
3 IDLE_SH	Shader (SH) is idle.

*Table continues on the next page...*

**GPU2D\_AQHidle field descriptions (continued)**

Field	Description
4 IDLE_PA	Primitive Assembly (PA) is idle.
5 IDLE_SE	Setup Engine (SE) is idle.
6 IDLE_RA	Rasterizer (RA) is idle.
7 IDLE_TX	TX is idle.
8 IDLE_VG	VG is idle.
9 IDLE_IM	IM is idle.
10 IDLE_FP	FP is idle.
11 IDLE_TS	TS is idle.
12–30 -	This field is reserved. Reserved.
31 AXI_LP	AXI is in low power mode.

**16.5.5.3 AXI Configuration Register (GPU2D\_AQAxConfig)**

Controls the AXI interface for the IP.

Address: 400C\_F000h base + 8h offset = 400C\_F008h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R

**GPU2D\_AQAxConfig field descriptions**

Field	Description
0–3 AWID	Write address ID. This signal is the identification tag for the write address group of signals.
4–7 ARID	Read address ID. This signal is the identification tag for the read address group of signals.
8–11 AWCACHE	Cache type. This signal indicates the bufferable, cacheable, write-through, write-back, and allocate attributes of the transaction.
12–15 ARCACHE	Cache type. This signal indicates the bufferable, modifiable, allocatable attributes of the transaction.
16–31 -	This field is reserved. Reserved

### 16.5.5.4 AXI Status Register (GPU2D\_AQAxisStatus)

Provides status of the AXI Read/Write transactions.

Address: 400C\_F000h base + Ch offset = 400C\_F00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved								RD_ERR_ID				WR_ERR_ID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPU2D\_AQAxisStatus field descriptions**

Field	Description
31–10 -	This field is reserved. Reserved
9 DET_RD_ERR	Detects AXI Read error.
8 DET_WR_ERR	Detects AXI Write error.
7–4 RD_ERR_ID	Detects AXI Read error ID.
WR_ERR_ID	Detects AXI Write error ID.

### 16.5.5.5 Interrupt Acknowledge Register (GPU2D\_AQIntrAcknowledge)

This is Interrupt Acknowledge register where each bit represents a corresponding event being triggered. Reading from this register clears the outstanding interrupt.

Address: 400C\_F000h base + 10h offset = 400C\_F010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	INTR_VEC																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPU2D\_AQIntrAcknowledge field descriptions**

Field	Description
INTR_VEC	Represents the event being triggered.

**16.5.5.6 Interrupt Enable Register (GPU2D\_AQIntrEnbl)**

This is Interrupt Enable register where each bit enables a corresponding event.

Address: 400C\_F000h base + 14h offset = 400C\_F014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	INTR_ENBL_VEC																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPU2D\_AQIntrEnbl field descriptions**

Field	Description
INTR_ENBL_VEC	Interrupt enable for the 32-bit Interrupt Acknowledge (AQIntrAcknowledge) register. Every bit represents an interrupt from the GPU2D core. When any of these bits is set, an interrupt is sent to the CPU to read this register.

**16.5.5.7 Identification Register (GPU2D\_AQIdent)**

Identification register. This register has no set reset value.

Address: 400C\_F000h base + 18h offset = 400C\_F018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

GPU2D\_Features field descriptions

Field	Description
0 FAST_CLEAR	Fast clear. 0 NONE 1 AVAILABLE
1 SPECIAL_ANTI_ALIASING	Full-screen anti-aliasing. 0 NONE 1 AVAILABLE
2 PIPE_3D	3D pipe. 0 NONE 1 AVAILABLE
3 DXT_TEXTURE_COMPRESSION	DXT texture compression.

Table continues on the next page...

## GPU2D\_Features field descriptions (continued)

Field	Description
	0 NONE 1 AVAILABLE
4 DEBUG_MODE	Debug registers. 0 NONE 1 AVAILABLE
5 ZCOMPRESSION	Depth and color compression. 0 NONE 1 AVAILABLE
6 YUV420_FILTER	YUV 4:2:0 support in filter blit. 0 NONE 1 AVAILABLE
7 MSAA	MSAA support. 0 NONE 1 AVAILABLE
8 DC	Shows if there is a display controller in the IP. 0 NONE 1 AVAILABLE
9 PIPE_2D	Shows if there is 2D engine. 0 NONE 1 AVAILABLE
10 ETC1_ TEXTURE_ COMPRESSION	ETC1 texture compression. 0 NONE 1 AVAILABLE
11 FAST_SCALER	Shows if the IP has HD scaler. 0 NONE 1 AVAILABLE
12 HIGH_ DYNAMIC_ RANGE	Shows if the IP has HDR support. 0 NONE 1 AVAILABLE
13 YUV420_TILER	YUV 4:2:0 tiler is available. 0 NONE 1 AVAILABLE
14 MODULE_CG	Second level clock gating is available. 0 NONE 1 AVAILABLE
15 MIN_AREA	IP is configured to have minimum area.

Table continues on the next page...

## GPU2D\_Features field descriptions (continued)

Field	Description
	0 NONE 1 AVAILABLE
16 NO_EZ	IP does not have early-Z. 0 NONE 1 AVAILABLE
17 NO422_ TEXTURE	IP does not have 422 texture input format. 0 NONE 1 AVAILABLE
18 BUFFER_ INTERLEAVING	IP supports interleaving depth and color buffers. 0 NONE 1 AVAILABLE
19 BYTE_WRITE_ 2D	Supports byte write in 2D. 0 NONE 1 AVAILABLE
20 NO_SCALER	IP does not have 2D scaler. 0 NONE 1 AVAILABLE
21 YUY2_ AVERAGING	YUY2 averaging support in resolve. 0 NONE 1 AVAILABLE
22 HALF_PE_ CACHE	PE cache is half. 0 NONE 1 AVAILABLE
23 HALF_TX_ CACHE	TX cache is half. 0 NONE 1 AVAILABLE
24 YUY2_RENDER_ TARGET	YUY2 support in PE and YUY2 to RGB conversion in resolve. 0 NONE 1 AVAILABLE
25 MEM32_BIT_ SUPPORT	32 bit memory address support. 0 NONE 1 AVAILABLE
26 PIPE_VG	VG pipe is present. 0 NONE 1 AVAILABLE
27 VGTS	VG tessellator is present.

Table continues on the next page...

**GPU2D\_Features field descriptions (continued)**

Field	Description
	0 NONE 1 AVAILABLE
28 FE20	FE 2.0 is present. 0 NONE 1 AVAILABLE
29 BYTE_WRITE_3D	3D PE has byte write capability. 0 NONE 1 AVAILABLE
30 RS_YUV_TARGET	Supports resolving into YUV target. 0 NONE 1 AVAILABLE
31 FE20_BIT_INDEX	Supports 20 bit index. 0 NONE 1 AVAILABLE

**16.5.5.9 Chip Identification Register (GPU2D\_ChipId)**

Shows the ID for the chip in BCD. This register has no set reset value.

Address: 400C\_F000h base + 20h offset = 400C\_F020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPU2D\_MinorFeatures0 field descriptions

Field	Description
31 ENHANCE_VR	Enhance VR and add a mode to walk 16 pixels in 16-bit mode in Vertical pass to improve \$ hit rate when rotating 90/270.  0 NONE 1 AVAILABLE
30 CORRECT_STENCIL	Correct stencil behavior in depth only.  0 NONE 1 AVAILABLE
29 A8_TARGET_SUPPORT	2D engine supports A8 target.  0 NONE 1 AVAILABLE

Table continues on the next page...

**GPU2D\_MinorFeatures0 field descriptions (continued)**

Field	Description
28 NEW_TEXTURE	New texture unit is available. 0 NONE 1 AVAILABLE
27 HIERARCHICAL_Z	Hierarchical Z is supported. 0 NONE 1 AVAILABLE
26 BYPASS_IN_MSAA	Shader supports bypass mode when MSAA is enabled. 0 NONE 1 AVAILABLE
25 VAA	VAA is available or not. 0 NONE 1 AVAILABLE
24 BUG_FIXES0	Bug Fixes 0 0 NONE 1 AVAILABLE
23 SHADER_MSAA_SIDEHAND	Put the MSAA data into sideband fifo. 0 NONE 1 AVAILABLE
22 MC_20	New style MC with separate paths for color and depth. 0 NONE 1 AVAILABLE
21 DEFAULT_REG0	Unavailable registers will return 0. 0 NONE 1 AVAILABLE
20 EXTRA_SHADER_INSTRUCTIONS1	Sqrt, sin, cos instructions are available. 0 NONE 1 AVAILABLE
19 SHADER_GETS_W	W is sent to SH from RA. 0 NONE 1 AVAILABLE
18 VG_21	Minor updates to VG pipe (Event generation from VG, TS, PE). Tiled image support. 0 NONE 1 AVAILABLE
17 VG_FILTER	VG filter is available. 0 NONE 1 AVAILABLE

*Table continues on the next page...*

**GPU2D\_MinorFeatures0 field descriptions (continued)**

Field	Description
16 EXTRA_SHADER_INSTRUCTIONS0	Floor, ceil, and sign instructions are available. 0 NONE 1 AVAILABLE
15 COMPRESSION_FIFO_FIXED	If this bit is not set, the FIFO counter should be set to 50. Else, the default should remain. 0 NONE 1 AVAILABLE
14 TS_EXTENDED_COMMANDS	New commands added to the tessellator. 0 NONE 1 AVAILABLE
13 VG_20	Major updates to VG pipe (TS buffer tiling. State masking.). 0 NONE 1 AVAILABLE
12 SUPER_TILED_32X32	32x32 super tile is available. 0 NONE 1 AVAILABLE
11 SEPARATE_TILE_STATUS_WHEN_INTERLEAVED	Use 2 separate tile status buffers in interleaved mode. 0 NONE 1 AVAILABLE
10 TILE_STATUS_2BITS	2 bits are used instead of 4 bits for tile status. 0 NONE 1 AVAILABLE
9 RENDER_8K	Supports 8K render target. 0 NONE 1 AVAILABLE
8 CORRECT_AUTO_DISABLE	Auto disable in FC is correct. 0 NONE 1 AVAILABLE
7 2DPE20	2D PE 2.0 is present. 0 NONE 1 AVAILABLE
6 FAST_CLEAR_FLUSH	Proper flush is done in fast clear cache. 0 NONE 1 AVAILABLE
5 SPECIAL_MSAA_LOD	Special LOD calculation when MSAA is on. 0 NONE 1 AVAILABLE

*Table continues on the next page...*

**GPU2D\_MinorFeatures0 field descriptions (continued)**

Field	Description
4 CORRECT_ TEXTURE_ CONVERTER	Driver hack is not needed.  0 NONE 1 AVAILABLE
3 TEXTURE8_K	Supports 8Kx8K textures.  0 NONE 1 AVAILABLE
2 ENDIANNESS_ CONFIG	Configurable endianness support.  0 NONE 1 AVAILABLE
1 DUAL_RETURN_ BUS	Dual Return Bus from HI to clients.  0 NONE 1 AVAILABLE
0 FLIP_Y	Y flipping capability is added to resolve.  0 NONE 1 AVAILABLE

**16.5.5.15 Cache Control Register (GPU2D\_CacheControl)**

Address: 400C\_F000h base + 38h offset = 400C\_F038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**GPU2D\_ChipSpecs field descriptions**

Field	Description
0–3 STREAMS	Number of vertex streams.
4–7 TEMP_ REGISTERS	Log2 of temporary registers.
8–11 THREAD_ COUNT	Log2 of thread count.

*Table continues on the next page...*

**GPU2D\_ChipSpecs field descriptions (continued)**

Field	Description
12–16 VERTEX_ CACHE_SIZE	Number of entries in the vertex shader cache.
17–19 -	This field is reserved. Reserved
20–24 NUM_SHADER_ CORES	Number of shader cores.
25–27 NUM_PIXEL_ PIPES	Number of pixel pipes.
28–31 VERTEX_ OUTPUT_ BUFFER_SIZE	Log2 of vertex output buffer size.

**16.5.5.20 Write Data Count Register (GPU2D\_TotalWriteBursts)**

Total write Data Count in terms of 64bits. This register has no reset value.

Address: 400C\_F000h base + 4Ch offset = 400C\_F04Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPU2D\_TotalWriteBursts field descriptions**

Field	Description
COUNT	Total write Data Count in terms of 64bits. This register has no reset value.

### 16.5.5.21 Write REQ Count Register (GPU2D\_TotalWriteReqs)

Total write Request Count. This register has no reset value.

Address: 400C\_F000h base + 50h offset = 400C\_F050h

**GPU2D\_TotalWriteReqs field descriptions**

Field	Description
COUNT	Total write Request Count. This register has no reset value.

### 16.5.5.22 Total WLAST Count Register (GPU2D\_TotalWriteLasts)

Total WLAST Count. This is used to match with GCTotalWriteReqs. This register has no reset value.

Address: 400C\_F000h base + 54h offset = 400C\_F054h

**GPU2D\_TotalWriteLasts field descriptions**

Field	Description
COUNT	Specifies the WLAST count. This is used to match with GCTotalWriteReqs.

16.5.5.23    Total Read Data Count Register (GPU2D\_TotalReadBursts)

Total Read Data Count in terms of 64bits. This register has no reset value.

Address: 400C\_F000h base + 58h offset = 400C\_F058h

GPU2D\_TotalReadBursts field descriptions

Field	Description
COUNT	Total Read Data Count in terms of 64bits. This register has no reset value.

16.5.5.24    Total Read REQ Count Register (GPU2D\_TotalReadReqs)

Total Read Request Count. This register has no reset value.

Address: 400C\_F000h base + 5Ch offset = 400C\_F05Ch

GPU2D\_TotalReadReqs field descriptions

Field	Description
COUNT	Total Read Request Count. This register has no reset value.

### 16.5.5.25 Total RLAST Count Register (GPU2D\_TotalReadLasts)

Total RLAST Count. This is used to match with GCTotalReadReqs. This register has no reset value.

Address: 400C\_F000h base + 60h offset = 400C\_F060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COUNT																															
W

**GPU2D\_AxiControl field descriptions**

Field	Description
WR_FULL_BURST_MODE	Write Full Burst Mode 0 NO_BURST_RESET_VALUE 1 BURST_RESET_VALUE

16.5.5.30 Minor Features Register 1 (GPU2D\_MinorFeatures1)

Shows which features are enabled in this chip. This register has no set reset value.

Address: 400C\_F000h base + 74h offset = 400C\_F074h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RSUV_SWIZZLE	V2_COMPRESSION	VG_DOUBLE_BUFFER	BUG_FIXES1	BUG_FIXES2	TEXTURE_STRIDE	Reserved									
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPU2D\_MinorFeatures1 field descriptions**

Field	Description
0 RSUV_SWIZZLE	Resolve UV swizzle. 0 NONE 1 AVAILABLE
1 V2_ COMPRESSION	V2 compression. 0 NONE 1 AVAILABLE
2 VG_DOUBLE_ BUFFER	Double buffering support for VG (second TS-->VG semaphore is present). 0 NONE 1 AVAILABLE
3 BUG_FIXES1	Bug Fixes 1 0 NONE 1 AVAILABLE
4 BUG_FIXES2	Bug Fixes 2 0 NONE 1 AVAILABLE
5 TEXTURE_ STRIDE	Texture has stride and memory addressing. 0 NONE 1 AVAILABLE
6–31 -	This field is reserved. Reserved

### 16.5.5.31 Total Cycle Counter Register (GPU2D\_TotalCycles)

Total cycles. This register is a free running counter. It can be reset by writing 0 to it.

Address: 400C\_F000h base + 78h offset = 400C\_F078h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### GPU2D\_TotalCycles field descriptions

Field	Description
CYCLES	Total cycles.

### 16.5.5.32 Total Idle Cycle Register (GPU2D\_TotalIdleCycles)

Total cycles where the GPU is idle. It is reset when gcTotalCycles register is written to. It looks at all the blocks but FE when determining the IP is idle.

Address: 400C\_F000h base + 7Ch offset = 400C\_F07Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CYCLES																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### GPU2D\_TotalIdleCycles field descriptions

Field	Description
CYCLES	Total cycles where the GPU is idle.

### 16.5.5.33 Chip Specification Register (GPU2D\_ChipSpecs2)

Specs for the chip. This register has no reset value.

Address: 400C\_F000h base + 80h offset = 400C\_F080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CYCLES																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### GPU2D\_ChipSpecs2 field descriptions

Field	Description
CYCLES	Specs for the chip.

### 16.5.5.34 Power Control Register (GPU2D\_ModulePowerControls)

The Power Management register set has just a few registers for controlling clock gating within the core. GC400 allows the user to control the clock gating of each internal module independently of the other modules. Users can access all of these registers via the AHB Bus.

Control register for module level power controls.

Address: 400C\_F000h base + 84h offset = 400C\_F084h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	ENABLE_MODULE_CLOCK_GATING	DISABLE_STALL_MODULE_CLOCK_GATING	DISABLE_STARVE_MODULE_CLOCK_GATING	Reserved	TURN_ON_COUNTER				Reserved								
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0

2D Graphics Processing Unit (GPU2D) (R-Series only)

GPU2D\_ModulePowerControls field descriptions

Field	Description
0 ENABLE_ MODULE_ CLOCK_GATING	Enables module level clock gating.
1 DISABLE_ STALL_ MODULE_ CLOCK_GATING	Disables module level clock gating for stall condition.
2 DISABLE_ STARVE_ MODULE_ CLOCK_GATING	Disables module level clock gating for starve/idle condition.
3 -	This field is reserved. Reserved
4-7 TURN_ON_ COUNTER	Number of clock cycles to wait after turning on the clock.
8-15 -	This field is reserved. Reserved
16-31 TURN_OFF_ COUNTER	Counter value for clock gating the module if the module is idle for this amount of clock cycles.

### 16.5.5.35 Power Level Register (GPU2D\_ModulePowerModuleControl)

Module level control registers.

Address: 400C\_F000h base + 88h offset = 400C\_F088h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPU2D\_ModulePowerModuleControl field descriptions**

Field	Description
0 DISABLE_MODULE_CLOCK_GATING_FE	Disables module level clock gating for FE.
1 DISABLE_MODULE_CLOCK_GATING_DE	Disables module level clock gating for DE.
2 DISABLE_MODULE_CLOCK_GATING_PE	Disables module level clock gating for PE.

*Table continues on the next page...*

**GPU2D\_ModulePowerModuleControl field descriptions (continued)**

Field	Description
3 DISABLE_ MODULE_ CLOCK_ GATING_SH	Disables module level clock gating for SH.
4 DISABLE_ MODULE_ CLOCK_ GATING_PA	Disables module level clock gating for PA.
5 DISABLE_ MODULE_ CLOCK_ GATING_SE	Disables module level clock gating for SE.
6 DISABLE_ MODULE_ CLOCK_ GATING_RA	Disables module level clock gating for RA.
7 DISABLE_ MODULE_ CLOCK_ GATING_TX	Disables module level clock gating for TX.
8 DISABLE_ MODULE_ CLOCK_ GATING_VG	Disables module level clock gating for VG.
9 DISABLE_ MODULE_ CLOCK_ GATING_IM	Disables module level clock gating for IM.
10 DISABLE_ MODULE_ CLOCK_ GATING_FP	Disables module level clock gating for FP.
11 DISABLE_ MODULE_ CLOCK_ GATING_TS	Disables module level clock gating for TS.
12–31 -	This field is reserved. Reserved

### 16.5.5.36 Power Status Register (GPU2D\_ModulePowerModuleStatus)

Module level control status.

Address: 400C\_F000h base + 8Ch offset = 400C\_F08Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MODULE_CLOCK_GATED_FE	MODULE_CLOCK_GATED_DE	MODULE_CLOCK_GATED_PE	MODULE_CLOCK_GATED_SH	MODULE_CLOCK_GATED_PA	MODULE_CLOCK_GATED_SE	MODULE_CLOCK_GATED_RA	MODULE_CLOCK_GATED_TX	MODULE_CLOCK_GATED_VG	MODULE_CLOCK_GATED_IM	MODULE_CLOCK_GATED_FP	MODULE_CLOCK_GATED_TS	Reserved			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

2D Graphics Processing Unit (GPU2D) (R-Series only)

GPU2D\_ModulePowerModuleStatus field descriptions

Field	Description
0 MODULE_ CLOCK_ GATED_FE	Module level clock gating is ON for FE.
1 MODULE_ CLOCK_ GATED_DE	Module level clock gating is ON for DE.
2 MODULE_ CLOCK_ GATED_PE	Module level clock gating is ON for PE.
3 MODULE_ CLOCK_ GATED_SH	Module level clock gating is ON for SH.
4 MODULE_ CLOCK_ GATED_PA	Module level clock gating is ON for PA.
5 MODULE_ CLOCK_ GATED_SE	Module level clock gating is ON for SE.

Table continues on the next page...

**GPU2D\_ModulePowerModuleStatus field descriptions (continued)**

Field	Description
6 MODULE_ CLOCK_ GATED_RA	Module level clock gating is ON for RA.
7 MODULE_ CLOCK_ GATED_TX	Module level clock gating is ON for TX.
8 MODULE_ CLOCK_ GATED_VG	Module level clock gating is ON for VG.
9 MODULE_ CLOCK_ GATED_IM	Module level clock gating is ON for IM.
10 MODULE_ CLOCK_ GATED_FP	Module level clock gating is ON for FP.
11 MODULE_ CLOCK_ GATED_TS	Module level clock gating is ON for TS.
12–31 -	This field is reserved. Reserved

## 16.6 Video subsystem

### 16.6.1 Introduction

The video subsystem consists of an analog video front end (AFE), a digital video decoder, and video interface unit. The AFE accepts NTSC or PAL input from a device such as an analog camera. The video decoder provides YUV444-formatted data to the video interface unit (VIU).

Figure 16-42. Video subsystem block diagram

## 16.6.2 External signal description

The following table is a list of signals driven by external pins.

Table 16-40. Video subsystem external signals

Name	Module	Description	Input/Output
VADCSE0	Video AFE	Composite video input 0	Input
VADCSE1	Video AFE	Composite video input 1	Input
VADCSE2	Video AFE	Composite video input 2	Input
VADCSE3	Video AFE	Composite video input 3	Input
VADC_AFE_BANDGAP	Video AFE	Band gap decoupling	Input/Output

### 16.6.3 Analog front end (AFE)

The analog front end (AFE) digitizes an analog video signal such as from an inexpensive analog camera. The video signal can be selected from one of four inputs, VIN0-VIN3, through register control.

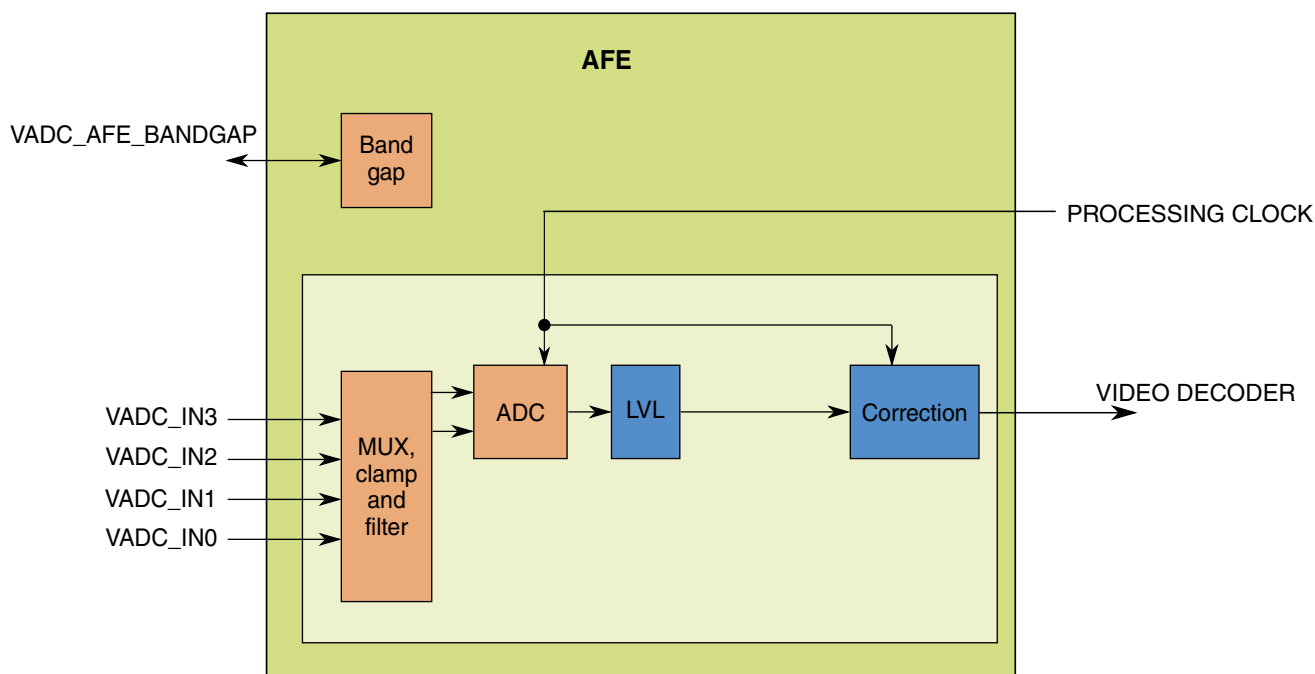

Figure 16-43. Analog front end block diagram

#### 16.6.3.1 AFE features

The AFE includes the following features.

- Internal voltage and current reference generator
- 10-bit resolution
- 4 analog inputs. All inputs usable for CVBS.
- Programmable anti-aliasing filter, gain, and clamp

### 16.6.3.2 AFE controller preset

The AFE module does not have a correct default configuration after reset. It is necessary to preset the controller's default configuration before configuring the controller with operational settings. This is done by writing to the following addresses with the corresponding data:

**Table 16-41. AFE default configuration**

Address	Data
0X400C7420	0x25
0X400C7430	0x05
0X400C742C	0x0f
0X400C7440	0x10
0X400C7444	0x05

#### NOTE

These addresses are for preset purposes only. The registers are not documented as they have no application level usage.

### 16.6.4 AFE memory map and registers

#### NOTE

The AFE registers must be programmed before enabling the Video ADC clock. Refer to the CCM\_CSCDR1 register settings in the Clock Control Module chapter for more information.

**AFE memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

R	0								clamp_current_reg_override		clamp_updn_reg_override		clamp_dacdata_weight		clamp_dacdata_extra	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### AFE\_CLMPAMP field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 clamp_current_reg_override	Override clamp current ports and control through registers. 0 Ports 1 Register
5 clamp_updn_reg_override	Override clamp up down ports and control through registers. 0 Ports 1 Register
4–3 clamp_dacdata_weight	Maps clamp_current input to clampdac_data port in mixed-signal block. 00 No shift 01 Shift by 1 10 Shift by 2 11 Shift by 3
clamp_dacdata_extra	Clamp DAC extra data  Defines non-assigned bits when in current leakage mode. Fills out missing bits when mapping from five bits to eight bits.

### 16.6.4.18 Clamp Control (AFE\_CLAMP)

Address: 400C\_7000h base + 45Ch offset = 400C\_745Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								clamp_pwm_mode	clamp_up_down_polarity	clamp_irefselect	clamp_lowcurrmode	clamp_inen_reg	clamp_ipen_reg	Reserved	nclamp_powersave
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### AFE\_CLAMP field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 clamp_pwm_mode	Enable PWM mode 0 Constant 1 PWM
6 clamp_up_down_polarity	Defines polarity of MSB in clamp_current port. 0 Non-inverted 1 Inverted
5 clamp_irefselect	Enable current reference to the clamp DAC. 0 Off 1 On
4 clamp_lowcurrmode	Enable low current mode 0 Normal 1 Low current
3 clamp_inen_reg	Clamp down. Remove charge. Only valid when clamp_updn_reg_override. 0 No pump down 1 Pump down
2 clamp_ipen_reg	Clamp up. Add charge. Only valid when clamp_updn_reg_override.

Table continues on the next page...

**AFE\_CLAMP field descriptions (continued)**

Field	Description
	0 No pump up 1 Pump up
1 Reserved	This field must remain set to 0.  This field is reserved.
0 nclamp_ powersave	Active-low power save  0 Power save 1 Normal

**16.6.4.19 Input Buffer (AFE\_INPBUF)**

Address: 400C\_7000h base + 460h offset = 400C\_7460h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**AFE\_INPFLT field descriptions**

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–3 mux_enlf	Analog input enable  Selects which input port is used by the ADC. <ul style="list-style-type: none"> <li>• 0x0: all ports disabled</li> <li>• 0x1: Port 0</li> <li>• 0x2: Port 1</li> <li>• 0x4: Port 2</li> <li>• 0x8: Port 3</li> </ul> All other bit combinations are invalid.
2 mux_filterbypass	Fiter bypass  Bypasses filter when set together with AFE_INPBUF[mux_buffer_bp_en].  0   Disable bypass 1   Enable bypass
1 mux_filter_15m_en	15 MHz filter enable  Selects 15 MHz low-pass filter when set together with AFE_INPBUF[mux_buffer_15m_en].  0   Disable filter 1   Enable filter
0 mux_ pdcurrentmirror	Power down current mirror  Enable buffter current mirrors  0   Power down 1   Normal

### 16.6.4.21 ADC Digital Gain (AFE\_ADCDGN)

Address: 400C\_7000h base + 468h offset = 400C\_7468h

#### AFE\_ADCDGN field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 adc_digital_gain_ bypass	Bypass digital gain 0 Normal 1 Bypass
adc_digital_gain	ADC digital gain  Gain is equal to $1 + \text{adc\_digital\_gain}/256$ .

### 16.6.4.22 Off-Chip Drive (AFE\_OFFDRV)

Address: 400C\_7000h base + 46Ch offset = 400C\_746Ch

**AFE\_OFFDRV field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–4 input_pulldown_en	Input pull-down enable  Enable (1) or disable (0) pull down input ports. Each port is mapped to its respective bit and should be set to the inverse of AFE_INPLFT[mux_enlf].  Bit 4 Pull-down input 0 Bit 5 Pull-down input 1 Bit 6 Pull-down input 2 Bit 7 Pull-down input 3
Reserved	This field is reserved.

**16.6.4.23 Acc ID (AFE\_ACC\_ID)**

Address: 400C\_7000h base + 800h offset = 400C\_7800h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### AFE\_ASAREG field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–5 asa_reg	ADC sample acquisition
4 Reserved	This field is reserved.
3 asa_reg9	ADC sample acquisition. Enable 9 slices. Only one of bits 4 down-to 1 can be set. 0 Disable 1 Enable 9 Slices
2 asa_reg5	ADC sample acquisition. Enable 5 slices. Only one of bits 4 down-to 1 can be set. 0 Disable 1 Enable 5 Slices
1 asa_reg3	ADC sample acquisition. Enable 3 slices. Only one of bits 4 down-to 1 can be set. 0 Disable 1 Enable 3 slices
0 Reserved	This field is reserved.

16.6.4.25 ADC Sample Compensation (AFE\_ASCREG)

Address: 400C\_7000h base + 810h offset = 400C\_7810h

AFE\_ASCREG field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–1 Reserved	This field is reserved.
0 asc_reg	ADC offset compensation  Disables digital slice-to-slice offset compensation.  0    Enable slice-to-slice offset compensation 1    Disable slice-to-slice offset compensation

### 16.6.4.26 Block Level Control Register (AFE\_BLCREG)

Address: 400C\_7000h base + 814h offset = 400C\_7814h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0								Reserved							start_cal	en_bypass
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### AFE\_BLCREG field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–2 Reserved	This field is reserved.
1 start_cal	Start calibration Starts calibration when set to 1.  0 Normal 1 Start
0 en_bypass	Enable bypass  0 Normal 1 Bypass

16.6.4.27 ADC Operation Controller 0 (AFE\_AOCREG0)

Address: 400C\_7000h base + 824h offset = 400C\_7824h

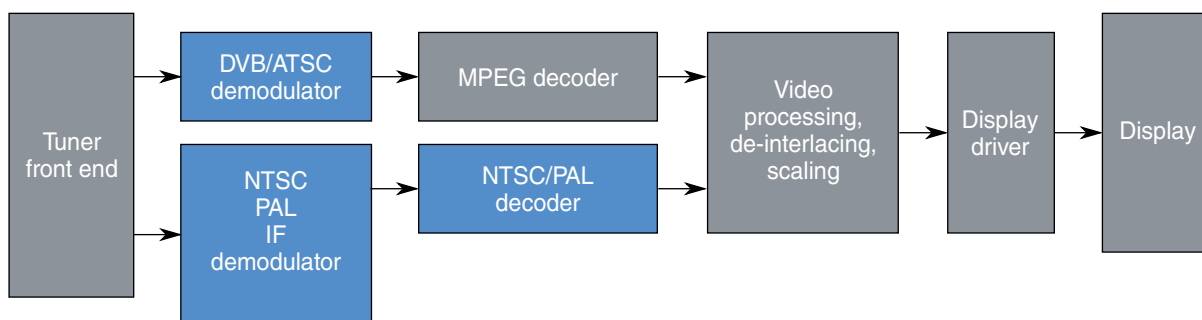

AFE\_AOCREG0 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–1 Reserved	This field is reserved.
0 start_cal	Start calibration  0 Normal 1 Start

16.6.5 Video decoder

The video decoder is comprised of the following blocks.

- DVB/ATSC demodulator
- NTSC/PAL IF demodulator
- NTSC/PAL decoder
- Video processing, noise reduction, de-interlacing, and scaling

**Figure 16-44. Video decoder block diagram**

### 16.6.5.1 Video decoder features

The video decoder includes the following features.

- Accepts NTSC (J, M, 4.43), PAL (B, D, G, H, I, M, N, Nc) Video
- Adaptive 2-D, 5-line, adaptive comb filter for composite video inputs
- NTSC/PAL decoder
- Automatic video standard detection (NTSC/PAL) and switching
- Datapath/clocking architecture encompasses a time base corrector for VCR signals
- Luma passband is flat to >6MHz
- Brightness, Contrast, Saturation, Hue, Sharpness Control
- Internal Phase-Locked Loop (PLL) for Line-Locked Clock and Sampling
- Anti-aliasing filter

### 16.6.5.2 VDEC controller preset

The Video Decoder module does not have a correct default configuration after reset. It is necessary to preset the controller's default configuration before configuring the controller with operational settings. This is done by writing to the following addresses with the corresponding data:

**Table 16-42. VDEC default configuration**

Address	Data
0x400C8050	0x10
0x400C804C	0x13
0x400C8004	0x34
0x400C8008	0x01
0x400C800C	0x18
0x400C8010	0x34

*Table continues on the next page...*

**Table 16-42. VDEC default configuration (continued)**

Address	Data
0x400C803C	0x20
0x400C8124	0x02
0x400C8128	0x20
0x400C812C	0x08
0x400C8130	0x08
0x400C8080	0x20
0x400C8074	0x90
0x400C80CC	0xa0
0x400C80F4	0x41
0x400C8100	0x81
0x400C80E8	0x80
0x400C801C	0x02
0x400C8030	0x04
0x400C80F0	0xFF

**NOTE**

These addresses are for preset purposes only. The registers are not documented as they have no application level usage.

**VDEC\_VSCON1 field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 rh_8or16	Vsync detector Select vsync detector 0 new 16 long vsync detector 1 old shorter vsync detector
6 rh_modadd_dis	Debug Debug test mode only
5 rh_vsynchronhalfmode	Vsync half mode Use half lines instead of quarter lines.
4 rh_dis_vsynchrondetect	Disable vsync detection When set, do not look for any new vsync phases. Coast in previously found phase.
3 rh_robust625det	Robust 625 detection Selects a more robust method of determining 525 or 625 line mode. In particular this will coast in the last known mode in the event of no signal.
rh_vdet_dbg	Vsync debug mode Sets the Vsync debug output mode that can be seen by setting VIDOUTDBG[r_sel2] to 1. 0 Predicted location of Vsync 1 High when a new Vphase is set in the IP

*Table continues on the next page...*

**VDEC\_VSCON1 field descriptions (continued)**

Field	Description
2	Very simple Vsync detector for debug output only
3	High when several valid Vsyzns in a row are detected
4	High when this field's possible Vsync phases are looked at
5	The many detected Vsyzns (false and real)
6	High when twice as many Vsync phases are matching (i.e., twice as many as the 3 debug output).
7	Low-pass filtered luma falling edge detector. This is a crude Vsync detector used in conjunction with other methods to remove false detections

**16.6.6.9 VSync Control 2 (VDEC\_VSCON2)**

Address: 400C\_8000h base + 64h offset = 400C\_8064h

## VDEC\_YCDEL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–4 rd_lumadel	Luma delay  Luma delay relative to chroma in half pixel increments  0 new 16 long vsync detector 1 old shorter vsync detector
3 Reserved	This field is reserved.

Table continues on the next page...

**VDEC\_YCDEL field descriptions (continued)**

Field	Description
2 rd_wide	Wide mode  Force the chroma output low pass filter into wide mode. Undefined if this field and rd_narrow are both set to 1.
1 rd_narrow	Narrow mode  Force the chroma output low-pass filter into narrow mode. Undefined if this field and rd_wide are both set to 1.
0 rd_nopalave	No PAL averaging  Turn off the two-line PAL chroma averaging. For debug only.

**16.6.6.11 After Clamp (VDEC\_AFTCLP)**

Address: 400C\_8000h base + 70h offset = 400C\_8070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## VDEC\_CHBTH field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
rd_ch_thresh	Chroma burst threshold  This is the level above which the chroma burst must be in order to process chroma. Below this value no chroma is assumed. Accepts unsigned number from 0 to 127.

## 16.6.6.20 Sharpness Improvement (VDEC\_SHPIMP)

Address: 400C\_8000h base + A4h offset = 400C\_80A4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																rd_slope								rd_peak							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## VDEC\_SHPIMP field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–4 rd_slope	Slope  Slope value is a signed number.  0x0 No effect 0x1 - 0x7 Positive slope compensation 0xf - 0x8 Negative slope compensation
rd_peak	Peak

Table continues on the next page...

**VDEC\_SHPIMP field descriptions (continued)**

Field	Description
	Added luma sharpness
0	No sharpness increase
15	Maximum sharpness increase

**16.6.6.21 Chroma PLL and Input Mode (VDEC\_CHPLLIM)**

Address: 400C\_8000h base + A8h offset = 400C\_80A8h

## VDEC\_VIDMOD field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

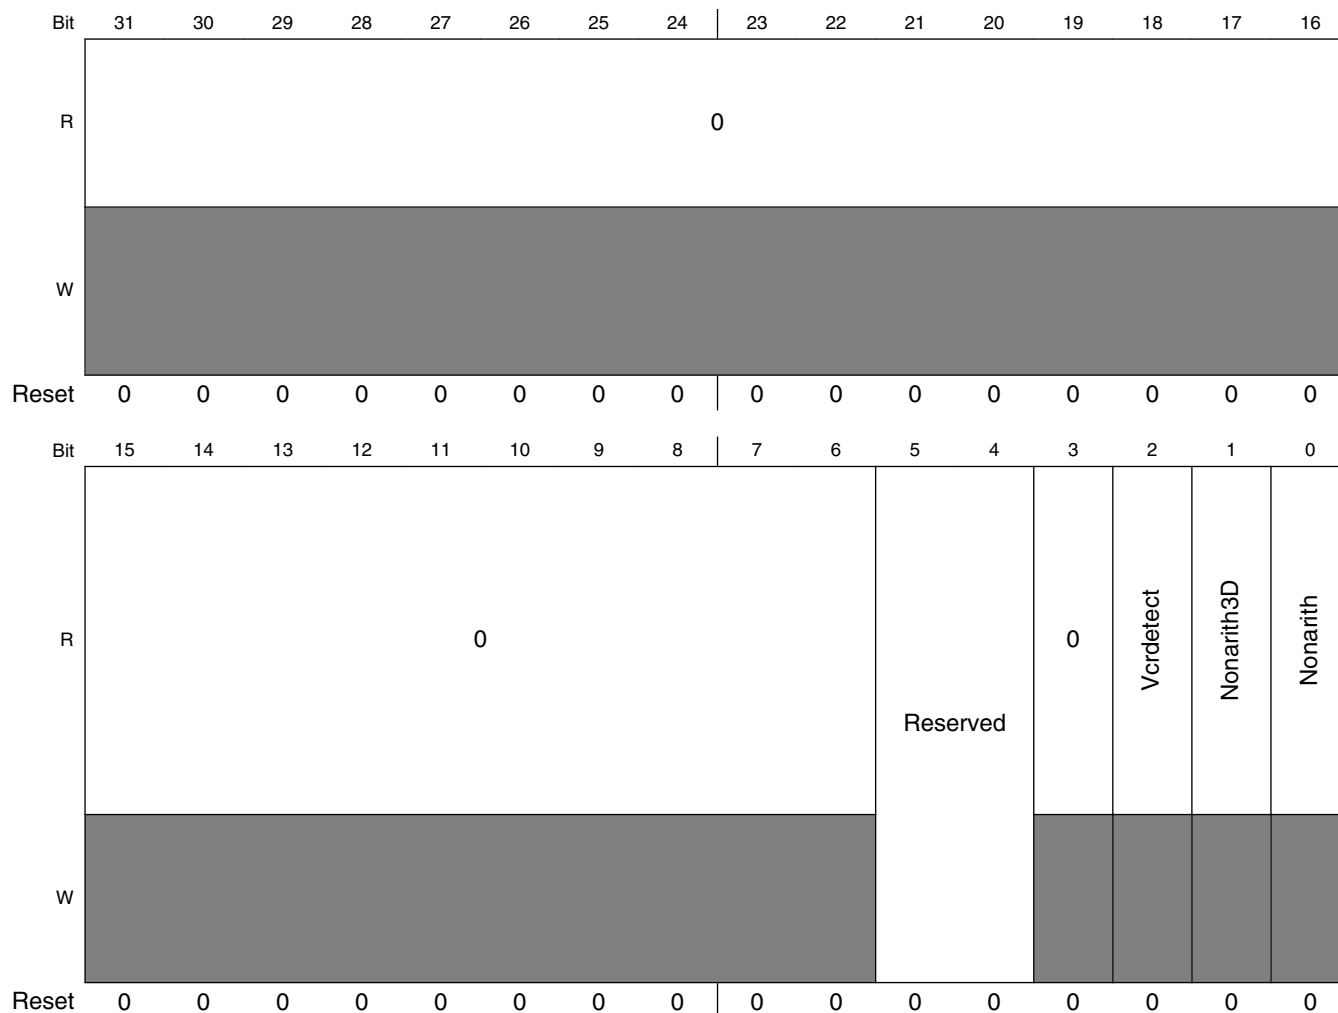

Table continues on the next page...

**VDEC\_VIDMOD field descriptions (continued)**

Field	Description
7 Pal	PAL detected 0 PAL modulation not detected. 1 PAL modulation detected.
6 F443	4.43MHz chroma detected 0 No chroma carrier in the 4.43MHz range is detected. 1 A chroma carrier in the 4.43MHz range is detected.
5 Secam	SECAM detected 0 SECAM modulation not detected. 1 SECAM modulation detected.
4 m625	625 mode 0 The signal is not in 625 line mode. 1 The signal is in 625 line mode.
3 ch_locked	Chroma locked 0 Not locked to the chroma carrier 1 Locked to the chroma carrier
2 chroma	Chroma carrier detected 0 A chroma carrier is not present. 1 A chroma carrier is present.
1 Hlocked	Hsync locked 0 Not locked to the Hsync 1 Locked to the Hsync
0 havesignal	Have signal 0 A valid video signal is not detected. 1 A valid video signal is detected.

### 16.6.6.23 Video Status (VDEC\_VIDSTS)

Address: 400C\_8000h base + B0h offset = 400C\_80B0h

**VDEC\_VIDSTS field descriptions**

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 Reserved	This field is reserved.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Vcrdetect	VCR detected High when a VCR signal is detected
1 Nonarith3D	Nonarithmetic 3D ratio High when an invalid nonarithmetic ratio for 3D comb is detected

*Table continues on the next page...*

**VDEC\_VIDSTS field descriptions (continued)**

Field	Description
0 Nonarith	Invalid nonarithmetic ratio  High when an invalid nonarithmetic ratio detected

**16.6.6.24 Noise Detector (VDEC\_NOISE)**

Address: 400C\_8000h base + B4h offset = 400C\_80B4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**VDEC\_STDDBG field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 rd_fc_maual	Manual carrier frequency Enable manual Fc carrier frequency instead of hardcoded internal frequencies.
6 ntscj	NTSC keep pedestal When this field is set to 1, detection of NTSC will not remove the pedestal level.
5 force_2dntsc443	Force 2D NTSC 443 For the use of the 2D comb filter in NTSC 443 mode
4 Reserved	This field is reserved.
3 force_havesignal	Force have signal Override the video signal detector so as to appear to always have a valid video signal.
2 Reserved	This field is reserved.
standard_filter	Standard filter This field should be set to 3. Lower values cause faster standards detect.

16.6.6.26 Manual Override (VDEC\_MANOVR)

NOTE

Pink cast over images in PAL mode can be got rid of by writing a value of 0xFD in this register. Upper nibble 0xF overrides auto detect of PAL and SECAM, while lower nibble 0xD selects PAL manually.

Address: 400C\_8000h base + BCh offset = 400C\_80BCh

VDEC\_MANOVR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 pal_override	PAL override 0 No override 1 Override PAL mode auto detection
6 f443_override	443 override 0 No override 1 Override 443 mode auto detection
5 secam_override	SECAM override 0 No override 1 Override SECAM mode auto detection
4 line625_override	Line 625 override

Table continues on the next page...

**VDEC\_MANOVR field descriptions (continued)**

Field	Description
	0 No override 1 Override 625-line mode auto detection
3 pal_manual	PAL manual override 0 No override 1 Override manual setting of PAL mode with auto mode
2 four43_manual	443 manual override 0 No override 1 Override manual setting of 443 mode with auto mode
1 secam_manual	SECAM manual 0 No override 1 Manual setting of SECAM mode with auto mode is overridden
0 manual_625	Manual 625 0 No override 1 Manual setting of 625 line mode with auto mode is overridden

**16.6.6.27 VSync and Signal Thresholds (VDEC\_VSSGTH)**

Address: 400C\_8000h base + C8h offset = 400C\_80C8h

#### VDEC\_HACTE field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ro_hactiveend	H active end  Programs the end of the Hactive output. Measured in pixels before the Hsync falling edge. The longer total line of 625 line modes is automatically taken care of.

### 16.6.6.32 V Active Start (VDEC\_VACTS)

Address: 400C\_8000h base + E0h offset = 400C\_80E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																ro_vactivestart															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**VDEC\_VACTS field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ro_vactivestart	V active start  Programs the start of the Vactive output. Measured in half lines after the Vsync

**16.6.6.33 V Active End (VDEC\_VACTE)**

Address: 400C\_8000h base + E4h offset = 400C\_80E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**VDEC\_VACTE field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ro_vactiveend	V active end  Programs the end of the Vactive output. Measured in half lines before the Vsync.

**16.6.6.34 HSync Tip (VDEC\_HSTIP)**

Address: 400C\_8000h base + ECh offset = 400C\_80ECh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**VDEC\_HSTIP field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
rh_tipgate_start	Tip gate start  Set the position in pixels of the start of the Hsync tip gate, which is always 32 pixels. This is used in the after clamp.

### 16.6.6.35 Bluescreen Y (VDEC\_BLSCRY)

Address: 400C\_8000h base + F4h offset = 400C\_80F4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																bluescreen_y															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### VDEC\_BLSCRY field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
bluescreen_y	Bluescreen Y  The Y output value with in blue screen mode which is set when there is no valid video signal input detected.

### 16.6.6.36 Bluescreen Cr (VDEC\_BLSCRCR)

Address: 400C\_8000h base + F8h offset = 400C\_80F8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																bluescreen_cr															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### VDEC\_BLSCRCR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
bluescreen_cr	Bluescreen Cr  The Cr output value when in bluescreen mode, which is set when there is no valid video signal input detected.

### 16.6.6.37 Bluescreen Cb (VDEC\_BLSCRCB)

Address: 400C\_8000h base + FCh offset = 400C\_80FCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																bluescreen_cb															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**VDEC\_BLSCRCB field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
bluescreen_cb	Blue screen Cb  The Cb output value when in blue screen mode, which is set when there is no valid video signal input detected.

**16.6.6.38 Luma AGC Control 2 (VDEC\_LMAGC2)**

Address: 400C\_8000h base + 104h offset = 400C\_8104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																ragc_target															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**VDEC\_LMAGC2 field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ragc_target	AGC target  Sets the sync tip to black level target value for the AGC.

**16.6.6.39 Chroma AGC Control 2 (VDEC\_CHAGC2)**

Address: 400C\_8000h base + 10Ch offset = 400C\_810Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																rd_chagc_target															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**VDEC\_CHAGC2 field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
rd_chagc_target	Chroma AGC target  Sets the burst target height for the chroma AGC.

### 16.6.6.40 Minimum Threshold (VDEC\_MINTH)

Address: 400C\_8000h base + 114h offset = 400C\_8114h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																minthresh															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### VDEC\_MINTH field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
minthresh	Minimum threshold  Sets the threshold for the minimum filter in the Hsync PLL. Larger values improve noise immunity.

### 16.6.6.41 Vertical Lines High (VDEC\_VFRQOH)

Address: 400C\_8000h base + 11Ch offset = 400C\_811Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																vfreqo															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### VDEC\_VFRQOH field descriptions

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
vfreqo	Vertical frequency  Number of half vertical lines detected in video field. If the number is odd then signal is interlaced video.

16.6.6.42 Vertical Lines Low (VDEC\_VFRQOL)

Address: 400C\_8000h base + 120h offset = 400C\_8120h

- \* Notes:
- x = Undefined at reset.

VDEC\_VFRQOL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
vfreqo	Vertical frequency  Number of half vertical lines detected in video field. If the number is odd then signal is interlaced video.

16.7 Video Interface Unit (VIU)

16.7.1 Introduction

The VIU is a bridge between video decoder and system memory. It accepts an ITU656 compatible video stream, or parallel YUV/RGB input, converting image data between YUV and RGB color spaces, scaling image size, adjusting the brightness/contrast, and writing image data to memory with many kinds of image data formats.

The figure below shows a block diagram of the Video-In 3 (VIU3).

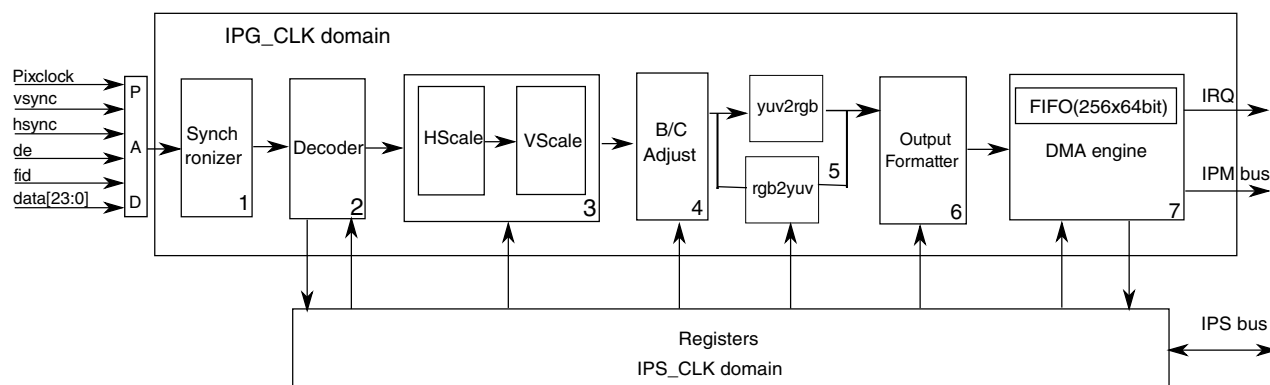

Figure 16-45. VIU3 Block Diagram

**NOTE**

RGB888 in to RGB888 out with no signal quality loss is supported when blocks 2 to 5 are set to transparent mode.

**16.7.2 Features**

- Supports from QVGA to XVGA input/output resolution
- 8-bit ITU656 video input<sup>1</sup>
- RGB888/RGB666/RGB565 parallel input
- RGB888 input with one color component transferred per clock
- 24-bit YUV parallel input from analog video decoder
- Up to 1/8 video down-scaling on horizontal and vertical direction
- Up to 2/1 horizontal video up-scaling
- Horizontal mirroring
- Brightness/contrast adjust
- YUV to RGB 888/565 conversion
- RGB to YUV conversion when input is RGB
- Simple de-interlace function (weaving) for interlaced or pseudo interlaced video input
- Internal DMA engine for transferring data from FIFO to system memory

1. When down scaling and/or B/C adjust is enabled, the two LSB's of the 10-bit input are ignored.

## 16.7.3 Video Input Signal Mapping

Table 16-43. Video Input Signals

Signal	RGB565	RGB666	RGB888	RGB888 (3 cycle)	ITU656 (10-bit)	ITU656 (8-bit)	Parallel YUV (24-bit)

## 16.7.4 Memory map and register definition

The memory map for the VIU3 module is given below. The total address for each register is the sum of the base address for the VIU3 module and the address offset for each register. Also, please note that the bit order for each register bit field is [highest:lowest], whereas the overall register bits are numbered [lowest:highest].

**VIU3 memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400C_9000	Status And Configuration Register (VIU3_SCR)	32	R/W	0280_0000h	<a href="#">16.7.4.1/ 3635</a>
400C_9004	Luminance Coefficients For Red, Green And Blue Matrix (VIU3_LUMA_COMP)	32	R/W	9512_A254h	<a href="#">16.7.4.2/ 3638</a>
400C_9008	Chroma Coefficients For Red Matrix (VIU3_CHROMA_RED)	32	R/W	0331_0000h	<a href="#">16.7.4.3/ 3639</a>
400C_900C	Chroma Coefficients For Green Matrix (VIU3_CHROMA_GREEN)	32	R/W	0660_0F38h	<a href="#">16.7.4.4/ 3640</a>
400C_9010	Chroma Coefficients For Blue Matrix (VIU3_CHROMA_BLUE)	32	R/W	0000_0409h	<a href="#">16.7.4.5/ 3640</a>
400C_9014	Base Address Of Every Field/Frame Of Picture In Memory (VIU3_DMA_ADDR)	32	R/W	0000_0000h	<a href="#">16.7.4.6/ 3641</a>
400C_9018	Horizontal DMA Increment (VIU3_DMA_INC)	32	R/W	0000_0000h	<a href="#">16.7.4.7/ 3641</a>
400C_901C	Input Video Pixel and Line Count (VIU3_INVSZ)	32	R/W	00F0_02D0h	<a href="#">16.7.4.8/ 3642</a>
400C_9020	High IPM Request Priority Alarm (VIU3_HPRALRM)	32	R/W	0000_0090h	<a href="#">16.7.4.9/ 3642</a>
400C_9024	Programable Alpha Value (VIU3_ALPHA)	32	R/W	0000_00FFh	<a href="#">16.7.4.10/ 3643</a>
400C_9028	Down Scaling Factor In Horizontal Direction (VIU3_HFACTOR)	32	R/W	0000_0100h	<a href="#">16.7.4.11/ 3643</a>
400C_902C	Down Scaling Factor In Vertical Direction (VIU3_VFACTOR)	32	R/W	0000_0100h	<a href="#">16.7.4.12/ 3643</a>
400C_9030	Down Scaling Destination Pixel and Line Count (VIU3_VID_SIZE)	32	R/W	00F0_02D0h	<a href="#">16.7.4.13/ 3644</a>
400C_9034	B/C Adjust Look-up-table Current Address (VIU3_LUT_ADDR)	32	R/W	0000_0000h	<a href="#">16.7.4.14/ 3644</a>
400C_9038	B/C Adjust Look-up-table Data Entry (VIU3_LUT_DATA)	32	R/W	Undefined	<a href="#">16.7.4.15/ 3645</a>
400C_903C	Extended Configuration Register (VIU3_EXT_CONFIG)	32	R/W	0000_0100h	<a href="#">16.7.4.16/ 3645</a>
400C_9040	Red, Green and Blue Coefficients for Luminance component (VIU3_RGB_Y)	32	R/W	2108_1032h	<a href="#">16.7.4.17/ 3647</a>

*Table continues on the next page...*

## VIU3 memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400C_9044	Red, Green and Blue Coefficients for Chroma U component (VIU3_RGB_U)	32	R/W	1304_A8E1h	<a href="#">16.7.4.18/3648</a>
400C_9048	Red, Green and Blue Coefficients for Chroma V component (VIU3_RGB_V)	32	R/W	3845_E024h	<a href="#">16.7.4.19/3648</a>

### 16.7.4.1 Status And Configuration Register (VIU3\_SCR)

## Video Interface Unit (VIU)

### VIU3\_SCR field descriptions

Field	Description
31 MODE32BIT	Select 32-bit or 16-bit output from the output formatter (block 6 in <a href="#">Figure 16-45</a> )  <b>NOTE:</b> For RGB666 parallel input, when MODE32BIT is cleared, the output is {R[5:1], G[5:0], B[5:1]}; when MODE32BIT is set, the output is {R[5:0], 2'b00, G[5:0], 2'b00, B[5:0], 2'b00}  0 16-bit RGB or YUV 4:2:2 output 1 32-bit RGB or YUV 4:4:4 output. DITHER_ON and ROUND_ON are ignored if output is 32-bit RGB.
30 ROUND_ON	Round is on. Used when video data is stored in buffer as RGB565 format.
29 DITHER_ON	Dithering is on. Used when video data is stored in buffer as RGB565 format and ROUND_ON is not set.
28 FIELD_NO	Field number, extracted from ITU-656 stream.
27 DMA_ACT	DMA transfer of current field/frame is busy (write by software, cleared at end of transfer). When DMA_ACT is cleared, input video data is ignored and not put into FIFO.
26 SCALER_EN	Down scaling enable.
25 YUV2RGB_EN	YUV to RGB conversion enable.
24 BC_EN	Bright/Contrast adjust enable.
23 MODE444	YUV 4:4:4 mode enable bit. When it is set ITU decoder sends out YUV 4:4:4 format data, otherwise YUV 4:2:2 is sent by default. Down scaler works on YUV 4:2:2 format. So this bit shall be cleared when scaling is enabled.
22 RESERVED	This field is reserved.

Table continues on the next page...

## VIU3\_SCR field descriptions (continued)

Field	Description
21 ERROR_IRQ	Interrupt status bit. Write '1' to clear ERROR_IRQ.
20 DMA_END_IRQ	Interrupt status bit. Write '1' to clear DMA_END_IRQ.
19 VSTART_IRQ	Interrupt status bit. Write '1' to clear VSTART_IRQ.
18 HSYNC_IRQ	Interrupt status bit. Write '1' to clear HSYNC_IRQ.
17 VSYNC_IRQ	Interrupt status bit. Write '1' to clear VSYNC_IRQ.
16 FIELD_IRQ	Interrupt status bit. Write '1' to clear FIELD_IRQ.
15 RESERVED	This field is reserved.
14 ECC_EN	When this bit is set ECC errors generate ERROR_IRQ and the nature of ECC error gets reflected on the ERROR_CODE bit field.
13 ERROR_EN	Interrupt enable bit for ERROR_IRQ.
12 DMA_END_EN	Interrupt enable bit for DMA_END_IRQ.
11 VSTART_EN	Interrupt enable bit for VSTART_IRQ.
10 HSYNC_EN	Interrupt enable bit for HSYNC_IRQ.
9 VSYNC_EN	Interrupt enable bit for VSYNC_IRQ.
8 FIELD_EN	Interrupt enable bit for FIELD_IRQ.
7-4 ERROR_CODE	<p>Error code. Signals errors that triggered error IRQ. Other values not given are reserved.</p> <p>0000 No error</p> <p>0001 DMA arm command given during vertical active, DMA_ACT does not accept the value on IPS bus.</p> <p>0010 DMA arm command given during vertical blanking when DMA_ACT is set.</p> <p>0100 Line too long</p> <p>0101 Too many lines in a field/frame</p> <p>0110 Line too short</p> <p>0111 Not enough lines in a field/frame</p> <p>1000 FIFO overflow</p> <p>1001 FIFO underflow</p> <p>1010 One bit ECC error</p> <p>1011 Two or more bits ECC error</p>
3-1 FORMAT_CTRL	<p>Output pixel data format control. See below or refer to <a href="#">Figure 16-45</a> for detailed definition. Here 32-bit means MODE32BIT is set and 16-bit means MODE32BIT is cleared. RGB mode means YUV2RGB_EN is set and YUV mode means YUV2RGB_EN is cleared. C means U or V. Dummy means "don't care" data.</p> <p>16-bit RGB mode:</p> <p>3'b000: {R[7:3], G[7:2], B[7:3]};</p>

Table continues on the next page...

**VIU3\_SCR field descriptions (continued)**

Field	Description
	3'b001: {G[4:2], B[7:3], R[7:3], G[7:5]};  32-bit RGB mode: 3'b000: {alpha, R, G, B}; 3'b001: {alpha, B, G, R}; 3'b010: {R, G, B, alpha}; 3'b011: {B, G, R, alpha};  16-bit YUV mode: 3'b000: {C,Y}; 3'b001: {Y,C};  32-bit YUV mode: 3'b000: {dummy, Y, U, V}; 3'b001: {dummy, Y, V, U}; 3'b010: {dummy, U, V, Y}; 3'b011: {dummy, V, U, Y}; 3'b100: {Y, U, V, dummy}; 3'b101: {Y, V, U, dummy}; 3'b110: {U, V, Y, dummy}; 3'b111: {V, U, Y, dummy};
0 SOFT_RESET	Writing 1 to this bit generates an internal reset to all components except registers in the VIU3 block. This bit should be set by software when an error interrupt is detected, and it needs to be cleared by software to release the software reset.

**16.7.4.2 Luminance Coefficients For Red, Green And Blue Matrix (VIU3\_LUMA\_COMP)**

The RGB pixel value is computed using following formulae:

$$\text{Red} = \frac{(Y - 16) \cdot Y\_RED}{512} + \frac{(Cr - 128) CR\_RED}{512} + \frac{(Cb - 128) CB\_RED}{512}$$

$$\text{Green} = \frac{(Y - 16) \cdot Y\_GREEN}{512} + \frac{(Cr - 128) CR\_GREEN}{512} + \frac{(Cb - 128) CB\_GREEN}{512}$$

$$\text{Blue} = \frac{(Y - 16) \cdot Y\_BLUE}{512} + \frac{(Cr - 128) CR\_BLUE}{512} + \frac{(Cb - 128) CB\_BLUE}{512}$$

The multiplications with Y\_red, Y\_green, and Y\_blue are unsigned multiplications. The multiplications with Cr\_red, Cb\_red, Cr\_green, Cb\_green, Cr\_blue, and Cb\_blue are signed multiplications. The addition is saturated to prevent overflow.

Address: 400C\_9000h base + 4h offset = 400C\_9004h

**VIU3\_LUMA\_COMP field descriptions**

Field	Description
31–22 Y_RED	(Y_RED[9:0]) Luminance coefficient for red matrix.
21 RESERVED	This field is reserved.
20–11 Y_GREEN	(Y_GREEN[9:0]) Luminance coefficient for green matrix.
10 RESERVED	This field is reserved.
Y_BLUE	(Y_BLUE[9:0]) Luminance coefficient for blue matrix.

### 16.7.4.3 Chroma Coefficients For Red Matrix (VIU3\_CHROMA\_RED)

Address: 400C\_9000h base + 8h offset = 400C\_9008h

**VIU3\_CHROMA\_RED field descriptions**

Field	Description
31–27 RESERVED	This field is reserved.
26–16 CR_RED	(CR_RED[10:0]) Cr coefficient for red matrix.
15–12 RESERVED	This field is reserved.
CB_RED	(CB_RED[11:0]) Cb coefficient for red matrix.

**16.7.4.4 Chroma Coefficients For Green Matrix (VIU3\_CHROMA\_GREEN)**

Address: 400C\_9000h base + Ch offset = 400C\_900Ch

## VIU3\_INVSZ field descriptions

Field	Description
31–16 LINEC	(LINEC[15:0]) Expected number of active lines in each input video field/frame. It shall only be configured when DMA is non-active, during vertical blanking. If more lines are found during data receive part, a "too many lines" error interrupt is generated when ERROR_IRQ is set. Redundant lines are discarded. If fewer lines are found during data receive part, a "not enough lines error interrupt is generated when ERROR_IRQ is set.
PIXELC	(PIXELC[15:0]) Expected number of active pixels in each input video line, it shall be an integer multiple of 4. It shall only be configured when DMA is non-active, during vertical blanking. If more pixels are found during data receive part, a "line too long" error interrupt is generated when ERROR_IRQ is set. Redundant pixels are discarded. If less pixels are found during data receive part, a line too short error interrupt is generated when ERROR_IRQ is set.

## 16.7.4.9 High IPM Request Priority Alarm (VIU3\_HPRALRM)

Address: 400C\_9000h base + 20h offset = 400C\_9020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## VIU3\_EXT\_CONFIG field descriptions

Field	Description
31–13 RESERVED	This field is reserved.
12 CS_EN	<p>Chroma swap enable bit. It's used to control how combining Y and C when output format is YUV422 mode. By default, for YUV422 mode(for example, assume 4 pixels per line here), the data in memory is Y0U0, Y1V0, Y2U2, Y3V2. When CS_EN is set, it becomes Y0V0, Y1U0, Y2V2, Y3U2. An application senario of CS_EN is that when mirror is on, the data will be Y3V2, Y2U2, Y1V0, Y0U0 by default. The first chrmo is V, instead of U. If CS_EN is set, the output data become Y3U2, Y2V2, Y1U0, Y0V0.</p> <p>0 Chroma swap is disabled. 1 Chroma swap is enabled.</p>
11 LENDIAN	<p>Data endian control bit. This bit controls the endian of the IPM data bus.</p> <p>0 Big endian 1 Little endian</p>
10 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
9 RGB2YUV_EN	RGB to YUV conversion enable
8 DE_VALID	<p>External data enable indicator is valid at parallel input modes.</p> <p>0 DE is invalid 1 DE is valid</p>
7–5 INP_FORMAT	<p>Input video format select bits. It should be set correctly according to the video input.</p> <p>000 10/8bit ITU stream 001 24bit parallel YUV. Normally it is YUV444 010 Reserved 011 Reserved 100 24bit parallel RGB. It is RGB888 101 8bit serial RGB. It is RGB888 110 18bit parallel RGB. It is RGB666 111 16bit parallel RGB. It is RGB565</p>
4 PCLK_POL	<p>Pixel clock polarity control bit. pix_clk will be reversed when the bit is set.</p> <p>0 Active high 1 Active low</p>
3 VSYNC_POL	<p>Vsync polarity control bit. Vsync will be reversed when the bit is set.</p> <p>0 Active high 1 Active low</p>
2 HSYNC_POL	<p>Hsync polarity control bit. Hsync will be reversed when the bit is set.</p> <p>0 Active high 1 Active low</p>
1 DE_POL	<p>Data enable polarity control bit. DE will be reversed when the bit is set.</p> <p>0 Active high 1 Active low</p>
0 HMIRROR_EN	Horizontal mirror enable.

### 16.7.4.17 Red, Green and Blue Coefficients for Luminance component (VIU3\_RGB\_Y)

The YUV pixel value is computed using the following formulae:

$$Y = \frac{R_Y \cdot R}{512} + \frac{G_Y \cdot G}{512} + \frac{B_Y \cdot B}{512} + 16$$

$$U = \left( -\frac{R_U \cdot R}{512} \right) + \left( -\frac{G_U \cdot G}{512} \right) + \frac{B_U \cdot B}{512} + 128$$

$$V = \frac{R_V \cdot R}{512} - \frac{G_V \cdot G}{512} - \frac{B_V \cdot B}{512} + 128$$

All coefficients are unsigned.

Address: 400C\_9000h base + 40h offset = 400C\_9040h

## 16.7.5 Functional Description

The VIU3 accepts parallel RGB, serial RGB, parallel YUV and ITU-R BT.656 compatible video streams on its parallel interface, decodes it and optionally performs processes like scaling, brightness and contrast adjust, RGBYUV to YUVRGB conversion, and de-interlace (weaving), then stores the result video stream to the system memory which can then be displayed by a display controller, or post processed.

Functions of the VIU3 are designed in a way that they can be flexibly enabled or disabled by software. But there are a few limitations as listed below:

- The down scaler works on YUV 4:2:2 format or RGB888 formats, so to enable the scaler, decoder shall be configured in YUV 4:2:2 or RGB888 mode.
- To use the scaler, progressive video input shall be used for display quality's sake, and the de-interlace shall be disabled.

### 16.7.5.1 Input Formats

VIU3 accepts parallel RGB, serial RGB, parallel YUV and ITU-R BT.656 compatible video streams on its parallel interface. Below is the description for the timing of input video formats.

#### 16.7.5.1.1 ITU656

The ITU-R BT.656-4 recommendation describes the means of interconnecting digital television equipment operating on the 525-line or 625-line standards and combines with the 4:2:2 encoding parameters as defined in the ITU-R BT.601 recommendation.

The data stream structure on ITU-R BT.656-4 interface is shown in the following figure. There are two timing reference signals, one at the beginning of each video data block (start of active video, SAV) and one at the end of each video data block (end of active video, EAV).

**Figure 16-46. Interface Data Stream of ITU-R BT.656-4**

Each timing reference signal consists of a four-word sequence in the following format: FF 00 00 XY. Values are expressed in hexadecimal notation. Value FF and 00 are reserved to be used in the timing reference signals.

The first three words are a fixed preamble. The fourth word contains information defining field 2 identification, the state of field blanking, and the state of line blanking. The assignment of bits within the timing reference signal is shown in the table below.

**Table 16-44. Video Timing Reference Codes**

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9(MSB)	1	0	0	1
8	1	0	0	F(0: field 1, 1: field 2)
7	1	0	0	V(0: elsewhere, 1: field blanking)
6	1	0	0	H(0: in SAV, 1: in EAV)
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

In above table, bits P0, P1, P2, P3 have states dependent on the states of the bits F, V and H. At the receiver side this arrangement permits one-bit errors to be corrected and two-bit errors to be detected.

Progressive video is also composed of fields; but instead of containing even lines in one field and odd lines in the other, the fields contain contiguous lines, i.e., field0 contains lines 1,2,3,... and field1 contains rest of the lines starting from (last line number of field0 + 1). And the F bit cannot be ignored in case of progressive frame.

Refer to the ITU-R BT.656-4 recommendation for more details.

### 16.7.5.1.2 Parallel Input Format

VIU3 also accepts parallel input video formats. It includes 24bit RGB888, YUV444, 18bit RGB666 and 16bit RGB565 formats. Their data streams are similar. The following caveats apply to the timing diagram below:

- FID must change state 3 Hsync pulses into Vsync.
- FID signalling is optional
- The first -//- break represents at least 10 lines.
- A field should contain more than 16 active lines.
- Hsync pulse should be longer than 60 pixel clock cycles.
- A active line should contain more than 24 pixels.

Figure 16-47. Parallel Input Timing

### 16.7.5.1.3 Parallel YC Format

Parallel YC video should be in YUV222 format. The timing diagram is provided below.

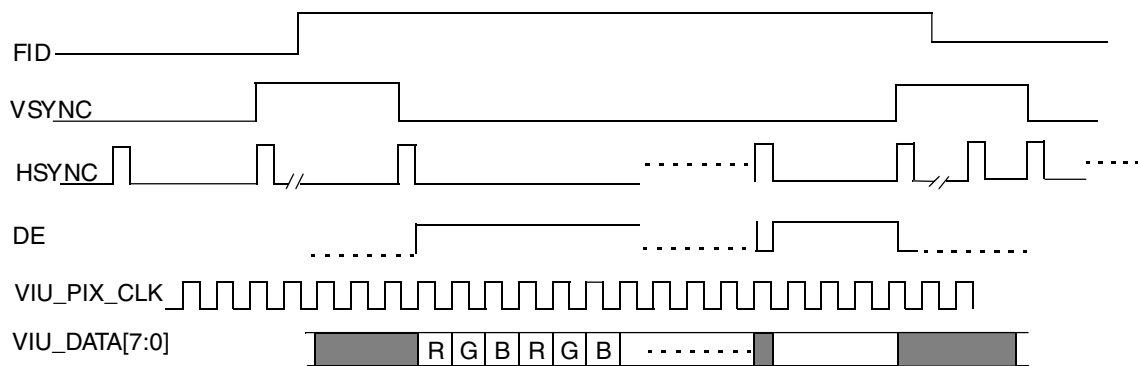

Figure 16-48. Parallel YC Timing

### 16.7.5.1.4 Serial RGB888 Format

The timing diagram of serial RGB888 is shown below.

**Figure 16-49. Serial RGB888 Timing**

### 16.7.5.2 Input Synchronizer

The Synchronizer block (1) captures ITU656 protocol signals from the interface, and synchronizes them to the IPG\_CLK domain.

### 16.7.5.3 Decoder

The ITU Decoder block (2) detects the ITU656 timing reference signal (consists of a four-word sequence in the following format: FF-00-00-XY) and extracts HSYNC, VSYNC, field number signals and video data from the ITU data stream. The format of active pixel data from the ITU stream is YUV 4:2:2. The decoder block can directly send out this YUV 4:2:2 data, or interpolate it to YUV 4:4:4 format and send it out. This is determined by the MODE444 field in the SCR register. This bit shall be set if the down-scaler is enabled, because the down-scaler works on YUV 4:4:4 data format.

### 16.7.5.4 Scaling

VIU3 supports up to 1/8 horizontal and vertical down-scaling, as well as 2x horizontal up-scaling.

#### 16.7.5.4.1 Down Scaling

The Down-scaler block (3) performs down-scaling to the incoming video stream. It is able to scale down the input video stream by a fractional scaling ratio up to 1/8. The down-scaler block can be enabled/disabled by software via the SCALER\_EN bit in the SCR register. To use the down-scaler video data extracted from ITU decoder shall be in YUV 4:4:4 format.

The down-scaler uses a bi-linear filter with simple linear interpolation between the two nearest neighbors, on both horizontal and vertical direction. Scaling is firstly done on the horizontal direction (called XScale), and then the vertical direction (called YScale). Different scaling factors are supported on horizontal direction and vertical direction.

Assuming the scaling factors are (factor\_h, factor\_v), in theory for every pixel (x, y) of the scaled picture the coordinates of the corresponding pixel in the incoming picture (x1, y1) can be calculated by multiplying the coordinates with the scaling factors, say ( $x1 = x * factor\_h$ ,  $y1 = y * factor\_v$ ). Now because the scaling factors can be fractions, the coordinates (x1, y1) are not integer anymore, they are fractional values. The scalers use the integer part of (x1, y1) to find the two neighboring pixels from the incoming picture as input to the filters, and the fractional part to derive the weighting factors for interpolation.

The scaling factors, (factor\_h, factor\_v), are both 11 bit with the lower 8 bit as the fractional part and the highest 3 bit the integer part. It is capable of scaling the input picture by up to 8, in steps of 1/256. It is by 8 if the factor is programmed as all zeros.

Instead of using multipliers to calculate (x1, y1), two 20-bit phase accumulator is used to step through the source pixels/or lines, where the lower 8 bit is the fractional part. For every output pixel/or line the phase adder is added to the accumulator. With the 12 bit integer part of the accumulator, up to 4096 source pixels/or lines can be supported.

So for each target pixel, the current accumulator position is used to determine how the pixel is going to be produced. As an example, accumulator value 0x123.3a means the step position is between pixel[0x123] and pixel[0x124], and the output pixel will be calculated by  $(pixel[0x124] * (0x100 - 0x3a) + pixel[0x123] * 0x3a) >> 8$ . The same concept is used for horizontal and vertical scaling.

Because of the vertical scaling, a line buffer is used for each color component to store the data from horizontal scaling, it stores one line of data. Size of the line buffer determines the maximum video output size after scaling.

The scaling factors are programmed via the HFACTOR and VFACTOR registers. Video size after scaling is programmed via the VID\_SIZE register.

Three scalers are instantiated in the down-scaler block, one for each component.

#### 16.7.5.4.2 Up-scaling

The theory of up-scaling is the same with down-scaling. When HFACTOR is smaller than 1, up-scaling is implemented by VIU3 scaler. But note that VIU3 does not support vertical up-scaling, and HFACTOR should not be less than 0.5.

**Note**

The scaled pixel count per line shall be an integer multiple of 2 in 32-bit output mode, or 4 in 16-bit output mode. The user shall divide the input pixel count by the horizontal scaling factor and truncate the result to a multiple of 2 or 4.

**Note**

To achieve good display quality, progressive video input shall be used if down-scaling is needed.

### 16.7.5.5 Brightness and Contrast Adjust

The B/C Adjust block (4) performs brightness and contrast adjustment on the input video stream via three internal look-up-tables, one table per color component. Each table contains 256 8-bit entries, it maps every incoming pixel to the value of one of its entries according to the original value of the pixel. This feature allows the user to adjust brightness and/or contrast of the incoming picture according to three arbitrary adjustment curves, one adjustment curve per color component.

To use this feature, the B/C adjust look-up-table shall be programmed in software in the following format.

**Table 16-45. B/C Adjust Look-up-table Format**

Color Component	BC LUT Offset	Local Address [1:0]			
		00	01	10	11
Y	0x000	BC0 <sub>Y</sub>	BC1 <sub>Y</sub>	BC2 <sub>Y</sub>	BC3 <sub>Y</sub>
	.....				
	0x0FC	BC252 <sub>Y</sub>	BC253 <sub>Y</sub>	BC254 <sub>Y</sub>	BC255 <sub>Y</sub>
U	0x100	BC0 <sub>U</sub>	BC1 <sub>U</sub>	BC2 <sub>U</sub>	BC3 <sub>U</sub>
	.....				
	0x1FC	BC252 <sub>U</sub>	BC253 <sub>U</sub>	BC254 <sub>U</sub>	BC255 <sub>U</sub>
V	0x200	BC0 <sub>V</sub>	BC1 <sub>V</sub>	BC2 <sub>V</sub>	BC3 <sub>V</sub>
	.....				
	0x2FC	BC252 <sub>V</sub>	BC253 <sub>V</sub>	BC254 <sub>V</sub>	BC255 <sub>V</sub>

Two registers are provided to program the look-up-table, they are LUT\_ADDR and LUT\_DATA. LUT\_ADDR is the current address pointer, which always points to the current table offset to be programmed. It can be set by software, and it increases (by 4) automatically when each word is written to the table, and it falls back to 0x000 if the current value is 0x2FC and the last word is written to the table. LUT\_DATA is the table

data entry, data written to this register will be stored into the table, to the address pointed to by LUT\_ADDR. This register shall only be written by 4-byte word. With the combination of these two registers the user can program the B/C look-up-table conveniently, either program the whole table, or reprogram the table for one color component only, or even change one single arbitrary word in the table.

The B/C adjust can be enabled/disabled by software via the BC\_EN bit in the SCR register.

### 16.7.5.6 YUV to RGB Conversion

The YUV2RGB block (5) is used to convert YUV (4:2:2 or 4:4:4) to RGB (888 or 565). The coefficients of the YUV to RGB conversion matrix are programmed via four registers. When the input is YUV 4:2:2, it is interpolated to YUV 4:4:4 first.

### 16.7.5.7 Round and Dither

In RGB565 output mode, when pixel data is converted from RGB888 to RGB565 the image is anamorphic more or less, because of losing color information conveyed by the least significant two or three bits of the original color components, which are dropped. VIU3 block provides two simple algorithms, round and dither, to compensate this color information loss.

#### 16.7.5.7.1 Round

In round mode, VIU3 will round to 1 in LSB if the decimal fraction is bigger than 0.5 and ignore the smaller fraction when ROUND\_ON is set in the SCR register.

#### 16.7.5.7.2 Dither

Dither is a little more complex but better than round for recovering image. It is a statistical compensation algorithm. It does not render all pixels with the same grey or color level, but some with the lower one, and some with a color level of 1 LSB more. The selection of adding one LSB or not depends on the position of the pixel on the screen.

The figure below shows the implementation of dither in the VIU3 block.

Figure 16-50. Dither Implementation

The number above the pixel position in the diagram is the compensation value for this pixel. When pixels have a value of 0.25, they are rendered 0 in 75% of the pixels and 1 in 25% of pixels. This averages to 0.25. Similarly, pixel values of 0.5, 0.75, and 1.0 are rendered 50%, 75% and 100% of the pixels as 1. For human eyes, this rendering result of dither makes the holistic image smoother and closer to the original one.

### 16.7.5.8 Output Formatter

The Output Formatter block (6) accepts YUV or RGB data from the YUV2RGB block, arranges them in expected format, and then sends it to the DMA engine. The FORMAT\_CTRL field in SCR register controls how the VIU3 stores data to system memory; see the following figure for details.>

Table 16-46. VIU3 Output Data Stream Format

Pixel Format	FORMAT_CTRL <sup>1</sup>	Local Address [2:0]							
		000	001	010	011	100	101	110	111
RGB 565	000	R0[7:3], G0[7:2], B0[7:3]		R1[7:3], G1[7:2], B1[7:3]		R2[7:3], G2[7:2], B2[7:3]		R3[7:3], G3[7:2], B3[7:3]	
	001 <sup>2</sup>	G0[4:2], B0[7:3], R0[7:3], G0[7:5]		G1[4:2], B1[7:3], R1[7:3], G1[7:5]		G2[4:2], B2[7:3], R2[7:3], G2[7:5]		G3[4:2], B3[7:3], R3[7:3], G3[7:5]	
RGB 8888	000	A0	R0	G0	B0	A1	R1	G1	B1
	001	A0	B0	G0	R0	A1	B1	G1	R1
	010	R0	G0	B0	A0	R1	G1	B1	A1
	011	B0	G0	R0	A0	B1	G1	R1	A1
YUV 4:2:2	000	U0	Y0	V0	Y1	U2	Y2	V2	Y3
	001	Y0	U0	Y1	V0	Y2	U2	Y3	V2
YUV 4:4:4	000	dummy	Y0	U0	V0	dummy	Y1	U1	V1
	001	dummy	Y0	V0	U0	dummy	Y1	V1	U1
	010	dummy	U0	V0	Y0	dummy	U1	V1	Y1
	011	dummy	V0	U0	Y0	dummy	V1	U1	Y1
	100	Y0	U0	V0	dummy	Y1	U1	V1	dummy
	101	Y0	V0	U0	dummy	Y1	V1	U1	dummy
	110	U0	V0	Y0	dummy	U1	V1	Y1	dummy
	111	V0	U0	Y0	dummy	V1	U1	Y1	dummy

1. All values not shown in the table shall be considered as reserved and shall not be used.
2. This format is basically intended for data communication with any little-endian peripheral in the system, assuming big-endian system memory is used.

### NOTE

RGB666 input can be stored in memory in RGB565 or RGB8888 formats. When stored as RGB565, the R[0] and B[0] component of RGB666 input will be discarded. When stored as RGB8888, the RGB666 input data will be reflected in memory as {R[5:0], 2'b00, G[5:0], 2'b00, B[5:0], 2'b00}. The position of Alpha bit will depend on the FORMAT\_CTRL setting.

#### 16.7.5.9 High Priority Alarm

FIFO\_FILL is a status field which indicates the amount of data in the FIFO. The HI\_PRIO\_ALARM register is a threshold such that, when the data number in the FIFO is larger than HI\_PRIO\_ALARM, the DMA request will be high-priority on the AMBA crossbar side. The purpose of this register is to enhance DMA performance. Normally the reset value should be sufficient; however, if the FIFO is seen to overflow, the user should lower the threshold in order to allow the DMA to service the FIFO more frequently.

#### 16.7.5.10 DMA and De-interlace

The DMA engine block (7) functions as the FIFO controller and DMA engine. It stores the data from the output formatter block into a FIFO and then writes them to system memory via the IPM interface.

VIU3 block has an embedded DMA. When video data is converted to RGB format and placed into a 256 × 64 bit FIFO, it waits to be transferred to memory by the internal DMA.

After doing some necessary register configuration, such as coefficients, INVSZ and DMA\_ADDR, user can activate DMA by setting the DMA\_ACT of the status and configuration register. But note that DMA\_ACT can be configured only during vertical blanking since the VIU3 block will not transfer a fragment of video field to memory. If it is configured during field active time, DMA transfer cannot be started and an error interrupt will be asserted.

The VIU3 block asserts a transfer request when there is enough data in the FIFO for one transfer. Normally one transfer conveys 32 bytes from FIFO to memory. At the end of a line, all remaining data is transferred, though it may not be as much as 32 bytes.

VIU3 also provides a simple way to de-interlace for interlaced or pseudo-interlaced video images. It is implemented by setting the DMA\_ADDR and DMA\_INC registers.

The figure below shows the implementation of de-interlace. The value of DMA\_INC is added to the rounded address at the end of every active line. So, when DMA\_INC is zero, pixel data is stored in memory line by line, meaning de-interlace is off, as shown in figure (1) and (2); otherwise, when DMA\_INC equals to one-line memory mapped pixel size and  $\text{DMA\_ADDR}(2) = \text{DMA\_ADDR}(1) + \text{DMA\_INC}$ , the odd field and even field will be merged into one frame in memory, as shown in figure (3).

Here DMA\_ADDR(1) means base address of field 1, and DMA\_ADDR(2) means base address of field 2. Memory mapped line size means memory size that is occupied by one active line pixels. It depends on pixel number of one line and video data format (RGB888 or RGB565). See the register description section for more details.

**Figure 16-51. Implementation of De-interlace**

When the HMIRROR\_EN bit is set in the EXT\_CONFIG register, the image can be mirrored in the horizontal direction, as illustrated below.

**Figure 16-52. Horizontal Image Mirror**

### 16.7.5.11 Error Case

Normally, the user should provide a standard and totally ITU-compatible video stream to the VIU3 block. However, it is difficult to avoid unexpected errors all the time. VIU3 can manage error cases like ECC error, line too long, line too short, too many lines, not enough lines in a field, and FIFO overflow.

- ECC error: ITU stream provides 4-bit error correcting code P[3:0] in its SAV and EAV. It is decoded in VIU3 to use the correct field number, horizontal sync and vertical sync bits. It can correct one bit errors and find two bit errors. When an ECC error is found, an interrupt is asserted.
- Line too long error: When pixels of active line is longer than PIXELC, a line too long error interrupt is asserted and redundant pixels are discarded.
- Too many lines error: When active lines of a field are bigger than LINEC, a too many lines error interrupt is asserted and redundant lines are discarded.
- Line too short error: When pixels of active line is less than PIXELC, a line too short error interrupt is asserted.
- Not enough line error: When active lines of a field is less than LINEC, a not enough line error interrupt is asserted.
- FIFO overflow error: If the system bus is blocked for a long time, video data is stored in FIFO and causes FIFO overflow. When FIFO overflow occurs, an interrupt is asserted and incoming data is discarded until FIFO works normally again. Current field is jumbled. However, VIU3 recovers to work at the next field if the bus is unblocked at that time.
- FIFO underflow: When the FIFO is read when it is empty, a FIFO underflow error interrupt is asserted. Normally, this error should not occur.

VIU3 can manage the above error cases to a certain extent. However, when it does not recover to a working state the user should write the `SOFT_RESET` bit of the status and configuration register to reset the VIU3 block.

### 16.7.6 Initialization/Application Information

Initialization steps and startup information are given below.

### 16.7.6.1 Initialization Information

When the VIU3 block comes out of reset, software should implement the following steps to start this block.

1. Program the SCR register to set the VIU3 to the desired operation mode
  - To enable YUV 4:2:2 to 4:4:4 interpolation in the ITU decoder, set the MODE444 bit<sup>1</sup>
  - To enable the down-scaler, set the SCALER\_EN bit
  - To enable B/C adjust, set the BC\_EN bit
  - To enable RGB565 output mode, set the YUV2RGB\_EN bit and clear the MODE32BIT bit. Optionally set the DITHER\_ON bit or the ROUND\_ON bit to enable dither or round<sup>2</sup>
  - To enable RGB8888 output mode, set the YUV2RGB\_EN and MODE32BIT bits
  - To enable YUV output mode, clear the YUV2RGB\_EN bit
2. Set the FORMAT\_CTRL field so that the VIU3 outputs data in the correct format. Configure the input video size via the INVSZ register.
3. If it is desired to use RGB output, configure YUV to RGB conversion coefficients or use the default values after reset.
4. If it is desired to use the down scaling function, program the down scaling factors and destination video size after scaling.
5. If it is desired to use the B/C adjust function, program the B/C adjust look-up-table via the LUT\_DATA and LUT\_ADDR registers.
6. Configure the HPRALRM and ALPHA registers if necessary.
7. Set the VSYNC\_EN and/or FIELD\_EN bits in the SCR register to enable vsync or field interrupt. Meanwhile, disable error interrupt.
8. When software receives a vsync interrupt and/or field interrupt, read FIELD\_NO bit of the SCR register<sup>3</sup>.

---

1. MODE444 bit shall not be set when the down-scaler is enabled.

2. If DITHER\_ON or ROUND\_ON are both set, only round will be enabled.

3. Reading the FIELD\_NO bit is optional, especially in progressive video input mode.

9. According to the FIELD\_NO bit, program the DMA\_ADDR register. This is the field start address in system memory, or frame start address in progressive video input mode.
10. If it is desired to use the de-interlace (weaving) function, program the line start address offset value in the DMA\_INC register<sup>1</sup>.
11. Clear error status first if necessary.
12. Write the DMA\_ACT bit of the SCR register to start FIFO and DMA transfer. This operation actually starts the VIU3 to operate.

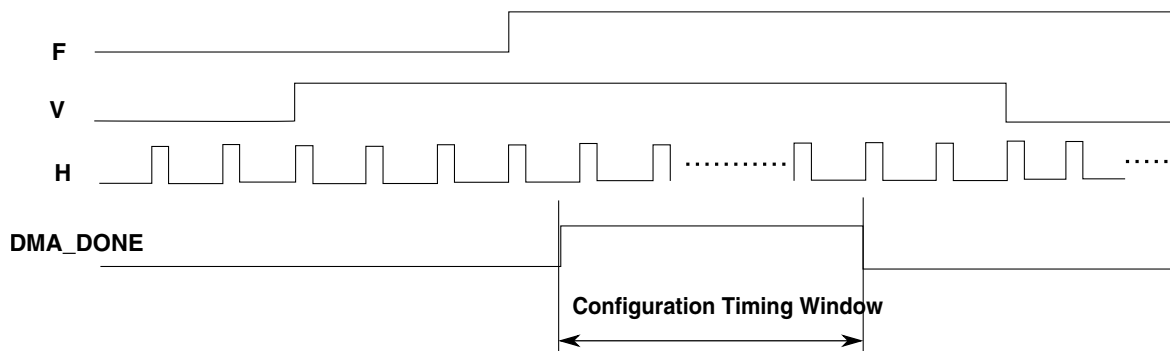

### 16.7.6.2 Application Information

Normally, the user shall not change the register values of the function enable bits, input/output video size, color conversion coefficients, DMA\_INC, MODE32BIT, scaling factors and B/C adjust look-up-table contents after VIU3 is started up. When the video input source is changed, the user should reset the VIU3 and re-configure the related registers.

#### 16.7.6.2.1 Register Configuration Timing Window

As mentioned above, dynamic configuration of registers is not recommended because it may cause error if it is not configured in a certain timing window, especially for INVSZ and DMA\_INC.

Register configuration timing window is shown in the below diagram. All registers, except for the SOFT\_RESET bit, are recommended to be configured during vertical blanking, after DMA transfer is done and the field identification bit is changed (field interrupt is asserted).

**Figure 16-53. Register Configuration Timing Window**

1. Progressive video input shall be used when down scaling is enabled for better display quality.

# Appendix A

## Pinout Quick Reference Guide

### A.1 Pinouts Overview

Below is a quick reference guide to the pinouts on the VFxxx Controller devices. For more information, and part number and package-specific pinout details, refer to the data sheets.

### A.2 Pinouts Quick Reference

Table A-1. VFxxx Controller Pinouts

F-Series (176qfp)	R-Series (176qfp)	F-Series & R-Series (324bga)	Pin Name
		Y2	ADC0SE8
		W2	ADC0SE9
