Section number	Title	Page
----------------	-------	------

## Chapter 1 About This Document

1.1	Overview.....	135
1.1.1	Purpose.....	135
1.1.2	Audience.....	135
1.1.3	Reference Manual Overview.....	135
1.1.4	Related Resources.....	136
1.2	Conventions.....	136
1.2.1	Numbering systems.....	136
1.2.2	Typographic notation.....	137
1.2.3	Special terms.....	137

## Chapter 2 Introduction

2.1	VFxxx Controller Platform.....	139
2.2	Feature Set.....	140
2.3	Detailed Block Diagram.....	142
2.4	VFxxx Controller Device Configuration.....	143
2.5	Modules on the device.....	145
2.5.1	Clocks.....	145
2.5.2	Platform Modules.....	146
2.5.3	System Modules.....	149
2.5.4	Memories and Memory Interfaces.....	150
2.5.5	Audio modules.....	152
2.5.6	Timer modules.....	153
2.5.7	Communication interfaces.....	154
2.5.8	Graphics Modules.....	156
2.5.9	Analog modules.....	157

## Chapter 3

Section number	Title	Page
	<b>Chip Configuration</b>	
3.1	Introduction.....	159
3.2	Core modules.....	159
3.2.1	Cortex-M4 Processor Core.....	159
3.2.2	Cortex-M4 Instruction Fetches on the System Bus.....	161
3.2.3	Cortex-A5 Processor Core.....	162
3.2.4	Interrupt Assignments.....	164
3.3	DMAMUX Request Sources.....	171
3.3.1	DMAMUX Request Sources.....	171
3.4	Wakeup Unit (WKPU).....	176
3.4.1	WKPU configuration.....	176
3.5	CMU Chip Signals.....	177
3.5.1	CMU Chip Signals.....	177
3.6	Cyclic Redundancy Check (CRC).....	178
3.6.1	CRC Reverse Logic Functions.....	178
3.7	External Watchdog Monitor.....	178
3.8	Timers.....	179
3.8.1	FlexTimer.....	179
3.8.1.1	Instantiation Information.....	179
3.8.1.2	FTM Clock Input.....	179
3.8.1.3	FTM Hardware Triggers.....	179
3.8.1.4	FTM output triggers for other modules.....	182
3.8.1.5	FTM Global Time Base.....	182
3.8.1.6	FTM Fault Detection Inputs.....	183
3.8.2	Programmable Interrupt Timer(PIT).....	183
3.8.2.1	PIT Instantiations.....	183
3.8.2.2	PIT/DMA Periodic Trigger Assignments .....	183
3.8.3	Programmable Delay Block (PDB).....	184
3.8.3.1	PDB Instantiation.....	184

Section number	Title	Page
3.8.3.1.1	PDB Output Triggers.....	184
3.8.3.1.2	PDB Input Trigger Connections.....	184
3.8.3.2	PDB Module Interconnections.....	185
3.8.3.3	DMA support on PDB .....	185
3.8.3.4	PDB in Low-Power modes.....	185
3.8.3.5	PDB implementation with ADC.....	186
3.8.4	Low-Power Timer (LPTMR).....	187
3.8.4.1	LPTMR prescaler/glitch filter clocking options.....	187
3.9	External memory interfaces.....	187
3.9.1	Quad SPI.....	187
3.9.1.1	QuadSPI Instances.....	187
3.9.1.2	QuadSPI Memory Interface.....	188
3.9.1.3	QuadSPI Buffer.....	188
3.9.1.4	QuadSPI Clocking.....	189
3.9.1.5	Booting from QuadSPI.....	189
3.9.2	DRAM Controller.....	189
3.9.2.1	DDR maximum address space.....	189
3.9.3	Nand Flash Controller.....	190
3.9.3.1	Instantiation.....	190
3.9.4	FlexBus Controller.....	190
3.9.4.1	FlexBus signal multiplexing.....	190
3.9.4.2	VFxxx Controller restrictions.....	192
3.9.4.3	FlexBus Signal Multiplexing.....	192
3.9.4.4	FlexBus External Signal.....	193
3.9.4.5	FlexBus Security.....	193
3.9.4.6	Instantiation Information.....	193
3.9.4.7	FlexBus Chip Select Control Register (CSCR0) Reset Value.....	195
3.9.4.8	Bus Timeout.....	195
3.10	Communication interfaces.....	195

Section number	Title	Page
3.10.1	10/100 Ethernet Subsystem.....	195
3.10.1.1	Instantiation Information.....	195
3.10.1.2	MII and RMI configuration.....	196
3.10.1.3	IEEE 1588 Timers.....	197
3.10.1.4	Ethernet Operation in Low Power Modes.....	197
3.10.1.5	Ethernet Subsystem Interrupts.....	199
3.10.1.6	Ethernet switch register reset values.....	200
3.10.2	USB 2.0 HS/FS/LS Dual Role (Host / Device) Controller.....	200
3.10.2.1	USB Configuration and Options.....	200
3.10.2.2	USB Host initialization and bring up.....	200
3.10.2.3	SOF for USB Audio.....	203
3.10.2.4	OverCurrent and VBUS Connection.....	204
3.10.3	Secure Digital Host Controller (SDHC).....	205
3.10.3.1	SD bus pullup/pulldown constraints.....	205
3.10.3.2	SDHC Wakeup.....	206
3.10.3.2.1	Setting Wake Up Events.....	206
3.10.3.3	SDHC Software Guidelines.....	206
3.10.4	UART.....	207
3.10.4.1	UART configuration information.....	207
3.10.4.2	UART wakeup.....	207
3.10.4.3	UART interrupts.....	207
3.10.5	FlexCAN.....	208
3.10.5.1	Instantiation.....	208
3.10.6	MediaLB Device Module (MLB50).....	209
3.10.6.1	Instantiation.....	209
3.10.7	SPI.....	209
3.10.7.1	SPI Instantiation.....	209
3.10.7.2	Number of PCS.....	210
3.10.8	Inter-Integrated Circuit (I2C).....	211

Section number	Title	Page
3.10.8.1	Instantiation Information.....	211
3.11	Analog.....	211
3.11.1	12-bit Analog to Digital Converter (ADC).....	211
3.11.1.1	ADC Instantiation .....	211
3.11.1.2	Voltage reference selection (REFSEL settings).....	212
3.11.1.3	DMA Support on ADC.....	212
3.11.1.4	ADC Channel Assignments.....	212
3.11.1.5	ADC interconnections.....	213
3.11.1.6	ADC Calibration.....	213
3.11.1.7	Temperature Sensor.....	214
3.11.2	12-Bit Digital-to-Analog Converter (DAC).....	214
3.11.2.1	12-bit DAC Instantiation.....	214
3.11.2.2	12-bit DAC External Reference.....	214
3.11.2.3	DMA support on DAC.....	215
3.11.2.4	DAC interconnections.....	215
3.12	Display/Video interfaces.....	215
3.12.1	Display Control Unit.....	215
3.12.1.1	Instantiation.....	215
3.12.2	Timing Controller (TCON).....	215
3.12.2.1	Instantiation.....	215
3.12.3	RLE Decoder (RLE).....	216
3.12.3.1	Instantiation.....	216
3.12.4	Segmented LCD Controller.....	216
3.12.4.1	Instantiation.....	216
3.12.4.2	Number of Front and Back Planes.....	216
3.12.4.3	LCD clock selection.....	216
3.12.4.4	Settings during STANDBY mode.....	217
3.12.4.5	Segment LCD configuration.....	217
3.12.5	Video Interface Unit(VIU).....	218

Section number	Title	Page
3.12.5.1	Instantiation.....	218
3.12.6	Video ADC(VADC).....	218
3.12.6.1	Instantiation.....	218
3.13	Audio Subsystem.....	219
3.13.1	Audio Subsystem Modules.....	219
3.13.1.1	Audio Subsystem Overview.....	219
3.13.1.2	Synchronous Audio Interface (SAI).....	220
3.13.1.2.1	SAI3 register details.....	220
3.13.1.2.2	Simultaneous SAI DMA requests.....	221
3.13.1.2.3	SAI transmitter and receiver options for MCLK selection.....	221
3.13.1.2.4	SAI in Stop mode.....	221
3.13.1.3	Enhanced Serial Audio Interface (ESAI).....	221
3.13.1.4	ESAI Bus Interface and FIFO (ESAI_BIFIFO).....	222
3.14	Miscellaneous.....	222
3.14.1	GPIO.....	222
3.14.1.1	GPIO Mapping.....	222
3.14.1.2	Configuring a pin as GPIO.....	226
3.14.1.3	Port 4 Register Differences.....	226

## Chapter 4 Memory Map

4.1	System memory map.....	229
4.2	Peripheral Bridge 0 (AIPS-Lite 0) Memory Map.....	231
4.3	Peripheral Bridge 1 (AIPS-Lite 1) Memory Map.....	234
4.4	Private Peripheral Bus (PPB) memory map.....	238

## Chapter 5 Chip IO and Pinmux

5.1	Pinouts.....	239
5.2	Input/Output Multiplexer Controller (IOMUXC).....	239
5.2.1	Overview.....	239

Section number	Title	Page
5.2.2	Functional Description.....	240
5.2.3	Daisy chain - multi pads driving same module input pin.....	244
5.2.4	IOMUXC register groups.....	245
5.2.5	Memory map and register definition.....	245
5.2.5.1	Software MUX Pad Control Register 0 (IOMUXC_PTA6).....	256
5.2.5.2	Software MUX Pad Control Register 1 (IOMUXC_PTA8).....	257
5.2.5.3	Software MUX Pad Control Register 2 (IOMUXC_PTA9).....	259
5.2.5.4	Software MUX Pad Control Register 3 (IOMUXC_PTA10).....	261
5.2.5.5	Software MUX Pad Control Register 4 (IOMUXC_PTA11).....	263
5.2.5.6	Software MUX Pad Control Register 5 (IOMUXC_PTA12).....	264
5.2.5.7	Software MUX Pad Control Register 6 (IOMUXC_PTA16).....	266
5.2.5.8	Software MUX Pad Control Register 7 (IOMUXC_PTA17).....	268
5.2.5.9	Software MUX Pad Control Register 8 (IOMUXC_PTA18).....	270
5.2.5.10	Software MUX Pad Control Register 9 (IOMUXC_PTA19).....	271
5.2.5.11	Software MUX Pad Control Register 10 (IOMUXC_PTA20).....	273
5.2.5.12	Software MUX Pad Control Register 11 (IOMUXC_PTA21).....	275
5.2.5.13	Software MUX Pad Control Register 12 (IOMUXC_PTA22).....	277
5.2.5.14	Software MUX Pad Control Register 13 (IOMUXC_PTA23).....	278
5.2.5.15	Software MUX Pad Control Register 14 (IOMUXC_PTA24).....	280
5.2.5.16	Software MUX Pad Control Register 15 (IOMUXC_PTA25).....	282
5.2.5.17	Software MUX Pad Control Register 16 (IOMUXC_PTA26).....	283
5.2.5.18	Software MUX Pad Control Register 17 (IOMUXC_PTA27).....	285
5.2.5.19	Software MUX Pad Control Register 18 (IOMUXC_PTA28).....	287
5.2.5.20	Software MUX Pad Control Register 19 (IOMUXC_PTA29).....	288
5.2.5.21	Software MUX Pad Control Register 20 (IOMUXC_PTA30).....	290
5.2.5.22	Software MUX Pad Control Register 21 (IOMUXC_PTA31).....	292
5.2.5.23	Software MUX Pad Control Register 22 (IOMUXC_PTB0).....	294
5.2.5.24	Software MUX Pad Control Register 23 (IOMUXC_PTB1).....	295
5.2.5.25	Software MUX Pad Control Register 24 (IOMUXC_PTB2).....	297

Section number	Title	Page
5.2.5.26	Software MUX Pad Control Register 25 (IOMUXC_PTB3).....	299
5.2.5.27	Software MUX Pad Control Register 26 (IOMUXC_PTB4).....	301
5.2.5.28	Software MUX Pad Control Register 27 (IOMUXC_PTB5).....	302
5.2.5.29	Software MUX Pad Control Register 28 (IOMUXC_PTB6).....	304
5.2.5.30	Software MUX Pad Control Register 29 (IOMUXC_PTB7).....	306
5.2.5.31	Software MUX Pad Control Register 30 (IOMUXC_PTB8).....	308
5.2.5.32	Software MUX Pad Control Register 31 (IOMUXC_PTB9).....	309
5.2.5.33	Software MUX Pad Control Register 32 (IOMUXC_PTB10).....	311
5.2.5.34	Software MUX Pad Control Register 33 (IOMUXC_PTB11).....	313
5.2.5.35	Software MUX Pad Control Register 34 (IOMUXC_PTB12).....	315
5.2.5.36	Software MUX Pad Control Register 35 (IOMUXC_PTB13).....	316
5.2.5.37	Software MUX Pad Control Register 36 (IOMUXC_PTB14).....	318
5.2.5.38	Software MUX Pad Control Register 37 (IOMUXC_PTB15).....	320
5.2.5.39	Software MUX Pad Control Register 38 (IOMUXC_PTB16).....	321
5.2.5.40	Software MUX Pad Control Register 39 (IOMUXC_PTB17).....	323
5.2.5.41	Software MUX Pad Control Register 40 (IOMUXC_PTB18).....	325
5.2.5.42	Software MUX Pad Control Register 41 (IOMUXC_PTB19).....	326
5.2.5.43	Software MUX Pad Control Register 42 (IOMUXC_PTB20).....	328
5.2.5.44	Software MUX Pad Control Register 43 (IOMUXC_PTB21).....	330
5.2.5.45	Software MUX Pad Control Register 44 (IOMUXC_PTB22).....	331
5.2.5.46	Software MUX Pad Control Register 45 (IOMUXC_PTC0).....	333
5.2.5.47	Software MUX Pad Control Register 46 (IOMUXC_PTC1).....	335
5.2.5.48	Software MUX Pad Control Register 47 (IOMUXC_PTC2).....	337
5.2.5.49	Software MUX Pad Control Register 48 (IOMUXC_PTC3).....	338
5.2.5.50	Software MUX Pad Control Register 49 (IOMUXC_PTC4).....	340
5.2.5.51	Software MUX Pad Control Register 50 (IOMUXC_PTC5).....	342
5.2.5.52	Software MUX Pad Control Register 51 (IOMUXC_PTC6).....	344
5.2.5.53	Software MUX Pad Control Register 52 (IOMUXC_PTC7).....	345
5.2.5.54	Software MUX Pad Control Register 53 (IOMUXC_PTC8).....	347

Section number	Title	Page
5.2.5.55	Software MUX Pad Control Register 54 (IOMUXC_PTC9).....	349
5.2.5.56	Software MUX Pad Control Register 55 (IOMUXC_PTC10).....	351
5.2.5.57	Software MUX Pad Control Register 56 (IOMUXC_PTC11).....	352
5.2.5.58	Software MUX Pad Control Register 57 (IOMUXC_PTC12).....	354
5.2.5.59	Software MUX Pad Control Register 58 (IOMUXC_PTC13).....	356
5.2.5.60	Software MUX Pad Control Register 59 (IOMUXC_PTC14).....	358
5.2.5.61	Software MUX Pad Control Register 60 (IOMUXC_PTC15).....	359
5.2.5.62	Software MUX Pad Control Register 61 (IOMUXC_PTC16).....	361
5.2.5.63	Software MUX Pad Control Register 62 (IOMUXC_PTC17).....	363
5.2.5.64	Software MUX Pad Control Register 63 (IOMUXC_PTD31).....	365
5.2.5.65	Software MUX Pad Control Register 64 (IOMUXC_PTD30).....	366
5.2.5.66	Software MUX Pad Control Register 65 (IOMUXC_PTD29).....	368
5.2.5.67	Software MUX Pad Control Register 66 (IOMUXC_PTD28).....	370
5.2.5.68	Software MUX Pad Control Register 67 (IOMUXC_PTD27).....	371
5.2.5.69	Software MUX Pad Control Register 68 (IOMUXC_PTD26).....	373
5.2.5.70	Software MUX Pad Control Register 69 (IOMUXC_PTD25).....	375
5.2.5.71	Software MUX Pad Control Register 70 (IOMUXC_PTD24).....	376
5.2.5.72	Software MUX Pad Control Register 71 (IOMUXC_PTD23).....	378
5.2.5.73	Software MUX Pad Control Register 72 (IOMUXC_PTD22).....	380
5.2.5.74	Software MUX Pad Control Register 73 (IOMUXC_PTD21).....	382
5.2.5.75	Software MUX Pad Control Register 74 (IOMUXC_PTD20).....	383
5.2.5.76	Software MUX Pad Control Register 75 (IOMUXC_PTD19).....	385
5.2.5.77	Software MUX Pad Control Register 76 (IOMUXC_PTD18).....	387
5.2.5.78	Software MUX Pad Control Register 77 (IOMUXC_PTD17).....	389
5.2.5.79	Software MUX Pad Control Register 78 (IOMUXC_PTD16).....	390
5.2.5.80	Software MUX Pad Control Register 79 (IOMUXC_PTD0).....	392
5.2.5.81	Software MUX Pad Control Register 80 (IOMUXC_PTD1).....	394
5.2.5.82	Software MUX Pad Control Register 81 (IOMUXC_PTD2).....	396
5.2.5.83	Software MUX Pad Control Register 82 (IOMUXC_PTD3).....	397

Section number	Title	Page
5.2.5.84	Software MUX Pad Control Register 83 (IOMUXC_PTD4).....	399
5.2.5.85	Software MUX Pad Control Register 84 (IOMUXC_PTD5).....	401
5.2.5.86	Software MUX Pad Control Register 85 (IOMUXC_PTD6).....	403
5.2.5.87	Software MUX Pad Control Register 86 (IOMUXC_PTD7).....	404
5.2.5.88	Software MUX Pad Control Register 87 (IOMUXC_PTD8).....	406
5.2.5.89	Software MUX Pad Control Register 88 (IOMUXC_PTD9).....	408
5.2.5.90	Software MUX Pad Control Register 89 (IOMUXC_PTD10).....	410
5.2.5.91	Software MUX Pad Control Register 90 (IOMUXC_PTD11).....	411
5.2.5.92	Software MUX Pad Control Register 91 (IOMUXC_PTD12).....	413
5.2.5.93	Software MUX Pad Control Register 92 (IOMUXC_PTD13).....	415
5.2.5.94	Software MUX Pad Control Register 93 (IOMUXC_PTB23).....	416
5.2.5.95	Software MUX Pad Control Register 94 (IOMUXC_PTB24).....	418
5.2.5.96	Software MUX Pad Control Register 95 (IOMUXC_PTB25).....	420
5.2.5.97	Software MUX Pad Control Register 96 (IOMUXC_PTB26).....	422
5.2.5.98	Software MUX Pad Control Register 97 (IOMUXC_PTB27).....	423
5.2.5.99	Software MUX Pad Control Register 98 (IOMUXC_PTB28).....	425
5.2.5.100	Software MUX Pad Control Register 99 (IOMUXC_PTC26).....	427
5.2.5.101	Software MUX Pad Control Register 100 (IOMUXC_PTC27).....	428
5.2.5.102	Software MUX Pad Control Register 101 (IOMUXC_PTC28).....	430
5.2.5.103	Software MUX Pad Control Register 102 (IOMUXC_PTC29).....	432
5.2.5.104	Software MUX Pad Control Register 103 (IOMUXC_PTC30).....	434
5.2.5.105	Software MUX Pad Control Register 104 (IOMUXC_PTC31).....	435
5.2.5.106	Software MUX Pad Control Register 105 (IOMUXC_PTE0).....	437
5.2.5.107	Software MUX Pad Control Register 106 (IOMUXC_PTE1).....	439
5.2.5.108	Software MUX Pad Control Register 107 (IOMUXC_PTE2).....	440
5.2.5.109	Software MUX Pad Control Register 108 (IOMUXC_PTE3).....	442
5.2.5.110	Software MUX Pad Control Register 109 (IOMUXC_PTE4).....	444
5.2.5.111	Software MUX Pad Control Register 110 (IOMUXC_PTE5).....	445
5.2.5.112	Software MUX Pad Control Register 111 (IOMUXC_PTE6).....	447

Section number	Title	Page
5.2.5.113	Software MUX Pad Control Register 112 (IOMUXC_PTE7).....	449
5.2.5.114	Software MUX Pad Control Register 113 (IOMUXC_PTE8).....	450
5.2.5.115	Software MUX Pad Control Register 114 (IOMUXC_PTE9).....	452
5.2.5.116	Software MUX Pad Control Register 115 (IOMUXC_PTE10).....	454
5.2.5.117	Software MUX Pad Control Register 116 (IOMUXC_PTE11).....	455
5.2.5.118	Software MUX Pad Control Register 117 (IOMUXC_PTE12).....	457
5.2.5.119	Software MUX Pad Control Register 118 (IOMUXC_PTE13).....	459
5.2.5.120	Software MUX Pad Control Register 119 (IOMUXC_PTE14).....	460
5.2.5.121	Software MUX Pad Control Register 120 (IOMUXC_PTE15).....	462
5.2.5.122	Software MUX Pad Control Register 121 (IOMUXC_PTE16).....	464
5.2.5.123	Software MUX Pad Control Register 122 (IOMUXC_PTE17).....	465
5.2.5.124	Software MUX Pad Control Register 123 (IOMUXC_PTE18).....	467
5.2.5.125	Software MUX Pad Control Register 124 (IOMUXC_PTE19).....	469
5.2.5.126	Software MUX Pad Control Register 125 (IOMUXC_PTE20).....	470
5.2.5.127	Software MUX Pad Control Register 126 (IOMUXC_PTE21).....	472
5.2.5.128	Software MUX Pad Control Register 127 (IOMUXC_PTE22).....	474
5.2.5.129	Software MUX Pad Control Register 128 (IOMUXC_PTE23).....	475
5.2.5.130	Software MUX Pad Control Register 129 (IOMUXC_PTE24).....	477
5.2.5.131	Software MUX Pad Control Register 130 (IOMUXC_PTE25).....	479
5.2.5.132	Software MUX Pad Control Register 131 (IOMUXC_PTE26).....	480
5.2.5.133	Software MUX Pad Control Register 132 (IOMUXC_PTE27).....	482
5.2.5.134	Software MUX Pad Control Register 133 (IOMUXC_PTE28).....	484
5.2.5.135	Software MUX Pad Control Register 134 (IOMUXC_PTA7).....	486
5.2.5.136	Software MUX DDR RESET Pad Configuration Register (IOMUXC_DDR_RESETB).....	488

## Chapter 6

### Clocks and Power Management

6.1	Clocking Overview.....	633
6.1.1	Introduction.....	633
6.1.2	High Level Clocking Diagram.....	633
6.1.3	Clock Sources.....	635
6.1.4	CMU Block Diagram.....	636
6.1.5	PLL Summary.....	637
6.1.5.1	PLL Block Diagram.....	637
6.1.5.2	Spread Spectrum (SSC).....	638
6.1.5.3	PLL Summary.....	639
6.1.6	PLL Features.....	641
6.1.6.1	528 MHz Phase Locked Loop.....	641
6.1.6.2	High Frequency PLL .....	641
6.1.6.3	Ethernet PLL .....	642
6.1.7	PLL/PFD Configuration.....	643
6.1.7.1	PLL Configuration.....	643
6.1.7.1.1	Typical PLL Configuration.....	643
6.1.7.2	PFD Configuration.....	644
6.1.7.2.1	Typical PFD Configuration.....	644
6.1.8	Clock Configuration.....	645
6.1.9	Clock Modes.....	646
6.1.9.1	Synchronous Mode.....	646
6.1.9.1.1	Synchronous Mode.....	646
6.1.9.2	Asynchronous Mode.....	647
6.1.9.2.1	Asynchronous DDR mode.....	647
6.1.10	Clock Gating.....	647
6.1.10.1	Clock Gating.....	647
6.1.11	Peripheral Clocks.....	648

Section number	Title	Page
6.1.11.1	Module clocks.....	648
6.1.11.2	FlexCAN Clocking.....	648
6.1.11.3	FTM clocking.....	649
6.1.11.4	NFC clocking.....	649
6.1.11.5	QuadSPI Clocking.....	650
6.1.11.6	Ethernet RMII/MII Clocking.....	650
6.1.11.7	Ethernet Timer Clocking.....	650
6.1.11.8	eSDHC Clocking.....	651
6.1.11.9	DCU clocking.....	651
6.1.11.10	ESAI clocking.....	652
6.1.11.11	SPDIF Clocking.....	652
6.1.11.12	SAI clocking.....	652
6.1.11.13	Video ADC clock.....	653
6.1.11.14	GPU clocking.....	653
6.1.11.15	SWO Clocking.....	654
6.1.11.16	Trace clocking.....	654
6.1.12	Appendix.....	655
6.1.13	Maximum Frequencies Supported.....	655
6.2	Clock Controller Module (CCM).....	656
6.2.1	Introduction.....	656
6.2.1.1	Overview.....	656
6.2.1.2	Features.....	657
6.2.1.3	CCM Block Diagram.....	657
6.2.2	Memory Map and Registers.....	659
6.2.2.1	CCM Control Register (CCM_CCR).....	661
6.2.2.2	CCM Status Register (CCM_CSR).....	663
6.2.2.3	CCM Clock Switcher Register (CCM_CCSR).....	664
6.2.2.4	CCM ARM Clock Root Register (CCM_CACRR).....	666
6.2.2.5	CCM Serial Clock Multiplexer Register 1 (CCM_CSCMR1).....	669

Section number	Title	Page
6.2.2.6	CCM Serial Clock Divider Register 1 (CCM_CSCDR1).....	671
6.2.2.7	CCM Serial Clock Divider Register 2 (CCM_CSCDR2).....	674
6.2.2.8	CCM Serial Clock Divider Register 3 (CCM_CSCDR3).....	676
6.2.2.9	CCM Serial Clock Multiplexer Register 2 (CCM_CSCMR2).....	678
6.2.2.10	CCM Testing Observability Register (CCM_CTOR).....	681
6.2.2.11	CCM Low Power Control Register (CCM_CLPCR).....	683
6.2.2.12	CCM Interrupt Status Register (CCM_CISR).....	687
6.2.2.13	CCM Interrupt Mask Register (CCM_CIMR).....	689
6.2.2.14	CCM Clock Output Source Register (CCM_CCOSR).....	690
6.2.2.15	CCM General Purpose Register (CCM_CGPR).....	695
6.2.2.16	CCM Clock Gating Register (CCM_CCGR $n$ ).....	696
6.2.2.17	CCM Module Enable Override Register (CCM_CMEOR $n$ ).....	702
6.2.2.18	CCM PLL PFD Disable Status Register (CCM_CPPDSR).....	705
6.2.2.19	CCM CORE Wakeup Register (CCM_CCOWR).....	707
6.2.2.20	CCM Platform Clock Gating Register (CCM_CCPGR $n$ ).....	708
6.2.3	Sync Signals.....	711
6.2.4	Accessory clocks.....	711
6.2.5	CKIL Synchronizing to ipg_clk.....	711
6.2.6	Low Power Clock Gating module (LPCG).....	711
6.2.7	Power modes.....	714
6.3	Slow Clock Source Controller Module (SCSC).....	714
6.3.1	Introduction.....	714
6.3.2	Memory Map and Registers.....	715
6.3.2.1	SIRC Control Register (SCSC_SIRC_CTR).....	715
6.3.2.2	SOSC Control (SCSC_SOSC_CTR).....	716
6.4	Clock Monitor Unit (CMU).....	717
6.4.1	Introduction.....	717
6.4.1.1	Main features.....	718
6.4.2	Block diagram.....	718

Section number	Title	Page
6.4.3	Signals.....	718
6.4.4	Register description and memory map.....	719
6.4.4.1	CMU Control Status Register (CMU_CSR).....	720
6.4.4.2	CMU Frequency Display Register (CMU_FDR).....	721
6.4.4.3	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR).....	722
6.4.4.4	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR).....	722
6.4.4.5	CMU Interrupt Status Register (CMU_ISR).....	723
6.4.4.6	CMU Measurement Duration Register (CMU_MDR).....	725
6.4.5	Functional description.....	725
6.4.5.1	Frequency meter.....	725
6.4.5.2	CLKMN0_RMT supervisor.....	726
6.4.5.3	CLKMN1 supervisor.....	726
6.5	Power Management.....	727
6.5.1	Introduction.....	727
6.5.2	Power domains.....	728
6.5.3	Low-power modes.....	729
6.5.3.1	Run mode.....	730
6.5.3.2	LPRun mode.....	730
6.5.3.3	ULPRun mode.....	730
6.5.3.4	Wait mode.....	730
6.5.3.5	Stop mode.....	731
6.5.3.5.1	Stop mode entry sequence (clock-gating mode).....	731
6.5.3.5.2	Optional stop mode entry sequence.....	731
6.5.3.6	LPStopn modes.....	732
6.5.3.6.1	LPStopn mode entry sequence (power-gating mode).....	732
6.5.3.6.2	Optional LPStopn mode entry sequence.....	733
6.5.3.7	Interrupt connectivity.....	733
6.6	Global Power Controller (GPC).....	734
6.6.1	Introduction.....	734

Section number	Title	Page
6.6.2	Features.....	734
6.6.3	GPC Memory/Register Map.....	734
6.6.3.1	Power Gating Control Register (GPC_PGCR).....	735
6.6.3.2	Power Gating Status Register (GPC_PGSR).....	737
6.6.3.3	Low Power Mode Register (GPC_LPMR).....	737
6.6.3.4	Interrupt Mask Register 1 (GPC_IMR1).....	739
6.6.3.5	Interrupt Mask Register 2 (GPC_IMR2).....	741
6.6.3.6	Interrupt Mask Register 3 (GPC_IMR3).....	744
6.6.3.7	Interrupt Mask Register (GPC_IMR4).....	747
6.6.3.8	Interrupt Status Register 1 (GPC_ISR1).....	748
6.6.3.9	Interrupt Status Register 2 (GPC_ISR2).....	750
6.6.3.10	Interrupt Status Register 3 (GPC_ISR3).....	752
6.6.3.11	Interrupt Status Register 4 (GPC_ISR4).....	755
6.6.4	Functional Description.....	756
6.6.4.1	Power Shutdown Controller.....	756
6.6.4.2	Power Gating Controller.....	757
6.6.4.2.1	Functional Mode.....	757
6.6.4.2.1.1	LPSTOP Entry Sequence (PG Entry Sequence).....	757
6.6.4.2.1.2	LPStop Mode Exit Sequence.....	758
6.6.4.2.1.3	Stop Mode Entry Sequence.....	759
6.6.4.2.1.4	Stop Mode Exit Sequence.....	759
6.6.4.2.1.5	Well Bias Stop mode entry sequence.....	759
6.6.4.2.1.6	Well Bias Stop mode exit sequence.....	760
6.6.4.2.1.7	Inhibit Stop and FIRC Control.....	760
6.7	Voltage Regulators.....	761
6.7.1	Overview.....	761
6.7.1.1	Signal Description.....	762
6.7.1.2	Digital Interface Block Diagram.....	763
6.7.2	Memory Map and Registers.....	763

Section number	Title	Page
6.7.2.1	Control Register (VREG_CTRL).....	763
6.7.2.2	Status register (VREG_STAT).....	765
6.7.3	Functional Description.....	766
6.7.3.1	High Power or Main Regulator (HPREG).....	766
6.7.3.2	Low Power Regulator (LPREG).....	766
6.7.3.3	Ultra Low Power Regulator (ULPREG).....	766
6.7.3.4	LVDs and POR.....	767
6.7.3.5	Power Up Sequencing.....	767
6.7.3.6	STOP Mode.....	768
6.7.3.7	Low Power Stop Mode (LPSTOP) .....	768
6.7.3.8	Well Bias STOP Mode.....	768
6.8	Analog Components Control Digital Interface (ANADIG).....	769
6.8.1	Overview.....	769
6.8.2	Memory Map and Registers.....	769
6.8.2.1	Anadig Registers.....	769
6.8.2.1.1	PLL3 Control register (ANADIG_PLL3_CTRL).....	771
6.8.2.1.2	PLL7 Control register (ANADIG_PLL7_CTRL).....	773
6.8.2.1.3	PLL2 Control register (ANADIG_PLL2_CTRL).....	775
6.8.2.1.4	PLL2 Spread Spectrum definition register (ANADIG_PLL2_SS).....	777
6.8.2.1.5	PLL2 Numerator definition register (ANADIG_PLL2_NUM).....	778
6.8.2.1.6	PLL2 Denominator definition register (ANADIG_PLL2_DENOM).....	778
6.8.2.1.7	PLL4 Control register (ANADIG_PLL4_CTRL).....	779
6.8.2.1.8	PLL4 Numerator register (ANADIG_PLL4_NUM).....	780
6.8.2.1.9	PLL4 Denominator register (ANADIG_PLL4_DENOM).....	781
6.8.2.1.10	PLL6 Control register (ANADIG_PLL6_CTRL).....	782
6.8.2.1.11	PLL6 Numerator register (ANADIG_PLL6_NUM).....	783
6.8.2.1.12	PLL6 Denominator register (ANADIG_PLL6_DENOM).....	784
6.8.2.1.13	PLL5 Control register (ANADIG_PLL5_CTRL).....	785
6.8.2.1.14	ANADIG PLL3 PFD definition register (ANADIG_PLL3_PFD).....	786

Section number	Title	Page
6.8.2.1.15	ANADIG PLL2 PFD definition register (ANADIG_PLL2_PFD).....	789
6.8.2.1.16	ANADIG Regulator 1P1 definition register (ANADIG_REG_1P1).....	792
6.8.2.1.17	ANADIG Regulator 3P0 definition register (ANADIG_REG_3P0).....	793
6.8.2.1.18	ANADIG Regulator 2P5 definition register (ANADIG_REG_2P5).....	796
6.8.2.1.19	ANADIG Analog Miscellaneous definition register (ANADIG_ANA_MISC0)	798
6.8.2.1.20	ANADIG Analog Miscellaneous definition register (ANADIG_ANA_MISC1)	800
6.8.2.1.21	PLL1 Control register (ANADIG_PLL1_CTRL).....	802
6.8.2.1.22	PLL1 Spread Spectrum register (ANADIG_PLL1_SS).....	804
6.8.2.1.23	PLL1 Numerator register (ANADIG_PLL1_NUM).....	805
6.8.2.1.24	PLL1 Denominator register (ANADIG_PLL1_DENOM).....	805
6.8.2.1.25	ANADIG PLL1_PFD definition register (ANADIG_PLL1_PFD).....	806
6.8.2.1.26	ANADIG PLL Lock register (ANADIG_PLL_LOCK).....	808

## Chapter 7

### SNVS, Reset, eFuse, and Boot

7.1	Secure Non-Volatile Storage (SNVS).....	809
7.1.1	SNVS overview.....	809
7.1.1.1	SNVS features.....	810
7.1.1.2	Modes of operation.....	811
7.1.2	SNVS structure.....	811
7.1.2.1	SNVS_HP (high-power domain).....	812
7.1.2.2	Non-secure real-time counter.....	813
7.1.2.2.1	Calibrating the time counter.....	813
7.1.2.2.2	Time counter alarm.....	813
7.1.2.2.3	Periodic interrupt.....	814
7.1.3	SNVS_LP (low-power domain).....	814
7.1.3.1	Behavior during system power down.....	815
7.1.3.2	Monotonic Counter (MC).....	815
7.1.4	SNVS reset and system powerup.....	816
7.1.5	SNVS interrupts and alarms.....	816

Section number	Title	Page
7.1.6	Programming guidelines.....	816
7.1.6.1	RTC control bits setting.....	816
7.1.6.2	RTC value read.....	817
7.1.6.3	General initialization guidelines.....	818
7.1.7	SNVS memory map/register definition.....	818
7.1.7.1	SNVS_HP Lock register (SNVS_HPLR).....	820
7.1.7.2	SNVS_HP Command register (SNVS_HPCOMR).....	823
7.1.7.3	SNVS_HP Control register (SNVS_HPCR).....	825
7.1.7.4	SNVS_HP Status register (SNVS_HPSR).....	827
7.1.7.5	SNVS_HP Real-Time Counter MSB Register (SNVS_HPRTCMR).....	828
7.1.7.6	SNVS_HP Real-Time Counter LSB Register (SNVS_HPRTCLR).....	829
7.1.7.7	SNVS_HP Time Alarm MSB Register (SNVS_HPTAMR).....	829
7.1.7.8	SNVS_HP Time Alarm LSB Register (SNVS_HPTALR).....	830
7.1.7.9	SNVS_LP Lock Register (SNVS_LPLR).....	831
7.1.7.10	SNVS_LP Control Register (SNVS_LPCR).....	833
7.1.7.11	SNVS_LP Status Register (SNVS_LPSR).....	834
7.1.7.12	SNVS_LP Secure Monotonic Counter MSB Register (SNVS_LPSMCMR).....	836
7.1.7.13	SNVS_LP Secure Monotonic Counter LSB Register (SNVS_LPSMCLR).....	836
7.1.7.14	SNVS_LP General-Purpose Register (SNVS_LPGPR).....	837
7.1.7.15	SNVS_HP Version ID Register 1 (SNVS_HPVIDR1).....	837
7.1.7.16	SNVS_HP Version ID Register 2 (SNVS_HPVIDR2).....	838
7.2	Reset.....	839
7.2.1	Introduction.....	839
7.2.2	Reset Sources.....	839
7.2.3	Reset Functions.....	839
7.2.4	Clock Monitor.....	840
7.3	System Reset Controller (SRC).....	841
7.3.1	Introduction.....	841
7.3.2	SRC Overview.....	841

Section number	Title	Page
7.3.2.1	Features.....	842
7.3.3	Memory Map and Register Definition.....	842
7.3.3.1	Register Descriptions.....	842
7.3.3.2	SRC Control Register (SRC_SCR).....	844
7.3.3.3	SRC Boot Mode Register 1 (SRC_SBMR1).....	845
7.3.3.4	SRC Status Register (SRC_SRSR).....	845
7.3.3.5	SRC_SECR.....	849
7.3.3.6	SRC Reset Interrupt Configuration Register (SRC_SICR).....	850
7.3.3.7	SRC Interrupt Masking Register (SRC_SIMR).....	852
7.3.3.8	SRC Boot Mode Register 2 (SRC_SBMR2).....	854
7.3.3.9	General Purpose Register (SRC_GPR $n$ ).....	855
7.3.3.10	MISC0 (SRC_MISC0).....	855
7.3.3.11	MISC1 (SRC_MISC1).....	857
7.3.3.12	MISC2 (SRC_MISC2).....	859
7.3.3.13	MISC3 (SRC_MISC3).....	860
7.3.4	Functional Description.....	861
7.3.4.1	Reset Sources.....	861
7.3.4.2	Destructive reset sequence.....	862
7.3.4.3	Functional reset sequence.....	863
7.3.4.4	External reset sequence.....	864
7.3.4.5	Standby reset sequence.....	865
7.3.4.6	Memory Repair.....	867
7.3.4.7	BOOTMOD Pin Latching.....	868
7.4	On-Chip One Time Programmable Controller (OCOTP).....	870
7.4.1	Introduction.....	870
7.4.2	Overview of On-Chip OTP (OCOTP) controller.....	870
7.4.3	Top-level symbol and functional overview.....	870
7.4.3.1	Operation.....	871
7.4.3.1.1	Fuse shadow memory footprint.....	871

Section number	Title	Page
7.4.3.1.1.1	Fuse map address table.....	872
7.4.3.1.2	Fuse values.....	873
7.4.3.1.3	Fuse protection and overrides.....	873
7.4.3.1.4	Fuse blowing.....	873
7.4.3.1.5	Fuse and shadow register read.....	874
7.4.3.1.6	Fuse and Shadow Register Writes.....	874
7.4.3.1.7	Write postamble.....	876
7.4.3.2	OTP read/write timing parameters.....	876
7.4.3.3	Behavior During Reset.....	877
7.4.3.4	Secure JTAG control.....	877
7.4.4	OCOTP memory map/register definition.....	878
7.4.4.1	OTP Controller Control Register (OCOTP_CTRLn).....	881
7.4.4.2	OTP Controller Timing Register (OCOTP_TIMING).....	883
7.4.4.3	OTP Controller Write Data Register (OCOTP_DATA).....	883
7.4.4.4	OTP Controller Read Control Register (OCOTP_READ_CTRL).....	884
7.4.4.5	OTP Controller Read Data Register (OCOTP_READ_FUSE_DATA).....	885
7.4.4.6	Software Controllable Set Register (OCOTP_SCSn).....	885
7.4.4.7	OTP Controller CRC address (OCOTP_CRC_ADDR).....	886
7.4.4.8	OTP Controller CRC Value Register (OCOTP_CRC_VALUE).....	887
7.4.4.9	OTP Controller Version Register (OCOTP_VERSION).....	887
7.4.4.10	Value of OTP Bank0 Word0 (Lock controls) (OCOTP_LOCK).....	887
7.4.4.11	Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP_CFG0).....	890
7.4.4.12	Value of OTP Bank0 Word2 (Configuration and Manufacturing Info.) (OCOTP_CFG1).....	891
7.4.4.13	Value of OTP Bank0 Word5 (Configuration and Manufacturing Info.) (OCOTP_CFG4).....	891
7.4.4.14	Value of OTP Bank0 Word6 (Configuration and Manufacturing Info.) (OCOTP_CFG5).....	895
7.4.4.15	Value of Bank1 Word6 (Temperature Sensor calibration OCOTP_ANA_TEMPSENSE) (OCOTP_TEMPSENSE).....	897
7.4.4.16	Value of OTP Bank1 Word7 (General Purpose Customer Defined Info.) (OCOTP_ANA2).....	898
7.4.4.17	Value of OTP Bank4 Word0 (Secure JTAG Response Field) (OCOTP_RESP0).....	898

Section number	Title	Page
7.4.4.18	Value of OTP Bank4 Word1 (Secure JTAG Response Field) (OCOTP_HSJC_RESP1).....	899
7.4.4.19	Value of OTP Bank4 Word2 (MAC Address) (OCOTP_MAC0).....	899
7.4.4.20	Value of OTP Bank4 Word3 (MAC Address) (OCOTP_MAC1).....	900
7.4.4.21	Value of OTP Bank4 Word4 (MAC Address) (OCOTP_MAC2).....	900
7.4.4.22	Value of OTP Bank4 Word5 (MAC Address) (OCOTP_MAC3).....	901
7.4.4.23	Value of OTP Bank4 Word6 (HW Capabilities) (OCOTP_GP1).....	901
7.4.4.24	Value of OTP Bank4 Word7 (HW Capabilities) (OCOTP_GP2).....	902
7.4.4.25	Value of OTP Bank7 Word5 (Memory Related Info.) (OCOTP_RNG).....	902
7.4.4.26	Value of OTP Bank7 Word7 (Memory Related Info.) (OCOTP_VTMON).....	903
7.4.4.27	Value of OTP Bank15 Word0 (OCOTP_CRC0).....	904
7.4.4.28	Value of OTP Bank15 Word1 (OCOTP_CRC1).....	904
7.4.4.29	Value of OTP Bank15 Word2 (OCOTP_CRC2).....	905
7.4.4.30	Value of OTP Bank15 Word3 (OCOTP_CRC3).....	905
7.4.4.31	Value of OTP Bank15 Word4 (OCOTP_CRC4).....	906
7.4.4.32	Value of OTP Bank15 Word5 (OCOTP_CRC5).....	906
7.4.4.33	Value of OTP Bank15 Word6 (OCOTP_CRC6).....	907
7.4.4.34	Value of OTP Bank15 Word7 (OCOTP_CRC7).....	907
7.5	System Boot.....	908
7.5.1	Introduction.....	908
7.5.2	Boot Modes.....	909
7.5.2.1	Boot Mode Pin Settings.....	910
7.5.2.2	High Level Boot Sequence.....	910
7.5.2.3	Boot From Fuses Mode (BOOT_MODE [1:0] = 0b00).....	912
7.5.2.4	Mode: Serial Downloader Mode (BOOT_MODE [1:0] = 0b01).....	912
7.5.2.5	Boot from RCON (BOOT_MODE [1:0] = 0b10).....	913
7.5.3	Device Configuration.....	914
7.5.3.1	Boot eFUSE Descriptions.....	914
7.5.3.2	GPIO Boot Overrides.....	916
7.5.3.3	Device Configuration Data.....	917

Section number	Title	Page
7.5.4	Device Initialization.....	917
7.5.4.1	Internal ROM / RAM Memory Map.....	918
7.5.4.2	Boot Block Activation.....	918
7.5.4.3	Clocks at Boot Time.....	919
7.5.4.4	Enabling MMU and Caches.....	923
7.5.4.5	WDOG_ENABLE eFUSE.....	924
7.5.4.6	Watchdog Reset Boot Mode.....	925
7.5.4.7	Exception Handling.....	925
7.5.4.8	Interrupt Handling during Boot.....	925
7.5.4.9	Persistent Bits.....	926
7.5.5	Boot Devices (Internal Boot).....	926
7.5.5.1	QuadSPI Serial Flash Memory Boot.....	927
7.5.5.1.1	QuadSPI eFUSE Configuration.....	927
7.5.5.1.2	QuadSPI Serial Flash BOOT Operation.....	927
7.5.5.1.3	IOMUX Configuration for QuadSPI.....	928
7.5.5.1.4	CCM Settings in various modes .....	929
7.5.5.1.5	QuadSPI Configuration Parameters.....	929
7.5.5.1.6	QuadSPI boot flow chart.....	932
7.5.5.1.7	QuadSPI register boot ROM reset values.....	934
7.5.5.2	NOR Flash Boot using FlexBus Interface.....	934
7.5.5.2.1	NOR Flash eFUSE Configuration.....	935
7.5.5.2.2	NOR Flash Boot Operation.....	935
7.5.5.2.3	NOR Flash Configuration Block.....	936
7.5.5.2.4	CCM Settings in various modes .....	938
7.5.5.2.5	IOMUX Configuration for FlexBus.....	938
7.5.5.3	Serial ROM Boot using SPI/I2C Interface.....	939
7.5.5.3.1	Serial ROM eFUSE Configuration.....	939
7.5.5.3.2	SPI Boot.....	940
7.5.5.3.3	IOMUX Configuration for SPI.....	942

Section number	Title	Page
7.5.5.3.4	I2C Boot.....	943
7.5.5.3.5	IOMUX Configuration for I2C.....	944
7.5.5.4	FlexCAN Boot.....	945
7.5.5.4.1	FlexCAN eFUSE Configuration.....	945
7.5.5.4.2	FlexCAN Configuration Parameters.....	945
7.5.5.4.3	FlexCAN Boot Operation.....	946
7.5.5.4.4	IOMUX Configuration for FlexCAN.....	949
7.5.5.5	SD/MMC Boot.....	950
7.5.5.5.1	SD/MMC eFUSE Configuration.....	950
7.5.5.5.2	MMC and eMMC Boot.....	952
7.5.5.5.3	SD, eSD Boot.....	959
7.5.5.5.4	IOMUX Configuration for SD/MMC.....	960
7.5.5.5.5	CCM Settings in various modes.....	960
7.5.5.5.6	Redundant Boot Support for Expansion Device.....	961
7.5.5.6	NAND Flash Boot using NFC Interface.....	962
7.5.5.6.1	NAND Flash eFUSE Configuration.....	962
7.5.5.6.2	NAND Flash Boot Flow and BOOT Control Blocks (BCB).....	963
7.5.5.6.3	Firmware Configuration Block (FCB).....	965
7.5.5.6.4	Discovered Bad Block Table (DBBT).....	967
7.5.5.6.5	Typical NAND Page Organization.....	967
7.5.5.6.6	Bad Block Handling in the ROM.....	968
7.5.5.6.7	Setup DMA for DDR Transfers.....	970
7.5.5.6.8	IOMUX Configuration for NFC.....	970
7.5.5.6.9	CCM Settings in various modes.....	970
7.5.6	Program Image.....	971
7.5.6.1	Image Vector Table and Boot Data.....	971
7.5.6.1.1	Image Vector Table Structure.....	972
7.5.6.1.2	Boot Data Structure.....	973
7.5.6.2	Device Configuration Data (DCD).....	973

Section number	Title	Page
7.5.6.2.1	Write Data Command.....	974
7.5.6.2.2	Check Data Command.....	976
7.5.6.2.3	NOP Command.....	977
7.5.7	Plugin Image.....	978
7.5.8	Serial Downloader (BOOT_MODE [1:0] = 0b01).....	979
7.5.8.1	USB Boot Flow.....	980
7.5.8.1.1	USB Configuration Details.....	980
7.5.8.1.2	IOMUX Configuration for USB.....	981
7.5.8.2	UART Boot Flow.....	981
7.5.8.2.1	UART eFUSE Configuration.....	981
7.5.8.2.2	IOMUX Configuration for UART.....	982
7.5.8.3	Serial Download protocol.....	982
7.5.8.3.1	SDP Command.....	983
7.5.8.3.1.1	READ REGISTER.....	983
7.5.8.3.1.2	WRITE REGISTER.....	984
7.5.8.3.1.3	WRITE_FILE.....	985
7.5.8.3.1.4	ERROR_STATUS.....	986
7.5.8.3.1.5	DCD WRITE.....	987
7.5.8.3.1.6	JUMP ADDRESS.....	988
7.5.9	Recovery Devices.....	989
7.5.10	HAB Re-Authentication at Low Power Standby Exit.....	989
7.5.11	Running Secondary Core.....	990
7.5.12	Appendix.....	990
7.5.12.1	IOMUX and GPIO Pad Settings for BOOT Interfaces.....	990
7.5.12.2	Fuse RCON Mapping.....	990
7.5.12.3	PLL Configuration after BOOT.....	991
7.5.12.4	Basic CCM Settings.....	991
7.6	Fusemap.....	992
7.6.1	Boot Fusemap.....	992

Section number	Title	Page
7.6.2	Fusemap Descriptions Table.....	992
7.6.3	Lock Fusemap.....	999

## Chapter 8 Analog and Misc Control

8.1	12-bit Digital-to-Analog Converter (DAC).....	1001
8.1.1	Introduction.....	1001
8.1.2	Features.....	1001
8.1.3	Block diagram.....	1002
8.1.4	Memory map/register definition.....	1003
8.1.4.1	DAC Data Register (DACx_DATn).....	1004
8.1.4.2	DAC Status and Control Register (DACx_STATCTRL).....	1005
8.1.5	Functional description.....	1007
8.1.5.1	DAC data buffer operation.....	1007
8.1.5.1.1	DAC data buffer interrupts.....	1008
8.1.5.1.2	Modes of DAC data buffer operation.....	1008
8.1.5.2	DMA operation.....	1009
8.1.5.3	Resets.....	1009
8.1.5.4	Low-Power mode operation.....	1009
8.2	Analog-to-Digital Converter (ADC).....	1009
8.2.1	Overview.....	1009
8.2.1.1	Features.....	1010
8.2.1.2	ADC I/F block diagram.....	1010
8.2.1.3	ADC block diagram.....	1011
8.2.1.4	ADC module interface.....	1012
8.2.1.5	Modes of Operation.....	1013
8.2.2	External Signals.....	1013
8.2.3	Functional Description.....	1013
8.2.3.1	Clock Select and Divide Control.....	1014
8.2.3.2	Voltage Reference Selection .....	1015

Section number	Title	Page
8.2.3.3	Conversion Control.....	1015
8.2.3.3.1	Initiating Conversions.....	1016
8.2.3.3.2	Completing Conversions.....	1016
8.2.3.3.3	Aborting Conversions.....	1017
8.2.3.3.4	Power Control.....	1017
8.2.3.3.5	Sample Time and Total Conversion Time.....	1018
8.2.3.3.6	Conversion Time Examples.....	1020
8.2.3.3.6.1	Typical conversion time configuration.....	1020
8.2.3.3.6.2	Long conversion time configuration.....	1020
8.2.3.3.6.3	Short conversion time configuration.....	1021
8.2.3.3.7	Hardware Average Function.....	1022
8.2.3.4	Automatic Compare Function.....	1022
8.2.3.5	Calibration Function.....	1023
8.2.3.6	User Defined Offset Function .....	1024
8.2.3.7	Temperature Sensor.....	1025
8.2.3.8	MCU Wait Mode Operation.....	1025
8.2.3.9	MCU Stop Mode Operation.....	1026
8.2.3.9.1	Stop Mode With ADACK Disabled.....	1026
8.2.3.9.2	Stop Mode With ADACK Enabled.....	1026
8.2.4	Initialization Information.....	1027
8.2.4.1	ADC Module Initialization Example.....	1027
8.2.4.1.1	Initialization Sequence.....	1027
8.2.4.1.2	Pseudo-Code Example.....	1027
8.2.5	Application Information.....	1029
8.2.5.1	Sources of Error.....	1029
8.2.5.1.1	Sampling Error.....	1029
8.2.5.1.2	Pin Leakage Error.....	1030
8.2.5.1.3	Noise-Induced Errors.....	1030
8.2.5.1.4	Code Width and Quantization Error.....	1031

Section number	Title	Page
8.2.5.1.5	Linearity Errors.....	1031
8.2.5.1.6	Code Jitter, Non-Monotonicity, and Missing Codes.....	1032
8.2.6	Memory map and register definition.....	1033
8.2.6.1	Control register (ADCx_HC0).....	1034
8.2.6.2	Status register (ADCx_HS).....	1036
8.2.6.3	Data result register (ADCx_R0).....	1037
8.2.6.4	Configuration register (ADCx_CFG).....	1038
8.2.6.5	General control register (ADCx_GC).....	1040
8.2.6.6	General status register (ADCx_GS).....	1042
8.2.6.7	Compare value register (ADCx_CV).....	1043
8.2.6.8	Offset correction value register (ADCx_OFS).....	1044
8.2.6.9	Calibration value register (ADCx_CAL).....	1045
8.2.6.10	Pin control register (ADCx_PCTL).....	1045
8.3	Miscellaneous Control Module (MCM).....	1049
8.3.1	Introduction.....	1049
8.3.1.1	Features.....	1049
8.3.2	Memory map/register descriptions.....	1049
8.3.2.1	Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC).....	1050
8.3.2.2	Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC).....	1050
8.3.2.3	Control Register (MCM_CR).....	1051
8.3.2.4	Interrupt Status and Control Register (MCM_ISCR).....	1052
8.3.2.5	Fault address register (MCM_FADR).....	1055
8.3.2.6	Fault attributes register (MCM_FATR).....	1056
8.3.2.7	Fault data register (MCM_FDR).....	1058
8.3.3	Functional description.....	1059
8.3.3.1	Interrupts.....	1059
8.3.3.1.1	Determining source of the interrupt.....	1059
8.4	Miscellaneous System Control Module (MSCM).....	1059
8.4.1	Overview.....	1059

Section number	Title	Page
8.4.2	Chip Configuration and Boot.....	1060
8.4.3	MSCM Memory Map/Register Definition.....	1061
8.4.3.1	CPU Configuration Memory Map and Registers.....	1061
8.4.3.2	MSCM Interrupt Router Memory Map and Register Descriptions.....	1061
8.4.3.3	MSCM Access Control and TrustZone Security (ACTZS) Memory Map and Registers.....	1062
8.4.3.4	Processor X Type Register (MSCM_CPxTYPE).....	1072
8.4.3.5	Processor X Number Register (MSCM_CPxNUM).....	1073
8.4.3.6	Processor X Master Register (MSCM_CPxMASTER).....	1073
8.4.3.7	Processor X Count Register (MSCM_CPxCOUNT).....	1075
8.4.3.8	Processor X Configuration 0 Register (MSCM_CPxCFG0).....	1076
8.4.3.9	Processor X Configuration 1 Register (MSCM_CPxCFG1).....	1077
8.4.3.10	Processor X Configuration 2 Register (MSCM_CPxCFG2).....	1078
8.4.3.11	Processor X Configuration 3 Register (MSCM_CPxCFG3).....	1080
8.4.3.12	Processor 0 Type Register (MSCM_CP0TYPE).....	1083
8.4.3.13	Processor 0 Number Register (MSCM_CP0NUM).....	1084
8.4.3.14	Processor 0 Master Register (MSCM_CP0MASTER).....	1085
8.4.3.15	Processor 0 Count Register (MSCM_CP0COUNT).....	1086
8.4.3.16	Processor 0 Configuration 0 Register (MSCM_CP0CFG).....	1087
8.4.3.17	Processor 0 Configuration 1 Register (MSCM_CP0CFG1).....	1088
8.4.3.18	Processor 0 Configuration 2 Register (MSCM_CP0CFG2).....	1089
8.4.3.19	Processor 0 Configuration 3 Register (MSCM_CP0CFG3).....	1091
8.4.3.20	Processor 1 Type Register (MSCM_CP1TYPE).....	1094
8.4.3.21	Processor 1 Number Register (MSCM_CP1NUM).....	1095
8.4.3.22	Processor 1 Master Register (MSCM_CP1MASTER).....	1096
8.4.3.23	Processor 1 Count Register (MSCM_CP1COUNT).....	1097
8.4.3.24	Processor 1 Configuration 0 Register (MSCM_CP1CFG).....	1098
8.4.3.25	Processor 1 Configuration 1 Register (MSCM_CP1CFG1).....	1099
8.4.3.26	Processor 1 Configuration 2 Register (MSCM_CP1CFG2).....	1100
8.4.3.27	Processor 1 Configuration 3 Register (MSCM_CP1CFG3).....	1102

Section number	Title	Page
8.4.3.28	Interrupt Router CP0 Interrupt Register (MSCM_IRCP0IR).....	1105
8.4.3.29	Interrupt Router CP1 Interrupt Register (MSCM_IRCP1IR).....	1107
8.4.3.30	Interrupt Router CPU Generate Interrupt Register (MSCM_IRCPGIR).....	1109
8.4.3.31	Interrupt Router Shared Peripheral Routing Control Register n (MSCM_IRSPRCn).....	1110
8.4.3.32	ACTZS TrustZone Enable Register (MSCM_TZENR).....	1111
8.4.3.33	ACTZS TrustZone Interrupt Register (MSCM_TZIR).....	1114
8.4.3.34	ACTZS CSLn Interrupt Enable Register (MSCM_CSlier).....	1116
8.4.3.35	ACTZS CSLn Interrupt Register (MSCM_CSliR).....	1119
8.4.3.36	ACTZS CSLn Interrupt Overrun Register (MSCM_CSOVR).....	1121
8.4.3.37	ACTZS CSLn Fail Status Address (Low) Register (MSCM_CSFARn).....	1124
8.4.3.38	ACTZS CSLn Fail Status Control Register (MSCM_CSFCRn).....	1126
8.4.3.39	ACTZS CSLn Fail Status Master ID Register (MSCM_CSFIRn).....	1127

## Chapter 9 ARM Platform and Debug

9.1	Peripheral Bridge (AIPS-Lite).....	1129
9.1.1	Introduction.....	1129
9.1.1.1	Features.....	1129
9.1.1.2	General operation.....	1129
9.1.2	Memory map/register definition.....	1130
9.1.3	Functional description.....	1130
9.1.3.1	Access support.....	1130
9.2	Semaphores (SEMA4).....	1131
9.2.1	Introduction .....	1131
9.2.1.1	Multi-Core Programming 101: Software Gates.....	1131
9.2.1.2	Overview.....	1133
9.2.1.3	Features.....	1134
9.2.1.4	Modes of Operation.....	1135
9.2.2	External Signal Description.....	1135
9.2.3	Memory map and register definition.....	1135

Section number	Title	Page
9.2.3.1	Semaphores Gate 3 Register (SEMA4_Gate03).....	1137
9.2.3.2	Semaphores Gate 2 Register (SEMA4_Gate02).....	1138
9.2.3.3	Semaphores Gate 1 Register (SEMA4_Gate01).....	1139
9.2.3.4	Semaphores Gate 0 Register (SEMA4_Gate00).....	1140
9.2.3.5	Semaphores Gate 7 Register (SEMA4_Gate07).....	1141
9.2.3.6	Semaphores Gate 6 Register (SEMA4_Gate06).....	1142
9.2.3.7	Semaphores Gate 5 Register (SEMA4_Gate05).....	1143
9.2.3.8	Semaphores Gate 4 Register (SEMA4_Gate04).....	1144
9.2.3.9	Semaphores Gate 11 Register (SEMA4_Gate11).....	1145
9.2.3.10	Semaphores Gate 10 Register (SEMA4_Gate10).....	1146
9.2.3.11	Semaphores Gate 9 Register (SEMA4_Gate09).....	1147
9.2.3.12	Semaphores Gate 8 Register (SEMA4_Gate08).....	1148
9.2.3.13	Semaphores Gate 15 Register (SEMA4_Gate15).....	1149
9.2.3.14	Semaphores Gate 14 Register (SEMA4_Gate14).....	1150
9.2.3.15	Semaphores Gate 13 Register (SEMA4_Gate13).....	1151
9.2.3.16	Semaphores Gate 12 Register (SEMA4_Gate12).....	1152
9.2.3.17	Semaphores Processor n IRQ Notification Enable (SEMA4_CPnINE).....	1153
9.2.3.18	Semaphores Processor n IRQ Notification (SEMA4_CPnNTF).....	1155
9.2.3.19	Semaphores (Secure) Reset Gate n (SEMA4_RSTGT).....	1156
9.2.3.20	Semaphores (Secure) Reset IRQ Notification (SEMA4_RSTNTF).....	1158
9.2.4	Functional Description.....	1159
9.2.4.1	SEMA4_GATEn Operation.....	1159
9.2.4.2	SEMA4_CPnNTF Operation.....	1161
9.2.5	Initialization Information.....	1164
9.2.6	Application Information.....	1164
9.3	On-Chip Memory Controller (OCMEM).....	1166
9.3.1	Overview.....	1166
9.3.2	Functional Description.....	1166
9.3.2.1	OCRAM Error Correcting Code (ECC).....	1167

Section number	Title	Page
9.3.2.1.1	ECC Checkbit / Syndrome Coding.....	1169
9.3.2.1.2	ECC and System Performance Implications.....	1173
9.3.2.2	OCRAM_gfx Pixel Conversion.....	1173
9.3.2.2.1	OCRAM_gfx Pixel Converter Functional Description.....	1174
9.3.2.2.1.1	RGB565.....	1174
9.3.2.2.1.2	ARGB1555.....	1175
9.3.2.2.1.3	ARGB4444.....	1175
9.3.2.2.1.4	ARGB8888 Conversions to 16-bit Pixel Data.....	1175
9.3.2.3	Pixel Conversion and System Performance Implications.....	1177
9.3.3	OCMEM Memory Map/Register Definition.....	1177
9.3.3.1	On-Chip Memory Descriptor Register (OCMEM_OCMDR <sub>n</sub> ).....	1178
9.3.3.2	On-Chip Memory ECC Control Register (OCMEM_OCMECR).....	1182
9.3.3.3	On-Chip Memory ECC Interrupt Register (OCMEM_OCMEIR).....	1184
9.3.3.4	On-Chip Memory ECC Error Generation Register (OCMEM_OCMEGR).....	1186
9.3.3.5	On-Chip Memory ECC Fault Address Register (OCMEM_OCMFAR).....	1189
9.3.3.6	On-Chip Memory ECC Fault Attribute Register (OCMEM_OCMFTR).....	1190
9.3.3.7	On-Chip Memory ECC Fault Data Register (OCMEM_OCMFDR).....	1191
9.4	Local Memory Controller (LMEM).....	1192
9.4.1	Introduction.....	1192
9.4.1.1	Block Diagram.....	1192
9.4.1.2	Cache features.....	1194
9.4.2	Memory Map and Registers.....	1196
9.4.2.1	Cache control register (LMEM_PCCCR).....	1196
9.4.2.2	Cache line control register (LMEM_PCCLCR).....	1198
9.4.2.3	Cache search address register (LMEM_PCCSAR).....	1200
9.4.2.4	Cache read/write value register (LMEM_PCCCVR).....	1201
9.4.2.5	Cache control register (LMEM_PSCCR).....	1202
9.4.2.6	Cache line control register (LMEM_PSCLCR).....	1203
9.4.2.7	Cache search address register (LMEM_PSCSAR).....	1206

Section number	Title	Page
9.4.2.8	Cache read/write value register (LMEM_PSCCVR).....	1207
9.4.3	Functional Description.....	1207
9.4.3.1	LMEM Function.....	1207
9.4.3.1.1	Processor Code accesses.....	1208
9.4.3.1.2	Processor System accesses.....	1208
9.4.3.1.3	Backdoor port accesses.....	1208
9.4.3.2	SRAM Function.....	1208
9.4.3.2.1	SRAM Configuration.....	1208
9.4.3.2.2	SRAM Arrays.....	1209
9.4.3.2.3	SRAM Accesses.....	1209
9.4.3.3	Cache Function.....	1210
9.4.3.4	Cache Control.....	1211
9.4.3.4.1	Cache set commands.....	1211
9.4.3.4.2	Cache line commands.....	1212
9.4.3.4.2.1	Executing a series of line commands using cache addresses.....	1213
9.4.3.4.2.2	Executing a series of line commands using physical addresses.....	1213
9.4.3.4.2.3	Line command results.....	1214
9.5	System Bus Interconnect.....	1215
9.5.1	Overview.....	1215
9.5.2	Features.....	1217
9.5.3	NIC301 Physical Structure and Programming Model.....	1218
9.5.3.1	NIC301 Physical Structure.....	1218
9.5.3.2	NIC301 Programming Model.....	1221
9.5.3.3	NIC301 Bus Arbitration.....	1225
9.6	AHB-TrustZone Address Space Controller (AHBTZASC).....	1226
9.6.1	Overview.....	1226
9.6.2	AHB-TZASC Programming Model Differences vs. (AXI) TZASC.....	1226
9.6.3	AHB-TZASC Memory Map/Register Definition.....	1227
9.6.3.1	Configuration Register (AHB-TZASC_CONFIG).....	1229

Section number	Title	Page
9.6.3.2	Action Register (AHB-TZASC_ACTION).....	1230
9.6.3.3	Lockdown Range Register (AHB-TZASC_LOCKDOWN_RANGE).....	1230
9.6.3.4	Lockdown Select Register (AHB-TZASC_LOCKDOWN_SELECT).....	1231
9.6.3.5	Interrupt Status Register (AHB-TZASC_INT_STATUS).....	1231
9.6.3.6	Interrupt Clear Register (AHB-TZASC_INT_CLEAR).....	1232
9.6.3.7	Fail Address Low Register (AHB-TZASC_FAIL_ADDRESS_LOW).....	1232
9.6.3.8	Fail Address High Register (AHB-TZASC_FAIL_ADDRESS_HIGH).....	1233
9.6.3.9	Fail Control Register (AHB-TZASC_FAIL_CONTROL).....	1233
9.6.3.10	Fail ID Register (AHB-TZASC_FAIL_ID).....	1234
9.6.3.11	Speculation Control Register (AHB-TZASC_SPECULATION_CONTROL).....	1234
9.6.3.12	Security Inversion Enable Register (AHB-TZASC_SECURITY_INVERSION_EN).....	1235
9.6.3.13	Region Setup Low n Register (AHB-TZASC_REGION_SETUP_LOW_n).....	1235
9.6.3.14	Region Setup High n Register (AHB-TZASC_REGION_SETUP_HIGH_n).....	1236
9.6.3.15	Region Attributes n Register (AHB-TZASC_REGION_ATTRIBUTES_n).....	1236
9.7	Watchdog Timer (WDOG).....	1237
9.7.1	Overview.....	1237
9.7.1.1	Features.....	1238
9.7.2	External signals.....	1239
9.7.3	Clocks.....	1239
9.7.4	Watchdog mechanism and system integration.....	1239
9.7.5	Functional description.....	1240
9.7.5.1	Timeout event.....	1240
9.7.5.1.1	Servicing WDOG to reload the counter.....	1241
9.7.5.2	Interrupt event .....	1241
9.7.5.3	Power-down counter event.....	1241
9.7.5.4	Low power modes.....	1242
9.7.5.4.1	STOP and DOZE mode.....	1242
9.7.5.4.2	WAIT mode.....	1242
9.7.5.5	Debug mode.....	1242

Section number	Title	Page
9.7.5.6	Operations.....	1243
9.7.5.6.1	Watchdog reset generation.....	1243
9.7.5.6.2	WDOG_B generation.....	1243
9.7.5.7	Reset.....	1245
9.7.5.8	Interrupt.....	1246
9.7.5.9	Flow Diagrams.....	1246
9.7.6	Initialization.....	1248
9.7.7	WDOG Memory Map/Register Definition.....	1249
9.7.7.1	Watchdog Control Register (WDOG_WCR).....	1249
9.7.7.2	Watchdog Service Register (WDOG_WSR).....	1251
9.7.7.3	Watchdog Reset Status Register (WDOG_WRSR).....	1252
9.7.7.4	Watchdog Interrupt Control Register (WDOG_WICR).....	1253
9.7.7.5	Watchdog Miscellaneous Control Register (WDOG_WMCR).....	1254
9.8	External Watchdog Monitor (EWM).....	1254
9.8.1	Introduction.....	1254
9.8.1.1	Features.....	1255
9.8.1.2	Modes of Operation.....	1255
9.8.1.2.1	Stop Mode.....	1255
9.8.1.2.2	Wait Mode.....	1256
9.8.1.2.3	Debug Mode.....	1256
9.8.1.3	Block Diagram.....	1256
9.8.2	EWM Signal Descriptions.....	1257
9.8.3	Memory Map/Register Definition.....	1258
9.8.3.1	Control Register (EWM_CTRL).....	1258
9.8.3.2	Service Register (EWM_SERV).....	1259
9.8.3.3	Compare Low Register (EWM_CMPL).....	1259
9.8.3.4	Compare High Register (EWM_CMPH).....	1260
9.8.3.5	Clock Control Register (EWM_CLKCTRL).....	1260
9.8.3.6	Clock Prescaler Register (EWM_CLKPRESCALER).....	1261

Section number	Title	Page
9.8.4	Functional Description.....	1262
9.8.4.1	The EWM_out Signal.....	1262
9.8.4.2	The EWM_in Signal.....	1263
9.8.4.3	EWM Counter.....	1263
9.8.4.4	EWM Compare Registers.....	1263
9.8.4.5	EWM Refresh Mechanism.....	1264
9.8.4.6	EWM Interrupt.....	1264
9.8.4.7	Selecting the EWM counter clock.....	1264
9.8.4.8	Counter clock prescaler.....	1265
9.9	Watchdog Configuration (WCON).....	1265
9.9.1	Watchdog Scheme.....	1265
9.9.2	Watchdog Connectivity.....	1266
9.9.3	WDOG clocking options.....	1267
9.9.4	WDOG Debug requirement.....	1268
9.10	Wakeup Unit (WKPU).....	1268
9.10.1	Introduction.....	1268
9.10.2	Features.....	1269
9.10.3	External signal description.....	1270
9.10.4	WKPU memory map and register definition.....	1270
9.10.4.1	NMI Status Flag Register (WKPU_NSR).....	1271
9.10.4.2	NMI Configuration Register (WKPU_NCR).....	1272
9.10.4.3	Wakeup/Interrupt Status Flag Register (WKPU_WISR).....	1274
9.10.4.4	Interrupt Request Enable Register (WKPU_IRER).....	1275
9.10.4.5	Wakeup Request Enable Register (WKPU_WRER).....	1275
9.10.4.6	Wakeup/Interrupt Rising-Edge Event Enable Register (WKPU_WIREER).....	1276
9.10.4.7	Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU_WIFEER).....	1276
9.10.4.8	Wakeup/Interrupt Filter Enable Register (WKPU_WIFER).....	1277
9.10.4.9	Wakeup/Interrupt Pullup Enable Register (WKPU_WIPUER).....	1277
9.10.5	Functional description.....	1278

Section number	Title	Page
9.10.5.1	Non-maskable interrupts.....	1278
9.10.5.1.1	NMI management.....	1279
9.10.5.2	External wakeups/interrupts.....	1280
9.10.5.2.1	External interrupt management.....	1281
9.10.5.3	On-chip wakeups.....	1282
9.10.5.3.1	On-chip wakeup management.....	1282
9.10.6	Initialization Information.....	1282
9.10.6.1	Glitch Filter and Pad Configuration.....	1282
9.10.6.2	Non-Maskable Interrupts.....	1282
9.10.6.3	Reset Request.....	1283
9.11	System Debug.....	1284
9.11.1	Overview.....	1284
9.11.2	System Level Debug Architecture.....	1285
9.11.3	Test and Debug Access Port Connectivity.....	1287
9.11.4	JTAG to SWD cJTAG switching sequence.....	1288
9.11.4.1	JTAG-to-SWD change sequence.....	1288
9.11.4.2	JTAG-to-cJTAG change sequence.....	1288
9.11.4.3	System JTAG Controller (JTAGC).....	1289
9.11.4.4	Debug Access Port (DAP) TAP.....	1290
9.11.4.4.1	ROM Table.....	1291
9.11.4.4.1.1	CM4 ROM table.....	1292
9.11.4.4.1.2	CA5 ROM table.....	1292
9.11.4.4.1.3	DAP ROM table.....	1293
9.11.5	Debug Port Pin Descriptions.....	1294
9.11.6	Secure JTAG Controller (SJC).....	1295
9.11.6.1	Challenge Response Access Sequence.....	1295
9.11.7	Debug Status and Control Registers.....	1296
9.11.7.1	Miscellaneous Debug Module (MDM) AP Control Register.....	1296
9.11.7.2	Miscellaneous Debug Module (MDM) AP Status Register.....	1298

Section number	Title	Page
9.11.8	Debug Resets.....	1299
9.11.9	Trace Architecture.....	1299
9.11.9.1	Data Watchpoint and Trace (DWT).....	1301
9.11.9.2	Flash Patch and Breakpoints (FPB) (CM4 only).....	1302
9.11.9.3	Instrumentation Trace Macrocell (ITM).....	1302
9.11.9.4	Embedded Trace Macrocell (ETM).....	1303
9.11.9.5	CoreSight Embedded Trace Buffer (ETB).....	1303
9.11.9.6	Trace Port Interface Unit (TPIU).....	1304
9.11.9.7	Serial Wire Output.....	1304
9.11.9.8	Performance Monitoring Unit (for CA5 Only).....	1305
9.11.9.9	Embedded Cross Trigger.....	1305
9.11.9.9.1	CM4 CTI Triggers.....	1306
9.11.9.9.2	CA5 CTI Triggers.....	1307
9.11.10	Low Power Debug.....	1308
9.11.11	Secured JTAG.....	1309
9.11.11.1	Additional Authentication Interface.....	1309
9.11.12	Configuration sequence.....	1310
9.11.12.1	Halt mode.....	1310
9.11.12.2	Monitor mode.....	1311
9.12	System JTAG Controller (SJC).....	1311
9.12.1	Introduction.....	1311
9.12.2	External signal description.....	1311
9.12.2.1	External signal overview.....	1311
9.12.2.2	TAP controller.....	1312
9.12.2.3	Accessing ExtraDebug register.....	1314
9.12.3	JTAG Instruction Register (SJIR).....	1315
9.12.3.1	BYPASS instruction.....	1316
9.12.3.2	ENABLE_ExtraDebug instruction.....	1316
9.12.4	Security.....	1317

Section number	Title	Page
9.12.4.1	JTAG Security Modes.....	1317
9.12.4.1.1	Mode 1: no debug—maximum security.....	1317
9.12.4.1.2	Mode 2: secure JTAG—high security.....	1318
9.12.4.1.2.1	Challenge/response mechanism.....	1318
9.12.4.1.3	Mode 3: JTAG enabled—low security.....	1319
9.12.4.2	Software enabled JTAG.....	1319
9.12.5	Programmable registers.....	1320
9.12.5.1	Security Status Register (SJC_SSR).....	1321

## Chapter 10

### External Memory and Mass Storage

10.1	LPDDR2/DDR3 SDRAM Memory Controller (DDRMC).....	1323
10.1.1	Introduction.....	1323
10.1.2	Block diagram.....	1324
10.1.3	Modes of Operation.....	1324
10.1.3.1	Low Power Modes.....	1324
10.1.4	Signal Description.....	1325
10.1.4.1	Detailed Signal Descriptions.....	1325
10.1.5	Memory map and register description.....	1332
10.1.5.1	Control Register 0 (DDRMC_CR00).....	1341
10.1.5.2	Control Register 1 (DDRMC_CR01).....	1342
10.1.5.3	Control Register 2 (DDRMC_CR02).....	1343
10.1.5.4	Control Register 3 (DDRMC_CR03).....	1344
10.1.5.5	Control Register 4 (DDRMC_CR04).....	1344
10.1.5.6	Control Register 5 (DDRMC_CR05).....	1345

## Chapter 11 Connectivity

11.1	Universal Serial Bus Controller(USB).....	1911
------	---	------

Section number	Title	Page
11.1.1	Overview.....	1911
11.1.2	Features.....	1912
11.1.2.1	Ports.....	1913
11.1.2.1.1	Modes of Operation.....	1913
11.1.2.1.2	Normal Mode.....	1913
11.1.2.1.3	Low Power Mode.....	1914
11.1.3	Non-core Registers.....	1914
11.1.3.1	USB Control Register (USBCx_CTRL).....	1916
11.1.3.2	UTMI PHY Control Register (USBCx_PHY).....	1919
11.1.4	Core Registers.....	1920
11.1.4.1	Identification register (USBx_ID).....	1924
11.1.4.2	Hardware General (USBx_HWGENERAL).....	1925
11.1.4.3	Host Hardware Parameters (USBx_HWHOST).....	1926
11.1.4.4	Device Hardware Parameters (USBx_HWDEVICE).....	1927
11.1.4.5	TX Buffer Hardware Parameters (USBx_HWTXBUF).....	1927
11.1.4.6	RX Buffer Hardware Parameters (USBx_HWRXBUF).....	1928
11.1.4.7	General Purpose Timer #0 Load (USBx_GPTIMER0LD).....	1928
11.1.4.8	General Purpose Timer #0 Controller (USBx_GPTIMER0CTRL).....	1929
11.1.4.9	General Purpose Timer #1 Load (USBx_GPTIMER1LD).....	1930
11.1.4.10	General Purpose Timer #1 Controller (USBx_GPTIMER1CTRL).....	1931
11.1.4.11	System Bus Config (USBx_SBUSCFG).....	1932
11.1.4.12	Capability Register Length (USBx_CAPLENGTH).....	1933
11.1.4.13	Host Controller Interface Version (USBx_HCVERSION).....	1933
11.1.4.14	Host Controller Structural Parameters (USBx_HCSPARAMS).....	1934
11.1.4.15	Host Controller Capability Parameters (USBx_HCCPARAMS).....	1935
11.1.4.16	Device Controller Interface Version (USBx_DCVERSION).....	1936
11.1.4.17	Device Controller Capability Parameters (USBx_DCCPARAMS).....	1937
11.1.4.18	USB Command Register (USBx_USBCMD).....	1937
11.1.4.19	USB Status Register (USBx_USBSTS).....	1942

Section number	Title	Page
11.1.4.20	Interrupt Enable Register (USB <sub>x</sub> _USBINTR).....	1946
11.1.4.21	USB Frame Index (USB <sub>x</sub> _FRINDEX).....	1948
11.1.4.22	Frame List Base Address (USB <sub>x</sub> _PERIODICLISTBASE).....	1949
11.1.4.23	Device Address (USB <sub>x</sub> _DEVICEADDR).....	1950
11.1.4.24	Next Asynch. Address (USB <sub>x</sub> _ASYNCLISTADDR).....	1951
11.1.4.25	Endpoint List Address (USB <sub>x</sub> _ENDPTLISTADDR).....	1951
11.1.4.26	Programmable Burst Size (USB <sub>x</sub> _BURSTSIZE).....	1952
11.1.4.27	TX FIFO Fill Tuning (USB <sub>x</sub> _TXFILLTUNING).....	1952
11.1.4.28	Endpoint NAK (USB <sub>x</sub> _ENDPTNAK).....	1954
11.1.4.29	Endpoint NAK Enable (USB <sub>x</sub> _ENDPTNAKEN).....	1954
11.1.4.30	Port Status & Control (USB <sub>x</sub> _PORTSC1).....	1955
11.1.4.31	On-The-Go Status & control (USB <sub>x</sub> _OTGSC).....	1961
11.1.4.32	USB Device Mode (USB <sub>x</sub> _USBMODE).....	1964
11.1.4.33	Endpoint Setup Status (USB <sub>x</sub> _ENDPTSETUPSTAT).....	1965
11.1.4.34	Endpoint Initialization (USB <sub>x</sub> _ENDPTPRIME).....	1966
11.1.4.35	Endpoint De-Initialize (USB <sub>x</sub> _ENDPTFLUSH).....	1967
11.1.4.36	Endpoint Status (USB <sub>x</sub> _ENDPTSTAT).....	1967
11.1.4.37	Endpoint Complete (USB <sub>x</sub> _ENDPTCOMPLETE).....	1968
11.1.4.38	Endpoint Control0 (USB <sub>x</sub> _ENDPTCTRL0).....	1969
11.1.4.39	Endpoint Controln (USB <sub>x</sub> _ENDPTCTRL <sub>n</sub> ).....	1970
11.1.5	Functional description.....	1973
11.1.5.1	USB dual role device/host controller.....	1973
11.1.5.1.1	Host mode.....	1973
11.1.5.1.2	Peripheral (Device) Mode.....	1973
11.1.5.2	USB Power Control Block.....	1974
11.1.5.2.1	Entering Low Power Suspend mode.....	1974
11.1.5.2.2	Wake-up events.....	1974
11.1.5.2.2.1	Host mode events.....	1974
11.1.5.2.2.2	Device mode events.....	1975

Section number	Title	Page
11.1.5.3	Interrupts.....	1976
11.1.5.3.1	USB core interrupts.....	1976
11.1.5.3.2	USB wake-up interrupts.....	1976
11.1.6	USB operation model.....	1977
11.1.6.1	Register interface.....	1977
11.1.6.1.1	Configuration, Control and Status Register Set.....	1978
11.1.6.1.2	Identification registers.....	1979
11.1.6.2	Host data structures.....	1979
11.1.6.2.1	Periodic Frame List.....	1980
11.1.6.2.2	Asynchronous List Queue Head Pointer.....	1982
11.1.6.2.3	Isochronous (High-Speed) Transfer Descriptor (iTDD).....	1983
11.1.6.2.3.1	Next Link Pointer-Host Data Structures.....	1984
11.1.6.2.3.2	iTDD Transaction Status and Control List.....	1984
11.1.6.2.3.3	iTDD Buffer Page Pointer List (Plus).....	1986
11.1.6.2.4	Split Transaction Isochronous Transfer Descriptor (siTD).....	1987
11.1.6.2.4.1	Next Link Pointer.....	1988
11.1.6.2.4.2	siTD Endpoint Capabilities/Characteristics.....	1988
11.1.6.2.4.3	siTD Transfer State.....	1989
11.1.6.2.4.4	siTD Buffer Pointer List (plus).....	1990
11.1.6.2.4.5	siTD Back Link Pointer.....	1991
11.1.6.2.5	Queue Element Transfer Descriptor (qTD).....	1991
11.1.6.2.5.1	Next qTD Pointer.....	1992
11.1.6.2.5.2	Alternate Next qTD Pointer.....	1993
11.1.6.2.5.3	qTD Token.....	1993
11.1.6.2.5.4	qTD Buffer Page Pointer List.....	1996
11.1.6.2.6	Queue Head.....	1996
11.1.6.2.6.1	Queue Head Horizontal Link Pointer.....	1997
11.1.6.2.6.2	Queue Head Endpoint Capabilities/Characteristics.....	1998
11.1.6.2.6.3	Transfer Overlay-Queue Head.....	2000

Section number	Title	Page
11.1.6.2.7	Periodic Frame Span Traversal Node (FSTN) .....	2001
11.1.6.2.7.1	FSTN Normal Path Pointer .....	2002
11.1.6.2.7.2	FSTN Back Path Link Pointer .....	2002
11.1.6.3	Host Operational Model .....	2003
11.1.6.3.1	Host Controller Initialization .....	2003
11.1.6.3.2	Port Routing and Control .....	2004
11.1.6.3.2.1	Port Routing Control through EHCI Configured (CF) Bit .....	2006
11.1.6.3.2.2	Port Routing Control through PortOwner and Disconnect Event .....	2007
11.1.6.3.2.3	Example Port Routing State Machine .....	2009
11.1.6.3.2.4	Port Power .....	2010
11.1.6.3.2.5	Port Reporting Over-Current .....	2011
11.1.6.3.3	Suspend/Resume-Host Operational Model .....	2012
11.1.6.3.3.1	Port Suspend/Resume .....	2012
11.1.6.3.4	Schedule Traversal Rules .....	2014
11.1.6.3.4.1	Example - Preserving Micro-Frame Integrity .....	2016
11.1.6.3.5	Periodic Schedule Frame Boundaries vs Bus Frame Boundaries .....	2019
11.1.6.3.6	Periodic Schedule .....	2022
11.1.6.3.7	Managing Isochronous Transfers Using iTDs .....	2023
11.1.6.3.7.1	Host Controller Operational Model for iTDs .....	2023
11.1.6.3.7.2	Software Operational Model for iTDs .....	2025
11.1.6.3.8	Asynchronous Schedule .....	2028
11.1.6.3.8.1	Adding Queue Heads to Asynchronous Schedule.....	2030
11.1.6.3.8.2	Removing Queue Heads from Asynchronous Schedule .....	2030
11.1.6.3.8.3	Empty Asynchronous Schedule Detection .....	2033
11.1.6.3.8.4	Restarting Asynchronous Schedule Before EOF .....	2033
11.1.6.3.8.5	Asynchronous Schedule Traversal: Start Event.....	2036
11.1.6.3.8.6	Reclamation Status Bit (USBSTS Register) .....	2037
11.1.6.3.9	Operational Model for Nak Counter.....	2037

Section number	Title	Page
11.1.6.3.9.1	Nak Count Reload Control .....	2039
11.1.6.3.10	Managing Control/Bulk/Interrupt Transfers through Queue Heads.....	2040
11.1.6.3.10.1	Fetch Queue Head .....	2043
11.1.6.3.10.2	Advance Queue .....	2043
11.1.6.3.10.3	Execute Transaction .....	2044
11.1.6.3.10.4	Write Back qTD .....	2050
11.1.6.3.10.5	Follow Queue Head Horizontal Pointer .....	2051
11.1.6.3.10.6	Buffer Pointer List Use for Data Streaming with qTDs .....	2051
11.1.6.3.10.7	Adding Interrupt Queue Heads to the Periodic Schedule .....	2054
11.1.6.3.10.8	Managing Transfer Complete Interrupts from Queue Heads ....	2054
11.1.6.3.11	Ping Control .....	2055
11.1.6.3.12	Split Transactions .....	2056
11.1.6.3.12.1	Split Transactions for Asynchronous Transfers .....	2056
11.1.6.3.12.2	Split Transaction Interrupt .....	2059
11.1.6.3.12.3	Split Transaction Isochronous .....	2074
11.1.6.3.13	Host Controller Pause .....	2090
11.1.6.3.14	Port Test Modes -Host Operational Model.....	2091
11.1.6.3.15	Interrupts-Host Operational Model.....	2091
11.1.6.3.15.1	Transfer/Transaction Based Interrupts .....	2093
11.1.6.3.15.2	Host Controller Event Interrupts .....	2095
11.1.6.4	EHCI Deviation.....	2097
11.1.6.4.1	Embedded Transaction Translator Function.....	2098
11.1.6.4.1.1	Capability Registers.....	2098
11.1.6.4.1.2	Operational Registers.....	2098
11.1.6.4.1.3	Discovery-EHCI Deviation.....	2099
11.1.6.4.1.4	Data Structures.....	2099
11.1.6.4.1.5	Operational Model.....	2100
11.1.6.4.2	Device Operation.....	2102
11.1.6.4.3	USB.USBMODE Register.....	2102

Section number	Title	Page
	11.1.6.4.3.1 Non-Zero Fields the Register File.....	2103
	11.1.6.4.3.2 SOF Interrupt.....	2103
11.1.6.4.4	Embedded Design Interface.....	2103
	11.1.6.4.4.1 Frame Adjust Register.....	2103
11.1.6.4.5	Miscellaneous variations from EHCI.....	2103
	11.1.6.4.5.1 Programmable Physical Interface Behaviour.....	2104
	11.1.6.4.5.2 Discovery.....	2104
	11.1.6.4.5.3 Port Test Mode.....	2105
11.1.6.5	Device Data Structures.....	2105
	11.1.6.5.1 Endpoint Queue Head (dQH).....	2106
	11.1.6.5.1.1 Endpoint Capabilities/Characteristics.....	2107
	11.1.6.5.1.2 Transfer Overlay-Endpoint Queue Head.....	2108
	11.1.6.5.1.3 Current dTD Pointer.....	2108
	11.1.6.5.1.4 Set-up Buffer.....	2109
	11.1.6.5.2 Endpoint Transfer Descriptor (dTD).....	2109
11.1.6.6	Device Operational Model.....	2111
	11.1.6.6.1 Device Controller Initialization.....	2111
	11.1.6.6.2 Port State and Control.....	2112
	11.1.6.6.2.1 Bus Reset.....	2114
	11.1.6.6.2.2 Suspend/Resume.....	2115
	11.1.6.6.2.3 Managing Endpoints.....	2116
	11.1.6.6.2.4 Endpoint Initialization.....	2117
	11.1.6.6.2.5 Stalling.....	2117
	11.1.6.6.2.6 Data Toggle .....	2118
	11.1.6.6.3 Operational Model For Packet Transfers.....	2120
	11.1.6.6.3.1 Interrupt/Bulk Endpoint Operational Model.....	2120
	11.1.6.6.3.2 Control Endpoint Operation Model.....	2123
	11.1.6.6.3.3 Isochronous Endpoint Operational Model.....	2126
	11.1.6.6.4 Managing Queue Heads.....	2128

Section number	Title	Page
11.1.6.6.4.1	Queue Head Initialization.....	2129
11.1.6.6.4.2	Operational Model For Setup Transfers.....	2130
11.1.6.6.5	Managing Transfers with Transfer Descriptors.....	2131

11.5.5.10.4	Output Queue Manager.....	2495
11.5.5.10.4.1	Weighted Fair Queuing Scheduling Algorithm.....	2495
11.5.5.10.5	Congestion Management.....	2495
11.5.5.11	Reset and stop functions.....	2496
11.5.5.11.1	Stop Controls.....	2496
11.5.5.11.2	Port Disable.....	2496
11.5.5.11.3	Port 0 Input Protection.....	2496
11.5.5.11.4	Port 1/2 Input Protection.....	2497
11.5.5.11.5	DMA Bus Error.....	2497

## Chapter 12

### Low Speed Communications and Interconnects

12.1	Flexible Controller Area Network (FlexCAN).....	2499
12.1.1	Introduction.....	2499
12.1.1.1	Overview.....	2500
12.1.1.2	FlexCAN module features.....	2501
12.1.1.3	Modes of operation.....	2502
12.1.2	FlexCAN signal descriptions.....	2504
12.1.2.1	CAN Rx .....	2504
12.1.2.2	CAN Tx .....	2504
12.1.3	Memory map/register definition.....	2504
12.1.3.1	FlexCAN memory mapping.....	2504
12.1.3.2	Module Configuration Register (CANx_MCR).....	2515
12.1.3.3	Control 1 register (CANx_CTRL1).....	2519
12.1.3.4	Free Running Timer (CANx_TIMER).....	2522
12.1.3.5	Rx Mailboxes Global Mask Register (CANx_RXMGMASK).....	2523
12.1.3.6	Rx 14 Mask register (CANx_RX14MASK).....	2524
12.1.3.7	Rx 15 Mask register (CANx_RX15MASK).....	2525
12.1.3.8	Error Counter (CANx_ECR).....	2526
12.1.3.9	Error and Status 1 register (CANx_ESR1).....	2527

Section number	Title	Page
12.1.3.10	Interrupt Masks 2 register (CANx_IMASK2).....	2531
12.1.3.11	Interrupt Masks 1 register (CANx_IMASK1).....	2532
12.1.3.12	Interrupt Flags 2 register (CANx_IFLAG2).....	2532
12.1.3.13	Interrupt Flags 1 register (CANx_IFLAG1).....	2533
12.1.3.14	Control 2 register (CANx_CTRL2).....	2535
12.1.3.15	Error and Status 2 register (CANx_ESR2).....	2539
12.1.3.16	CRC Register (CANx_CRCCR).....	2540
12.1.3.17	Rx FIFO Global Mask register (CANx_RXFGMASK).....	2541
12.1.3.18	Rx FIFO Information Register (CANx_RXFIR).....	2542
12.1.3.19	Rx Individual Mask Registers (CANx_RXIMRn).....	2542
12.1.3.20	Memory Error Control Register (CANx_MECR).....	2543
12.1.3.21	Error Injection Address Register (CANx_ERRIAR).....	2545
12.1.3.22	Error Injection Data Pattern Register (CANx_ERRIDPR).....	2546
12.1.3.23	Error Injection Parity Pattern Register (CANx_ERRIPPR).....	2547
12.1.3.24	Error Report Address Register (CANx_RERRAR).....	2547
12.1.3.25	Error Report Data Register (CANx_RERRDR).....	2549
12.1.3.26	Error Report Syndrome Register (CANx_RERRSYNR).....	2549
12.1.3.27	Error Status Register (CANx_ERRSR).....	2552
12.1.3.80	Message buffer structure.....	2553
12.1.3.81	Rx FIFO structure.....	2559
12.1.4	Functional description.....	2561
12.1.4.1	Transmit process.....	2562
12.1.4.2	Arbitration process.....	2562
12.1.4.2.1	Lowest-number Mailbox first.....	2563
12.1.4.2.2	Highest-priority Mailbox first.....	2563
12.1.4.2.2.1	Local Priority disabled.....	2564
12.1.4.2.2.2	Local Priority enabled.....	2564
12.1.4.2.3	Arbitration process (continued).....	2565
12.1.4.3	Receive process.....	2566

Section number	Title	Page
12.1.4.4	Matching process.....	2568
12.1.4.5	Move process.....	2573
12.1.4.5.1	Move-in.....	2573
12.1.4.5.2	Move-out.....	2574
12.1.4.6	Data coherence.....	2574
12.1.4.6.1	Transmission abort mechanism.....	2574
12.1.4.6.2	Mailbox inactivation.....	2576
12.1.4.6.3	Mailbox lock mechanism.....	2576
12.1.4.7	Rx FIFO.....	2578
12.1.4.8	CAN protocol related features.....	2579
12.1.4.8.1	Remote frames.....	2579
12.1.4.8.2	Overload frames.....	2580
12.1.4.8.3	Time stamp.....	2581
12.1.4.8.4	Protocol timing.....	2581
12.1.4.8.5	Arbitration and matching timing.....	2584
12.1.4.9	Clock domains and restrictions.....	2586
12.1.4.10	Modes of operation details.....	2586
12.1.4.10.1	Freeze mode.....	2586
12.1.4.10.2	Module Disable mode.....	2587
12.1.4.10.3	Stop mode.....	2588
12.1.4.11	Interrupts.....	2589
12.1.4.12	Bus interface.....	2590
12.1.4.13	Detection and Correction of Memory Errors.....	2591
12.1.4.13.1	Sources of the Memory Access.....	2592
12.1.4.13.2	Error Indication.....	2592
12.1.4.13.3	Error Reporting.....	2593
12.1.4.13.4	Response to Errors.....	2593
12.1.4.13.5	Error Injection.....	2594
12.1.5	Initialization/application information.....	2594

Section number	Title	Page
12.1.5.1	FlexCAN initialization sequence.....	2594
12.2	Inter-Integrated Circuit (I2C).....	2596
12.2.1	Overview.....	2596
12.2.2	Introduction to I2C.....	2597
12.2.2.1	Definition: I2C module.....	2597
12.2.2.2	Advantages of the I2C bus.....	2597
12.2.2.3	Module block diagram.....	2597
12.2.2.4	Features.....	2598
12.2.2.5	Modes of operation.....	2599
12.2.2.6	Definition: I2C conditions.....	2600
12.2.3	External signal descriptions.....	2601
12.2.3.1	Signal overview.....	2601
12.2.3.2	Detailed external signal descriptions.....	2601
12.2.4	Memory map and register definition.....	2601
12.2.4.1	Register accessibility.....	2602
12.2.4.2	Register figure conventions.....	2602
12.2.4.3	I2C Bus Address Register (I2Cx_IBAD).....	2604
12.2.4.4	I2C Bus Frequency Divider Register (I2Cx_IBFD).....	2605
12.2.4.5	I2C Bus Control Register (I2Cx_IBCR).....	2605
12.2.4.6	I2C Bus Status Register (I2Cx_IBSR).....	2607
12.2.4.7	I2C Bus Data I/O Register (I2Cx_IBDR).....	2608
12.2.4.8	I2C Bus Interrupt Config Register (I2Cx_IBIC).....	2609
12.2.4.9	I2C Bus Debug Register (I2Cx_IBDBG).....	2610
12.2.5	Functional description.....	2611
12.2.5.1	Notes about module operation.....	2611
12.2.5.2	Transactions.....	2611
12.2.5.2.1	Protocol overview.....	2612
12.2.5.2.2	Transaction protocol definitions.....	2612
12.2.5.2.3	I2C calling address requirements.....	2613

Section number	Title	Page
12.2.5.2.4	High-level protocol steps.....	2613
12.2.5.2.5	START condition.....	2613
12.2.5.2.6	Slave address transmission.....	2614
12.2.5.2.7	Data transmission.....	2614
12.2.5.2.8	STOP condition.....	2615
12.2.5.2.9	Repeated START condition.....	2615
12.2.5.3	Arbitration procedure.....	2615
12.2.5.4	Clock behavior.....	2616
12.2.5.4.1	Clock synchronization.....	2616
12.2.5.4.2	Clock stretching.....	2617
12.2.5.4.3	Handshaking.....	2617
12.2.5.4.4	Clock rate and IBFD settings.....	2617
12.2.5.4.4.1	Timing definitions.....	2617
12.2.5.4.4.2	Divider and hold values.....	2618
12.2.5.5	Interrupts.....	2623
12.2.5.5.1	Interrupt vector.....	2623
12.2.5.5.2	Interrupt description.....	2624
12.2.5.6	STOP mode.....	2624
12.2.5.7	DEBUG mode.....	2625
12.2.5.8	DMA interface.....	2627
12.2.6	Initialization/application information.....	2628
12.2.6.1	Recommended interrupt service flow.....	2628
12.2.6.2	General programming guidelines (for both master and slave mode).....	2629
12.2.6.2.1	Initializing the I2C module.....	2630
12.2.6.2.2	Software response after a transfer.....	2630
12.2.6.3	Programming guidelines specific to master mode.....	2631
12.2.6.3.1	Generating START.....	2631
12.2.6.3.2	Transmit/receive sequence.....	2632
12.2.6.3.3	Generating STOP.....	2634

Section number	Title	Page
12.2.6.3.4	Generating repeated START.....	2634
12.2.6.3.5	Loss of arbitration.....	2634
12.2.6.4	Programming guidelines specific to slave mode.....	2635
12.2.6.5	DMA application information.....	2635
12.2.6.5.1	DMA mode, master transmit.....	2636
12.2.6.5.2	DMA mode, master reception.....	2637
12.2.6.5.3	Exiting DMA mode, system requirement considerations.....	2638
12.3	Universal Asynchronous Receiver/Transmitter (UART).....	2642
12.3.1	Introduction.....	2642
12.3.1.1	Features.....	2642
12.3.1.2	Modes of operation.....	2644
12.3.1.2.1	Run mode.....	2644
12.3.1.2.2	Stop mode.....	2644
12.3.2	UART signal descriptions.....	2644
12.3.2.1	Detailed signal descriptions.....	2644
12.3.3	Memory map and registers.....	2645
12.3.3.1	UART Baud Rate Registers: High (UARTx_BDH).....	2653
12.3.3.2	UART Baud Rate Registers: Low (UARTx_BDL).....	2654
12.3.3.3	UART Control Register 1 (UARTx_C1).....	2654
12.3.3.4	UART Control Register 2 (UARTx_C2).....	2656
12.3.3.5	UART Status Register 1 (UARTx_S1).....	2658
12.3.3.6	UART Status Register 2 (UARTx_S2).....	2661
12.3.3.7	UART Control Register 3 (UARTx_C3).....	2662
12.3.3.8	UART Data Register (UARTx_D).....	2664
12.3.3.9	UART Match Address Registers 1 (UARTx_MA1).....	2665
12.3.3.10	UART Match Address Registers 2 (UARTx_MA2).....	2665
12.3.3.11	UART Control Register 4 (UARTx_C4).....	2666
12.3.3.12	UART Extended Data Register (UARTx_ED).....	2666
12.3.3.13	UART Infrared Register (UARTx_IR).....	2667

Section number	Title	Page
12.3.3.14	UART FIFO Parameters (UARTx_PFIFO).....	2668
12.3.3.15	UART FIFO Control Register (UARTx_CFIFO).....	2670
12.3.3.16	UART FIFO Status Register (UARTx_SFIFO).....	2671
12.3.3.17	UART FIFO Transmit Watermark (UARTx_TWFIFO).....	2672
12.3.3.18	UART FIFO Transmit Count (UARTx_TCFIFO).....	2673
12.3.3.19	UART FIFO Receive Watermark (UARTx_RWFIFO).....	2673
12.3.3.20	UART FIFO Receive Count (UARTx_RCFIFO).....	2674
12.3.3.21	UART 7816 Control Register (UARTx_C7816).....	2674
12.3.3.22	UART 7816 Interrupt Enable Register (UARTx_IE7816).....	2676
12.3.3.23	UART 7816 Interrupt Status Register (UARTx_IS7816).....	2677
12.3.3.24	UART 7816 Wait Parameter Register (UARTx_WP7816T1).....	2678
12.3.3.25	UART 7816 Wait N Register (UARTx_WN7816).....	2679
12.3.3.26	UART 7816 Wait FD Register (UARTx_WF7816).....	2679

13.4.3.5	Interrupts.....	2954
13.4.3.6	DMA.....	2954
13.4.4	Application information.....	2955
13.4.4.1	Impact of using the prescaler and multiplication factor on timing resolution.....	2955

## Chapter 14

### DMA

14.1	Enhanced Direct Memory Access (eDMA).....	2957
14.1.1	Introduction.....	2957
14.1.1.1	eDMA system block diagram.....	2957
14.1.1.2	Block parts.....	2958
14.1.1.3	Features.....	2959
14.1.2	Modes of operation.....	2960
14.1.3	Memory map/register definition.....	2961

Section number	Title	Page
14.1.3.1	TCD memory.....	2961
14.1.3.2	TCD initialization.....	2961
14.1.3.3	TCD structure.....	2961
14.1.3.4	Reserved memory and bit fields.....	2962
14.1.3.5	Control Register (DMAx_CR).....	3015
14.1.3.6	Error Status Register (DMAx_ES).....	3018
14.1.3.7	Enable Request Register (DMAx_ERQ).....	3020
14.1.3.8	Enable Error Interrupt Register (DMAx_EEI).....	3024
14.1.3.9	Clear Enable Error Interrupt Register (DMAx_CEEI).....	3027
14.1.3.10	Set Enable Error Interrupt Register (DMAx_SEEI).....	3028
14.1.3.11	Clear Enable Request Register (DMAx_CERQ).....	3029
14.1.3.12	Set Enable Request Register (DMAx_SERQ).....	3030
14.1.3.13	Clear DONE Status Bit Register (DMAx_CDNE).....	3031
14.1.3.14	Set START Bit Register (DMAx_SSRT).....	3032
14.1.3.15	Clear Error Register (DMAx_CERR).....	3033
14.1.3.16	Clear Interrupt Request Register (DMAx_CINT).....	3034
14.1.3.17	Interrupt Request Register (DMAx_INT).....	3034
14.1.3.18	Error Register (DMAx_ERR).....	3038
14.1.3.19	Hardware Request Status Register (DMAx_HRS).....	3042
14.1.3.20	Channel n Priority Register (DMAx_DCHPRIn).....	3048
14.1.3.21	TCD Source Address (DMAx_TCDn_SADDR).....	3049
14.1.3.22	TCD Signed Source Address Offset (DMAx_TCDn_SOFF).....	3050
14.1.3.23	TCD Transfer Attributes (DMAx_TCDn_ATTR).....	3050
14.1.3.24	TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMAx_TCDn_NBYTES_MLNO).....	3051
14.1.3.25	TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMAx_TCDn_NBYTES_MLOFFNO).....	3052
14.1.3.26	TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMAx_TCDn_NBYTES_MLOFFYES).....	3053
14.1.3.27	TCD Last Source Address Adjustment (DMAx_TCDn_SLAST).....	3054

Section number	Title	Page
14.1.3.28	TCD Destination Address (DMAx_TCDn_DADDR).....	3055
14.1.3.29	TCD Signed Destination Address Offset (DMAx_TCDn_DOFF).....	3055
14.1.3.30	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMAx_TCDn_CITER_ELINKYES).....	3056
14.1.3.31	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMAx_TCDn_CITER_ELINKNO).....	3057
14.1.3.32	TCD Last Destination Address Adjustment/Scatter Gather Address (DMAx_TCDn_DLASTSGA).....	3058
14.1.3.33	TCD Control and Status (DMAx_TCDn_CSR).....	3059
14.1.3.34	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMAx_TCDn_BITER_ELINKYES).....	3061
14.1.3.35	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMAx_TCDn_BITER_ELINKNO).....	3062
14.1.4	Functional description.....	3063
14.1.4.1	eDMA basic data flow.....	3063
14.1.4.2	Fault reporting and handling.....	3066
14.1.4.3	Channel preemption.....	3069
14.1.4.4	Performance.....	3069
14.1.4.4.1	Peak transfer rates.....	3069
14.1.4.4.2	Peak request rates.....	3070
14.1.4.4.3	eDMA performance example.....	3072
14.1.5	Initialization/application information.....	3073
14.1.5.1	eDMA initialization.....	3073
14.1.5.2	Programming errors.....	3075
14.1.5.3	Arbitration mode considerations.....	3076
14.1.5.3.1	Fixed group arbitration, Fixed channel arbitration.....	3076
14.1.5.3.2	Fixed group arbitration, Round-robin channel arbitration.....	3077
14.1.5.4	Performing DMA transfers.....	3077
14.1.5.4.1	Single request.....	3077
14.1.5.4.2	Multiple requests.....	3079

Section number	Title	Page
14.1.5.4.3	Using the modulo feature.....	3081

14.2.4.2	DMA channels with no triggering capability.....	3096
14.2.4.3	Always-enabled DMA sources.....	3096
14.2.5	Initialization/application information.....	3098
14.2.5.1	Reset.....	3098
14.2.5.2	Enabling and configuring sources.....	3098

## Chapter 15

### Audio

Section number	Title	Page
15.1	Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI).....	3103
15.1.1	Introduction.....	3103
15.1.1.1	Features.....	3103
15.1.1.2	Block diagram.....	3103
15.1.1.3	Modes of operation.....	3104
15.1.1.3.1	Run mode.....	3104
15.1.1.3.2	Stop modes.....	3104
15.1.1.3.3	Debug mode.....	3104
15.1.2	External signals.....	3105
15.1.3	Memory map and register definition.....	3105
15.1.3.1	SAI Transmit Control Register (I2Sx_TCSR).....	3109
15.1.3.2	SAI Transmit Configuration 1 Register (I2Sx_TCR1).....	3112
15.1.3.3	SAI Transmit Configuration 2 Register (I2Sx_TCR2).....	3113
15.1.3.4	SAI Transmit Configuration 3 Register (I2Sx_TCR3).....	3114
15.1.3.5	SAI Transmit Configuration 4 Register (I2Sx_TCR4).....	3115
15.1.3.6	SAI Transmit Configuration 5 Register (I2Sx_TCR5).....	3116
15.1.3.7	SAI Transmit Data Register (I2Sx_TDRn).....	3117
15.1.3.8	SAI Transmit FIFO Register (I2Sx_TFRn).....	3118
15.1.3.9	SAI Transmit Mask Register (I2Sx_TMR).....	3118
15.1.3.10	SAI Receive Control Register (I2Sx_RCSR).....	3119
15.1.3.11	SAI Receive Configuration 1 Register (I2Sx_RCR1).....	3122
15.1.3.12	SAI Receive Configuration 2 Register (I2Sx_RCR2).....	3123
15.1.3.13	SAI Receive Configuration 3 Register (I2Sx_RCR3).....	3124
15.1.3.14	SAI Receive Configuration 4 Register (I2Sx_RCR4).....	3125
15.1.3.15	SAI Receive Configuration 5 Register (I2Sx_RCR5).....	3127
15.1.3.16	SAI Receive Data Register (I2Sx_RDRn).....	3127
15.1.3.17	SAI Receive FIFO Register (I2Sx_RFRn).....	3128
15.1.3.18	SAI Receive Mask Register (I2Sx_RMR).....	3128
15.1.4	Functional description.....	3129

Section number	Title	Page
15.1.4.1	SAI clocking.....	3129
15.1.4.1.1	Audio master clock.....	3129
15.1.4.1.2	Bit clock.....	3130
15.1.4.1.3	Bus clock.....	3130
15.1.4.2	SAI resets.....	3130
15.1.4.2.1	Software reset.....	3130
15.1.4.2.2	FIFO reset.....	3131
15.1.4.3	Synchronous modes.....	3131
15.1.4.3.1	Synchronous mode.....	3131
15.1.4.4	Frame sync configuration.....	3132
15.1.4.5	Data FIFO.....	3132
15.1.4.5.1	Data alignment.....	3132
15.1.4.5.2	FIFO pointers.....	3133
15.1.4.6	Word mask register.....	3134
15.1.4.7	Interrupts and DMA requests.....	3134
15.1.4.7.1	FIFO request flag.....	3134
15.1.4.7.2	FIFO warning flag.....	3135
15.1.4.7.3	FIFO error flag.....	3135
15.1.4.7.4	Sync error flag.....	3136
15.1.4.7.5	Word start flag.....	3136
15.2	Enhanced Serial Audio Interface (ESAI).....	3136
15.2.1	Overview.....	3136
15.2.1.1	Features.....	3138
15.2.1.2	Modes of Operation.....	3138
15.2.1.2.1	Normal/Network/On-Demand Mode Selection.....	3138
15.2.1.2.2	Synchronous/Asynchronous Operating Modes.....	3139
15.2.1.2.3	Frame Sync Selection.....	3139
15.2.1.2.4	Shift Direction Selection.....	3140
15.2.2	External Signals.....	3140

Section number	Title	Page
15.2.2.1	Serial Transmit 0 Data Pin.....	3141
15.2.2.2	Serial Transmit 1 Data Pin.....	3141
15.2.2.3	Serial Transmit 2/Receive 3 Data Pin.....	3141
15.2.2.4	Serial Transmit 3/Receive 2 Data Pin.....	3142
15.2.2.5	Serial Transmit 4/Receive 1 Data Pin.....	3142
15.2.2.6	Serial Transmit 5/Receive 0 Data Pin.....	3143
15.2.2.7	Receiver Serial Clock.....	3143
15.2.2.8	Transmitter Serial Clock.....	3144
15.2.2.9	Frame Sync for Receiver.....	3146
15.2.2.10	Frame Sync for Transmitter.....	3146
15.2.2.11	High Frequency Clock for Transmitter.....	3146
15.2.2.12	High Frequency Clock for Receiver.....	3147
15.2.2.13	Serial I/O Flags.....	3147
15.2.3	Functional Description.....	3148
15.2.3.1	ESAI After Reset.....	3148
15.2.3.2	ESAI Interrupt Requests.....	3149
15.2.3.3	ESAI DMA Requests from the FIFOs.....	3150
15.2.3.4	ESAI Transmit and Receive Shift Registers.....	3151
15.2.3.4.1	ESAI Transmit Shift Registers.....	3151
15.2.3.4.2	ESAI Receive Shift Registers.....	3154
15.2.4	Initialization Information.....	3154
15.2.4.1	ESAI Initialization.....	3154
15.2.4.2	ESAI Initialization Examples.....	3155
15.2.4.2.1	Initializing the ESAI using Personal Reset.....	3155
15.2.4.2.2	Initializing the ESAI Transmitter Section.....	3156
15.2.4.2.3	Initializing the ESAI Receiver Section.....	3156
15.2.5	ESAI Memory Map/Register Definition.....	3157
15.2.5.1	ESAI Transmit Data Register (ESAI_ETDR).....	3159
15.2.5.2	ESAI Receive Data Register (ESAI_ERDR).....	3159

Section number	Title	Page
15.2.5.3	ESAI Control Register (ESAI_ECR).....	3160
15.2.5.4	ESAI Status Register (ESAI_ESR).....	3161
15.2.5.5	Transmit FIFO Configuration Register (ESAI_TFCR).....	3163
15.2.5.6	Transmit FIFO Status Register (ESAI_TFSR).....	3165
15.2.5.7	Receive FIFO Configuration Register (ESAI_RFCR).....	3166
15.2.5.8	Receive FIFO Status Register (ESAI_RFSR).....	3168
15.2.5.9	Transmit Data Register n (ESAI_TXn).....	3169
15.2.5.10	ESAI Transmit Slot Register (ESAI_TSR).....	3169
15.2.5.11	Receive Data Register n (ESAI_RXn).....	3170
15.2.5.12	Serial Audio Interface Status Register (ESAI_SAISR).....	3171
15.2.5.13	Serial Audio Interface Control Register (ESAI_SAICR).....	3173
15.2.5.14	Transmit Control Register (ESAI_TCR).....	3176
15.2.5.15	Transmit Clock Control Register (ESAI_TCCR).....	3183
15.2.5.16	Receive Control Register (ESAI_RCR).....	3187
15.2.5.17	Receive Clock Control Register (ESAI_RCCR).....	3191
15.2.5.18	Transmit Slot Mask Register A (ESAI_TSMA).....	3194
15.2.5.19	Transmit Slot Mask Register B (ESAI_TSMB).....	3195
15.2.5.20	Receive Slot Mask Register A (ESAI_RSMA).....	3196
15.2.5.21	Receive Slot Mask Register B (ESAI_RSMB).....	3197
15.2.5.22	Port C Direction Register (ESAI_PPRC).....	3198
15.2.5.23	Port C Control Register (ESAI_PCRC).....	3198
15.3	Asynchronous Sample Rate Converter (ASRC).....	3199
15.3.1	Introduction .....	3199
15.3.1.1	Overview.....	3201
15.3.1.2	Features.....	3202
15.3.1.3	Modes of Operation.....	3202
15.3.1.3.1	Data Transfer Schemes.....	3202
15.3.1.3.1.1	Data Input Modes.....	3202
15.3.1.3.1.2	Data Output Modes.....	3204

Section number	Title	Page
15.3.1.3.2	Word Alignment Supported.....	3205
15.3.1.3.2.1	Input Data Alignment Modes.....	3205
15.3.1.3.2.2	Output Data Alignment Modes.....	3205
15.3.2	Interrupts.....	3206
15.3.3	DMA requests.....	3206
15.3.4	Programmable Registers.....	3207
15.3.4.1	ASRC Control Register (ASRC_ASRCCTR).....	3210
15.3.4.2	ASRC Interrupt Enable Register (ASRC_ASRIER).....	3212
15.3.4.3	ASRC Channel Number Configuration Register (ASRC_ASRCNCR).....	3214
15.3.4.4	ASRC Filter Configuration Status Register (ASRC_ASRCFG).....	3216
15.3.4.5	ASRC Clock Source Register (ASRC_ASRCSTR).....	3218
15.3.4.6	ASRC Clock Divider Register 1 (ASRC_ASRCDR1).....	3222
15.3.4.7	ASRC Clock Divider Register 2 (ASRC_ASRCDR2).....	3223
15.3.4.8	ASRC Status Register (ASRC_ASRSTR).....	3224
15.3.4.9	ASRC Parameter Register (ASRC_ASRPM <sub>n</sub> ).....	3227
15.3.4.10	ASRC ASRC Task Queue FIFO Register 1 (ASRC_ASRTFR1).....	3228
15.3.4.11	ASRC Channel Counter Register (ASRC_ASRCR).....	3229
15.3.4.12	ASRC Data Input Register for Pair <i>x</i> (ASRC_ASRDI <sub>n</sub> ).....	3230
15.3.4.13	ASRC Data Output Register for Pair <i>x</i> (ASRC_ASRDO <sub>n</sub> ).....	3230
15.3.4.14	ASRC Ideal Ratio for Pair A-High Part (ASRC_ASRIDRHA).....	3231
15.3.4.15	ASRC Ideal Ratio for Pair A -Low Part (ASRC_ASRIDRLA).....	3231
15.3.4.16	ASRC Ideal Ratio for Pair B-High Part (ASRC_ASRIDRHB).....	3232
15.3.4.17	ASRC Ideal Ratio for Pair B-Low Part (ASRC_ASRIDRLB).....	3232
15.3.4.18	ASRC Ideal Ratio for Pair C-High Part (ASRC_ASRIDRHC).....	3233
15.3.4.19	ASRC Ideal Ratio for Pair C-Low Part (ASRC_ASRIDRLC).....	3233
15.3.4.20	ASRC 76kHz Period in terms of ASRC processing clock (ASRC_ASR76K).....	3234
15.3.4.21	ASRC 56kHz Period in terms of ASRC processing clock (ASRC_ASR56K).....	3234
15.3.4.22	ASRC Misc Control Register for Pair A (ASRC_ASRCMCR).....	3235
15.3.4.23	ASRC FIFO Status Register for Pair A (ASRC_ASRFSTA).....	3237

Section number	Title	Page
15.3.4.24	ASRC Misc Control Register for Pair B (ASRC_ASRMCRB).....	3238
15.3.4.25	ASRC FIFO Status Register for Pair B (ASRC_ASRFSTB).....	3240
15.3.4.26	ASRC Misc Control Register for Pair C (ASRC_ASRMCRC).....	3241
15.3.4.27	ASRC FIFO Status Register for Pair C (ASRC_ASRFSTC).....	3243
15.3.4.28	ASRC Misc Control Register 1 for Pair <i>x</i> (ASRC_ASRMCR1 <i>n</i> ).....	3244
15.3.5	Functional Description.....	3245
15.3.5.1	Algorithm Description.....	3245
15.3.5.1.1	Signal Processing Flow.....	3245
15.3.5.1.2	Operation of the Filter.....	3248
15.3.5.1.2.1	Support of Physical Clocks.....	3249
15.3.6	Startup Procedure.....	3251
15.4	Sony/Philips Digital Interface (SPDIF).....	3255
15.4.1	Introduction .....	3255
15.4.1.1	Overview.....	3257
15.4.2	External Signal Description.....	3257
15.4.3	Functional Description.....	3257
15.4.3.1	SPDIF Receiver.....	3257
15.4.3.1.1	Audio Data Reception.....	3258
15.4.3.1.1.1	SPDIF receiver data registers - Behavior on overrun, underrun	3258
15.4.3.1.1.2	SPDIF receiver data registers - Automatic resynchronization of FIFOs.....	3259
15.4.3.1.1.3	Application Note.....	3259
15.4.3.1.2	Channel Status Reception.....	3261
15.4.3.1.2.1	Channel Status Interrupt.....	3261
15.4.3.1.3	User Bit Reception.....	3261
15.4.3.1.3.1	Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver.....	3261
15.4.3.1.3.2	Behavior of U Channel receive interface on incoming non-CD data.....	3263
15.4.3.1.4	Validity Flag Reception.....	3263

Section number	Title	Page
15.4.3.1.5	SPDIF Receiver Interrupt Exception Definition.....	3264
15.4.3.1.6	Standards Compliance.....	3264
15.4.3.1.7	SPDIF PLOCK Detection and Rxclk Output.....	3265
15.4.3.1.8	Measuring Frequency of SPDIF_RxClk.....	3265
15.4.3.2	SPDIF Transmitter.....	3266
15.4.3.2.1	Audio Data Transmission.....	3266
15.4.3.2.2	Channel Status Transmission.....	3267
15.4.3.2.3	Validity Flag Transmission.....	3267
15.4.4	Programmable Registers.....	3267
15.4.4.1	SPDIF Configuration Register (SPDIF_SCR).....	3269
15.4.4.2	CDText Control Register (SPDIF_SRCD).....	3271
15.4.4.3	PhaseConfig Register (SPDIF_SRPC).....	3272
15.4.4.4	InterruptEn Register (SPDIF_SIE).....	3274
15.4.4.5	InterruptStat Register (SPDIF_SIS).....	3277
15.4.4.6	InterruptClear Register (SPDIF_SIC).....	3280
15.4.4.7	SPDIFRxLeft Register (SPDIF_SRL).....	3282
15.4.4.8	SPDIFRxRight Register (SPDIF_SRR).....	3282
15.4.4.9	SPDIFRxCChannel_h Register (SPDIF_SRC SH).....	3283
15.4.4.10	SPDIFRxCChannel_l Register (SPDIF_SRC SL).....	3283
15.4.4.11	UchannelRx Register (SPDIF_SRU).....	3284
15.4.4.12	QchannelRx Register (SPDIF_SRQ).....	3284
15.4.4.13	SPDIFTxLeft Register (SPDIF_STL).....	3285
15.4.4.14	SPDIFTxRight Register (SPDIF_STR).....	3285
15.4.4.15	SPDIFTxCChannelCons_h Register (SPDIF_STC SCH).....	3286
15.4.4.16	SPDIFTxCChannelCons_l Register (SPDIF_STC SCL).....	3286
15.4.4.17	FreqMeas Register (SPDIF_SRFM).....	3287
15.4.4.18	SPDIFTxCk Register (SPDIF_STC).....	3287

## Chapter 16 Display

Section number	Title	Page
16.1	Display Control Unit (DCU).....	3289
16.1.1	Introduction.....	3289
16.1.1.1	Overview.....	3289
16.1.1.2	Features.....	3291
16.1.1.3	Modes of Operation.....	3292
16.1.2	External Signal Description.....	3293
16.1.2.1	Overview.....	3293
16.1.2.2	Detailed Signal Descriptions.....	3293
16.1.3	DCU4 Memory Map.....	3294
16.1.4	Memory Map and Registers.....	3294
16.1.4.1	Control Descriptor Cursor 1 Register (DCUx_CTRLDESCCOURSE1).....	3352
16.1.4.2	Control Descriptor Cursor 2 Register (DCUx_CTRLDESCCOURSE2).....	3352
16.1.4.3	Control Descriptor Cursor 3 Register (DCUx_CTRLDESCCOURSE3).....	3353
16.1.4.4	Control Descriptor Cursor 4 Register (DCUx_CTRLDESCCOURSE4).....	3354
16.1.4.5	DCU4 Mode Register (DCUx_DCU_MODE).....	3355
16.1.4.6	Background Register (DCUx_BGND).....	3357
16.1.4.7	Display Size Register (DCUx_DISP_SIZE).....	3358
16.1.4.8	Horizontal Sync Parameter Register (DCUx_HSYN_PARA).....	3358
16.1.4.9	Vertical Sync Parameter Register (DCUx_VSYN_PARA).....	3359

# Chapter 1

## About This Document

### 1.1 Overview

#### 1.1.1 Purpose

This document describes the features, architecture, and programming model of the NXP VFxxx Controller microprocessor (MPU).

This document is common for the VFxxx Controller F-Series and R-Series. Note however that some functions are only available on the F-series parts and others only on R-series parts. For a detailed feature list, refer to the data sheet for the specific family.

#### 1.1.2 Audience

This document is primarily intended for system architects and software application developers who are using, or considering using, a VFxxx Controller device in a system.

#### 1.1.3 Reference Manual Overview

This manual is intended to be a reference guide for both the VFxxx Controller F-Series and R-Series. As such, not all modules and features are available on both devices. For example, the MediaLB (MLB) and Graphics Processing Unit (GPU) modules are specific to the R-Series parts, and the Ethernet Switch (ESW) feature is only implemented on F-Series.

A comprehensive fuse map and a block diagram that encompasses all modules available on both F-Series and R-Series have been included in this manual. For the specific implementation of modules and features on your device, consult the F-Series and/or R-Series data sheets.

## 1.1.4 Related Resources

Type	Description	Resource
Data Sheet	The Data Sheet includes electrical characteristics and signal connections.	VYBRIDFSERIESEC for MVF* parts <sup>1</sup> VYBRIDRSERIESEC for SVF* parts <sup>1</sup>
Reference Manual	The Reference Manual contains a comprehensive description of the structure and function (operation) of the device.	This document
Chip Errata	The chip mask set Errata provides additional or corrective information for a particular device mask set.	VFxxx Controller Chip Errata <sup>1</sup>
Application Notes	Application Notes are engineering support documents that assist the user in evaluating the operation of a device product line, package type, or general application topic.	<ul style="list-style-type: none"> <li>• AN4651 <sup>1</sup> - TFT Panel Support in the Vybrid Microcontroller Family</li> <li>• AN4672 <sup>1</sup> - Using the Run-Length Decoding Features on Vybrid Devices</li> <li>• AN4647 <sup>1</sup> - Configuring and Using the 2D-ACE on Vybrid Microcontrollers</li> <li>• AN4635 <sup>1</sup> - Using the Vybrid TCON Module</li> <li>• AN4512 <sup>1</sup> - Quad Serial Peripheral Interface (QuadSPI) Module Updates</li> <li>• AN4947 <sup>1</sup> - Understanding Vybrid Architecture</li> <li>• AN4807 <sup>1</sup> - Vybrid Power Consumption and Options</li> </ul>

## 1.2 Conventions

### 1.2.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix 0b.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.

*Table continues on the next page...*

This suffix	Identifies a
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix 0x.

## 1.2.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
<i>placeholder, x</i>	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
code	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: <ul style="list-style-type: none"> <li>A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register.</li> <li>A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.</li> </ul>

## 1.2.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: <ul style="list-style-type: none"> <li>An active-high signal is asserted when high (1).</li> <li>An active-low signal is asserted when low (0).</li> </ul>
deasserted	Refers to the state of a signal as follows: <ul style="list-style-type: none"> <li>An active-high signal is deasserted when low (0).</li> <li>An active-low signal is deasserted when high (1).</li> </ul> <p>In some cases, deasserted signals are described as <i>negated</i>.</p>
reserved	Refers to a memory space, register, or field that is either reserved for future use or for which, when written to, the module or chip behavior is unpredictable.

*Table continues on the next page...*

## Conventions

Term	Meaning
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

# Chapter 2

## Introduction

### 2.1 VFxxx Controller Platform

This family of devices is NXP's latest Dual and Single Core offerings with ARM® Cortex®-A5 and ARM® Cortex®-M4 based processors for high end industrial and general purpose applications.

#### NOTE

Throughout this manual, ARM® Cortex®-A5 is referred to as Cortex-A5 or CA5. Also, ARM® Cortex®-M4 is referred to as Cortex-M4 or CM4.

These devices are highly integrated reducing system cost for target applications. The following features can be found on VFxxx Controller Processors. For part-specific features, refer to the data sheets.

- Cortex-A5 with TrustZone with 32 KB I-Cache/32 KB D-Cache
- Neon Media Processing Engine (MPE) co-processor and double precision Floating Point Unit (FPU)
- Cortex-M4 with 16 KB I-Cache/16 KB D-Cache
- 1.5 MB on-chip SRAM of which 512 KB optionally supports ECC
- Support for LPDDR2/DDR3
- Dual TFT display up to SVGA and optional 40x4 and 38x6 Segmented LCD
- Dual 10/100 Ethernet (R-Series)
- Dual 10/100 Ethernet with on-chip L2 Switch (F-Series only)
- Dual USB OTG with on-chip HS PHY and on-chip HS/FS/LS PHY
- OpenVG 1.1 GPU (R-Series only)
- Advanced Security supporting Symmetric with on-chip Tamper detection
- Rich set of communication peripherals and general purpose features
- Advanced digital audio support with multiple audio interfaces and hardware asynchronous sample-rate converter co-processor.
- Package options for 176 LQFP and 364 BGA

This family of devices is manufactured utilizing 40nm low-power process.

## 2.2 Feature Set

The following features can be found on the VFxxx Controller Processors. For part-specific features, refer to the data sheets.

**Table 2-1. Feature Set**

Operating Characteristics	<ul style="list-style-type: none"> <li>• Voltage range 3.0 V - 3.6 V</li> <li>• Temperature range (T<sub>J</sub>) -40 to 105 °C</li> <li>• Flexible modes of operation</li> </ul>
ARM Cortex-A5 Core	<ul style="list-style-type: none"> <li>• Up to 500 MHz (F-Series) or 400 MHz (R-Series) ARM Cortex-A5</li> <li>• 32 KB/32 KB I-/D- L1 Cache</li> <li>• 1.57 DMIPS/MHz based on ARMv7 architecture</li> <li>• NEON MPE co-processor</li> <li>• Dual precision FPU</li> <li>• Optional 512K L2 Cache</li> </ul>
ARM Cortex-M4 Core	<ul style="list-style-type: none"> <li>• Up to 167 MHz ARM Cortex M4</li> <li>• Build-in DSP capability</li> <li>• 16KB/16KB I-/D- L1 Cache</li> <li>• 1.25 DMIPS/MHz based on ARMv7 architecture</li> </ul>
Clocks	<ul style="list-style-type: none"> <li>• 6 Phase Locked Loops (PLLs)</li> <li>• 2 external crystal oscillators (XOSC)</li> <li>• 2 internal RC (IRC) oscillators</li> </ul>
System, protection and power management features	<ul style="list-style-type: none"> <li>• Flexible stop, wait, and run modes to provide lower power based on application needs.</li> <li>• Peripheral clock enable register can disable clocks to unused modules, thereby reducing currents</li> <li>• Low voltage warning and detect</li> <li>• Hardware CRC module to support fast cyclic redundancy checks (CRC)</li> <li>• 64-bit unique chip identifier</li> <li>• Hardware watchdog</li> <li>• External Watchdog Monitor (EWM)</li> <li>• Dual DMA controller with 32 channels (with DMAMUX)</li> </ul>
Debug	<ul style="list-style-type: none"> <li>• Standard JTAG</li> <li>• 16 bit Trace port</li> </ul>
Timers	<ul style="list-style-type: none"> <li>• General purpose timer (FTM)</li> <li>• Low Power Timer (LPTMR)</li> <li>• One Periodic Interrupt Timer (PIT) with 8 channels</li> <li>• IEEE® 1588 Timers (part of Ethernet Subsystem)</li> </ul>
Communications	<ul style="list-style-type: none"> <li>• UART(IrDA, and hardware flow control)</li> <li>• Serial peripheral interface (SPI)</li> <li>• I<sup>2</sup>C with SMBUS support</li> <li>• Dual USB 2.0 HS OTG Controller (Supports LS/FS/HS) with integrated PHYs</li> <li>• 4/8 bit Secure Digital Host controller</li> <li>• Local Media Bus (MLB50) (R-Series only)</li> <li>• Dual 10/100 Ethernet (R-Series)</li> </ul>

*Table continues on the next page...*

**Table 2-1. Feature Set (continued)**

	<ul style="list-style-type: none"> <li>• Dual 10/100 Ethernet with L2 Switch (F-Series only)</li> <li>• FlexCAN3</li> </ul>
Memory Interfaces	<ul style="list-style-type: none"> <li>• 8/16 bit DRAM Controller with support for LPDDR2/DDR3 - Up to 800MT/s (400 MHz)</li> <li>• 8/16-bit NAND Flash controller with ECC</li> <li>• 8/16/32 bit External bus (Flexbus)</li> <li>• Dual QuadSPI supporting Execute-In-Place (XIP), which means two ports can be used simultaneously. XIP mode on QuadSPI interface works in all modes: Single (1-bit data), Dual (2-bit data), or Quad (4-bit data)</li> </ul>
Graphics Display and Video	<ul style="list-style-type: none"> <li>• Dual Display Control Unit (DCU) with support for color TFT displays up to SVGA</li> <li>• Segment LCD (3V Glass only) configurable as 40x4, 38x6, and 36x8</li> <li>• Video Interface Unit (VIU) for camera input</li> <li>• OpenVG Graphics Processing Unit (GPU) (R-Series only)</li> <li>• Run Length Encoded (RLE) Decoder</li> <li>• Composite Video Decoder supporting PAL and NTSC</li> </ul>
Analog	<ul style="list-style-type: none"> <li>• 12-bit SAR ADC</li> <li>• 12-bit DAC</li> </ul>
Audio	<ul style="list-style-type: none"> <li>• Synchronous Audio Interfaces (SAI) supporting I2S, AC97 and Codec/DSP interfaces</li> <li>• Enhanced Serial Audio Interface (ESAI)</li> <li>• Sony/Philips Digital Interface (SPDIF), Rx and Tx</li> <li>• Asynchronous Sample Rate Converter (ASRC)</li> </ul>
Human-Machine Interface (HMI)	<ul style="list-style-type: none"> <li>• GPIO pins with interrupt support, DMA request capability, digital glitch filter.</li> <li>• Hysteresis and configurable pull up/down device on all input pins</li> <li>• Configurable slew rate and drive strength on all output pins</li> </ul>
On-Chip RAM/ROM	<ul style="list-style-type: none"> <li>• 512 KB On-Chip SRAM with ECC</li> <li>• 1 MB On-Chip Graphics SRAM without ECC</li> <li>• 96KB On-Chip ROM</li> </ul>
Power Consumption	<ul style="list-style-type: none"> <li>• Low power modes (LP/ULPRUN, STOP, LPSTOP1, LPSTOP2 and LPSTOP3)</li> </ul>

Throughout this manual, ARM® Cortex®-A5 is referred to as Cortex-A5 or CA5. ARM® Cortex®-M4 is referred to as Cortex-M4 or CM4.

## 2.4 VFxxx Controller Device Configuration

The following table lists the superset configuration for each package within the device.

**Table 2-2. VFxxx Controller Device Configuration**

Device	VF3XX	VF3XXR	VF5XX	VF5XXR	VF6XX
<b>General</b>					
Cortex®-A5 Core Frequency	266 MHz	266 MHz	Up to 500 MHz	Up to 400 MHz	Up to 500 MHz
Cortex®-M4 Core Frequency	N/A	167 MHz	N/A	167 MHz	Up to 167 MHz
Package	176 LQFP	176 LQFP	364 BGA	364 BGA	364 BGA
Package Dimensions (mm <sup>2</sup> )	24 x 24 Pitch (0.5 mm)	24 x 24 Pitch (0.5 mm)	17 x 17 (Pitch 0.8mm)	17 x 17 (Pitch 0.8mm)	17 x 17 (Pitch 0.8mm)
<b>Core, Platform and Debug</b>					
DMA (with DMA Mux)	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes
Trace Port	8 bit Output Trace	8 bit Output Trace	16 bit Output Trace	16 bit Output Trace	16 bit Output Trace
<b>Security Subsystem</b>					
Random number generator accelerator (RNG)	1, (NIST SP 800-90)	N/A	1, (NIST SP 800-90)	N/A	1, (NIST SP 800-90)
External Tamper inputs	2	N/A	6	N/A	6
<b>On-Chip Memories</b>					
On-chip RAM	1.5 MB	1.5 MB	1.5 MB SRAM or 1 MB SRAM + 512 KB L2 Cache	1.5 MB SRAM or 1 MB SRAM + 512 KB L2 Cache	1.5 MB SRAM or 1 MB SRAM + 512 KB L2 Cache
ECC on On-chip RAM (512K)	1	1	1	1	1
On-Chip ROM	96 KB	96 KB	96 KB	96 KB	96 KB
<b>Memory Interfaces</b>					
DRAM Controller (LPDDR2/DDR3)	No	No	16 bit 8 bit	16 bit 8 bit	16 bit 8 bit
NAND Flash Controller	1 (8 bit)	1 (8 bit)	1 (16 bit)	1 (16 bit)	1 (16 bit)
Quad SPI	2	1	2	1	2
<b>Timers/PWM</b>					
FlexTimer (FTM0) channel pins	8 Ch	8 Ch	8 Ch	8 Ch	8 Ch
FlexTimer (FTM1) channel pins	2 Ch	2 Ch	2 Ch	2 Ch	2 Ch

Table continues on the next page...

**Table 2-2. VFxxx Controller Device Configuration (continued)**

Device	VF3XX	VF3XXR	VF5XX	VF5XXR	VF6XX
FlexTimer (FTM2) channel pins	2 Ch	2 Ch	2 Ch	2 Ch	2 Ch
FlexTimer (FTM3) channel pins	None	None	8 Ch	8 Ch	8 Ch
IEEE® 1588 Timers	4 Ch	4 Ch	8 Ch	8 Ch	8 Ch
Periodic Interrupt Timers(PITs)	4 Ch	4 Ch	8 Ch	8 Ch	8 Ch
Low power timer (LPTMR)	1	1	1	1	1
<b>Communication Interfaces</b>					
10/100 ENET with IEEE®1588	2	1	2	2	2
eSDHC	1 (8 bit)	1 (8 bit)	2 (8 bit and 4 bit)	2 (8 bit and 4 bit)	2 (8 bit and 4 bit)

## 2.5 Modules on the device

### 2.5.1 Clocks

The following clock modules are available on this device.

**Table 2-3. Clock modules**

Module	Description	Reference links to the related information <sup>1</sup>
Clock Controller Module (CCM)	<p>The Clock Controller Module controls the following functions:</p> <ul style="list-style-type: none"> <li>• Uses the available clock sources to generate clock roots to various parts of the device</li> <li>• Uses programmable bits to control frequencies of the clock roots</li> <li>• Controls the low power mechanism</li> <li>• Provides control signals to Low Power Clock Gating module (LPCG) for gating clocks</li> <li>• Provides handshake with System Reset Controller (SRC) for reset performance</li> <li>• Provides handshake with Global Power Controller (GPC) for low power mode operations</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Clocking Overview</a> to read about the overall clock distribution on this device. It provides an overview about the different clock sources their typical configuration, and module clocks on this device.</li> <li>• <a href="#">Clock Controller Module (CCM)</a> to read about module features, programming model, Low Power Clock gating, and auxiliary clocks on this device.</li> </ul>
Analog components control interface (ANADIG)	ANADIG is collection of digital interfaces and controllers of analog components, which include control registers for controlling analog components like device PLLs, PFDs, and regulators.	<ul style="list-style-type: none"> <li>• <a href="#">Clocking Overview</a>.</li> <li>• <a href="#">ANADIG</a> to read about the registers that control the PLLs, PFDs, and regulators on this device.</li> </ul>
Slow Clock Source Controller (SCSC)	Controls the module configures the Slow internal RC oscillator 128 KHz (SIRC) and Slow external crystal oscillator 32 KHz (SXOSC) on the device.	<ul style="list-style-type: none"> <li>• <a href="#">Clocking Overview</a>.</li> <li>• <a href="#">Introduction Slow Clock Source Controller (SCSC)</a></li> </ul>
Clock Monitor Unit (CMU)	Measures the frequency of clock sources	<ul style="list-style-type: none"> <li>• <a href="#">Clocking Overview</a>.</li> <li>• <a href="#">Clock Monitor Unit (CMU)</a> to read about module features, programming model, and signals.</li> <li>• <a href="#">CMU Chip Signals</a> section to view the mapping between CMU module signals and the chip-level signals.</li> </ul>

1. It is recommended to read the information in the order below.

## 2.5.2 Platform Modules

The following table lists all platform modules available on this device.

### NOTE

Shaded modules are ARM modules. For the detailed description about them, refer to the ARM website.

**Table 2-4. Platform modules**

Module	Description	Reference
ARM Cortex-A5	<p>The Cortex-A5 processor is a high-performance, low-power ARM macrocell with an L1 cache subsystem that provides full virtual memory capabilities. It supports:</p> <ul style="list-style-type: none"> <li>ARMv7-A instruction set architecture including <ul style="list-style-type: none"> <li>Includes Vector Floating-Point v4 (VFPv4) architecture</li> <li>NEON Media Processing Engine (MPE)</li> <li>TrustZone security</li> </ul> </li> <li>8-stage single issue pipeline implementation <ul style="list-style-type: none"> <li>1.57 DMIPS per MHz integer performance</li> <li>4-stage load/store pipeline</li> <li>5-stage FPU/MPE pipeline</li> </ul> </li> <li>64-bit AXI System Bus Interface supporting multiple outstanding transactions</li> <li>Processor-local Memories <ul style="list-style-type: none"> <li>2 way set-associative 32 KB Instruction Cache with 32 byte line size</li> <li>4 way set-associative 32 KB Data Cache with 32 byte line size</li> <li>Standard Cortex-A5 Memory Management Unit 64-bit AXI System Bus Interface supporting multiple outstanding transactions</li> </ul> </li> </ul>	For ARM Cortex-A5 processor documentation, refer to Cortex-A5 MPCore r0p1 Technical Reference Manual, DDI0434B at <a href="http://www.arm.com">http://www.arm.com</a>
CoreLink™ Level 2 Cache Controller	The addition of an on-chip secondary cache, also referred to as a Level 2 or L2 cache, is a recognized method of improving the performance of ARM-based systems when significant memory traffic is generated by the processor. By definition a secondary cache assumes the presence of a Level 1 or primary cache, closely coupled or internal to the processor.	For ARM Cache Controller documentation, refer to DDI0246F_I2c310_r3p2_trm at <a href="http://www.arm.com">http://www.arm.com</a>
ARM Cortex-M4 Core	The Cortex-M4 processor core brings next generation capabilities to its predecessor, the Cortex-M3. Its new capabilities provide backward compatibility with the Cortex-M3, while adding important features.	For ARM Cortex-M4 processor documentation, refer to Cortex-M4 User Guide Reference Material, DUI0553A at <a href="http://www.arm.com">http://www.arm.com</a>

**Table 2-4. Platform modules (continued)**

Module	Description	Reference
	<ul style="list-style-type: none"> <li>Each transfer is initiated by a peripheral, CPU, periodic timer interrupt or eDMA channel request</li> <li>Each DMA channel can optionally send an interrupt request to the CPU on completion of a single value or block transfer</li> <li>DMA transfers possible between memories, General Purpose I/Os (GPIOs) and Slave Peripherals that support DMA</li> <li>Programmable DMA Channel Mux allows assignment of any DMA source to any available DMA channel with up to a total of 64 potential request sources</li> </ul>	
Peripheral Bridge (AIPS-Lite)	<ul style="list-style-type: none"> <li>Supports up to 160 peripherals and two global external peripheral spaces</li> <li>Supports 8-, 16-, and 32-bit width peripheral slots</li> <li>Supports a pair of 32-bit transactions for selected 64-bit memory accesses</li> <li>Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate.</li> </ul>	Refer to the AIPS-lite chapter of this manual.
Semaphores (SEMA4)	<p>The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:</p> <ul style="list-style-type: none"> <li>Support for 16 hardware-enforced gates in a dual-processor configuration <ul style="list-style-type: none"> <li>Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array</li> <li>Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked</li> <li>Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability</li> </ul> </li> <li>Memory-mapped IPS slave peripheral platform module <ul style="list-style-type: none"> <li>Interface to the IPS bus for programming-model accesses</li> <li>Two outputs (one per processor) for interrupt notification of failed lock writes</li> </ul> </li> </ul>	Refer to the IPS_Semaphore chapter of this manual.

## 2.5.3 System Modules

The following system modules are available on this device.

**Table 2-5. System modules**

Module	Description	Reference links to the chip related information
<a href="#">Power management controller (PMC)</a>	The PMC provides the user with multiple power options. Ten different modes are supported that allow the user to optimize power consumption for the level of functionality needed. Includes power-on-reset (POR) and integrated low voltage detect (LVD) with reset (brownout) capability.	
<a href="#">Peripheral bridges</a>	The peripheral bridge converts the crossbar switch interface to an interface to access a majority of peripherals on the device.	
<a href="#">DMA multiplexer (DMAMUX)</a>	The DMA multiplexer selects from many DMA requests down to 16 for the DMA controller. There are 2 DMA multiplexers associated with each 32-channel DMA.	<a href="#">DMAMUX Request Sources</a>
<a href="#">Direct memory access (DMA) controller</a>	The DMA controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.	
<a href="#">External watchdog monitor (EWM)</a>	The EWM is a redundant mechanism to the software watchdog module that monitors both internal and external system operation for fail conditions.	
<a href="#">Software watchdog (WDOG)</a>	The WDOG monitors internal system operation and forces a reset in case of failure. It operates on SXOSC 32 KHz clock with a programmable refresh window to detect deviations in program flow or system frequency.	

## 2.5.4 Memories and Memory Interfaces

The following memories and memory interfaces are available on this device.

**Table 2-6. Memories and memory interfaces**

Module	Description	Reference links to chip related information
<a href="#">On-chip memory</a>	<ul style="list-style-type: none"> <li>The device Includes: <ul style="list-style-type: none"> <li>512 KB On-Chip SRAM with error correcting code (ECC)</li> <li>1 MB On-Chip Graphics SRAM without ECC</li> <li>96 KB On-Chip ROM</li> </ul> </li> </ul>	
<a href="#">Programmable Cyclic Redundancy Check (CRC32)</a>	The module generates 16/32-bit CRC code for error detection. The CRC module provides a programmable polynomial, SEED, and other parameters required to implement a 16-bit or 32-bit CRC standard. The 16/32-bit code is calculated for 8/16/32-bit data at a time. The data

	width and transpose features are selectable by a parameter.	
<a href="#">DRAM Memory Controller (DDRMC)</a>	<p>DDRMC is a complete embedded memory controller that interfaces to a PHY.</p> <p>The features of this Memory Controller include:</p> <ul style="list-style-type: none"> <li>• Supports interfacing to LPDDR2 and DDR3 memory types. It supports 8-bit and 16-bit memory interface.</li> <li>• Fully pipelined command, read and write data interfaces to the memory controller.</li> <li>• Advanced bank look-ahead features for high memory throughput.</li> <li>• Front-end interface to 2 standard AXI ports. A programmable register interface to control memory parameters and protocols including auto pre-charge.</li> <li>• Full initialization of memory on memory controller reset.</li> <li>• ECC functionality with single bit and double bit error reporting and automatic correction of single bit error events. 10-bit memory interface is required for ECC (8-bit user data + 2-bit ECC).</li> <li>• ECC functionality with single bit and double bit error reporting and automatic correction of single bit error events.</li> <li>• Clock frequencies from 100 MHz to 400 MHz supported.</li> <li>• Back-end interface to a PHY.</li> <li>• Integrates support for DDR pad calibration logic - both software and hardware auto modes</li> </ul>	<a href="#">DDR maximum address space</a>
<a href="#">FlexBus</a>	External bus interface with multiple independent, user-programmable chip-select signals that can interface with external SRAM, PROM, EPROM, EEPROM, flash, and other peripherals via 8-, 16- and 32-bit port sizes. Configurations include multiplexed or non-multiplexed address and data buses using 8-bit, 16-bit, 32-bit, and 16-byte line-sized transfers. Maximum frequency that FlexBus supports is 57 MHz	<ul style="list-style-type: none"> <li>• <a href="#">FlexBus signal multiplexing</a></li> <li>• <a href="#">FlexBus external signal</a></li> <li>• <a href="#">FlexBus security</a></li> <li>• <a href="#">Instantiation Information</a></li> <li>• <a href="#">FlexBus Chip Select Control Register (CSCR0) Reset Value</a></li> <li>• <a href="#">Bus Timeout</a></li> </ul>
<a href="#">NAND flash controller</a>	<p>8-bit and 16-bit NAND flash interface with 32-bit ECC error correction.</p> <ul style="list-style-type: none"> <li>• Supports all NAND Flash products regardless of density/organization (with page size of 512 K+16B/2 K+64B/4 K +128B/4 K+218B/8 K)</li> <li>• Two Configurable DMA channels</li> <li>• Maximum serial clock frequency 80 MHz</li> </ul>	<a href="#">Instantiation</a>
<a href="#">QuadSPI</a>	Interface for up to two external quad serial flash memories for code / data storage and code execution	<ul style="list-style-type: none"> <li>• <a href="#">QuadSPI Instances</a></li> <li>• <a href="#">QuadSPI Memory Interface</a></li> <li>• <a href="#">QuadSPI Buffer</a></li> <li>• <a href="#">Bootting from QuadSPI</a></li> </ul>

**Table 2-6. Memories and memory interfaces**

Module	Description	Reference links to chip related information
	<ul style="list-style-type: none"> <li>Supports industry standard single, dual and quad mode serial flashes</li> <li>Supports Double Data Rate (DDR) serial flash for high performance</li> <li>Maximum serial clock frequency 80 MHz</li> <li>Dual controller architecture enables simultaneous access to two external flashes resulting peak read bandwidth of 160 Mbytes/s</li> <li>Flexible buffering scheme, multi-master, prioritized access</li> </ul>	

## 2.5.5 Audio modules

The following audio modules are available on this device:

**Table 2-7. Audio modules**

Module	Description	Reference links to chip related information
<a href="#">Enhanced Serial Audio Interface (ESAI)</a>	Provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, Sony/Philips Digital Interface (SPDIF) transceivers, and other DSPs. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator.	<ul style="list-style-type: none"> <li><a href="#">Enhanced Serial Audio Interface (ESAI)</a></li> <li><a href="#">ESAI Bus Interface and FIFO (ESAI_BIFIFO)</a></li> </ul>
<a href="#">Sony/Philips Digital Interface (SPDIF)</a>	<p>The SPDIF is composed of two parts:</p> <ul style="list-style-type: none"> <li>SPDIF Receiver: The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.</li> <li>SPDIF Transmitter. For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers.</li> </ul>	
<a href="#">Asynchronous Sample Rate Converter (ASRC)</a>	Converts the sampling rate of a signal associated to an input clock into a signal associated to a different output clock. The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The ASRC supports up to 3 sampling rate pairs. The ASRC

**Table 2-9. Communication modules (continued)**

Module	Description	Reference links to the chip related information
<a href="#">Media Local Bus (MLB)</a> (R-Series only)	Implements the Physical Layer and Link Layer of the MediaLB specification, interfacing to an MLB controller. The MLB implements the 3-pin MLB mode and can run at speeds up to 1024Fs.	<a href="#">Instantiation</a>

## 2.5.8 Graphics Modules

The following core modules are available on the VFxxx Controller devices. For modules enabled on a specific part, refer to the data sheets.

**Table 2-10. Graphics/Display Modules**

Module	Description	Reference links to chip related information
<a href="#">Display Controller Unit (DCU4)</a>	It is a system master that fetches graphics stored in internal or external memory and displays them on a TFT LCD panel. It supports: <ul style="list-style-type: none"> <li>• Full RGB888 output to TFT LCD panel</li> <li>• 64 graphics layers, a default background color layer and a cursor layer with integrated blinking option</li> <li>• Blending of each pixel using up to 6 source layers dependent on size of panel</li> <li>• Programmable panel size up to XGA (1008x768)</li> <li>• Gamma correction with 8-bit resolution on each color component</li> <li>• Safety mode for tagging pixels on highest priority layers</li> <li>• Dedicated memory blocks to store a cursor and Color Look Up Tables (CLUTs)</li> <li>• Temporal Dithering</li> </ul>	<a href="#">DCU Instantiation</a>
<a href="#">GPU</a> (R-Series only)	Defines a high-performance graphics core designed for hardware acceleration of OpenVG vector graphics display on a variety of consumer devices.	
<a href="#">RLE</a>	Decodes data that has been compressed using a Run Length Encoding (RLE) scheme. It has input and output FIFO buffers directly connected to the crossbar switch and requires the CPU or DMA to push in the encoded data and then extract the decoded result. The module configuration is optimized for decoding data stored in a two-dimensional image format but can also be used to extract data stored as a linear array. <ul style="list-style-type: none"> <li>• 32 channels support independent</li> <li>• 8/16/32-bit single value or block transfers</li> <li>• Supports variable sized queues and circular queues</li> </ul>	<a href="#">RLE Instantiation</a>

Module	Description	Reference links to chip related information
<a href="#">Temperature Voltage Monitor</a>	<p>It contains the voltage and temperature monitor circuits. These circuits are put into a separate power domain. Its features are:</p> <ul style="list-style-type: none"> <li>• Low power designs to support the coin battery</li> <li>• Trimmable Voltage and Temperature detector thresholds</li> </ul>	
<a href="#">Power Management Unit (PMU)</a>	<p>The PMU of the device includes:</p> <ul style="list-style-type: none"> <li>• High power or main regulator (HPREG)</li> <li>• Voltage reference for HPREG</li> <li>• Low power regulator (LPREG)</li> <li>• Ultra low power regulator (ULPREG)</li> <li>• Voltage reference for LPREG and ULPREG</li> <li>• Low voltage detector for 3.3V supply</li> <li>• Separate Low voltage detectors for HPREG ,LPREG ,ULPREG output voltages</li> <li>• Power on Reset(POR)</li> <li>• Power up sequencing and testing</li> <li>• N-well bias circuit</li> </ul>	

# Chapter 3

## Chip Configuration

### 3.1 Introduction

This chapter provides implementation details of the modules that are described in this manual. Many modules used on this device are also used on other NXP processors, such as i.MX and Kinetis. Therefore, the module documentation is generic and may describe features or ports that are not used or not implemented on this processor. Likewise, there may be implementation details like interrupts, clock sources, and signal multiplexing that are specific for each device.

This chapter also provides the following information:

- Specific module-to-module interactions not necessarily discussed in the individual module chapters
- Number of instances of the module in the device and their features
- Number of instances of the module in the device and the differences in the features (if any)
- Register differences between the multiple instances of a module

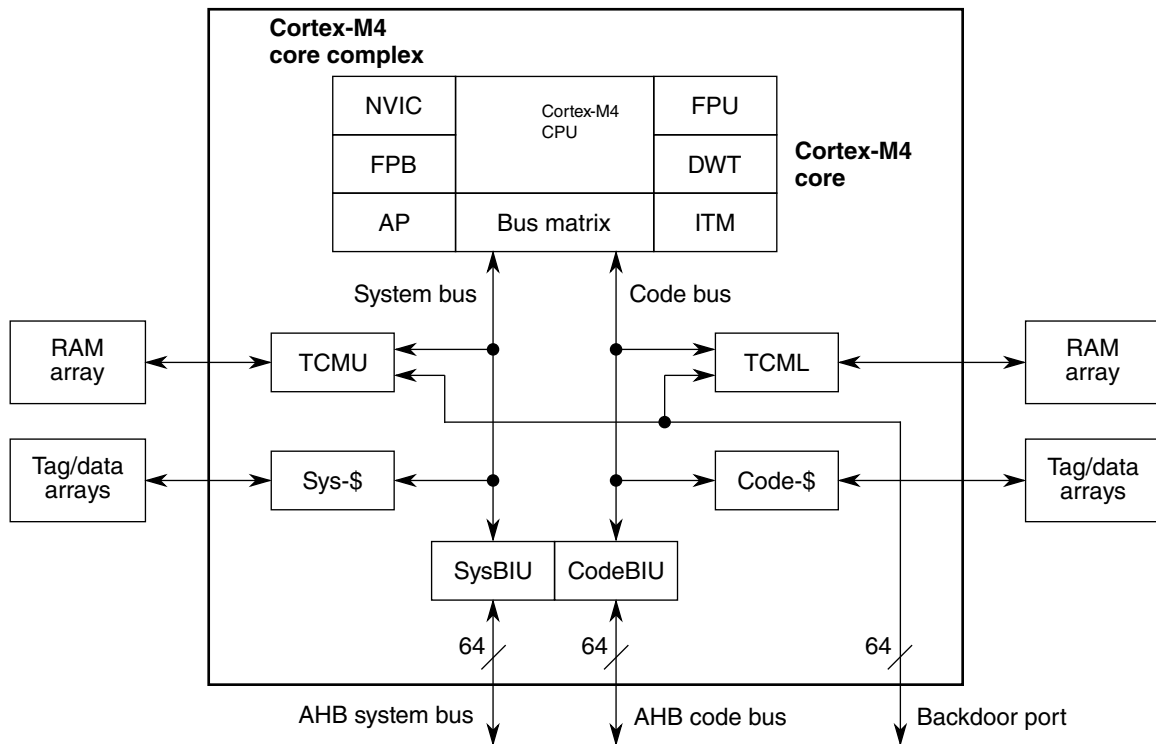

### 3.2 Core modules

#### 3.2.1 Cortex-M4 Processor Core

Cortex-M4 implements the ARMv7-ME instruction set architecture (ISA): this is the Thumb2 definition - it provides compatibility with Cortex-M3 and adds significant new capabilities with DSP and SIMD extensions. The basic multiply-accumulate instructions support operations up to  $32 \times 32 + 64$ . Cortex-M4 also includes a single-precision floating-point unit (FPU), which includes an extension register file of thirty-two 32-bit floating-point data registers. Cortex-M4 complex includes the FPU and two 32-bit system bus interfaces. The device Cortex-M4 implementations include two tightly-coupled local

memories and two cache memories connected to these bus interfaces although the device implementation connects to the 64-bit system bus interconnect and supports a 32-byte cache line size.

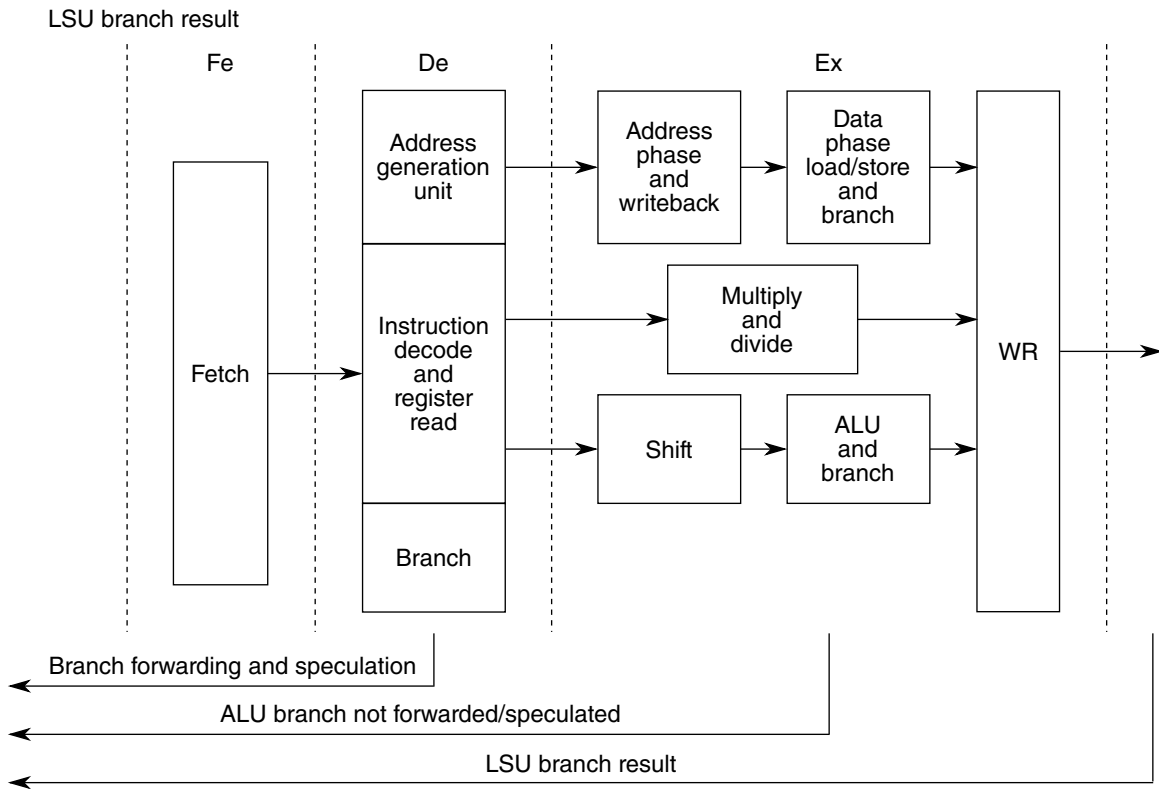

- L1 2-way set-associative 16kB Instruction cache with 32B line size length
- L1 2-way set-associative 16kB Data cache with 32B line size length

**Figure 3-1. Cortex-M4 Block Diagram**

Cortex-M4 core features a single issue, three stage pipeline microarchitecture. A high-level spatial pipeline block diagram of the CPU is shown below. The stages of the pipeline include:

- Fe - Instruction fetch stage where data is returned from instruction memory
- De - Instruction decode stage, generation of Load/Store Unit (LSU) address using forwarded register ports and immediate offset of LR register branch forwarding
- Ex - Instruction execute stage, single pipeline with multi-cycle stalls, LSU address/data pipelining to AHB interface, multiply/divide and ALU with branch result

**Figure 3-2. Cortex-M4 Pipeline Block Diagram**

### 3.2.2 Cortex-M4 Instruction Fetches on the System Bus

The Cortex-M4 processors implement multiple 32-bit bus interfaces that support a Harvard memory architecture. Specifically, the cores provide a modified Harvard connection with 2-cycle pipelined AMBA-AHB code and system buses. The modified Harvard memory architecture results since the bus interfaces are activated by address range and include both instruction fetches and operand data references on a given bus port. A traditional Harvard architecture separates instruction fetches and operand data references onto specific bus ports regardless of access address.

The code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on- and off-chip memories and peripheral accesses. This bus structure fully supports concurrent instruction fetch and data accesses, but the Cortex-M4 implementations can generate both types of references on each bus. Additionally, there is a separate 32-bit Private Peripheral Bus (PPB) connection to several important modules (for example, the Nested Vectored Interrupt Controller) accessible to only the core. By placing the various code and data sections in the appropriate locations within the memory map, overall system performance can be maximized.

To provide a “clean timing interface” on the core's system bus, instruction and vector fetch requests to this bus are registered. This increases fetch time by an additional cycle of latency because instructions fetched from the system bus take a minimum of two cycles. This also means that back-to-back instruction fetches from the system bus are not possible.

Instruction fetch requests to the code bus are not registered. It is recommended that performance critical code be located such that it fetches from the ICode bus interface as defined by addresses  $< 0x2000\_0000$  (the system bus interface includes the addresses  $\geq 0x2000\_0000$  and  $< 0xE000\_0000$  and the Private Peripheral Bus is used for addresses  $\geq 0xE000\_0000$ ).

### NOTE

In the device, the memory map includes aliased address spaces that are mapped into the ICode region for code sections that reside in the system address space. As a simple example, the DDR address space is located in the system region of the memory map, but a subset of this space is aliased so that it appears in the ICode region that instructions mapped into the DDR space can be executed as maximum performance.

## 3.2.3 Cortex-A5 Processor Core

The Cortex-A5 processor is a high-performance, low-power ARM macrocell with an L1 cache subsystem that provides full virtual memory capabilities. The core supports the ARMv7-A instruction set architecture (supporting 32-bit ARM plus 16- and 32-bit Thumb{-2} instructions) and the microarchitecture has been optimized for area, performance/power efficiency, scalability and flexibility. It is architecturally compatible with the Cortex-A9.

It includes both an FPU and the NEON Media Processing Engine. The Cortex-A5 Floating Point Unit (FPU) is a VFPv4-D16 implementation of the ARM v7 floating-point architecture. The unit provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-1985, IEEE Standard for Binary Floating-Point Arithmetic (IEEE 754).

The FPU includes all data processing instructions and data types in the VFPv4 architecture and fully supports single-precision and double-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU is tightly integrated to the Cortex-A5 processor pipeline.

The NEON Media Processing Engine (MPE) extends the capabilities of the FPU with an implementation of the ARM NEON Advanced SIMD v2 instruction set for further acceleration of media and signal processing functions. It includes an additional register set supporting a rich set of SIMD operations over 8, 16, and 32-bit integer and 32-bit floating-point data types. The Cortex-A5 implements TrustZone® Technology to ensure reliable implementation of security applications ranging from digital rights management to electronic payment.

**Figure 3-3. Cortex-A5 Processor Core Block Diagram**

The processor microarchitecture implements a single issue, 8-stage pipeline design capable of 1.57 DMIPS per MHz performance. For the device, the configurable L1 caches are defined as 32K I- and 32K D-Caches and the system bus interface is a high performance 64-bit AXI bus that supports multiple outstanding transactions and has over 3x the memory bandwidth of the ARM1176JZ-S.

- L1 2-way set-associative 32 KB Instruction cache with 32B line size length
- L1 4-way set-associative 32 KB Data cache with 32B line size length
- L2 8-way set associative 512 KB cache with 32B line size length

**Figure 3.** ARM Cortex-A5 pipelines. The basic integer pipeline is eight stages deep, including three prefetch stages that set up branch prediction. An instruction queue decouples the prefetch stages from the ALU section of the pipeline. A three-stage multiplier can execute 32- x 32-bit multiplies at a throughput rate of one instruction per cycle. Load/store instructions distribute the cache accesses over multiple stages to reduce critical timing paths. If the optional FPU or Neon extensions are present, a separate five-stage pipeline handles those operations.

**Figure 3-4. Cortex-A5 Processor Pipeline Organization**

### 3.2.4 Interrupt Assignments

Cortex-A5 uses the ARM Generic Interrupts Controller (GIC) architecture version 1.0.

Cortex-M4 uses the Nested Vectored Interrupt Controller (NVIC).

All peripheral interrupts on the device will be directed to a specific interrupt controller (GIC or NVIC) through an Interrupt Router module. In addition to the shared peripheral interrupts, there are CPU-to-CPU interrupts that will pass through the Interrupt Router. Finally, a small number of private peripheral interrupts to each core will connect directly to the NVIC or the GIC. For example, the L2 cache interrupts that are only relevant to the CortexA5 core. The GIC can support up to 16 Private Peripheral Interrupts (PPIs).

#### NOTE

This is a combined Reference Manual for both the VFxxx Controller F-Series and R-Series. Not all features listed in this

document are available on all parts. For features enabled on a specific part, refer to the data sheets.

The following diagram shows the high level architecture of the device interrupts.

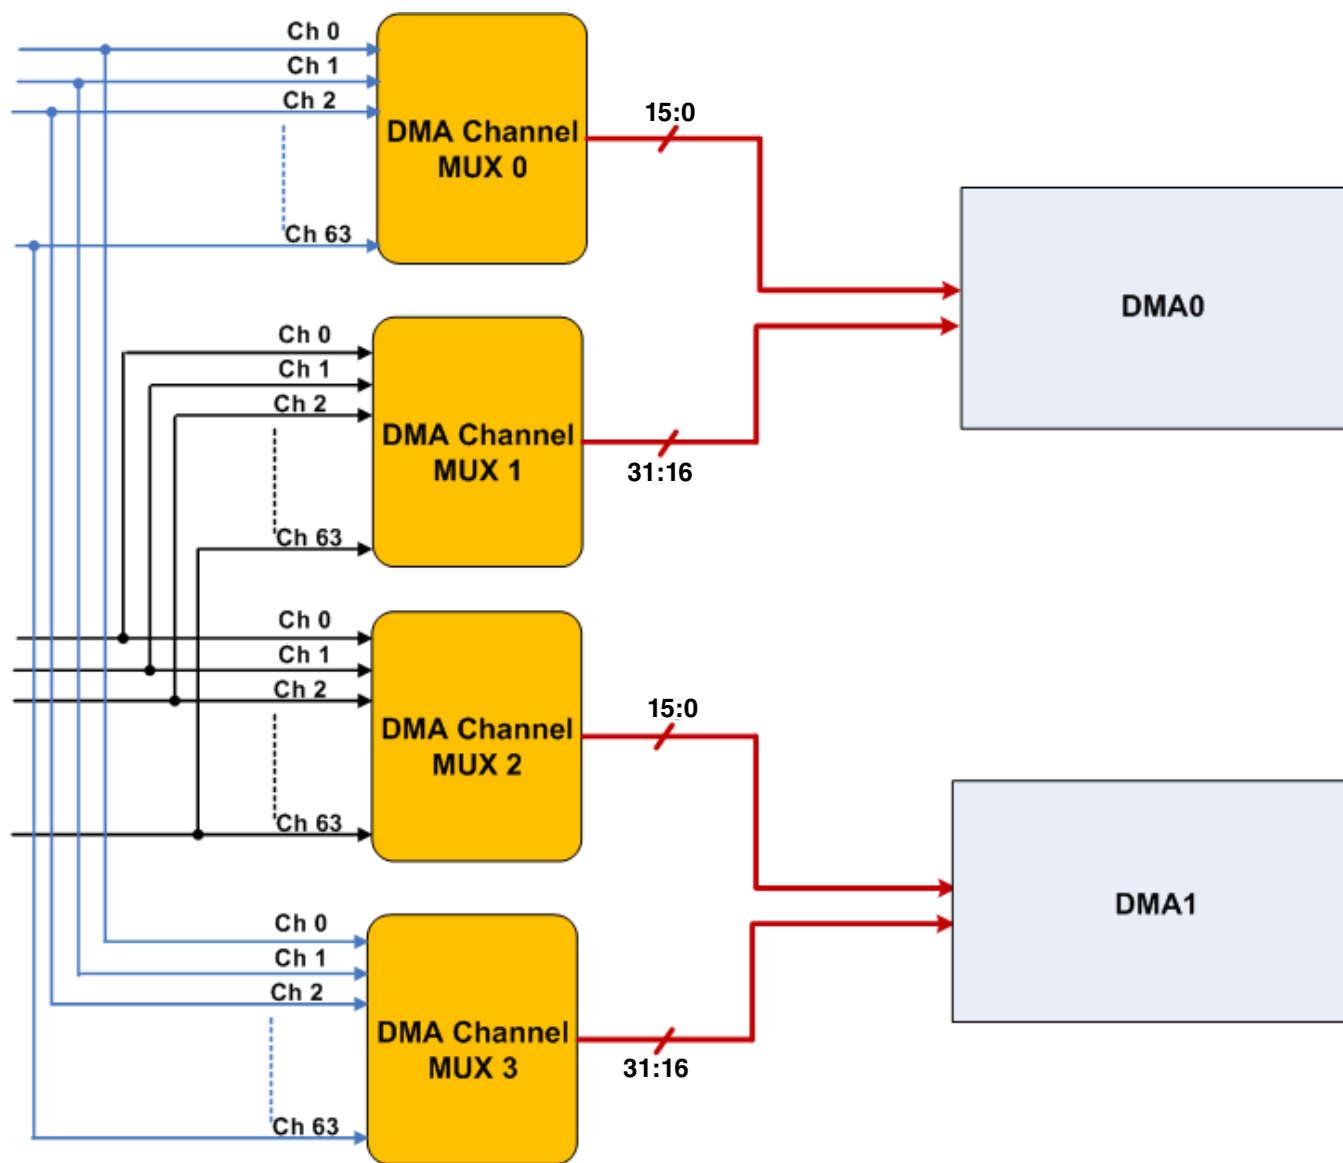

## 3.3 DMAMUX Request Sources

### 3.3.1 DMAMUX Request Sources

This device includes a DMA request mux that allows up to 64 DMA request signals to be mapped to any of the 16 DMA channels. The first four channels of DMAMUX provide periodic triggering capability. The trigger is generated by Periodic Interrupt Timer (PIT[3:0]).

Each DMA includes two DMA request MUXes that allows up to 126 DMA request signals. As shown in the figure below, requests from MUX0 can be mapped to any of the first 16 DMA0 channels [15:0] and from MUX1, to any of the upper 16 DMA0 channels [31:16]. Likewise, MUX2 can be mapped to any of the first 16 DMA1 channels [15:0] and from MUX3 to any of the upper 16 DMA1 channels [31:16].

**Figure 3-5. DMA Request MUX/DMA Structure**

To allow for flexibility and optimal usage of the available DMA channels some of the DMA request sources are available on both muxes.

Because of the mux there is not a hard correlation between any of the DMA request sources and a specific DMA channel.

### NOTE

Two duplicate Channel Muxes cannot be enabled simultaneously for two (same) peripherals.

**Table 3-2. DMA request sources - DMA0 (MUX 0)/DMA1 (MUX3)**

## 3.4 Wakeup Unit (WKPU)

### 3.4.1 WKPU configuration

The WKPU includes the following features.

- One NMI source
- 17 external interrupt sources with glitch filtering
- One external interrupt vector
- Four on-chip wakeup sources
- 12-bit address width
- 00000000b NMI default destination address

The table below shows the internal and external inputs to the WKUP module supported by the device. The signals are in the order that they appear in the wakeup unit Enable and Status registers. The first signal in the table corresponds to bit b0.

**Table 3-4. WKUP Pins**

Wakeup	Source	NVIC Interrupt ID	NMI
WKPU_P0	PTB0	INT92	No
WKPU_P1	PTB1	INT92	No
WKPU_P2	PTB2	INT92	No
WKPU_P3	PTB3	INT92	No
WKPU_P4	PTB4	INT92	No
WKPU_P5	PTB5	INT92	No
WKPU_P6	PTB6	INT92	No
WKPU_P7	PTB7	INT92	No
WKPU_P8	PTB11	INT92	No
WKPU_P9	PTB12	INT92	Yes
WKPU_P10	PTB14	INT92	No
WKPU_P11	PTB16	INT92	No
WKPU_P12	PTB19	INT92	No
WKPU_P13	PTB20	INT92	No
WKPU_P14	PTB27	INT92	No
WKPU_P15	PTC30	INT92	No
WKPU_P16	PTE20	INT92	No
WKPU_M0IF	LPTIMER	NA	NA
WKPU_M1IF	NA	NA	NA
WKPU_M2IF	ADC0	NA	NA
WKPU_M3IF	ADC1	NA	NA
WKPU_M4IF	-	NA	NA

## NOTE

The wakeup unit cannot wake the core from STOP mode as it needs the IPG-CLK to generate the wakeup interrupt.

## 3.5 CMU Chip Signals

### 3.5.1 CMU Chip Signals

This table correlate the chip-level signal name with the signal name used in the module's chapter.

**Table 3-5. CMU Signals Mapping**

Chip Signal Name	Module Signal Name
Bus Clock	CLKMN1f
FXOSC	CLKMN0_RMT
FIRC	CLKMT0_RMN
SIRC	CLKMT1
Tied to 0	CLKMT2

## 3.6 Cyclic Redundancy Check (CRC)

### 3.6.1 CRC Reverse Logic Functions

Reverse logic functions are not available in this implementation.

## 3.7 External Watchdog Monitor

The external watchdog monitor (EWM) has support for 4 clock sources, selectable in the EWM module's EWM\_CLKCTRL register. In this device, only the 32-KHz clock is used as source and is always selected.

The EWM input is pin PTE20 and the output pin is PTE28. To use these pins for EWM functionality, they must be configured in the IOMUX.

## 3.8 Timers

### 3.8.1 FlexTimer

#### 3.8.1.1 Instantiation Information

The following table shows how these modules are configured, including the number of channels supported.

**Table 3-6. FTM Instantiations**

	176 LQFP	364 BGA	Features/Usage
FTM0	8	8	3-phase motor + 2 general purpose or stepper motor
FTM1	2	2	Quadrature decoder or general purpose
FTM2	2	2	Quadrature decoder or general purpose
FTM3	0	8	3-phase motor + 2 general purpose or stepper motor

The FTM1 and FTM2 configuration differs from the FTM0 and FTM3 configuration by reduced number of channels and adding Quadrature decoder.

#### 3.8.1.2 FTM Clock Input

The FTM module's external clock input can be sourced from any of the slow oscillators, the fast oscillator, or the external audio master clock (EXT\_AUDIO\_MCLK).

For details, see [FTM clocking](#).

#### 3.8.1.3 FTM Hardware Triggers

Following table provides the hardware trigger options for FTMs.

**Table 3-7. FTM Hardware Trigger options**

Hardware Triggers	FTM0	FTM1	FTM2	FTM3
Trigger 1	ADC0	ADC0	ADC0	ADC0

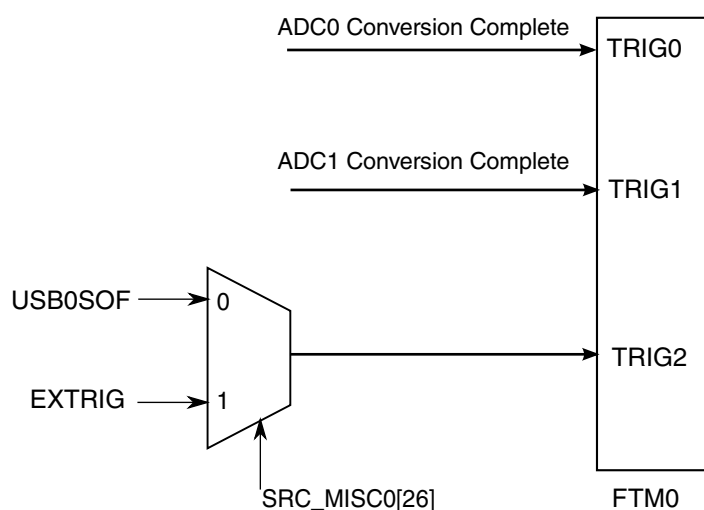

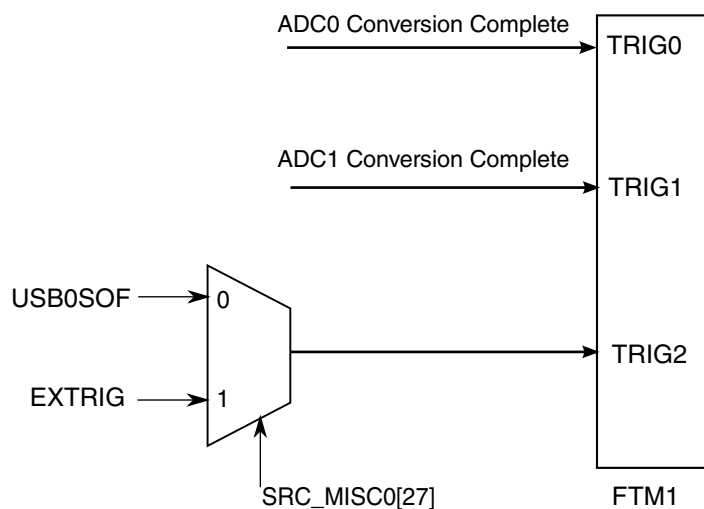

*Table continues on the next page...*

**Table 3-7. FTM Hardware Trigger options (continued)**

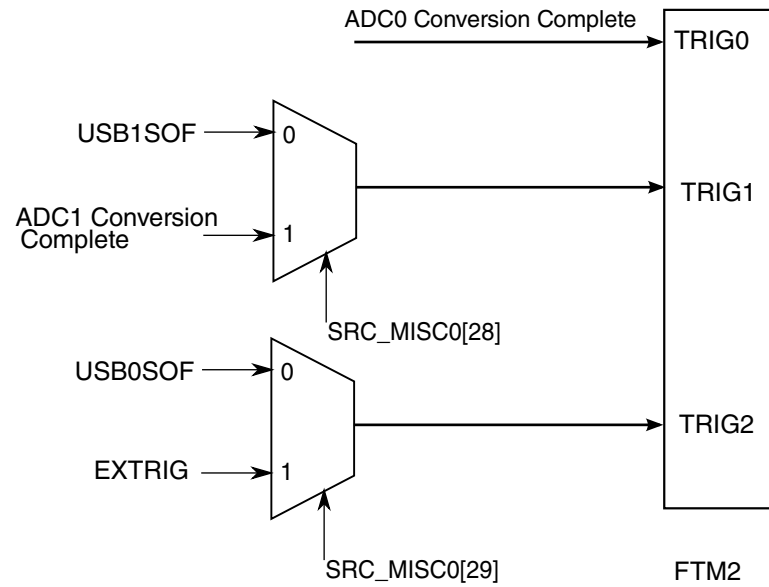

Hardware Triggers	FTM0	FTM1	FTM2	FTM3
Trigger 2	ADC1	ADC1	ADC1 or USB1 SOF	ADC1 or USB1 SOF
Trigger 3	EXTRIG or USB0 SOF	EXTRIG or USB0 SOF	EXTRIG or USB0 SOF	EXTRIG or USB0 SOF

Each flextimer has 3 trigger inputs (0/1/2) which are configured using SRC\_MISC0 register.

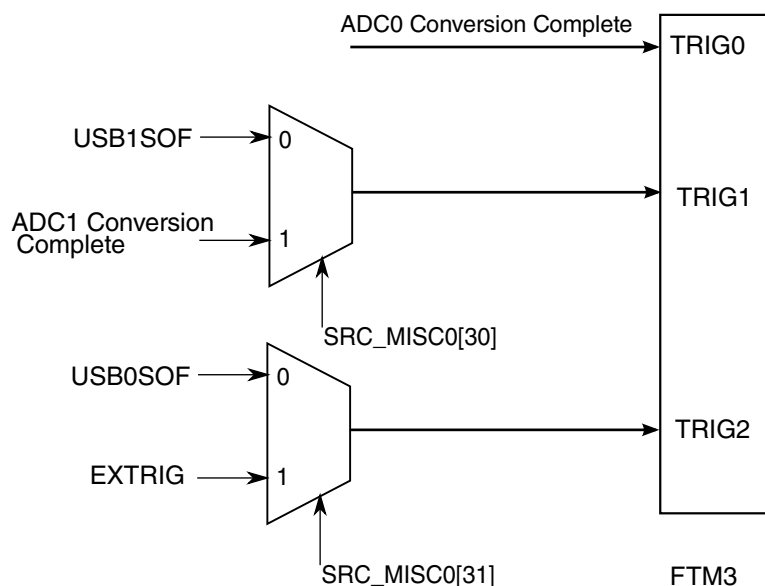

The following figures show the flextimer triggers for each instance.

**Figure 3-6. FTM0 Triggers****Figure 3-7. FTM1 Triggers**

**Figure 3-8. FTM2 Triggers**

**Figure 3-9. FTM3 Triggers**

### 3.8.1.4 FTM output triggers for other modules

Following are the FTM Output Triggers options

- ADC0
- ADC1
- DAC0
- DAC1

### 3.8.1.5 FTM Global Time Base

This chip provides the optional FTM global time base feature (see [Global time base \(GTB\)](#)).

FTM0 provides the only source for the FTM global time base. The other FTM modules can share the time base as shown in the following figure:

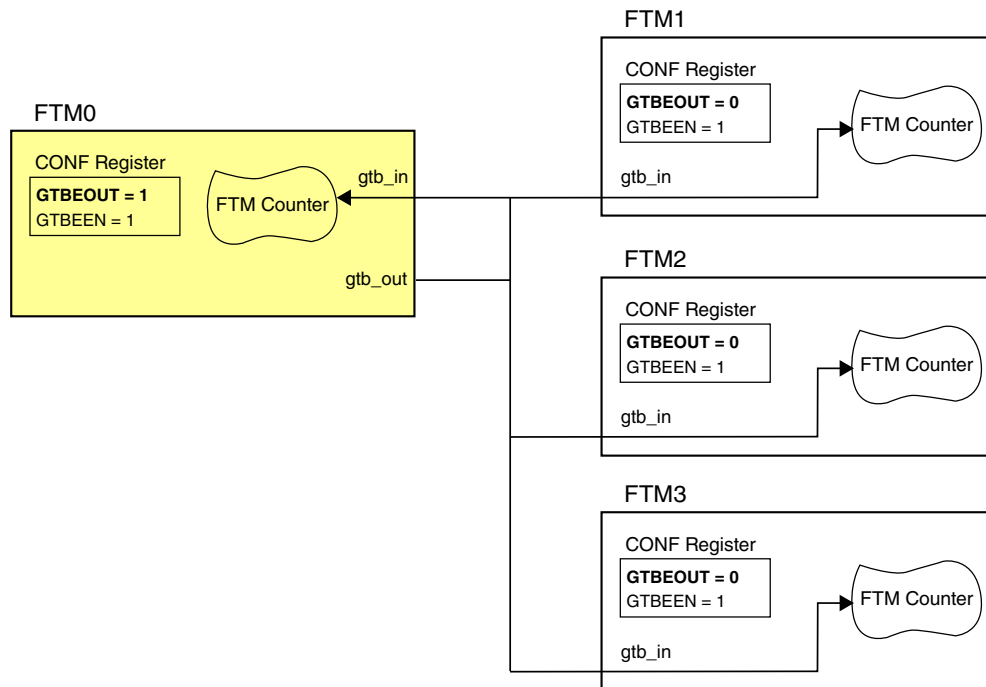

Figure 3-10. FTM Global Time Base Configuration

### 3.8.1.6 FTM Fault Detection Inputs

Fault inputs are useful for motor control. For motor control applications, the inputs come from a comparator. This device doesn't have an on-chip comparator; however, this device can still be used for Motor control. External interrupts (or GPIOs) from a comparator on the board can be used to indicate Fault inputs from the Motor.

In this case, the SRC would include the four Fault Inputs bits. Whenever a fault is asserted, software can write the appropriate register in SRC and this value will be driven internally to FTM.

## 3.8.2 Programmable Interrupt Timer(PIT)

### 3.8.2.1 PIT Instantiations

This device contains one PIT module with eight channels.

### 3.8.2.2 PIT/DMA Periodic Trigger Assignments

The PIT generates periodic trigger events to the DMA Mux as shown in the table below.

**Table 3-8. PIT channel assignments for periodic DMA triggering**

DMA Channel Number	PIT Channel
DMA Channel 0	PIT Channel 0
DMA Channel 1	PIT Channel 1
DMA Channel 2	PIT Channel 2
DMA Channel 3	PIT Channel 3

### NOTE

When DMA channel is enabled with periodic triggering capability, and using "always enabled" DMA sources, PIT trigger is ignored.

### NOTE

To implement gating the request from "always enabled" source, follow the steps below to re-assert the request:

1. Set DREQ bit in DMA\_TCDn\_CSR register and  
DMAMUX\_CHCFGn[ENBL] = 0
2. Set DMAMUX\_CHCFGn[ENBL] = 1, DMASREQ = channel in your DMA DONE interrupt service routine so that "always enabled" source could negate its request. Then, DMA request could be negated.

## 3.8.3 Programmable Delay Block (PDB)

### 3.8.3.1 PDB Instantiation

This device has one instance of PDB.

#### 3.8.3.1.1 PDB Output Triggers

**Table 3-9. PDB Output Triggers**

PDB Parameter	Value
Number of ADC channels	2
Number of pre-triggers per ADC channel	2
Number of DAC interval triggers	2
PulseOut channels	None

### 3.8.3.1.2 PDB Input Trigger Connections

Table 3-10. PDB Input Trigger Options

PDB Trigger	PDB Input
0000	External Trigger at RGPIO[25]
0001	PIT Ch 0 Output
0010	PIT Ch 1 Output
0011	PIT Ch 2 Output
0100	PIT Ch 3 Output
0101	PIT Ch 4 Output
0110	PIT Ch 5 Output
0111	PIT Ch 6 Output
1000	Init and Ext Triggers from FTM0
1001	Init and Ext Triggers from FTM1
1010	Init and Ext Triggers from FTM2
1011	Init and Ext Triggers from FTM3
1101	RTC Alarm
1110	LPT Output
1111	Software Trigger

### 3.8.3.2 PDB Module Interconnections

PDB trigger outputs	Connection
Channel 0 triggers	ADC0 trigger
Channel 1 triggers	ADC1 trigger

### 3.8.3.3 DMA support on PDB

The PDB supports the DMA request functionality. One DMA request is supported.

### 3.8.3.4 PDB in Low-Power modes

PDB is available in the WAIT, LPRUN, UPLRUN, and STOP modes. However, the PDB is in power-gated domain and is not available in the LPSTOP1, LPSTOP2, and LPSTOP3 Low-Power Stop modes. In Low-Power Stop modes, the ADC is triggered using the Low-Power Timer (LPTMR).

### 3.8.3.5 PDB implementation with ADC

The following figure illustrates the implementation of the PDB interface with ADC. There is one back-to-back acknowledgement from the ADC0 to channel 0 of the PDB. In this MCU, PDB back-to-back acknowledgement connection is implemented as follows:

- PDB channel 1 pre-trigger 0 acknowledgement input: ADC0SC1B\_COCO

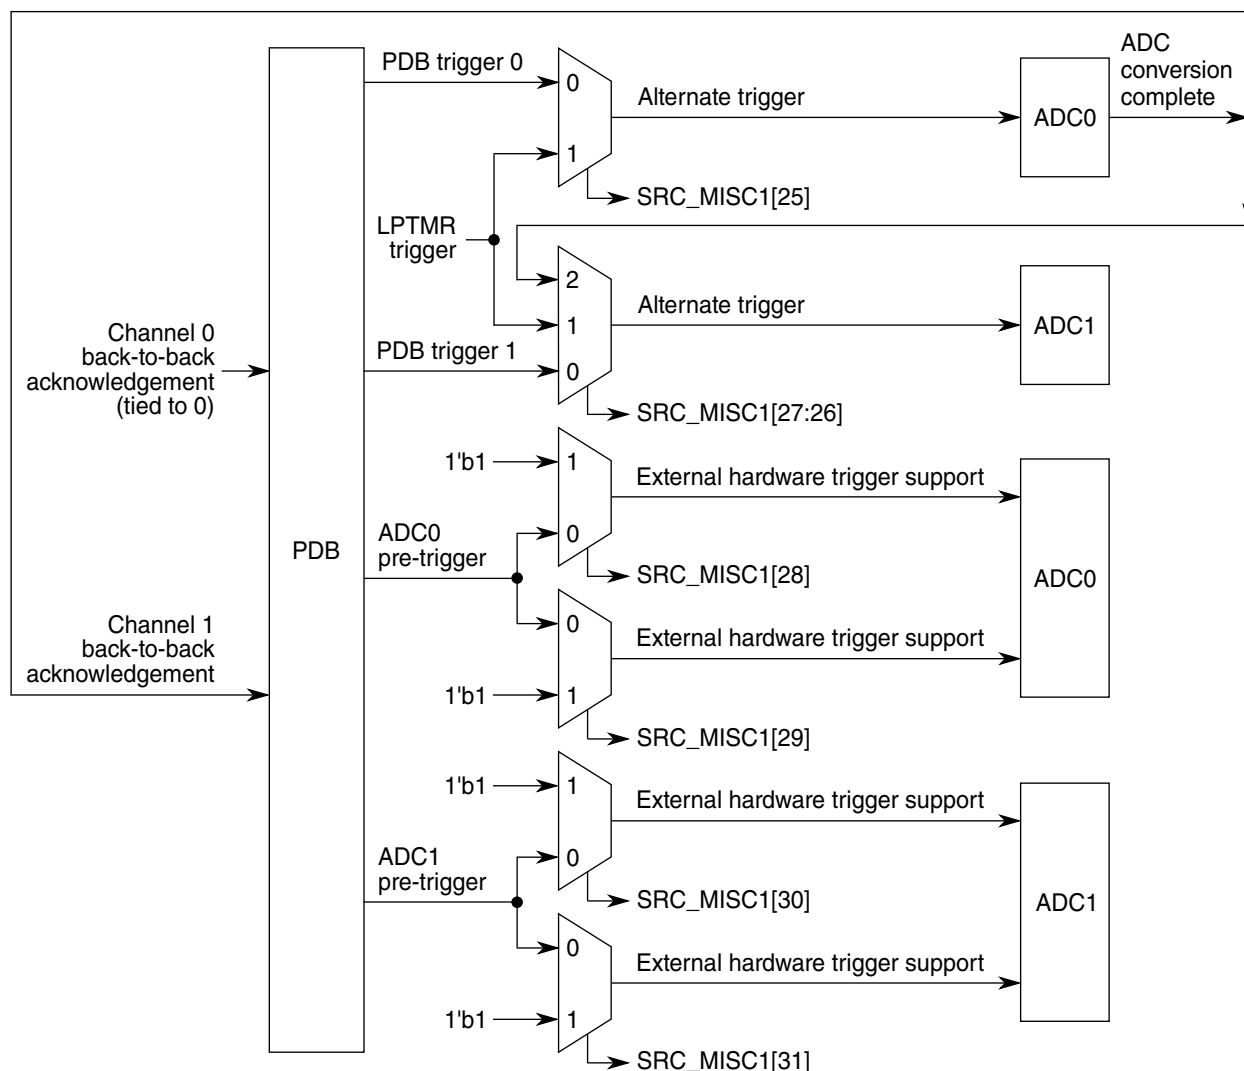

Figure 3-11. PDB implementation with ADC

## 3.8.4 Low-Power Timer (LPTMR)

### 3.8.4.1 LPTMR prescaler/glitch filter clocking options

The prescaler and glitch filter of the LPTMR module can be clocked from one of four sources determined by the LPTMR0\_PSR[PCS] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

#### NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

LPTMR0_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
00	0	24MHz FIRC
01	1	1KHz Derived from SIRC
10	2	32KHz SXOSC
11	3	128KHz SIRC

To read about clocking on this device, refer to [Clocking Overview](#).

## 3.9 External memory interfaces

### 3.9.1 Quad SPI

#### 3.9.1.1 QuadSPI Instances

There are two instances of the QuadSPI module on this device. QuadSPI0 supports two serial flash ports, while QuadSPI1 supports a single serial flash port. Each QuadSPI port implements two chip-selects (CS) enabling two separate serial flashes to be attached to each individual port. The dual CS arrangement also allows dual-die packaged serial flash to be connected to a single port of a QuadSPI. The 2-port configuration of QuadSPI0 allows two external flash devices to operate in a parallel read mode with read data from the flashes being recombined automatically in the QuadSPI module. This effectively enables an 8-bit flash interface, doubling the read bandwidth and is particularly useful for

XiP operation of fast fetch of graphics data from the external flash. Each QuadSPI implements a flexible 1 KB AHB buffer which can be configured in accordance with application needs.

**Table 3-11. Module Instances**

QuadSPI	Serial Flash Ports	# CS per Port	Parallel Mode	AHB Buffer Size	Peak DDR Read Bandwidth
QuadSPI0	2	2	Yes	1 KB	132 MB
QuadSPI1	1	1	No	1 KB	66 MB

QuadSPI0 and QuadSPI1 are available as multiplexing options on all package variants.

### NOTE

Quadspi DQS Loopback mode is not supported on this device.  
Any reference to it in this document should be ignored.

### 3.9.1.2 QuadSPI Memory Interface

Each port of QuadSPI supports the following signals:

- SCK: Serial Clock
- IO[0:3] : Serial I/O for command, address and data
- /CS: Chip Select
- /CS2: Chip Select 2; used to select second instance of QuadSPI or select a second flash device sharing SCK and IO[0:3]
- DQS: Data strobe signal for some manufacturers for DDR read timing at 50 MHz and above

### 3.9.1.3 QuadSPI Buffer

Each QuadSPI 4 implements a flexible AHB buffer scheme to support multiple data streams the. The buffer can be partitioned into four separate buffers of different size, each associated to specific bus masters. In addition, the buffers can be associated with one or other of the connected serial flashes or both simultaneously. For details on configuration of the AHB buffers, refer to the QuadSPI chapter in this reference manual.

### 3.9.1.4 QuadSPI Clocking

The QuadSPI module's clock configuration is entirely controlled in the CCM module (see [QuadSPI Clocking](#) for details). The SCLKCFG bit field in the QuadSPIx\_MCR register is not used.

### 3.9.1.5 Booting from QuadSPI

Available frequency in System Boot for booting through QuadSPI0 with multiple configuration (SDR, DDR modes):

**Table 3-12. Booting from QuadSPI**

	QuadSPI 0 in DDR Mode	QuadSPI 0 in SDR Mode
SCK frequency options in MHz	18	18, 60, 74

## 3.9.2 DRAM Controller

### 3.9.2.1 DDR maximum address space

The maximum address space available for the DDR controller is calculated using the following formula:

$$\text{Maximum Memory Size} = \text{Chip\_Selects} \times \text{Banks} \times 2^{\text{Address\_bits}} \times \text{Data\_Path\_Width}$$

The maximum values available for this device are:

- Chip selects = 1
- Device address = 16 rows + 10 columns = 26
- Number of banks = 8
- Memory data path width = 2 bytes

As a result, the maximum accessible memory area is 1 GB.

The address map for this configuration is shown below. Address bits 30–31 are not used. These bits are ignored when generating the address to the DRAM devices.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Don't care	Chip select	Row										Bank				Column								Data path							

Figure 3-12. Alternate memory map

### 3.9.3 Nand Flash Controller

#### 3.9.3.1 Instantiation

The NAND Flash Controller(NFC) interfaces standard NAND Flash devices to the IC and hides the complexities of accessing the NAND Flash. It provides a glueless interface to both 8-bit and 16-bit NAND Flash parts with page sizes of 512 bytes, 2 KB, 4 KB and 8 KB.

### 3.9.4 FlexBus Controller

#### 3.9.4.1 FlexBus signal multiplexing

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals is controlled by the port control and FlexBus modules. The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals are available from the module. Use the CSPMCR and port control registers to configure which control signal is available on the external pin.

The control signals are grouped as illustrated:

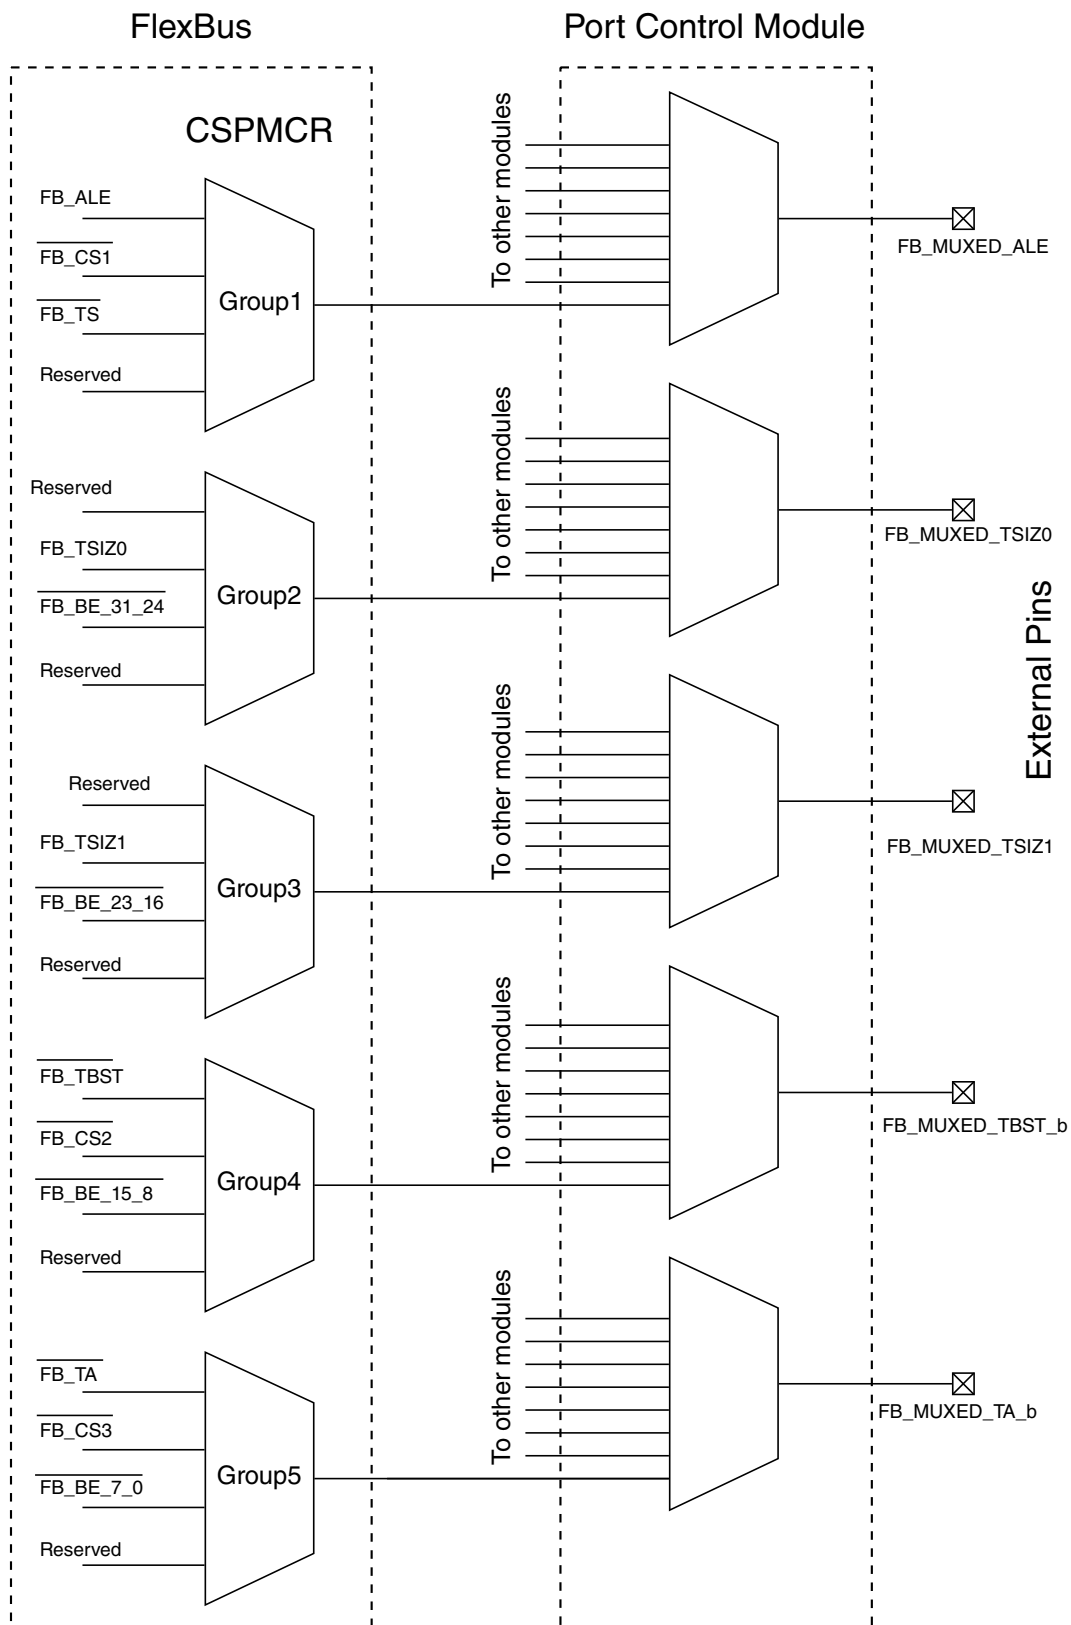

Figure 3-13. FlexBus control signal multiplexing

Therefore, use the CSPMCR and port control registers to configure which control signal is available on the external pin.

### 3.9.4.2 VFxxx Controller restrictions

VFxxx Controller-specific restrictions to Flexbus Multiplexing:

- Only chip-selects 0-3 are made available on pins.
- Only 32-byte bursts are supported; no 16-byte transfers
- Only Multiplexed Address/Data bus available.

### 3.9.4.3 FlexBus Signal Multiplexing

The table below shows the FlexBus signal multiplexing on this device.

**Table 3-13. FlexBus Multiplexing**

Flexbus Signal	CSPMCR bits	Value of CSPMCR bits	Pad Connected to	Pin Connected to	ALT Mode	Signal Name
FB_ALE	[31:28]	0	PAD[93]	PTB23	ALT4	FB_MUXED_ALE
FB_CS1_b	—	1	—	—	—	—

FB_BE_7_0_b	—	2	—	—	—	—

*Table continues on the next page...*

**Table 3-13. FlexBus Multiplexing (continued)**

Flexbus Signal	CSPMCR bits	Value of CSPMCR bits	Pad Connected to	Pin Connected to	ALT Mode	Signal Name
Reserved	—	Rest	—	—	—	—

### 3.9.4.4 FlexBus External Signal

The following sections correlate the chip-level signal with the signal name used in the module's chapter.

**Table 3-14. External Signals**

Chip signal name	Module Signal name
FB_BE3_B	FB_BE31_24_B
FB_BE2_B	FB_BE23_16_B
FB_BE1_B	FB_BE15_8_B
FB_BE0_B	FB_BE7_0_B

### 3.9.4.5 FlexBus Security

FlexBus accesses are moderated by AHB TrustZone that is part of platform.

### 3.9.4.6 Instantiation Information

The FlexBus module is pinned out with a 32-bit multiplexed address and data bus with four chip selects. The bus allows for the configurations listed in the table below. In configurations where the full 32-bit bus is not needed those signals can be used as GPIO or other multiplexed functions.

#### NOTE

By default, FlexBus clocks are disabled and have to be explicitly enabled by software.

**NOTE**

Any access to the FlexBus device without clocks initialized may hang the bus.

**Table 3-15. FlexBus Configurations**

Number of Address Lines	Number of Data Lines	Number of External Signals	CSCR[bit 9] setting	Mode
32	32/16/8	32 (FB_AD[31:0])	1	Multiplexed FB_AD[31:0] allows for full 32-bit address with multiplexed 32-bit, 16-bit, or 8-bit data. 8-bit data comes out on FB_AD[7:0].
24 or less	16/8	24 or less (FB_AD[23:0])	1	Multiplexed FB_AD[23:0] allows for up to 24 address lines with multiplexed 16-bit or 8-bit data. 8-bit data comes out on FB_AD[7:0]
24 or less	8	32 or less (FB_AD[23:0] + FB_AD[31:24])	0	Non-multiplexed mode. FB_A[24:0] are dedicated address lines. FB_D[7:0] (FB_AD[31:24] internally) are used as dedicated data lines.
16 or less	16	32 or less (FB_AD[15:0] + FB_AD[31:16])	0	Non-multiplexed mode. FB_A[15:0] are dedicated address lines. FB_D[15:0] (FB_AD[31:16] internally) are used as dedicated data lines.
0	32/16/8	32, 16, or 8 (FB_AD[31:0], FB_AD[31:16]/FB_AD[15:0], or FB_AD[31:24]/FB_AD[7:0])	0 or 1	Data only mode. Commonly used for interfacing to smart LCD devices. Support 32-bit, 16-bit, or 8-bit data. Either the upper or lower half of the data bus can be used as selected by CSCR[bit 9].

**NOTE**

CSCR[bit9] is configured by boot code when Flexbus is selected as boot device. It is configured by BOOT\_CFG1[0].

### 3.9.4.7 FlexBus Chip Select Control Register (CSCR0) Reset Value

On this device the Chip Select Control Register (CSCR0) resets to 0x003F\_FC00. Configure this register as needed before performing any FlexBus access.

For more information about CSCR0 control bits, see [Chip Select Control Register \(FB\\_CSCR<sub>n</sub>\)](#).

### 3.9.4.8 Bus Timeout

For scenarios where auto-acknowledge feature is disabled, device can hang if there is no external FB\_TA\_b received. To avoid this scenario, a monitor is provided that terminates a FlexBus transaction as bus error if it does not complete within the specified time. Refer to SRC\_MISC3 register description in [System Reset Controller](#) to get details about the configuration of this counter.

## 3.10 Communication interfaces

### 3.10.1 10/100 Ethernet Subsystem

#### 3.10.1.1 Instantiation Information

VFxxx Controller family devices will instantiate Ethernet modules as shown below.

**Table 3-16. Ethernet Instantiations**

	176 LQFP	364 BGA
10/100 Ethernet (MAC-NET)	1 (R-Series) 2 (F-Series)	2
L2 Ethernet Switch	None (R-Series) 1 (F-Series)	1

#### NOTE

MII mode is supported for MAC0 only and when MII mode for MAC0 is enabled, RMII of MAC1 cannot be used.

### 3.10.1.2 MII and RMII configuration

II is a 4-bit interface, which is clocked at 25 MHz to support 100 Mb/s and RMII is a 2-bit interface clocked at 50 MHz to support the same data rate. This device has two Ethernet MACs. MAC0 has been configured to support both RMII and MII, while MAC1 has been configured to support only RMII. Further, if MII interface on MAC0 is enabled, MAC1 cannot be used for RMII interface. Various pins used in RMII and MII for MAC0 and the pins that can be used are described below.

**Table 3-17. MII and RMII configuration for MAC0**

Ethernet signal name	Description	Pin configuration in MII mode	Pin configuration in RMII mode
Transmitter Signals			
TXD0	Transmit data bit 0 (MAC to PHY)	PTC7-ALT1	PTC7-ALT1
TXD1	Transmit data bit 1 (MAC to PHY)	PTC6-ALT1	PTC6-ALT1
TXD2	Transmit data bit 2 (MAC to PHY)	PTD18-ALT6	Not used in RMII mode
TXD3	Transmit data bit 3 (MAC to PHY)	PTD19-ALT6	Not used in RMII mode
TXEN	Transmit data valid (MAC to PHY)	PTC8-ALT1	PTC8-ALT1
TXER	Transmit data error (MAC to PHY)	PTD17-ALT6	Not used in RMII mode
TXCLK	Transmit Clock (PHY to MAC. Can be internal for RMII as well.)	PTA6-ALT2/ PTA9-ALT3	Both TX and RX clock in RMII mode are muxed into one signal. The source can be either: PTA6-ALT2/ PTA9-ALT3/PLL5 main clock/Audio Ext clock as explained in Section 9.11.6 Ethernet RMII Clocking.
Receiver Signals			
RXD0	Receive bit 0 (PHY to MAC)	PTC4-ALT1	PTC4-ALT1
RXD1	Receive bit 1 (PHY to MAC)	PTC3-ALT1	PTC3-ALT1
RXD2	Receive bit 2 (PHY to MAC)	PTD22-ALT0 (It is shared with RGPI0, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode
RXD3	Receive bit 3 (PHY to MAC)	PTD23-ALT0 (It is shared with RGPI0, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode
RX_CRS_DV	Receive data valid (PHY to MAC) and CRS in RMII mode.	PTC2-ALT1	PTC2-ALT1

Table continues on the next page...

**Table 3-17. MII and RMII configuration for MAC0 (continued)**

Ethernet signal name	Description	Pin configuration in MII mode	Pin configuration in RMII mode
RXER	Receive data error (PHY to MAC)	PTC5-ALT1	PTC5-ALT1
COL	Collision (PHY to MAC)	PTD20-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode
CRS	Carrier Sense (PHY to MAC)	PTD21-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode.
RXCLK	Receive Clock (PHY to MAC. Can be internal for RMII as well.)	PTA21-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	It is muxed with TXCLK. See above for details.
MDIO	Management I/O data (Bidirectional)	PTC1-ALT1	PTC1-ALT1
MDC	Management Clock (PHY to MAX. Can be internal as well.)	PTC0-ALT1	PTC0-ALT1

### 3.10.1.3 IEEE 1588 Timers

The ethernet module includes a four channel timer module for IEEE 1588 timestamping. The timer supports input capture (rising, falling, or both edges), output compare (toggle or pulse with programmable polarity). The timer matches on greater than or equal (the 1588 can skip numbers, so the counter might not ever exactly match the compare value).

The counter is able to operate asynchronously to the ethernet bus by using one of four clock sources. See Clocking Chapter for more details.

#### NOTE

For best jitter performance, use MII and not RMII for 1588 applications.

### 3.10.1.4 Ethernet Operation in Low Power Modes

#### Low Power modes with Ethernet only Operation

The Ethernet module is not fully operational in any low power modes. However, the module does support magic packet detection that can generate a wakeup in low power mode if enabled.

During low power operation:

- The MAC transmit logic is disabled
- The core FIFO receive/transmit functions are disabled
- The MAC receive logic is kept in normal mode, but it ignores all traffic from the line except magic packets.

The receive logic needed for magic packet detection is clocked using the externally-supplied RMII clock. This allows for the wakeup functionality in low power modes.

### NOTE

Wakeup from Magic Packet is supported on VFxxx Controller STOP mode but not supported on LPSTOP1/2/3 mode.

### Low Power modes with Dual Ethernet and L2 Switch operation (F-Series only)

In low power mode(STOP mode) , the ENET stops immediately and freezes operation, register values, state machines, and external pins. During this mode, the ENET clocks are shut down. Coming out of stop mode returns the ENET to operation from the state prior to stop mode entry.

### NOTE

Practically this would not occur as system would not go in Stop Mode during this mode. CPU enters or executes a stop instruction for the system to go in Stop mode (low power mode) when it sees inactivity or when the system is in idle state for a long period of time. In case there is no activity on the Ethernet Bus or no packets to forward to the other port, CPU may enter this mode. In that case, ENET should have the capability to wake up from stop mode in case of activity on Ethernet bus for the system to exit this mode (RMII clock would still be ON to interrupt the processor on looking at any activity on the RMII bus).

### Low Power modes with Dual Ethernet and L2 Switch Bypassed (F-Series only)

In this mode, the ENET stops immediately and freezes operation, register values, state machines, and external pins. During this mode, the ENET clocks are shut down. Coming out of low power mode returns the ENET to operation from the state prior to low power mode entry.

**NOTE**

Any activity on the Ethernet Bus (RMII/MII interface) would wake up the system and would exit from the low power mode. Similar to the previous case, system would not enter into this mode practically in case of an ongoing activity on packet transmission via RMII interface.

**Battery mode of operation**

The ENET does not support any Standby Mode of operation or a capability to operate on battery in case the main supply fails. The ENET would be disabled during this Mode.

**3.10.1.5 Ethernet Subsystem Interrupts**

The Ethernet has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate an interrupt request. See the following table:

**Table 3-18. Ethernet Subsystem Interrupts**

Interrupt request	Interrupt source
ENET interrupt	<ul style="list-style-type: none"> <li>• Transmit frame interrupt</li> <li>• Transmit buffer interrupt</li> <li>• Receive frame interrupt</li> <li>• Receive buffer interrupt</li> <li>• Wake-up</li> <li>• Payload receive error</li> <li>• Babbling receive error</li> <li>• Babbling transmit error</li> <li>• Graceful stop complete</li> <li>• MII interrupt – Data transfer done</li> <li>• Ethernet bus error</li> <li>• Late collision</li> <li>• Collision retry limit</li> </ul>
IEEE 1588 timer interrupt	<ul style="list-style-type: none"> <li>• Time stamp available</li> <li>• 1588 timer interrupt</li> </ul>
Ethernet Switch interrupt	<ul style="list-style-type: none"> <li>• Learning Interrupt</li> <li>• Output Discard for port 0 (OD0)</li> <li>• Output Discard for port 1 (OD1)</li> <li>• Output Discard for port 2 (OD2)</li> <li>• Receive Buffer Interrupt</li> <li>• Receive Frame Interrupt</li> <li>• Transmit Buffer Interrupt</li> <li>• Transmit Frame Interrupt</li> </ul>

### 3.10.1.6 Ethernet switch register reset values

Some of the Ethernet Switch registers have reset values that are specific to this device. These registers and reset values are listed below and supersede the default reset values given in the Ethernet Switch chapter.

**Table 3-19. Device-specific reset values**

Register	Reset value
ESW_REV	0x0001_0130

## 3.10.2 USB 2.0 HS/FS/LS Dual Role (Host / Device) Controller

### 3.10.2.1 USB Configuration and Options

USB Subsystem includes the following:-

- USB 2.0 HS/FS/LS Dual Role (Host / Device) Controller (x2)
- HS 2.0 integrated PHY (x 2)

### 3.10.2.2 USB Host initialization and bring up

**Table 3-20. Steps to start USB in Device mode**

Initialization
<ul style="list-style-type: none"> <li>• Power ON VFxxx Controller.</li> <li>• With all the regulators activated, they generate OK. Once, all regulators are up and OK will release functional reset.</li> <li>• The Core works on 24 Mhz IRC. It initializes the registers, configures generic interrupt controller, and initializes interrupt handlers.</li> <li>• Enable 24 MHz XTAL.</li> <li>• Once, XTAL OK is asserted, enables all PLL (mainly SYS PLL). <ul style="list-style-type: none"> <li>• Wait for PLL Lock. (Get status from ANADIG PLL registers.)</li> </ul> </li> <li>• After PLL are Locked, disable Clock gating and disable the bypass for PLL.</li> <li>• Switch the Clocks to PLL Clock.</li> <li>• Switch to USB specific configuration for running USB and initialize USB specific features with VFxxx Controller.</li> </ul>
Initializaing USB specific features
<ul style="list-style-type: none"> <li>• Disable the on-chip oscillator (XOSC 24M) powerdown in next powerdown. <ul style="list-style-type: none"> <li>• In register CCM Low Power control register (CCM_CLPCR) deassert SBYOS bit. CCM_CLPCR[SBYOS]= 0.</li> </ul> </li> <li>• Enable the USB regulator. Set bit# 0 (ENABLE_LINREG) in register ANADIG Regulator 3P0 definition register (Anadig_REG_3P0). This regulator works on 5V supply. This needs to be driven from outside the chip.</li> </ul>

*Table continues on the next page...*

**Table 3-20. Steps to start USB in Device mode (continued)**

<ul style="list-style-type: none"> <li>• Enable USB PLL and enable usb clocks: In ANADIG register--(Anadig_USB1_PLL_CTRL) and (Anadig_USB2_PLL_CTRL) enable EN_USB_CLKS and disable BYPASS, that is, <ul style="list-style-type: none"> <li>• Anadig_USB1_PLL_CTRL[POWER]=1</li> <li>• Anadig_USB1_PLL_CTRL[EN_USB_CLKS]=1</li> <li>• Anadig_USB1_PLL_CTRL[BYPASS]=0</li> </ul> </li> <li>• Start the USB PHY – <ul style="list-style-type: none"> <li>• Disable Soft reset of USB PHY – USBPHY_CTRLn[SFTRST]=0</li> <li>• Enable USB Clocks – USBPHY_CTRLn[CLKGATE]=0</li> <li>• For running the controller in LS mode, user needs to set bit#15 (ENUTMILEVEL3) and bit#14 (ENUTMILEVEL2)</li> <li>• In USB PHY Power-Down Register (USBPHY_PWD) clear all the bits and set them to zero. Anadig[USBPHY_PWD]= 0x0000_0000</li> </ul> </li> <li>• Optionally, one can enable the interrupt of USB controller going to the processor ARM Generic Interrupt Controller (GIC)-Enable Interrupt ID 107 (USB0) and Enable Interrupt ID 108 (USB1).</li> <li>• The user can set the WIE bit, if the GIC bit is configured. USBC0_CTRL[WIE]=1</li> <li>• Refer to “Starting USB Controller in HOST Mode”. Once, controller is set to host mode, user can start to next step.</li> <li>• Setup Memory for the USB controller to start communication: <ul style="list-style-type: none"> <li>• Configure the memory as per “Configure the USB controller to read the descriptor from the connected device and Set Address” for setting up memory for starting communication.</li> </ul> </li> <li>• User can wait for the device to detect, configure and connect for starting communication over USB. Refer to Detection for port status change, resetting the USB and speed of connected device.</li> <li>• Once the setup is complete--device connected and configured. One can start communication over usb. Refer to Starting the communication over the USB from Configured Connected Device.</li> </ul>
<b>Starting USB Controller in Host Mode</b>
<ul style="list-style-type: none"> <li>• By default the USB on VFxxx Controller is defaulted to device controller. For initializing them as a Host user has to do following steps: <ul style="list-style-type: none"> <li>• In USB_OTG1_USBCMD register, set the RST bit</li> <li>• Keeping polling for de-assertion of this bit.</li> <li>• In USBMODE register configure CM bit, that is, bit 1 and bit 0</li> <li>• Keep polling and writing back 2'b11 on CM if bit are not set to 11.</li> <li>• Once these bits are set to 11, controller is configured to function like a host.</li> <li>• Refer to “Setting Up device controller” for setup device interrupt and periodic index .</li> <li>• If Port Power is required then refer to “Enable the port power in device Controller”</li> </ul> </li> </ul>
<b>Enable the port power in Host controller</b>
<ul style="list-style-type: none"> <li>• In register Host Controller Structural Parameters (USBx_HCSPARAMS), read if implementation allows controlling the port power. If it reads back to '1', indicates the port power can be controlled. In that case, we can configure bit number 12 of Port Status &amp; Control (USBx_PORTSC1) register to enable port power.</li> </ul>
<b>Setting Up Host controller</b>
<ul style="list-style-type: none"> <li>• Setting Up interrupt threshold--In USB Command Register (USBx_USBCMD), set ITC bit to zero. Else set ITC bit as per system needs.</li> <li>• In USB Frame Index (USBx_FRINDEX), write 1 to the FRINDEX. This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Moreover, this register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit inside USB Status Register (USBx_USBSTS).</li> </ul>
<b>Detection for port status change, resetting the USB and speed of connected device</b>
<ul style="list-style-type: none"> <li>• Everything is set, now user can wait for connection of any external device to the host controller. To sense the device attached, user can poll or configure an interrupt waiting for USB_OTG1_USBSTS to check the change in the port status. <ul style="list-style-type: none"> <li>• Once bit2 of PCI bit is found asserted; deassert this bit by writing back 1 to the same location. This is W1C bit.</li> <li>• Poll for PORTSC0 register, bit #1, Current Status Change (CSC). If set to '1', set port change is detected. Now clear this bit by writing back '1' into the same location.</li> <li>• Check the connect status—Bit#0 of register OTG_PORTSC0. If found asserted port is connected. Else disconnect or under enumeration.</li> <li>• Check if UTMI clocks are OK in USBNC registers – USBCx_PHY – bit# 31.</li> <li>• Reset the USB port</li> </ul> </li> </ul>

*Table continues on the next page...*

**Table 3-20. Steps to start USB in Device mode (continued)**

<ul style="list-style-type: none"> <li>• IN USB Command Register (USBx_USBCMD), set RS bit#0. To start the controller.</li> <li>• Check bit#12 in USBSTS register – HCH. If set to 1, controller is in halted state.</li> <li>• Set bit#8 of PORTSC0 register for starting the reset sequence. Once this bit is written with 1, controller will start reset sequence (CHRIIP) for that port. <ul style="list-style-type: none"> <li>• Wait for USB_PORTSC[PR] bit to clear.</li> <li>• Now check for bit#2 of PORTSC register to check if the device is not disconnected due to reset sequence. If not, move to next step, else restart from “Detection for port change”.</li> <li>• Now check bit#27:26 of PORTSC register to check the port speed. If PSPD is found to be: <ul style="list-style-type: none"> <li>• 00 – Full speed</li> <li>• 01 – Low speed</li> <li>• 10 – High speed</li> </ul> </li> </ul> <p style="padding-left: 40px;">If found not connected, restart from “Detection for port change”.</p> </li> <li>• Configure the host controller to create channel between software running at processor and the device connected. <ul style="list-style-type: none"> <li>• The populated data structure for communication between the software and the device is kept in the memory. This structure needs to be kept at 64 byte aligned boundary address. The base address of this data structure needs to be loaded inside the controller to operate.</li> <li>• This address needs to be loaded at USB_OTG1_ASYNCLISTADDR.</li> </ul> </li> </ul>
Configure the USB controller to read the descriptor from the connected device and Set Address
<ul style="list-style-type: none"> <li>• Refer the EHCI Documentation for detailed configuration and running the USB. The method shown here is one of the method for Writing Software for running the USB on VFxxx Controller.</li> <li>• USB memory need to be initialized to get configured, check features and set address for starting communication over USB. <ul style="list-style-type: none"> <li>• Populate the Asynchronous Queue in Memory. <ul style="list-style-type: none"> <li>• Get device feature: Reading control descriptor \ Communicate to EP0, ADD0, read Descriptor.</li> <li>• Assign Address: If readback features are supported, and need not to suspend the USB port then assign Address.</li> <li>• Once address assignment is done, populate to new QTHed where further communication to happen with new address.</li> <li>• Read feature descriptor allocated to other endpoint of the connected device.</li> <li>• Once, all the device feature are read, firmware can communicate with device accordingly to access and control different feature by populating qTD for the feature.</li> </ul> </li> </ul> </li> <li>• The user needs to populate “Periodic framelist ” for isochronous and interrupt transfers and “asynchronous list” for control and bulk transfers. <ul style="list-style-type: none"> <li>• For running the controller in FS mode, user needs to set endpoint speed to FS in endpoint control populated in the memory. For LS mode, user need to set the endpoint to LS in endpoint control populated in the memory.</li> <li>• User has to dump the periodic framelist baseaddress into Frame List Base Address (USBx_PERIODICLISTBASE) register .</li> <li>• For Async transfer, user has to dump async framelist base address into Asynch. Address (USBx_ASYNCLISTADDR)</li> <li>• Please refer section " Host Data Structures" for more information on Periodic and Asynchronous Framelist.</li> </ul> </li> <li>• Now, controller waits for any device to connect. Once there is any port status change, controller will generate interrupt to the processor.</li> <li>• In register USBSTS, poll for USB Status, bit#0 for completion of command list given through Asynchronous queue.</li> </ul>
Starting the communication over the USB from Configured Connected Device
<ul style="list-style-type: none"> <li>• Refer the EHCI documentation for detailed configuration and running the USB. The method shown here is one of the method for Writing Software for running the USB on VFxxx Controller.</li> <li>• Read the “Host Data Structures” VFxxx Controller RM.</li> <li>• User needs to set following: <ul style="list-style-type: none"> <li>• Programming the endpoint capabilities/characteristics in the queue head with the capabilities of the endpoint and device to communicate. User can program following things in the register: Endpoint number, Endpoint speed, Endpoint max packet length, and device address .</li> </ul> </li> </ul>

**Table 3-20. Steps to start USB in Device mode**

- |   |
|---|
| <ul style="list-style-type: none"> <li>• Program the page offset in the queue head. Each page carries a packet to be transmitted. User can actually check the status of the transmission by looking into “Current qTD pointer”, “Next qTD pointer”, and “Alternate qTD pointer”</li> <li>• In register USBSTS, poll for USB Status, bit#0 for completion of command list given through Asynchronous queue.</li> <li>• After populating the entire structure into the memory, user has to set bit#7 in qTD token status. This bit is set by the software to enable the execution of transaction by the Host controller. Keep polling the remaining bits [6:0] for different communication issues.</li> </ul> |
|---|

### 3.10.2.3 SOF for USB Audio

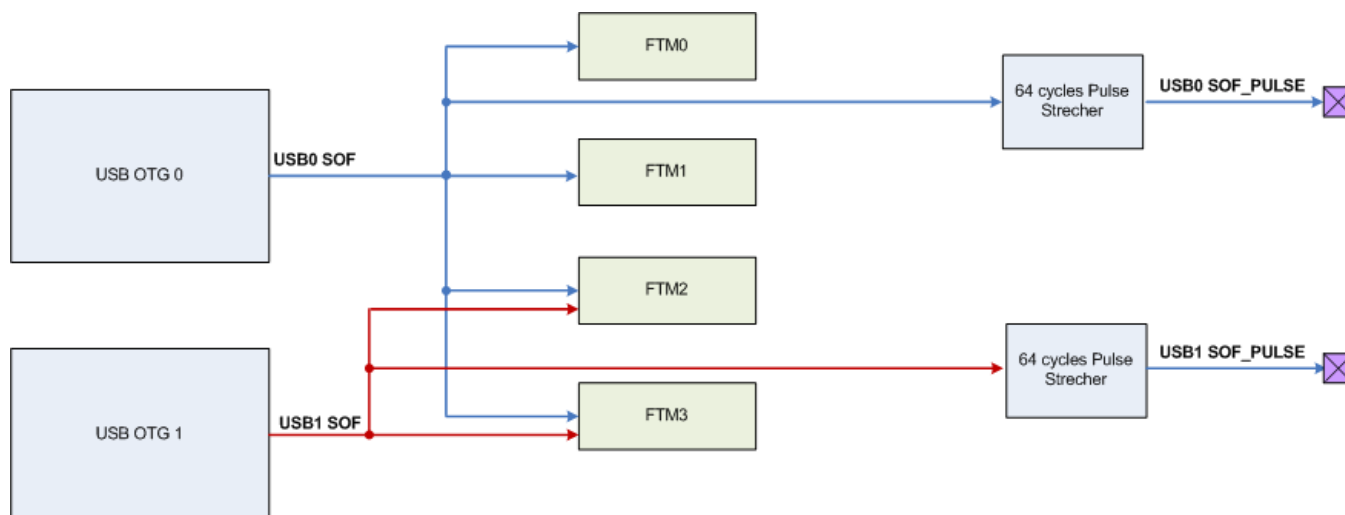

This is mainly applicable when Dual Role (Host / Device) Controller is working in Device Mode. For some of the USB Audio use-cases, require some sort of audio clock recovery capability. One way to do it is to use the Start of Frame (SOF) signal which is generated at the start of a microframe in the USB 2.0 HS. This is a signal with a rate of 125 microseconds. When operating in Full Speed mode, the SOF signal has a rate of 1 ms.

Pulse that asserts for 64 system clock cycles when the SOF token is detected on the USB bus when the USB controller is in device mode.

In order to properly support USB Audio Isochronous Asynchronous mode of operation, it is necessary to measure how many audio sample clock ticks occur between two consecutive occurrences of the SOF signal. This measurement is used to provide feedback to the USB audio source in order to speed up or slow down the audio sample delivery over the USB bus.

This is the method of estimating the ratio between the USB Host clock (SOF occurrences) and the local audio clock.

Figure below shows the USB SOF connectivity with FlexTimer to enable this scheme.

**Figure 3-14. USB SOF connectivity with FlexTimer**

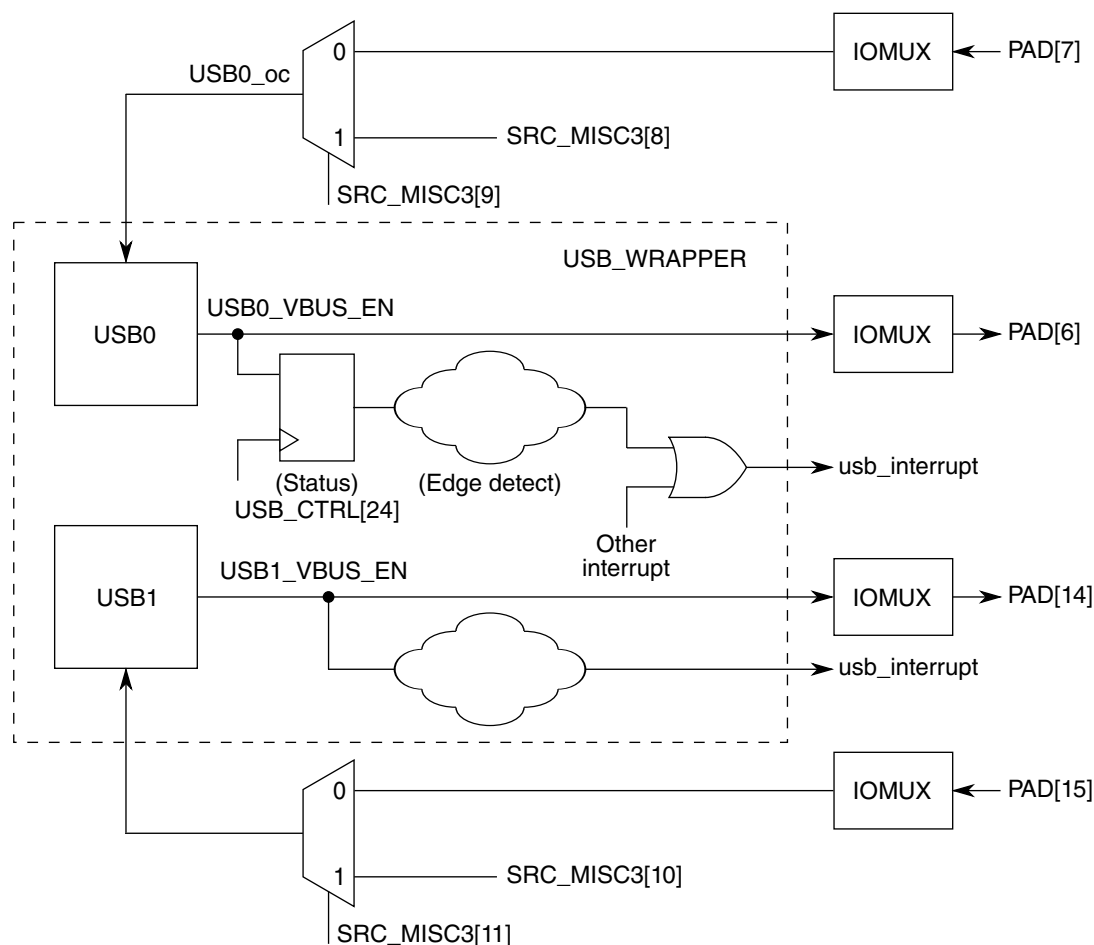

1. The two SOF signals (one from each USB port) must be brought to two timers channels of one FlexTimer. This flexibility is provided in FTM2 and FTM3 as shown in figure.
2. At least one of the SOF signals should be connected to one channel of a second FlexTimer. This will allow measuring of two sets of audio clock/SOF signals. To accomodate this USB0 SOF is connected to all Flextimers.

The audio master clock should also be provided as one of the clock options to FlexTimer.

### 3.10.2.4 OverCurrent and VBUS Connection

The figure below provides OverCurrent and VBUS Connection.

VBUS\_EN is routed to PAD as well as an interrupt from USB. Its status is in USB\_CTRL[24] and can be masked using USB\_CTRL[25].

**Figure 3-15. OverCurrent and VBUS Connection**

### 3.10.3 Secure Digital Host Controller (SDHC)

#### 3.10.3.1 SD bus pullup/pulldown constraints

The SD standard requires the SD bus signals (except the SD clock) to be pulled up during data transfers. The SDHC also provides a feature of detecting card insertion/removal, by detecting voltage level changes on DAT[3] of the SD bus. To support this DAT[3] must be pulled down. To avoid a situation where the SDHC detects voltage changes due to normal data transfers on the SD bus as card insertion/removal, the interrupt relating to this event must be disabled after the card has been inserted and detected. It can be re-enabled after the card is removed.

### 3.10.3.2 SDHC Wakeup

The SDHC controller is taken out of low power mode by some of its interrupts, known as wakeup interrupts. The SDHC can generate these interrupts even when clocks are not enabled. The three interrupts which can be used as wakeup events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

To make the interrupt a wakeup event, when all the clocks to the SDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set.

#### 3.10.3.2.1 Setting Wake Up Events

For the SDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode. Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

### 3.10.3.3 SDHC Software Guidelines

SDHC interrupt does not set under the following circumstances:

1. SDHC configured to generate wakeup on card interrupt. PLL3 is selected as SDHC's baud rate clock.
2. ESDHC clocks are disabled by SDHC\_SYSCCTL register. For details about the register, refer to the respective chapter in this document.
3. PLLs are powered down by software before entering into STOP mode.
4. ESDHC wakeup occurs because of card interrupt.
5. Bus clock restarts but PLL does not start as software directly jumps to SDHC ISR instead of PLL enabling routine.
6. CPU reads SDHC\_IRQSTAT register, but finds no bit set. The bit requires baud rate clock to get set, which needs PLL3 to get powered up.

## 3.10.4 UART

### 3.10.4.1 UART configuration information

This device contains up to six UART modules. This section describes how each module is configured on this device.

1. Standard features of all UARTs:
  - RS-485 support
  - Hardware flow control (RTS/CTS)
  - 9-bit UART to support address mark with parity
  - MSB/LSB configuration on data
2. All UARTs are clocked on the IPS bus clock. The maximum baud rate is 1/16 of related source clock frequency.
3. IrDA is available on all UARTs
4. UART0 and UART1 contains the standard features plus ISO7816
5. UART0 and UART1 contains 16-entry transmit and 16-entry receive FIFOs
6. All other UARTs contain a 8-entry transmit and 8-entry receive FIFOs
7. LIN 2.0 supported on all UARTs.

### 3.10.4.2 UART wakeup

The UART can be configured to generate an interrupt/wakeup on the first active edge that it receives.

### 3.10.4.3 UART interrupts

The UART has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request:

The status interrupt combines the following interrupt sources:

Source	UART 0	UART 1	UART 2	UART 3	UART 4	UART 5
Transmit data empty	x	x	x	x	x	x
Transmit complete	x	x	x	x	x	x

*Table continues on the next page...*

Source	UART 0	UART 1	UART 2	UART 3	UART 4	UART 5
Idle line	x	x	x	x	x	x
Receive data full	x	x	x	x	x	x
LIN break detect	x	x	x	x	x	x
RxD pin active edge	x	x	x	x	x	x
Initial character detect	x	x	—	—	—	—

The error interrupt combines the following interrupt sources:

Source	UART 0	UART 1	UART 2	UART 3	UART 4	UART 5
Receiver overrun	x	x	x	x	x	x

## 3.10.5 FlexCAN

### 3.10.5.1 Instantiation

There are two instances of the FlexCAN module on this device: FlexCAN0 and FlexCAN1.

Each FlexCAN is implemented with 64 message buffers each.

## 3.10.6 MediaLB Device Module (MLB50)

### 3.10.6.1 Instantiation

There is one instance of the MLB50 module on R-Series devices.

The MLB50 module is only available on the BGA version of this device.

The module interfaces to Intelligent Network Interface Controller (INIC50) via 3 external signals:

- MLBCLK(I)
- MLBDAT(I/O)
- MLBSIG(I/O)

MLB50 supports 3.3 V I/O

The MLB interface operates at up to 50 MB/s. Thus, the minimum continuous bandwidth to be supported over the NIC to the system memory is 50 MB/s. Typical data bandwidths are much less, however the maximum continuous bandwidth must be provided to guarantee meeting the full specification.

The MediaLB module is to be interfaced to this device via the peripheral bus and the high speed NIC. The peripheral bus is used to interface to the MediaLB control/status registers via the peripheral bus interface (PBI). The PBI is a slave on the peripheral bus. The MLB module registers are memory mapped by the AIPS(0). Data is transferred between the MLB module and the system memory via the high speed NIC. The interface to the NIC is AHB.

## 3.10.7 SPI

### 3.10.7.1 SPI Instantiation

This device contains up to 4 SPI modules.

**Table 3-21. SPI Instances**

SPI	176 LQFP	364 BGA
No. of SPI	3	4
SPI0 CTAR	4	4
SPI1 CTAR	2	2

*Table continues on the next page...*

**Table 3-21. SPI Instances (continued)**

SPI	176 LQFP	364 BGA
SPI2 CTAR	2	2
SPI3 CTAR	N/A	2
SPI0 Chip Selects	6	6
SPI1 Chip Selects	4	4
SPI2 Chip Selects	2	2
SPI3 Chip Selects	N/A	2
TX FIFO SPI0	4	4
RX FIFO SPI0	4	4
TX FIFO SPI1	4	4
RX FIFO SPI1	4	4
TX FIFO SPI2	4	4
RX FIFO SPI2	4	4
TX FIFO SPI3	N/A	4
RX FIFO SPI3	N/A	4

**NOTE**

The SPI's de-serial interface (DSI) and timed serial bus (TSB) features are not supported on any SPI instance

The SPI module is clocked by the internal bus clock. The module has an internal divider, with a minimum divide of two. Thus, the SPI can run at a maximum frequency of bus clock/2.

**3.10.7.2 Number of PCS**

Depending on the number of DSPI instances, the number of PCS varies from 2 to 6.

For :

- DSPI0 - 6
- DSPI1 - 4
- DSPI2 - 2
- DSPI3 - 2

## 3.10.8 Inter-Integrated Circuit (I2C)

### 3.10.8.1 Instantiation Information

This device contains up to four I2C modules, I2C0, I2C1, I2C2, and I2C3.

## 3.11 Analog

### 3.11.1 12-bit Analog to Digital Converter (ADC)

#### 3.11.1.1 ADC Instantiation

This device contains a total of 16 ADC pin inputs. The ADC signals are distributed around the chip in order to optimize the flexibility in layout and feature trade off for the user.

The ADC conversion channel is selected by setting the Pin Mux control bit.

The 364 BGA offers dedicated ADC channels on pads apart from ADC channels muxed with GPIO.

**Table 3-22. ADC instantiation**

Features	176 LQFP	364 BGA
No of ADC modules	2	2
No of Differential Channels	Not Supported	Not Supported
No of Single Ended Channels(muxed with GPIO)	6 + 6	8+8
No of dedicated single Ended Channels	None	2+2
VREFH/VREFL	Yes	Yes

### 3.11.1.2 Voltage reference selection (REFSEL settings)

The bit field definition for ADCx\_CFG[REFSEL] is as follows for this chip:

**Table 3-23. ADCx\_CFG[REFSEL] settings**

Bit value	Definition
00	Selects VREFH/VREFL as reference voltage. VREFH/VREFL are connected to VREFH_ADC and VREFL_ADC pads.
01	Selects VALTH/VALTL as reference voltage. VALTH/VALTL are connected to ADC reference voltage (1.2V) from Voltage Regulator.
10	Selects VBGH/VBGL as reference voltage. VBGH/VBGL are connected to ADC reference voltage (1.2V) from Voltage Regulator. (Same as 01 above).
11	Reserved

### 3.11.1.3 DMA Support on ADC

Applications may require continuous sampling of ADC (4K samples/sec at minimum) that may have considerable load on CPU. Though using PDB to trigger ADC may reduce some CPU load, ADC need to support DMA for higher performance where ADC is sampled at very high rate or cases where PDB is bypassed. ADC should trigger on-chip DMA (via DMA req) on conversion completion.

### 3.11.1.4 ADC Channel Assignments

**Table 3-24. ADC Channel Assignments**

ADC Channel	ADC0	ADC1	Type
0	PAD[8]	PAD[6]	External
1	PAD[9]	PAD[7]	External
2	PAD[22]	PAD[24]	External
3	PAD[23]	PAD[25]	External
4	PAD[26]	PAD[27]	External
5	PAD[103]	PAD[104]	External
6	PAD[59]	PAD[61]	External
7	PAD[60]	PAD[62]	External
8	Dedicated PAD - ADC0SE8	Dedicated PAD - ADC1SE8	External
9	Dedicated PAD - ADC0SE9	Dedicated PAD - ADC1SE9	External
10	DAC0 - external output	DAC1 - external output	Internal
11	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA

*Table continues on the next page...*

**Table 3-24. ADC Channel Assignments (continued)**

ADC Channel	ADC0	ADC1	Type
12	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
13	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
14	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
15	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
16	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
17	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
18	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
19	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
20	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
21	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
22	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
23	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
24	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
25	VREF from dedicated pad or PMU (select one based on register programming of ADC)	VREF from dedicated pad or PMU (select one based on register programming of ADC)	Internal
26	Temperature Sensor	Temperature Sensor	Internal
27	VREF from PMU	VREF from PMU	Internal
28	HI-Z	HI-Z	NA
29	HI-Z	HI-Z	NA
30	HI-Z	HI-Z	NA
31	HI-Z	HI-Z	NA

### 3.11.1.5 ADC interconnections

**Table 3-25. ADC interconnections**

Trigger Module	Trigger	Trigger
ADC	ADC0	ADC0
PDB	Trig0	Trig1
LPTIMER	LPTIMER-Trig	LPTIMER-Trig

### 3.11.1.6 ADC Calibration

The device fuse map (Bank7-Word5 ) has been assigned to store the 16-bit calibrated value for ADC0 and ADC1. This calibrated value is derived at room temperature, with nominal voltage and with max averaging. This calibrated value can be copied from Fuses

to ADC register to avoid running calibration sequence at reset. Alternatively, the calibration sequence can be run after each and every reset. Refer to [Calibration Function](#) for details.

3.11.1.7 Temperature Sensor

The on-chip temperature sensor is connected to Channel 26 of both ADC0 or ADC1 so either ADC can be used to read the sensor data.

The current temperature is obtained by the simplified formula: Current temperature = 25 + (tempsensor\_count – 866) \* -0.437870

A more accurate temperature is obtained by using the calibration data that is stored in the e-fuses. Fuse map Bank1 Word6 holds calibration data for the temperature sensor. This calibration data is obtained during the device's test procedure before it leaves the factory.

See the TEMPSENSE register in OCOTP for details.

3.11.2 12-Bit Digital-to-Analog Converter (DAC)

3.11.2.1 12-bit DAC Instantiation

Table 3-26. 12-bit DAC Instantiation

	176 LQFP	364 BGA
Number of 12-bit DACs	2	2

3.11.2.2 12-bit DAC External Reference

For this device, external voltage supplied to VREFH\_ADC pin is the only reference voltage for DAC reference. You need to set up DACx\_STATCTRL[DACRFS]=1 to select the valid VREFH\_ADC reference. When DACx\_STATCTRL[DACRFS]=0, the DAC reference is connected to an internal ground node and is not a valid voltage reference. Be aware that if the DAC and ADC use the VREFH\_ADC reference simultaneously, some degradation of ADC accuracy is to be expected due to DAC switching.

### 3.11.2.3 DMA support on DAC

Applications may require continuous sampling of DAC (4K samples/sec at minimum) that may have considerable load on CPU. The DAC supports DMA for higher performance where the DAC is sampled at a very high rate. To trigger a DMA request, the DAC uses the watermark and buffer bottom and up flags. The DAC must trigger on-chip DMA (via DMA request) on conversion completion.

### 3.11.2.4 DAC interconnections

**Table 3-27. DAC interconnections**

DAC trigger from PDB	Connection
DAC0	DAC refresh trigger 0
DAC1	DAC refresh trigger 1

## 3.12 Display/Video interfaces

### 3.12.1 Display Control Unit

#### 3.12.1.1 Instantiation

The DCU4 modules connect to the NIC301 as bus masters.

Each DCU4 interface is a 64-bit AXI

Each DCU features an APB interface for control.

HSYNC/VSYNC, DE and Pixel Clock connect to I/O as well as to inputs of a TCON module for generation of additional timing signals

### 3.12.2 Timing Controller (TCON)

#### 3.12.2.1 Instantiation

Number of TCON instances: 2 (one for each DCU)

Number of timing channels: 12

### 3.12.3 RLE Decoder (RLE)

#### 3.12.3.1 Instantiation

Number of RLE\_DEC instances: 1

Module is disabled by default.

### 3.12.4 Segmented LCD Controller

#### 3.12.4.1 Instantiation

There is one instance of the LCD module on this device that is connected to the AIPS peripheral bridge.

#### 3.12.4.2 Number of Front and Back Planes

**Table 3-28. Number of Front and Back Planes**

Parameter	Value
Number of front planes <sup>1</sup>	36 or 38 or 40
Number of back planes <sup>2</sup>	4 or 6 or 8

1. Software-configurable. Default assignment is 40 FP and 4 BP. BP0-3 are located on pads LCD40-43. FP0-39 are located at pads LCD0-39.
2. Software-configurable. See [LCD Driver Backplane Remapping](#) for different configurations.

#### 3.12.4.3 LCD clock selection

The LCD module can be optionally clocked by the system bus clock, the internal 128 KHz IRC or the external 32 KHz crystal clock.

Mode	Description
Normal Run Mode	In normal run modes the LCD is clocked by the system clock.
Low Power Mode	In low power modes of operation to conserve power the LCD module is optionally clocked by the internal 128 KHz IRC or the 32 KHz external crystal oscillator. These two clock sources are available in the low power domains.

The following table shows the clocks selected by the LCDCR[LCDOCS] bit.

**Table 3-29. LCD Clock Selection Based on LCDCR[LCDOCS]**

Value of LCDCR[LCDOCS]	Clock selected
1	32 kHz OSC
0	128 kHz OSC

#### 3.12.4.4 Settings during STANDBY mode

To keep the LCD driver shut down in STANDBY mode, the following settings are needed:

- LCDCR[LCDRST] = 0
- LCDCR[LCDRCS] = 0

To keep the LCD driver on (functioning) in STANDBY mode, the following settings are needed:

- LCDCR[LCDRST] = 1
- LCDCR[LCDRCS] = 1
- LCDCR[LCDOCS] = 0 or 1
  - If this field is 0, the LCD driver will operate from SIRC.
  - If this field is 1, the LCD driver will operate from SXOSC.

#### 3.12.4.5 Segment LCD configuration

In this device the LCD module will be part of the Low Power Domain to enable LCD display content to be maintained. For the display to be updated the MPU must wake up from Low Power mode.

**NOTE**

The device does not support 5V I/O, therefore the LCD module will interface only to 3.6V glass.

**Table 3-30. Number of Front and Back Planes**

Parameter	Value
Number of Front Planes	40 or 38 or 36
Number of Back Planes	4 or 6 or 8

**NOTE**

There are only ten LCDRAM registers (LCDRAM0-LCDRAM9) implemented on this device. The other registers (LCDRAM10-LCDRAM15) that are described in the LCD chapter are not available on this device.

**3.12.5 Video Interface Unit(VIU)**

**3.12.5.1 Instantiation**

Number of VIU3 instances: 1

**3.12.6 Video ADC(VADC)**

**3.12.6.1 Instantiation**

This device features one instance of the VideoADC

The VideoADC accepts up to 4 single-ended analog inputs.

The VideoADC digital output interfaces directly to the VIU module as shown below.

**NOTE**

This mux is controlled by the MISC2 register in the SRC module.

## 3.13 Audio Subsystem

### 3.13.1 Audio Subsystem Modules

#### 3.13.1.1 Audio Subsystem Overview

The modules that belong to the audio subsystem are the SAI0, SAI1, SAI2, SAI3, ESAI, ESAI\_BIFIFO, SPDIF and ASRC. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

SAI0-3 are synchronous audio interfaces used to transfer audio data. SAI0-3 are on the peripheral bus.

The ESAI (Enhanced Serial Audio Interface) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. The ESAI is connected to the IOMUX and to the ESAI\_BIFIFO module.

The ESAI\_BIFIFO (ESAI Bus Interface and FIFO) is the interface between the ESAI module and the shared peripheral bus. It contains the FIFOs used to buffer data to/from the ESAI, as well as providing the data word alignment and padding necessary to match the 24-bit data bus of the ESAI to the 32-bit data bus of the shared peripheral bus.

The SPDIF (Sony/Philips Digital Interface) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system. The SPDIF is connected to the shared peripheral bus.

The ASRC is a hardware audio sample rate converter supporting up to 10 channels split into 3 sampling rate pairs.

### 3.13.1.2 Synchronous Audio Interface (SAI)

The Synchronous Audio Interface (SAI) implements supports full-duplex serial interfaces with frame synchronization such as I2S, AC97, and codec/DSP interfaces.

This device implements four SAI modules. SAI0-2 are required for connected radio applications with Radio Tuner devices. SAI3 is added to support future expansion.

The following table shows the configuration of the SAIs:

**Table 3-31. SAI Configurations**

SAI Instance	Tx Data Lines	Rx Data Lines	Tx FIFO Depth	Rx FIFO Depth
SAI0	1	1	32	32
SAI1	1	1	32	32
SAI2	1	1	32	32
SAI3	1	1	64	64

#### 3.13.1.2.1 SAI3 register details

The dedicated SAI chapter documents the identically instantiated SAI0, SAI1, and SAI2. The following table summarizes SAI3 register details that differ from the other module instances.

**Table 3-32. SAI3 register differences from other SAI instances**

Instance	TCR1[TFW] and RCR1[RFW]	TFR[WFP], TFR[RFP], RFR[WFP], and RFR[RFP]
SAI3	Each field is 6 bits wide	Each field is 7 bits wide

### 3.13.1.2.2 Simultaneous SAI DMA requests

If all four instances of the SAI module issue DMA requests simultaneously, DMA must be configured in round robin arbitration mode.

### 3.13.1.2.3 SAI transmitter and receiver options for MCLK selection

For an internally generated bit clock of the transmitter or receiver, all SAI instances have the same options for selecting an audio master clock (MCLK) source. TCR2[MSEL] and RCR2[MSEL] independently select the MCLK source for the transmitter and receiver, respectively. The following table shows the MSEL settings and the corresponding available MCLK sources on this device.

**Table 3-33. SAI<sub>n</sub> transmitter and receiver options for MCLK selection**

TCR2[MSEL] or RCR2[MSEL]	MCLK source for internally generated bit clock of transmitter or receiver
00	Bus Clock
01	Clock selected by CCM_CSCMR1[SAI <sub>n</sub> _CLK_SEL]
10	Not supported
11	Not supported

### 3.13.1.2.4 SAI in Stop mode

MCU wakeup from an SAI module is not supported because the SAI clock is gated in Stop mode. Before the MCU enters Stop mode, you must disable operation of the SAI transmitter and receiver in Stop mode. More specifically:

1. In the SAI, program TCSR[STOPE] and RCSR[STOPE] to 0.
2. Execute the MCU's entry to Stop mode.

### 3.13.1.3 Enhanced Serial Audio Interface (ESAI)

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors.

The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. All serial transfers are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is also intended for periodic transfers; however, it supports up to 32 words (time

slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

The ESAI has 12 pins for data and clocking connection to external devices. The ESAI is internally connected to the ESAI\_BIFIFO, and does not connect directly to the shared peripheral bus. The ESAI interface is designed for a 24-bit data bus, while the shared peripheral data bus is 32-bit wide. Also, the ESAI data paths are only double buffered, not allowing efficient DMA service in the applications processor environment. The ESAI\_BIFIFO allows increasing the data buffering and data width matching to the shared peripheral bus.

### 3.13.1.4 ESAI Bus Interface and FIFO (ESAI\_BIFIFO)

The ESAI\_BIFIFO (ESAI Bus Interface and FIFO) is the interface between the ESAI module and the shared peripheral bus. It contains the FIFOs used to buffer data to/from the ESAI, as well as providing the data word alignment and padding necessary to match the 24-bit data bus of the ESAI to the 32-bit data bus of the shared peripheral bus..

There are two independent 128-word FIFOs, one servicing the ESAI transmit section, shared by the 6 ESAI transmitters, while the other 128-word FIFO services the ESAI receive section, shared by the 4 ESAI receivers. Each FIFO has a programmable watermark level where it can trigger a DMA service request.

The ESAI 24-bit data words are aligned and formatted according to the Transmit Word Alignment and Receive Word Alignment controls.

## 3.14 Miscellaneous

### 3.14.1 GPIO

#### 3.14.1.1 GPIO Mapping

**Table 3-34. RGPIO versus Pins**

RGPIO	In GPIO module	Corresponding Pin on the chip	IOMUX register name	IOMUX register address
RGPIO[0]	PORT0[0]	PTA6	IOMUXC_PTA6	40048000
RGPIO[1]	PORT0[1]	PTA8	IOMUXC_PTA8	40048004
RGPIO[2]	PORT0[2]	PTA9	IOMUXC_PTA9	40048008

*Table continues on the next page...*

**Table 3-34. RGPIO versus Pins (continued)**

RGPIO	In GPIO module	Corresponding Pin on the chip	IOMUX register name	IOMUX register address
RGPIO[3]	PORT0[3]	PTA10	IOMUXC_PTA10	4004800C

### 3.14.1.2 Configuring a pin as GPIO

To program a pin as GPIO:

1. Program the corresponding register in IOMUX. For example, to configure PORT0-pin16 (PTA16), program IOMUXC\_PTA16.
2. Program proper ALT mode in this register and program IBE (for Input) and OBE (for Output).
3. Program the GPIO registers (PDOR, PSOR, PCOR, PTOR, PDIR) you can set/reset this pin or read from this pin.

#### NOTE

For details about IOMUX and GPIO registers, see the respective chapters of this document.

### 3.14.1.3 Port 4 Register Differences

In this device, 135 PADs are implemented across 5 RGPIO port instances as  $4 \times 32 + 7$ . The last instance has only 7 PAD control registers. The dedicated RGPIO chapter documents the identically instantiated Port 0, 1, 2, and 3. The following table summarizes Port E register details that differ from the other module instances.

**Table 3-35. Port 4 register differences from other Port instances**

Instance	Port Data Output Register (GPIO_PDOR)	Port Data Input Register (GPIO_PDIR)
Port 4	PDO[6:0] field is 7 bits wide	PDI [6:0] field is 7 bits wide

# Chapter 4

## Memory Map

### 4.1 System memory map

The following table shows the high-level device memory map.

**Table 4-1. Device Memory Map**

CM4 Address Range [Start Addr - End Addr]	Size [MB]	CM4 Alias	System Address (A5) [Start Addr - End Addr]	Region Description
0x0000_0000 - 0x007f_ffff	8	0x0000_0000	0x0000_0000-0x007f_ffff	Boot ROM
0x0080_0000-0x0fff_ffff	248	0x8080_0000	Reserved	CM4 DDR code alias
0x1000_0000-0x17ff_ffff	128	0x2000_0000	Reserved	CM4 QuadSPI0 code alias
0x1800_0000-0x1eff_ffff	112	0x3000_0000	Reserved	CM4 FlexBus code alias
0x1f00_0000-0x1f7f_ffff	8	0x3f00_0000	Reserved	CM4 OCRAM code alias
0x1f80_0000-0x1fff_ffff	8	N/A	0x1f80_0000-0x1fff_ffff	CM4 TCML (code)
0x2000_0000-0x2fff_ffff	256	0x2000_0000	0x2000_0000-0x2fff_ffff	QuadSPI0 Memory
0x3000_0000-0x3eff_ffff	240	0x3000_0000	0x3000_0000-0x3eff_ffff	FlexBus
0x3f00_0000- 0x3F03_FFFF	0.25	0x3f00_0000	0x3f00_0000-0x3F03_FFFF	OCRAM - SysRAM0
0x3F04_0000 - 0x3F07_FFFF	0.25	0x3F04_0000	0x3F04_0000 - 0x3F07_FFFF	OCRAM - sysRAM1
0x3F08_0000 - 0x3F3F_FFFF	3.50	N/A	Reserved	Reserved
0x3f40_0000-0x3f47_ffff	.5	0x3f40_0000	0x3f40_0000-0x3f47_ffff	OCRAM - gfxRAM0
0x3f48_0000-0x3f4f_ffff	.5	0x3f48_0000	0x3f48_0000-0x3f4f_ffff	OCRAM – gfxRAM1 / L2 cache
0x3f50_0000-3f7f_ffff	3	N/A	Reserved	Reserved
0x3f80_0000-0x3fff_ffff	8	N/A	0x3f80_0000-0x3fff_ffff	CM4 TCMU (data)

0x7a00_0000-0x7bff_ffff	32	0x7a00_0000	0x7a00_0000 - 0x7bff_ffff	QuadSPI1 Rx buffer
0x7c00_0000-0x7dff_ffff	32	0x7c00_0000	0x7c00_0000 - 0x7dff_ffff	QuadSPI0 Rx buffer
0x7e00_0000-0x7e7f_ffff	8	0x7e00_0000	0x7e00_0000 - 0x7e7f_ffff	gfxRAM- RGB565 view
0x7e80_0000-0x7eff_ffff	8	0x7e80_0000	0x7e80_0000 - 0x7eff_ffff	gfxRAM- ARGB1555 view
0x7f00_0000-0x7f7f_ffff	8	0x7f00_0000	0x7f00_0000 - 0x7f7f_ffff	gfxRAM- ARGB4444 view
0x7f80_0000-0x7fff_ffff	8	N/A	Reserved	Reserved
0x8000_0000-0xdfff_ffff	1536		0x8000_0000-0xdfff_ffff	DDR
0xe000_0000-0xffff_ffff	512	N/A	Reserved	CM4 Private Peripheral Bus (PPB)
	512	N/A	0xe000_0000-0xffff_ffff	DDR (A5 only)

**NOTE**

64 KB/16 KB SRAM, which is retained in LPSTOP modes occupies the lower part of OCRAM-SysRAM0

**NOTE**

For OCRAM-gfxRAM region (0x3f40\_0000-0x3f4f\_ffff), if there is no L2 cache on the device, the entire 1 MB space based at 0x3f40\_0000 is allocated to gfxRAM. If the device has L2 cache, the first 512 KB (0x3f40\_0000 - 0x3f47\_ffff) is allocated to gfxRAM and the upper 512 KB is allocated to the L2 Cache data array.

**NOTE**

If there is an access to reserved/illegal memory space, then the system may hang, requiring a reset to recover. There is no time-out mechanism to recover from this scenario.

## 4.2 Peripheral Bridge 0 (AIPS-Lite 0) Memory Map

**NOTE**

Not all features are available on each device. For the features enabled on a specific part, refer to the data sheets.

**Table 4-2. Peripheral bridge 0 slot assignments**

**NOTE**

Access to non-implemented registers in the following modules may result in unwanted behavior:

- UART
- MLB
- NFC
- IOMUX
- ASRC
- SPDIF
- VIU
- TCON
- USB
- OCOTP
- ANADIG
- SDHC

## 4.4 Private Peripheral Bus (PPB) memory map

The PPB is part of the defined ARM bus architecture and provides access to select processor-local modules. These resources are only accessible from the core; other system masters do not have access to them.

**Table 4-4. PPB memory map**

System 32-bit Address Range	Resource
0xE000_0000–0xE000_0FFF	Instrumentation Trace Macrocell (ITM)
0xE000_1000–0xE000_1FFF	Data Watchpoint and Trace (DWT)
0xE000_2000–0xE000_2FFF	Flash Patch and Breakpoint (FPB)
0xE000_3000–0xE000_DFFF	Reserved
0xE000_E000–0xE000_EFFF	System Control Space (SCS) (for NVIC and FPU)
0xE000_F000–0xE004_0FFF	Reserved
0xE004_1000–0xE004_1FFF	Embedded Trace Macrocell (ETM)
0xE004_2000–0xE004_2FFF	Embedded Trace Buffer (ETB)
0xE004_3000–0xE004_3FFF	Embedded Trace Funnel
0xE004_4000–0xE004_4FFF	Cross Trigger Interface (CTI)
0xE005_0000–0xE007_4FFF	Reserved
0xE008_0000–0xE008_0FFF	Miscellaneous Control Module (MCM)
0xE008_1000–0xE008_1FFF	Reserved
0xE008_2000–0xE008_2FFF	Cache Controller
0xE008_3000–0xE00F_EFFF	Reserved
0xE00F_F000–0xE00F_FFFF	ROM Table - allows auto-detection of debug components

# Chapter 5

## Chip IO and Pinmux

### 5.1 Pinouts

For part number and package-specific pinout details, refer to the data sheets.

A [Quick Reference Guide](#) to the pinouts can also be found at the end of this document.

### 5.2 Input/Output Multiplexer Controller (IOMUXC)

#### 5.2.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the device to share one pad to several functional blocks. The sharing is done by multiplexing the pad input/output signals.

Every module requires a specific pad setting (such as pull up, keeper, and so on). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic iomux cells. Each basic iomux cell handles only one pad signal's muxing.

#### NOTE

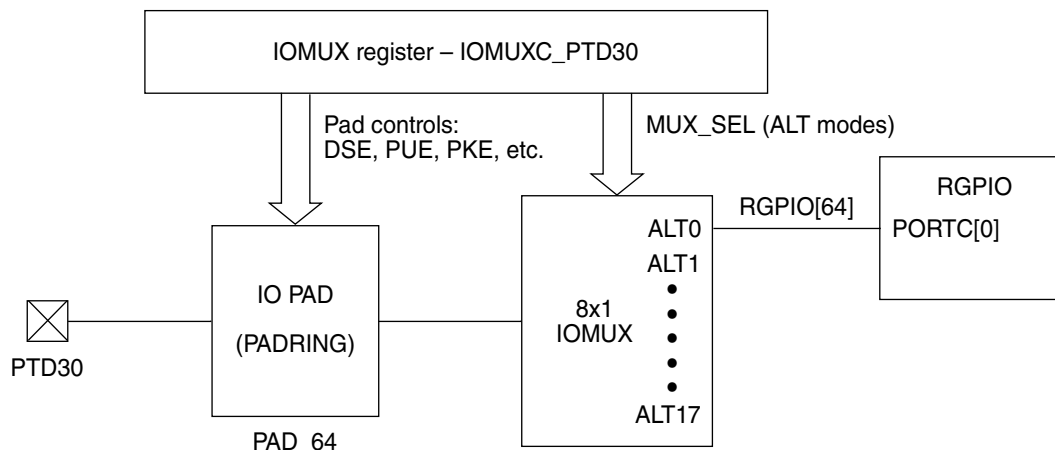

IOMUX registers control the PAD settings. To see the PAD mapping on this device with the PORT pins, refer to [GPIO Mapping](#)

#### NOTE

For TCON[x] signals, like tcon0 refer to DCU0\_TCONx signal and tcon1 refer to DCU1\_TCONx signal in the Pinouts table.

## 5.2.2 Functional Description

IOMUX module is used to configure the Pad settings through the IOMUX registers and multiplex multiple modules on to a single PAD and drive input to a module from multiple PADs. Muxing is done only on obe, ibe, ind and do and rest of the pad settings are through IOMUX registers. DDR pads are dedicated pads for DDR and there is no muxing on them.

**Figure 5-1. Path from the pint PTD30 to RGPIO**

The figure below shows the GPIO Pad .

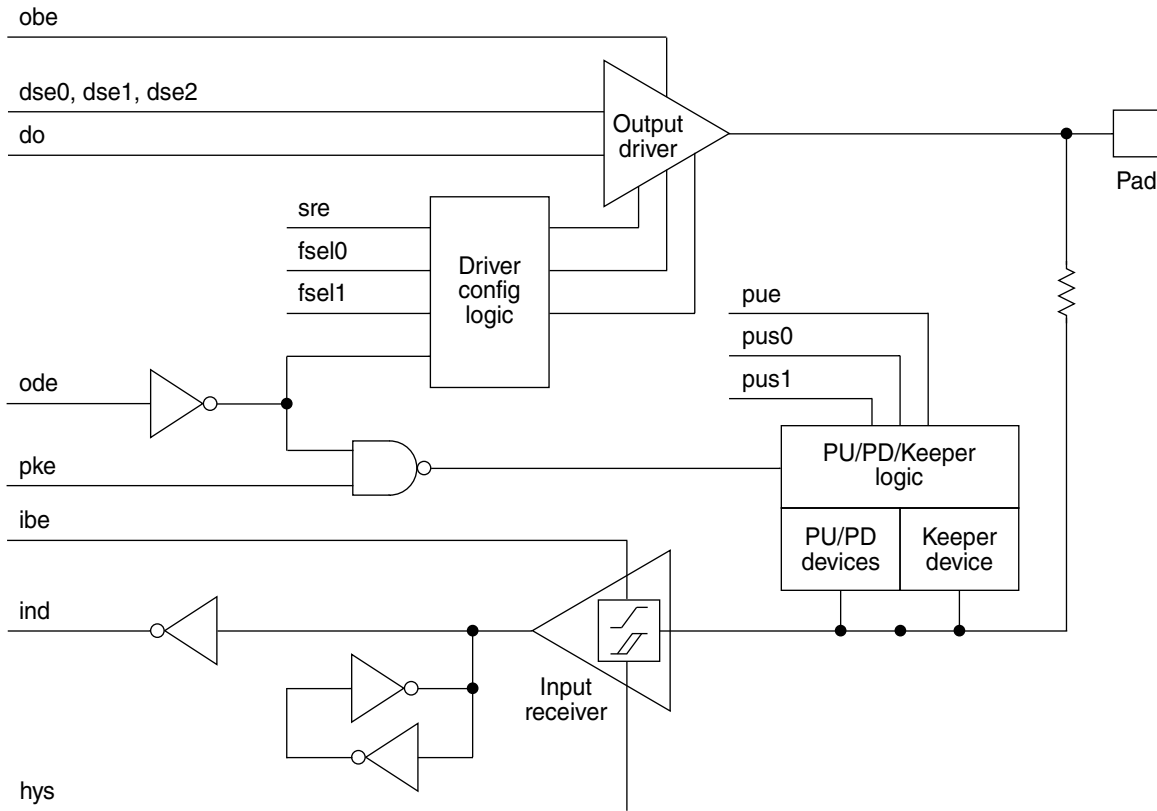

Figure 5-2. GPIO PAD

Table 5-1. Signal Description

Signal Name	Description	Description
Pad	Input/Output	I/O to external world
do	Input	Data coming from the core into the pad
obe	Input	Output enable
ode	Input	Select open drain or CMOS output
dse	Input	Drive Strength select
sre	Input	Slew rate of output buffer
fsel1, fsel0	Input	Slew rate control (SPEED setting)
pke	Input	Enable pull up, pull down and keeper capability
pue	Input	Enable pull-up/down or keeper
pus	Input	Pull-up/down select
ibe	Input	Input enable
ind	Output	Data coming out of the pad into the core
hys	Input	Select Schmitt trigger or CMOS input

**NOTE**

For DDR pads, there are additional control signals as explained in IOMUX register map to control DDR functionality.

**Table 5-2. Truth Table**

ode	obe	pke	pue	pus	do	dse	pad
Output Buffer Mode (functional)							
0	1	0	X	X	do	001, 010, 011, 100, 101, 110, 111	do
0	1	0	X	X	do	0	Z
0	0	0	X	X	X	X	Z
Output Buffer Mode + Keeper							
0	0	1	0	X	X	X	pad (keep previous state)
Output Buffer Mode + pull-up/pull-down resistors							
0	0	1	1	0	X	X	weak0 (pull-down 100 KOhm)
0	0	1	1	1	X	X	weak1 (pull-up 47 KOhm)
0	0	1	1	10	X	X	weak1 (pull-up 100 KOhm)
0	0	1	1	11	X	X	weak1 (pull-up 22 KOhm)
Open Drain Mode							
1	1	0	X	X	do	001, 010, 011, 100, 101, 110, 111	do
0	1	0	X	X	do	0	Z
1	0	0	X	X	X	X	Z
Open Drain Mode + Keeper/Pull-down							
1	1	1	0	X	0	X	0 (open drain + keeper)
1	1	1	0	X	1	X	weak0 (keeper)
1	1	1	1	0	1	X	0 (open drain + pull-down)
Open Drain Mode + Pull-up							
1	1	1	1	1	0	X	0 (open drain + pull-up 47 KOhm)
1	1	1	1	10	0	X	0 (open drain + pull-up 100 KOhm)

Table continues on the next page...

**Table 5-2. Truth Table (continued)**

ode	obe	pke	pue	pus	do	dse	pad
1	1	1	1	11	0	X	0 (open drain + pull-up 22 KOhm)
1	1	1	1	1	1	X	weak1 (open drain +pull-up 47 KOhm)
1	1	1	1	10	1	X	weak1 (open drain +pull-up 100 KOhm)
1	1	1	1	11	1	X	weak1 (open drain +pull-up 22 KOhm)
1	0	0	X	X	X	X	Z
1	0	1	0	X	X	X	pad (keep previous state)

**Table 5-3. Truth Table - Pad to Core**

ibe	pad	ind (keep previous state)
0	X	ind
1	pad	pad

### 5.2.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the IOMUXC\_SW\_MUX\_CTL\_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the IOMUXC\_SW\_MUX\_CTL\_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

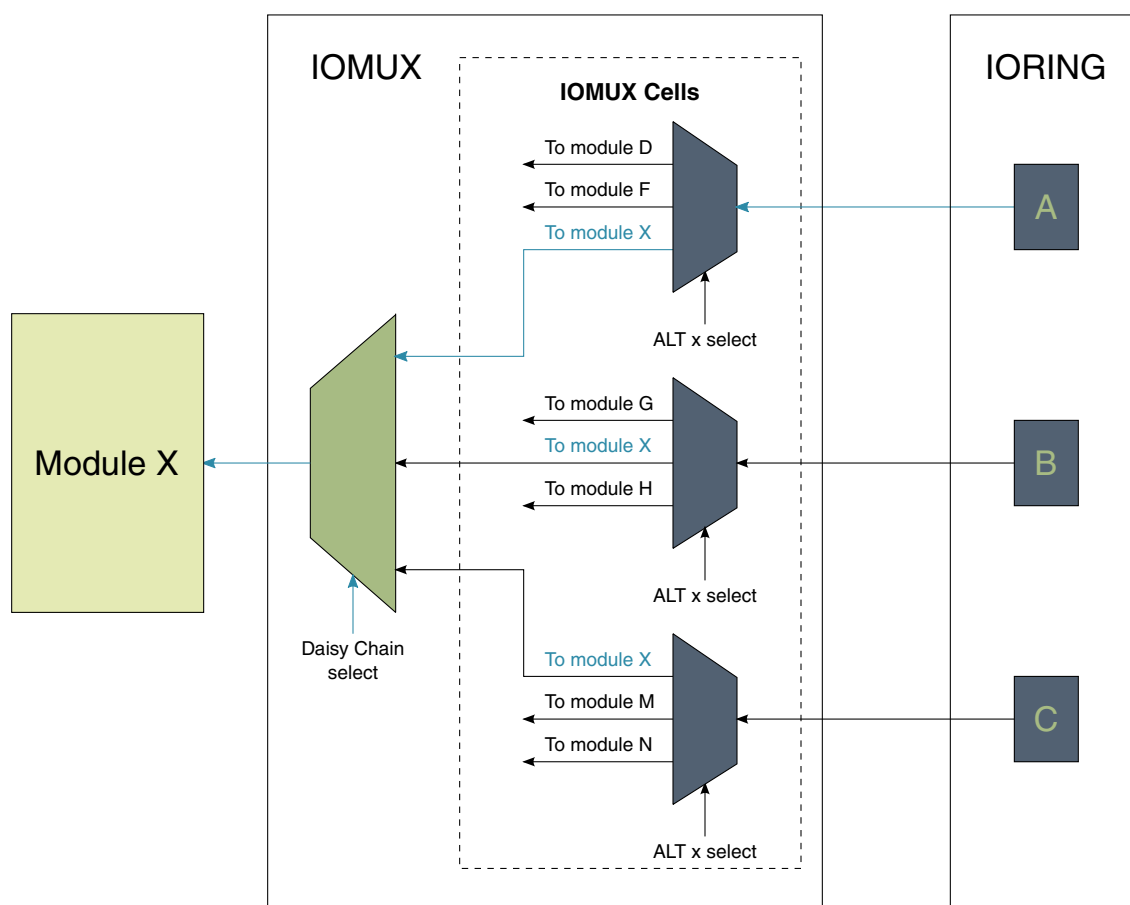

Figure 5-3. Daisy chain illustration

## 5.2.4 IOMUXC register groups

The main groups of the IOMUXC registers are:

- The General Purpose Registers IOMUXC\_GPR[13:0] are used to select operating modes for general features in the SoC, usually not related to the IOMUX itself.
- The Software MUX Control Registers are used to configure the IOMUX muxing, and "connect" the pad to a given port in a module.
- The PAD Settings Registers are used to control the pad settings configuration. For some pads (in order to save chip route) the pad settings are grouped in one register; changing the group register will affect the settings for all pads in the group.

[IOMUXC](#) shows the IOMUXC register summary.

## 5.2.5 Memory map and register definition

**IOMUXC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

#### IOMUXC\_PTA6 field descriptions

Field	Description
31–23 Reserved	This field is reserved.
22–20 MUX_MODE	<p>MUX Mode Select Field. Select 1 of 5 IOMUX modes to be used for pad: PTA6.</p> <p><b>NOTE:</b> Pad PTA6 is involved in Daisy Chain.</p> <ul style="list-style-type: none"> <li>Config CCM_ENET_EXT_CLK_SELECT_INPUT for mode ALT2.</li> </ul> <p>000 Select mux mode: ALT0 mux port: GPIO[0] of instance: rgpioc.            001 Select mux mode: ALT1 mux port: RMII_CLKOUT of instance: ccm.            010 Select mux mode: ALT2 mux port: RMII_CLKIN of instance: ccm. Used as MAC0-TXCLK when MAC0-MII is enabled.            100 Select mux mode: ALT4 mux port: TCON[11] of instance: tcon1.            111 Select mux mode: ALT7 mux port: DATA_OUT[20] of instance: tcon1.</p>
19–14 Reserved	This field is reserved.
13–12 SPEED	<p>Speed Field. Select one of the following values for pad: PTA6.</p> <p>00 Low (50 MHz)            01 medium (100MHz)            10 medium (100MHz)            11 high (200MHz)</p>
11 SRE	<p>Slew Rate Field. Select one of the following values for pad: PTA6.</p> <p>0 Slow Slew Rate            1 Fast Slew Rate</p>
10 ODE	<p>Open Drain Enable Field. Select one of the following values for pad: PTA6.</p> <p>0 Output is CMOS            1 Output is open drain</p>
9 HYS	<p>Hysteresis Enable Field. Select one of the following values for pad: PTA6.</p> <p>0 CMOS input            1 Schmitt trigger input</p>
8–6 DSE	Drive Strength Field. Select one of the following values for pad: PTA6.

Table continues on the next page...

**IOMUXC\_PTA6 field descriptions (continued)**

Field	Description
	000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm (40 Ohm if pad is DDR) 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: PTA6.  00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: PTA6.  0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: PTA6.  0 Keeper enable 1 Pull enable
1 OBE	Output Buffer Enable Field. Select one of the following values for pad: PTA6.  0 Disabled 1 Enabled
0 IBE	Input Buffer Enable Field. Select one of the following values for pad: PTA6.  0 Disabled 1 Enabled

<b>Field</b>	<b>Description</b>
10 ODE	Open Drain Enable Field. Select one of the following values for pad: PTE3. 0 Output is CMOS 1 Output is open drain
9 HYS	Hysteresis Enable Field. Select one of the following values for pad: PTE3. 0 CMOS input 1 Schmitt trigger input
8–6 DSE	Drive Strength Field. Select one of the following values for pad: PTE3. 000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm (40 Ohm if pad is DDR) 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: PTE3. 00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: PTE3. 0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: PTE3. 0 Keeper enable 1 Pull enable
1 OBE	Output Buffer Enable Field. Select one of the following values for pad: PTE3. 0 Disabled 1 Enabled
0 IBE	Input Buffer Enable Field. Select one of the following values for pad: PTE3. 0 Disabled 1 Enabled

**IOMUXC\_DDR\_DQS\_0 field descriptions (continued)**

Field	Description
16 DDR_INPUT	DDR / CMOS Input Mode Field. Select one of the following values for pad: DDR_DQS_0. 0 CMOS input type 1 Differential input mode
15–14 DDR_TRIM	DDR TRIM Field. Select one of the following values for pad: DDR_DQS_0. 00 Minimum do->pad delay 01 50 ps do->pad delay 10 100 ps do->pad delay 11 150 ps do->pad delay
13–10 Reserved	This field is reserved.
9 HYS	Hysteresis Enable Field. Select one of the following values for pad: DDR_DQS_0. 0 CMOS input 1 Schmitt trigger input
8–6 DSE	Drive Strength Field. Select one of the following values for pad: DDR_DQS_0. 000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm (40 Ohm if pad is DDR) 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: DDR_DQS_0. 00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: DDR_DQS_0. 0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: DDR_DQS_0. 0 Keeper enable 1 Pull enable
Reserved	This field is reserved.

### 5.2.5.180 Software MUX DDR RAS Pad Control Register (IOMUXC\_DDR\_RAS\_B)

5.2.6

Special Pad Settings

This section describes the special pad setting requirements for several modules in this device. DDR Pins are dedicated pins and do not have any alternate functionality on them. The settings of DDR Pins are controlled by IOMUX as well as DDR module. GPIO Pin settings (speed, sre, ode, hys, dse, pus, pke,pue) are controlled by IOMUX registers, however, special care needs to be taken for ibe/obe. The input buffer of the Pin is enabled by ibe bit in IOMUX register. The output buffer of the Pin is enabled by obe bit of IOMUX only if ALT Mode is configured as GPIO. In other ALT modes, the module configured for ALT mode drives the obe signal to output buffer of Pin and obe bit of IOMUX will have no effect. This is done to reduce the propagation delay it takes for module to enable ibe and data from pin to reach module. This helps to ease timing requirements for modules which enable/disable input buffer dynamically.

### 5.2.6.1 DUMMY PADS (DDR/QuadSPI)

There are two dummy pads that are useful for timing calibration of DDR. These pads are internal only, but their corresponding IOMUX register need to be programmed for correct operation of DDR. These registers are:

- IOMUXC\_DUMMY\_DDRBYTE1 (0x400482DC)
- IOMUXC\_DUMMY\_DDRBYTE2 (0x400482E0)

DDR: Dummy pads for DDR must be configured before any DDR I/O transactions are done. These pads simulate the input delay of the I/O buffers from the DRAM devices and DDR configures the delays accordingly.

QuadSPI: Dummy pads for QuadSPI can be used to loopback clock while interfacing with devices that do not provide external DQS.

### 5.2.6.2 SDHC

Although SDHC\_DCLK is output-only signal, `ibe` needs to be enabled as the module requires output clock to be looped-back through the pad's input buffer to ease timing requirements.

### 5.2.6.3 I2C

I2C pins, SCL and SDA are both Open-drain and bi-directional. Hence, ODE bit should be set in IOMUX registers and `ibe` enabled.

### 5.2.6.4 FlexBus

Flexbus module provides CSPMCR register for additional muxing apart from IOMUX. These registers may need to be programmed depending on the use-case desired.

### 5.2.6.5 LCD/ADC

When a pad is configured for LCD or ADC by programming appropriate ALT\_MODE, ensure that both `ibe/obe` of the pad are disabled and all pulls/keeper are disabled as well. This is because input and output buffer are for digital inputs and analog signals from/to LCD/ADC are connected through a resistor directly to pad. If `ibe/obe/pke` are set, then there will be leakage and potential performance degradation.

### 5.2.6.6 SCI

Pull-ups should be enabled to ensure there are no spurious transitions.

### 5.2.6.7 Reset Pin Configuration

The configuration of Reset Pin cannot be changed and is not controllable through IOMUX. Its configuration is fixed as follows:

- Speed: 100 Mhz
- Slew Rate: Slow
- Open Drain: Disable (Output is CMOS)
- Hysteresis: Disable (CMOS input)
- Drive Strength: 25 Ohm
- Pull Up/Down: 100KOhm Pull-UP
- Pull/Keep Enable: Enable
- Pull/Keep Select: Pull Selected
- ibe/obe/do/ind: Controlled through Reset Controller

### 5.2.6.8 Typical IOMUX Configuration

The table below shows the typical IOMUX configuration of pads for different modules on this device. This is sample configuration only and will change based on the instance of the module and pads involved.

**Table 5-4. Typical IOMUX Configuration**

Module Name	Signal Name	Direction	SPEED	HYS	ODE	PUE	SRE	DSE	PUS	PKE	IBE
ENET	RMII0_CRS_DV	Input	0	0	0	0	0	7	0	0	1

## 5.3 Port Control and Interrupts (PORT)

### 5.3.2 Features

The PORT module has the following features:

- Pin interrupt
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
  - Support for interrupt or DMA request configured per pin
  - Asynchronous wake-up in low-power modes
  - Pin interrupt is functional in all digital pin muxing modes
- Digital input filter
  - Digital input filter for each pin
  - Individual enable or bypass control field per pin
  - Selectable clock source for digital input filter with a five bit resolution on filter size
  - Functional in GPIO mode only

### 5.3.3 Modes of operation

#### 5.3.3.1 Run mode

In Run mode, the PORT operates normally.

#### 5.3.3.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

#### 5.3.3.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

In Stop mode, the digital input filters are bypassed unless they are configured to run from the 32-KHz FXOSC clock source.

#### 5.3.3.4 Debug mode

In Debug mode, PORT operates normally.

**PORT memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 5.3.7 Pin Control Register n (PORTx\_PCRn)

#### NOTE

See the Signal Multiplexing and Pin Assignment chapter for the reset value of this device.

See the GPIO Configuration section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins that are not available in a reduced-pin package offering. Unbonded pins not available in a package are disabled by default to prevent them from consuming power.

Address: Base address + 0h offset + (4d × i), where i=0d to 31d

#### PORTx\_PCRn field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 ISF	Interrupt Status Flag The pin interrupt configuration is valid in all digital pin muxing modes.  0 Configured interrupt is not detected. 1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 IRQC	Interrupt Configuration

Table continues on the next page...

**PORTx\_PCRn field descriptions (continued)**

Field	Description
	<p>The pin interrupt configuration is valid in all digital pin muxing modes. The corresponding pin is configured to generate interrupt/DMA request as follows:</p> <p>0000 Interrupt Status Flag (ISF) is disabled.  0001 ISF flag and DMA request on rising edge.  0010 ISF flag and DMA request on falling edge.  0011 ISF flag and DMA request on either edge.  0100 Reserved.  0101 Reserved.  0110 Reserved.  0111 Reserved.  1000 ISF flag and Interrupt when logic 0.  1001 ISF flag and Interrupt on rising-edge.  1010 ISF flag and Interrupt on falling-edge.  1011 ISF flag and Interrupt on either edge.  1100 ISF flag and Interrupt when logic 1.  1101 Reserved.  1110 Reserved.  1111 Reserved.</p>
Reserved	<p>This field is reserved.  This read-only field is reserved and always has the value 0.</p>

**5.3.8 Interrupt Status Flag Register (PORTx\_ISFR)**

The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Pin Control Register, and each flag can be cleared in either location.

Address: Base address + A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**PORTx\_DFWR field descriptions**

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FILT	Filter Length  The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches, in clock cycles, that the digital filter absorbs for the enabled digital filters. Glitches that are longer than this register setting will pass through the digital filter, and glitches that are equal to or less than this register setting are filtered. Changing the filter length must be done only after all filters are disabled.

**5.3.38 External interrupts**

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Active high level sensitive interrupt
- Active low level sensitive interrupt

- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin or at the output of the digital input filter, if the digital input digital filter is enabled. When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT\_ISFR or PORT\_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

### **5.3.39 Digital filter**

The digital filter capabilities of the PORT module are only available for GPIO inputs. All other pin functions are not filtered.

The clock used for all digital filters within one port can be configured between the bus clock or the 32-KHz FXOSC clock. This selection must be changed only when all digital filters for that port are disabled. If the digital filters for a port are configured to use the bus clock, then the digital filters are bypassed for the duration of Stop mode. While the digital filters are bypassed, the output of each digital filter always equals the input pin, but the internal state of the digital filters remains static and does not update due to any change on the input pin.

The filter width in clock size is the same for all enabled digital filters within one port and must be changed only when all digital filters for that port are disabled.

The output of each digital filter is logic zero after system reset and whenever a digital filter is disabled. After a digital filter is enabled, the input is synchronized to the filter clock, either the bus clock or the 32-KHz FXOSC clock. If the synchronized input and the output of the digital filter remain different for a number of filter clock cycles equal to the filter width register configuration, then the output of the digital filter updates to equal the synchronized filter input.

The maximum latency through a digital filter equals three filter clock cycles plus the filter width configuration register.

## 5.4 General-Purpose Input/Output (GPIO)

### 5.4.1 Features

Features of the GPIO module include:

- Port Data Input register visible in all digital pin-multiplexing modes
- Port Data Output register with corresponding set/clear/toggle registers

#### NOTE

The GPIO module is clocked by system clock.

### 5.4.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

**Table 5-5. Modes of operation**

Modes of operation	Description
Run	The GPIO module operates normally.
Wait	The GPIO module operates normally.
Stop	The GPIO module is disabled.
Debug	The GPIO module operates normally.

### 5.4.3 GPIO signal descriptions

**Table 5-6. GPIO signal descriptions**

GPIO signal descriptions	Description	I/O
PORT0[31:0]	General-purpose input/output	I/O

*Table continues on the next page...*

**Table 5-6. GPIO signal descriptions (continued)**

GPIO signal descriptions	Description	I/O
PORT1[31:0]	General-purpose input/output	I/O
PORT2[31:0]	General-purpose input/output	I/O
PORT3[31:0]	General-purpose input/output	I/O
PORT4[31:0]	General-purpose input/output	I/O

**NOTE**

Not all pins within each port are implemented on each device.  
See the chapter on signal multiplexing for the number of GPIO ports available in the device.

**5.4.3.1 Detailed signal description****Table 5-7. GPIO interface-detailed signal descriptions**

Signal	I/O	Description	
PORT0[31:0] PORT1[31:0] PORT2[31:0] PORT3[31:0] PORT4[31:0]	I/O	General-purpose input/output	
		State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.
		Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.  Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.

**NOTE**

Not all pins within each port are implemented on each device.  
See the chapter on signal multiplexing for the number of GPIO ports available in the device.

## 5.4.5 Port Data Output Register (GPIOx\_PDOR)

This register configures the logic levels that are driven on each general-purpose output pins.

## NOTE

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## GPIOx\_PDOR field descriptions

Field	Description
PDO	<p>Port Data Output</p> <p>Register bits for unbonded pins return a undefined value when read.</p> <p>0 Logic level 0 is driven on pin, provided pin is configured for general-purpose output.</p> <p>1 Logic level 1 is driven on pin, provided pin is configured for general-purpose output.</p>

### 5.4.6 Port Set Output Register (GPIOx\_PSOR)

This register configures whether to set the fields of the PDOR.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	PTSO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### GPIOx\_PSOR field descriptions

Field	Description
PTSO	<p>Port Set Output</p> <p>Writing to this register will update the contents of the corresponding bit in the PDOR as follows:</p> <p>0 Corresponding bit in PDORn does not change.</p> <p>1 Corresponding bit in PDORn is set to logic 1.</p>

### 5.4.7 Port Clear Output Register (GPIOx\_PCOR)

This register configures whether to clear the fields of PDOR.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	PTCO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### GPIOx\_PCOR field descriptions

Field	Description
PTCO	<p>Port Clear Output</p> <p>Writing to this register will update the contents of the corresponding bit in the Port Data Output Register (PDOR) as follows:</p> <p>0 Corresponding bit in PDORn does not change.</p> <p>1 Corresponding bit in PDORn is cleared to logic 0.</p>

5.4.8 Port Toggle Output Register (GPIOx\_PTOR)

Address: Base address + Ch offset

GPIOx\_PTOR field descriptions

Field	Description
PTTO	Port Toggle Output  Writing to this register will update the contents of the corresponding bit in the PDOR as follows:  0 Corresponding bit in PDORn does not change. 1 Corresponding bit in PDORn is set to the inverse of its existing logic state.

5.4.9 Port Data Input Register (GPIOx\_PDIR)

NOTE

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

Address: Base address + 10h offset

GPIOx\_PDIR field descriptions

Field	Description
PDI	Port Data Input  Reads 0 at the unimplemented pins for a particular device. Pins that are not configured for a digital function read 0. If the Port Control and Interrupt module is disabled, then the corresponding bit in PDIR does not update.  0 Pin logic level is logic 0, or is not configured for use by digital function. 1 Pin logic level is logic 1.

### 5.4.36 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The Port Data Input registers return the synchronized pin state after any enabled digital filter in the Port Control and Interrupt module. The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

# Chapter 6

## Clocks and Power Management

### 6.1 Clocking Overview

#### 6.1.1 Introduction

The clocking on this device is flexible and allows clock from multiple sources to be used across different IPs and peripherals. Clocks on the device are controlled by ANADIG, SCSC and CCM modules. All clock sources lead to the CCM module, which generates the root clocks for the bus and peripherals of the device. The control logic in CCM additionally generates special clocks for peripherals which run asynchronously to the root clock and are termed as Auxiliary clocks. This chapter provides a top level description of the clock sources and their arrangement.

Read the following chapters in conjunction with this chapter for the respective details.

- CCM - To program the selection of clock sources, refer to the registers in [Clock Controller Module \(CCM\)](#) chapter. CCM also controls clock gating on this device.
- ANADIG - To program the PLLs and PFDs configuration, refer to the registers in [ANADIG](#) chapter.
- SCSC - To configure SIRC and SOSC controls, refer to the registers in [SCSC](#) chapter.

#### 6.1.2 High Level Clocking Diagram

The figure below provides an overview of system clock generation on this device.

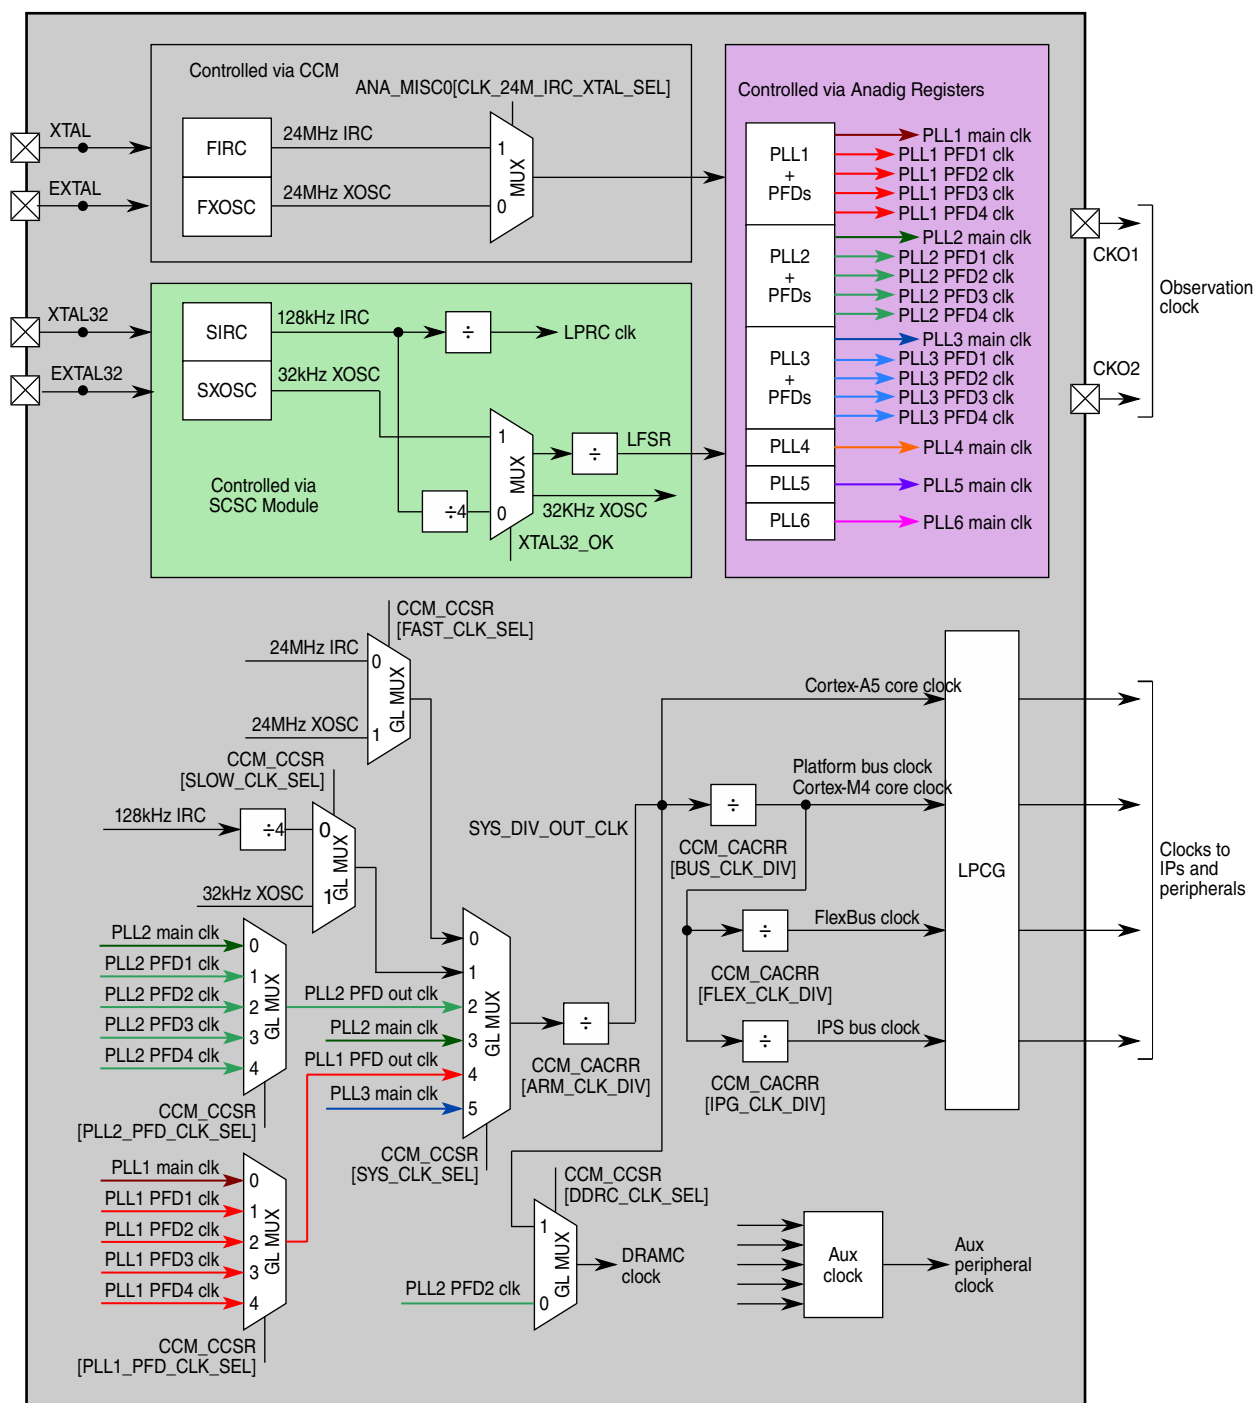

Figure 6-1. Clock Generation and Distribution

**NOTE**

XTAL32\_OK is an internal signal signifying availability of the SXOSC clock. If the external 32 KHz XOSC signal is not available, SIRC/4 is used instead.

**NOTE**

LPRC CLK - 1KHz clock that can be used by LPTMR counter.

**NOTE**

When switching clock sources on GL MUX, both active and target clock sources must be active.

**NOTE**

When using glitchless muxes, all source clocks must be present when switching source. After switching, any redundant clock source can be disabled if required.

The table below defines the clocks on the device.

**Table 6-1. Clock Definitions**

Clock	Definition
Platform Bus/Cortex-M4 Clock <sup>1</sup>	Cortex-M4, Network interconnect (NIC301), and the host bus interfaces of different IPs operate on this clock.
Cortex-A5 Core clock	Cortex-A5 core clock
IPS Clock	This is the register read/write interface clock for any IP and it is a gated version of the IPG clock automatically enabled when accessing the register interface. This clock is active only during register access.
IPG Bus Clock	IPG clock is half the frequency of platform bus clock. Internal engines for IPs work on this clock. Program CCM_CACRR[IPG_CLK_DIV] to 01.
Auxillary Clock	Asynchronous clocks required by individual IPs.
LFSR Clock	Divided SXOSC clock for tamper detection. Refer to the Security Reference Manual for details.
LPRC Clock	1 KHz clock that can be used by LPTMR counter. Refer to LPTMR_PSR register in the <a href="#">LPTMR chapter</a> for details.

1. Platform Bus/Cortex-M4 Clock, Cortex-A5 Core Clock, IPS Bus clock, and IPG Bus Clock are synchronus to each other.

### 6.1.3 Clock Sources

The device implements seven PLLs and four oscillators to meet the clocking requirements of the system. Some PLL outputs are fixed, while others are configurable. Three of the PLLs have further supplemented with Phase Fractional Divider (PFD) support, which generate independent clock frequencies using the VCO frequency generated by the PLLs. These PFD outputs can then be selected to clock the system and various modules.

In addition to the PLLs, the device also includes:

- 2 external crystal oscillators (XOSC)
  - Fast external crystal oscillator 24 MHz (FXOSC)
  - Slow external crystal oscillator 32 KHz (SXOSC)
- 2 internal RC (IRC) oscillators

- Fast internal RC oscillator 24 MHz (FIRC)
- Slow internal RC oscillator 128 KHz (SIRC)

### NOTE

FXOSC/FIRC clocks are configured by the CCM module.  
SXOSC/SIRC clocks are configured by the SCSC module.

### NOTE

If the external 32KHz XOSC signal is not available, the chip will automatically use the SIRC/4 clock to provide a 32KHz clock, provided the SIRC is not disabled by software.

### NOTE

PLL lock will fail if no 32 KHz is available. Either SXOSC or SIRC must be running for PLLs to lock.

## 6.1.4 CMU Block Diagram

The figure below provides an overview of the CMU implementation in the chip.

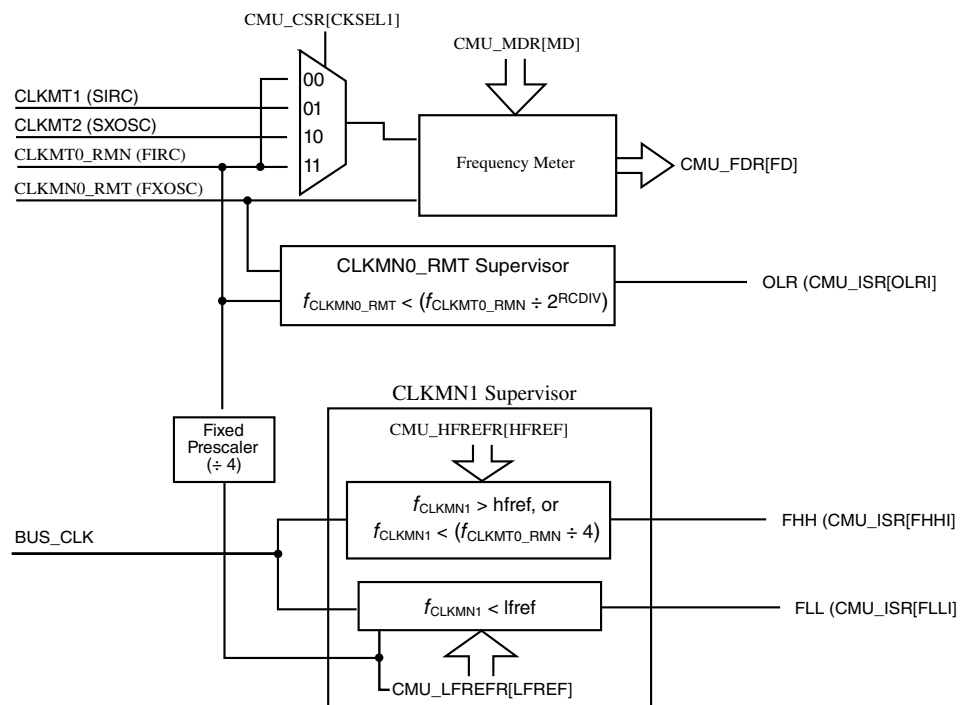

Figure 6-2. CMU Block Diagram

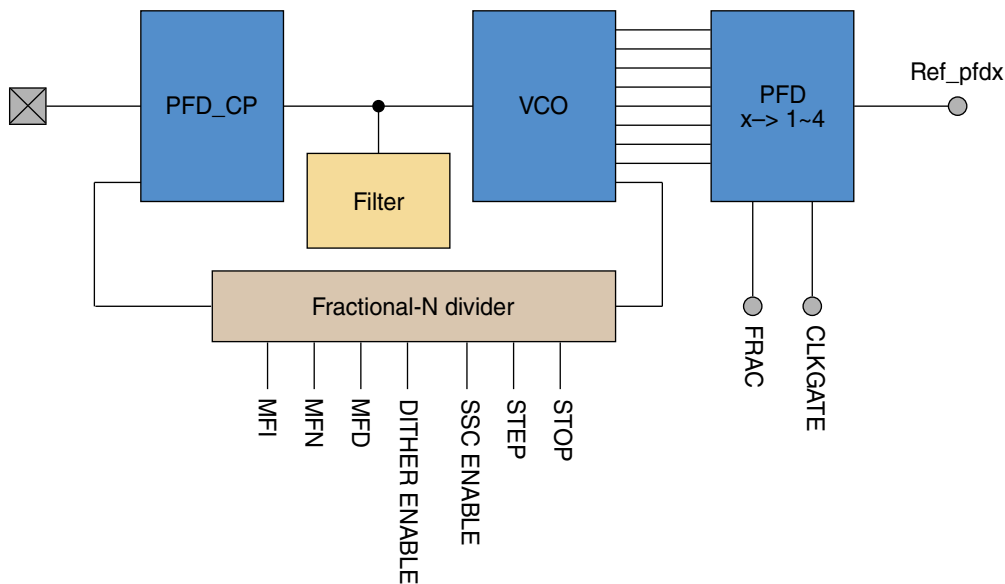

## 6.1.5 PLL Summary

### 6.1.5.1 PLL Block Diagram

The figure below provides an overview of PLL and PFD controls on this device. Only three of the PLLs have a corresponding PFD.

#### NOTE

PLL and PFD controls are programmed via ANADIG registers. The table below maps the bits/fields of ANADIG Registers to the figure below.

**Figure 6-3. PLL Block Diagram**

**Phase Fractional Divider (PFD)** — Each PFD works independently by interpolating the VCO of the PLL it is connected to. It takes the PLL VCO frequency and produces  $F_{vco} \cdot 18/N$  its PFD output, where  $N$  ranges from 12 to 35. The time to switch frequencies is much faster than a PLL, as the base PLL stays locked and changing the integer  $N$  just changes logical combination that controls the PFD output. These PFD outputs can be used by the system clocks or modules.

Table 6-2. PLL controls

PLL	Controller
MFI	Controlled via DIV_SELECT field of ANADIG PLL Control registers
MFN	Controlled via ANADIG PLL2 Numerator definition register, ANADIG PLL1 Numerator definition register, ANADIG PLL4 Numerator definition register, ANADIG PLL6 Numerator definition register
MFD	Controlled via ANADIG PLL2 Denominator definition register, ANADIG PLL4 Denominator definition register, ANADIG PLL6 Denominator definition register
STEP	Controlled via STEP field of ANADIG PLL2 Spread Spectrum definition register and PLL1 Spread Spectrum definition register
STOP	Controlled via STOP field of ANADIG PLL2 Spread Spectrum definition register and PLL1 Spread Spectrum definition register
SSC ENABLE	Controlled via ENABLE field of ANADIG PLL2 Spread Spectrum definition register and PLL1 Spread Spectrum definition register
DITHER ENABLE	Controlled via ANADIG PLL2 Control register, ANADIG PLL4 Control register, ANADIG PLL6 Control register, ANADIG PLL5 Control register, and ANADIG PLL1 Control register
FRAC	Controlled via PFD1_FRAC, PFD2_FRAC, PFD3_FRAC, PFD4_FRAC fields of ANADIG_PLL3_PFD definition, ANADIG_PLL2_PFD, and ANADIG_PLL1_PFD register
CLKGATE	Controlled via PFD1_CLKGATE, PFD2_CLKGATE, PFD3_CLKGATE, PFD4_CLKGATE bits of ANADIG_PLL3_PFD definition, ANADIG_PLL2_PFD, and ANADIG_PLL1_PFD register

### 6.1.5.2 Spread Spectrum (SSC)

PLL1 and PLL2 support the Spread Spectrum (SSC) on its output. In SSC mode, the recommended modulation frequency is 30 KHz and 2% (peak-peak) frequency spread is supported. Using the equations below, the appropriate values of STOP and STEP can be derived. It is important to note that only Down spread frequency modulation is supported.

$$\text{Spread Spectrum Range} = F_{\text{ref}} * \left( \frac{\text{STOP}}{\text{MFD}} \right)$$

$$\text{Modulation Frequency} = F_{\text{ref}} * \left( \frac{\text{STEP}}{2 * \text{STOP}} \right)$$

#### NOTE

"Spread Spectrum Range" is in Hz.

Example: To add 2% spread at 30kHz on default PLL1, the PLL1 MFD could be set to 10000 (this would not affect output as MFN = 0). The spread spectrum range would be 2% of 528MHz. From this we can work out that STOP should be set to 4400.

Using the recommended modulation frequency of 30kHz, the STEP value can be worked out to be 11.

$F_0 = F_{ref} * N$  Where, N = Total Loop Division (Integer + Fraction)

PLL output frequency variation with a 2% modulation is shown in the figure below.

Figure 6-4. PLL with 2% Frequency Down spread Modulation

### 6.1.5.3 PLL Summary

The table below describes the properties of PLLs on this device.

Table 6-3. PLL Properties

		Basic			Spread Spectrum Support	PFD Output	Comments
PLL	Description	Control	MFD	MFN	Available	Available	Comments
PLL1 (PLLSYS 528 MHz)	This is a system PLL that generates	Configurable DITHER and MFI	Configurable	Configurable	Yes	4	-

Table continues on the next page...

Table 6-3. PLL Properties (continued)

		Basic			Spread Spectrum Support	PFD Output	Comments
PLL	Description	Control	MFD	MFN	Available	Available	Comments
	the ARM subsystem clock.						
PLL2 (PLL 528 MHz)	This generates the PLL for DDR operation, as well as other modules.	Configurable DITHER and MFI	Configurable	Configurable	Yes	4	
PLL3 (USB0 PLL)	This generates a 480MHz clock to be used for USB0 and other modules.	No DITHER. Fixed MFI.	NA (Fixed)	NA (Fixed)	NO	4	VCO output is fixed at 480 MHz, with MFI set to 20
PLL4 (Audio PLL)	This is a fractional multiplier PLL for generating Audio frequencies.	Configurable DITHER and MFI	Configurable	Configurable	NO	None	
PLL5 (ENET PLL) <sup>1</sup>	This PLL is used to generate 50 or 25 MHz for the external Ethernet interface.	Configurable DITHER and MFI	NA (Fixed)	NA (Fixed)	NO	None	VCO Output fixed at 1000 MHz
PLL6 (Video PLL)	This is a fractional multiplier PLL for generating Video frequencies.	Configurable DITHER and MFI	Configurable	Configurable	NO	None	
PLL 7 (USB1 PLL)	This generates a 480 MHz clock to be used for USB1.	No DITHER. Fixed MFI.	NA (Fixed)	NA (Fixed)	NO	None	

1. USB1 PHY has a separate internal PLL, PLL7 generating 480 MHz, from the 24 MHz FXOSC. This PLL is only used by USB1 PHY and does not have any PFDs

## 6.1.6 PLL Features

### 6.1.6.1 528 MHz Phase Locked Loop

Features:

- Synthesizes low jitter clock from 24MHz reference clock.
- Nine phase outputs of 528 MHz, plus 4 PFDs.
- Spread Spectrum support
- 2.5V  $\pm 10\%$  Analog supply.
- 1.1V  $\pm 10\%$  digital supply

$$\text{PLL Output Frequency} = F_{\text{ref}} * \left( \text{MFI} + \frac{\text{MFN}}{\text{MFD}} \right)$$

In the above equation:

- MFI - Multiplication Factor Integer (ANADIG\_PLLx\_CTRL[DIV\_SELECT])
- MFN - Multiplication Factor Numerator (ANADIG\_PLLx\_NUM)
- MFD - Multiplication Factor Denominator (ANADIG\_PLLx\_DENOM)

$$\text{Spread Spectrum Range} = F_{\text{ref}} * \left( \frac{\text{STOP}}{\text{MFD}} \right)$$

$$\text{Modulation Frequency} = F_{\text{ref}} * \left( \frac{\text{STEP}}{2 * \text{STOP}} \right)$$

$$\text{PFDn Output Frequency} = \text{PLLx Output Frequency} * \left( \frac{18}{\text{PFDn\_FRAC}} \right)$$

MFD is in ANADIG\_PLLx\_DENOM, STEP and STOP are in ANADIG\_PLLx\_SS, and PFDn\_FRAC is in ANADIG\_PLLx\_PFD[PFDn\_FRAC]

For the electrical specifications, refer to the device Data Sheet.

#### NOTE

Registers that contain the configuration fields for the variables in the equations above for the 528 MHz PLLs are described in the [ANADIG Registers](#) chapter in this manual.

### 6.1.6.2 High Frequency PLL

There are two instances of this PLL:

- PLL4 - Used for audio clock generation
- PLL6 - Used for video clock generation

Features:

## PLL Features

- Synthesizes low jitter clock from 24 MHz reference clock
- Clock output frequency range is from 650 MHz to 1.3 GHz
- Fractional-N synthesizer
- 2.5 V+-10% Analog supply.
- 1.1 V+-10% digital supply

PLL Output frequency is calculated based on the below equations:

$$\text{PLL Output Frequency} = F_{\text{ref}} * \left( \text{MFI} + \frac{\text{MFN}}{\text{MFD}} \right)$$

In the above equation:

- MFI - Multiplication Factor Integer (ANADIG\_PLLx\_CTRL[DIV\_SELECT])
- MFN - Multiplication Factor Numerator (ANADIG\_PLLx\_NUM)
- MFD - Multiplication Factor Denominator (ANADIG\_PLLx\_DENOM)

$$\text{Modulation Frequency} = F_{\text{ref}} * \left( \frac{\text{STEP}}{2^{\text{STOP}}} \right)$$

Recommended modulation frequency is 30KHz. STEP and STOP are set in the ANADIG\_PLLx\_SS register.

For the Audio/Video PLL electrical specifications, refer to the device Data Sheet.

### NOTE

Registers that contain the configuration fields for the variables in the equations above for the for Audio/Video PLLs described in the [Anadig Registers](#) chapter in this manual.

## 6.1.6.3 Ethernet PLL

Features:

- Synthesizes low jitter clock from 24 MHz reference clock.
- VCO OSC frequency = 1000 MHz / 2
- Outputs:
  - Programmable divider - 25/50/100 (ENET reference)

### NOTE

Registers that contain the configuration fields for the variables in the equations above for the Ethernet PLL are described in the [ANADIG Registers](#) chapter in this manual. Some variables are fixed and are not available in the registers.

For the electrical specifications, refer to the device Data Sheet.

$$\text{PLL Output Frequency} = F_{\text{ref}} * \left( \text{MFI} + \frac{\text{MFN}}{\text{MFD}} \right)$$

Where:

- MFI: Multiplication Factor Integer
- MFN: Multiplication Factor Numerator
- MFD: Multiplication Factor Denominator

## 6.1.7 PLL/PFD Configuration

### 6.1.7.1 PLL Configuration

#### 6.1.7.1.1 Typical PLL Configuration

Table 6-4. Typical PLL Configurations

Name	MFI	MFN	MFD	PFD	PFD Setting	Output (MHz)
PLL1 (PLLSYS)	ANADIG_PLL1_CTRL[DIV_SELECT]=1 ( $24 \times 22 = 528$ MHz)	0x0	0x12	PFD1	'd19 (0x13)	500
				PFD2	'd21 (0x15)	452
				PFD3	'd24 (0x18)	396
				PFD4	'd18 (0x12)	528
PLL2 (PLL528)	ANADIG_PLL2_CTRL[DIV_SELECT]=1 ( $24 \times 22 = 528$ MHz)	0x0	0x12	PFD1	'd19 (0x13)	500
				PFD2	'd24 (0x18)	396
				PFD3	'd28 (0x1C)	339
				PFD4	'd23 (0x17)	413
PLL 3 (USB0 PLL)	ANADIG_PLL3_CTRL[DIV_SELECT]=0 ( $24 \times 20 = 480$ MHz)			PFD1	'd28 (0x1C)	Actual o/p 308 MHz
				PFD2	'd26 (0x1A)	332 MHz
				PFD3	'd29 (0x1D)/ 'd28 (0x1C)	298 MHz/ 309 MHz
				PFD4	'd27 (0x1B)	320 MHz
PLL4 (Audio PLL) (default)	0x31	0x04DD2F15	0x1FFFFFFDB	PLL Output = $24 \times 49.152 = 1179.648$ MHz <b>NOTE:</b> This when divided by 48 generates 512x48KHz		
PLL4 (other use case)	0x2F	0x0147AE13	0x1FFFFFFDB	PLL output = $24 \times 47.02 = 1128.48$ MHz <b>NOTE:</b> This when divided by 50 generates 512x44.1KHz		
PLL5 (ENET PLL)	0x29 (tied internally)	0xAAAAD44 (tied internally)	0x100003E6 (tied internally)	VCO Clock = $24 \times 41.66 = 1000$ , internally divided by 2 generates 500 MHz, <b>NOTE:</b> ANADIG_PLL5_CTRL[DIV_SELECT]=0x1 generates 50 MHz clock output.		
PLL6 (Video PLL)	0x2C	0xAAAAA9E	0x1FFFFFFDA	PLL output = $24 \times 44.33 = 1064$ MHz <b>NOTE:</b> This when divided by 8 generates 133 MHz		
PLL6 (default)	0x28	0x0	0x12	PLL output = $24 \times 40 = 960$ MHz		

Table continues on the next page...

**Table 6-4. Typical PLL Configurations (continued)**

Name	MFI	MFN	MFD	PFD	PFD Setting	Output (MHz)
				<b>NOTE:</b> This when divided by 8 generates 120 MHz		
PLL7 (USB1 PLL)	ANADIG_PLL7_CTRL[DIV_SELECT]=0 (24*20=480 MHz)					

## 6.1.7.2 PFD Configuration

### 6.1.7.2.1 Typical PFD Configuration

**Table 6-5. Typical PFD Configuration**

PLL	PFD	Frequency	Notes
PLL1	PFD1	500	-
	PFD2	452	For Cortex-A5 clock
	PFD3	396	Synchronous Cortex-A5
	PFD4	528	To generate x4 clock of 264 MHz for QSPI in DDR66 mode
PLL2	PFD1	500	Reserved
	PFD2	396	For DDR operation
	PFD3	339	For 339:166 synchronous DDR operation
	PFD4	413	For QSPI SDR 104 clock. Can also be used for GCC
PLL3	PFD1	308	Reserved for Audio clocking
	PFD2	332	-
	PFD3	298	Reserved for SDHC clocking. In case the above PFD1 is consumed in audio then we switch to PFD3
	PFD4	320	For QSPi x4 for DDR80. 320 MHz clk source requires setting of PFD4_Frac field in ANADIG_PLL3_PFD to 0x1b to allow DDR80 QuadSPI operation.

## 6.1.8 Clock Configuration

The following table provides the maximum frequencies of the listed peripherals. Refer to the data sheets for device-specific maximum frequencies.

**Table 6-6. Clocking Configuration**

Clocks	Maximum Frequency
Cortex-A5 Core Clock <sup>1</sup>	500 MHz (F-Series) 400 MHz (R-Series)
Cortex-M4 Core Clock	166 MHz
DDR Clock <sup>2</sup>	400 MHz <sup>3</sup>
Platform Bus or Cortex-M4 Clock	166 MHz
IPS or IPG Clock. This is derived from (Platform Bus or Cortex-M4 Clock)/CCM_CACRR[IPG_CLK_DIV]. Typical value for this divider is 2.	83 MHz
DCU Pixel Clock	from 5 - 60 MHz
SDHC Clock	50 MHz
Video ADC (V_CLK1)	133 MHz
Ethernet (RMII_CLK)	50 MHz
Audio	24.58 MHz
GPU (R-Series only)	400 MHz

1. Cortex-A5 core clock has to be synchronous to rest of the system.
2. DDR can be synchronous or asynchronous with a maximum speed of 400MHz.
3. Minimum frequency of DDR is 300 MHz

On this device, the modules listed below have the register interface working at the same frequency as Platform Bus clock.

- DCU0
- DCU1
- DMA\_CH\_MUX0
- DMA\_CH\_MUX1
- DMA\_CH\_MUX2
- DMA\_CH\_MUX3
- RLE
- SAI0
- SAI1
- SAI2
- SAI3
- SPDIF
- GCC
- TCON

For other modules on this device, the register interface work at the IPS clock frequency, which is half of Platform Bus clock. For example:

- DAC
- PDB
- PIT
- LPTMR
- SPI
- I2C
- UART
- LCD
- VIU

## 6.1.9 Clock Modes

### 6.1.9.1 Synchronous Mode

#### 6.1.9.1.1 Synchronous Mode

In this mode, Cortex-A5, BUS, Cortex-M4, and DDR clocks are synchronous to each other.

In the synchronous mode, all clocks are on the same source and have an integral ratio.

**Table 6-7. Synchronous Mode**

PFD Selected (Frequency)	Cortex-A5	DDR	BUS/Cortex-M4	IPG	Div Configurations
PLL1->PFD3 or PLL2->PFD2 (396MHz)	396	396	132	66	ARM_DIV = 1 BUS_DIV = 3 IPG_DIV = 2
PLL2->PFD3 (339Mhz)	339	339	169.5	84.75	ARM_DIV = 1 BUS_DIV = 2 IPG_DIV = 2
PLL1->PFD4 (528Mhz)	264	264	132	66	ARM_DIV = 2 BUS_DIV = 2 IPG_DIV = 2
PLL1->PFD1 or PLL2->PFD2 (500Mhz)	250	250	125	62.5	ARM_DIV = 2 BUS_DIV = 2 IPG_DIV = 2

## 6.1.9.2 Asynchronous Mode

### 6.1.9.2.1 Asynchronous DDR mode

In this mode, Cortex-A5, BUS, Cortex-M4 are synchronous and DDR clock is asynchronous.

In the asynchronous mode, DDR can be operated on different clock source for 400 MHz and Cortex-A5 can go up to 500 MHz (see data sheet for maximum frequency). To set up the DDR asynchronous mode, DDR register configuration needs to be done. Refer to [DDR Control Registers 117](#).

**Table 6-8. Asynchronous DDR mode**

PFD Used	Cortex-A5	DDR	BUS/Cortex-M4	IPG	Div Configurations
PLL2->PFD3 (339Mhz)	339	396	169.5	84.75	<ul style="list-style-type: none"> <li>• ARM_DIV = 1</li> <li>• BUS_DIV = 2</li> <li>• IPG_DIV = 2</li> </ul>
PLL1->PFD2 (452Mhz)	452	396	150.66	75.33	<ul style="list-style-type: none"> <li>• ARM_DIV = 1</li> <li>• BUS_DIV = 3</li> <li>• IPG_DIV = 2</li> </ul>

## 6.1.10 Clock Gating

### 6.1.10.1 Clock Gating

The device implements clock gating options for multiple peripherals to save power. The central clock gating is controlled through configuration of CCM Clock Gating Register (CCM\_CCGCR) registers for off-platform modules and CCM Platform Clock Gating Register (CCM\_CPGCR) for on platform modules. See the [CCM](#) chapter for details.

- All the on-platform module clocks are enabled by default.
- All the off-platform module clocks are disabled by default.
- Only CCM and SRC can be accessed without any IPS configuration.
- All auxillary clocks are implemented using asynchronous clock muxes. To avoid any glitch at the output, select the clock source and then enable the clock gating.

#### NOTE

A transfer error is observed if an access is made to a module that does not have a clock enabled.

**NOTE**

The Low Power Clock Gating module further gates the clock to various peripherals.

## 6.1.11 Peripheral Clocks

### 6.1.11.1 Module clocks

The following table summarizes the clocks associated with each module.

**Table 6-9. Module clocks**

Modules	AHB	IPG Bus Clock	IPS Clock	Relation b/w IPG and IPS	RAM	Baud	Spl care on baud	Any other alternate	Comments
FlexRay	Yes	-	-	-	-	-	-	-	-
ENET_DP RAM	85	85	42.5	-	170	Auxiliary	mii_clk = 100, RMII = 50MHz	-	IPG clock > 50MHz to support both MII/RMII

### 6.1.11.2 FlexCAN Clocking

**Figure 6-5. FlexCAN Clocking**

### 6.1.11.3 FTM clocking

This section shows FlexTimer clocking.

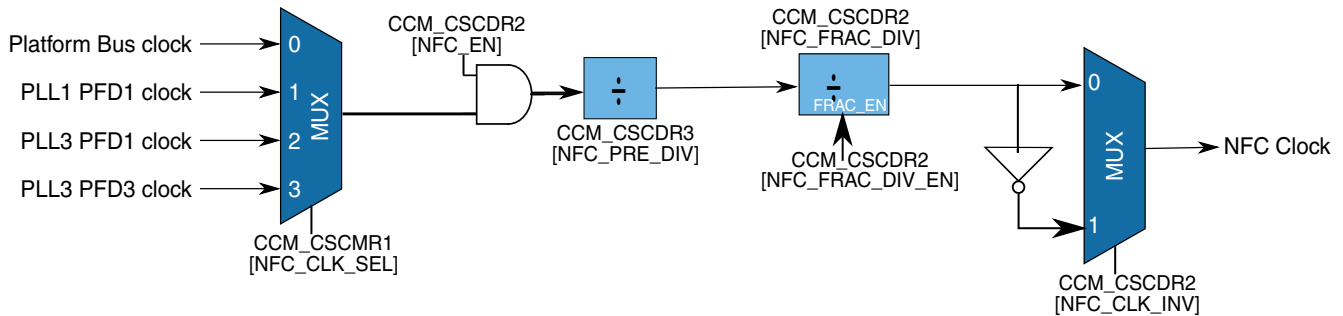

**Figure 6-6. FTM Clocking**

For the clock signal description, refer to the CCM chapter.

### 6.1.11.4 NFC clocking

This section shows NAND Flash Controller (NFC) clocking.

**Figure 6-7. NFC Clocking**

For the clock signal description, refer to the Clock Controller Module (CCM) chapter

### 6.1.11.5 QuadSPI Clocking

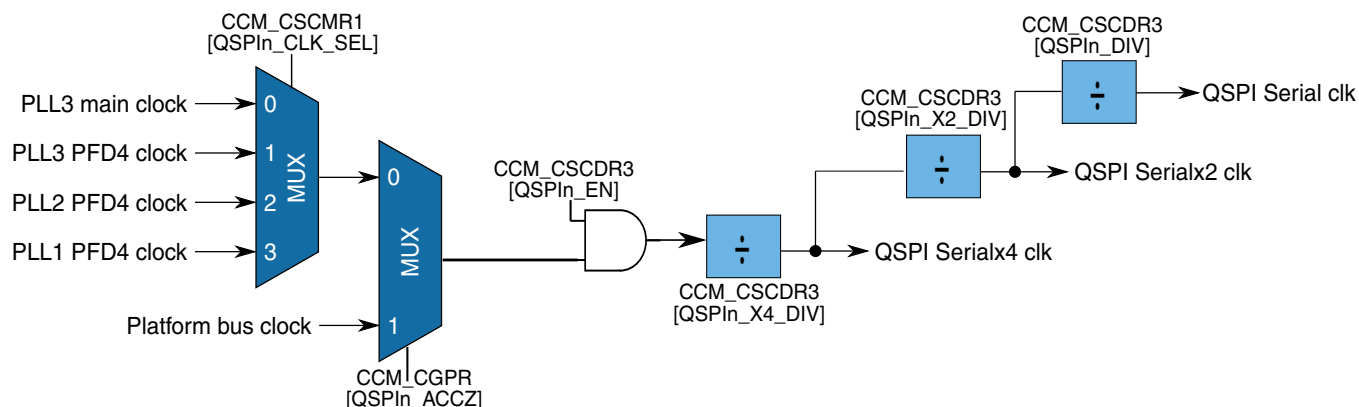

Figure 6-8. QuadSPI Clocking

### 6.1.11.6 Ethernet RMII/MII Clocking

This section shows Ethernet RMII/MII Clocking.

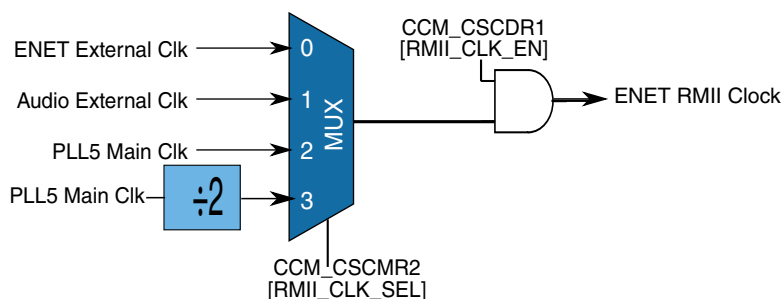

Figure 6-9. ENET RMII/MII Clocking

#### NOTE

When Ethernet MII clocking is used RMII clocking cannot be used. Ethernet MII TXClk is driven by ENET External Clk (PTA6/PTA9) and Ethernet MII RXClk is driven by PTA21.

### 6.1.11.7 Ethernet Timer Clocking

This section shows Ethernet Timer clocking.

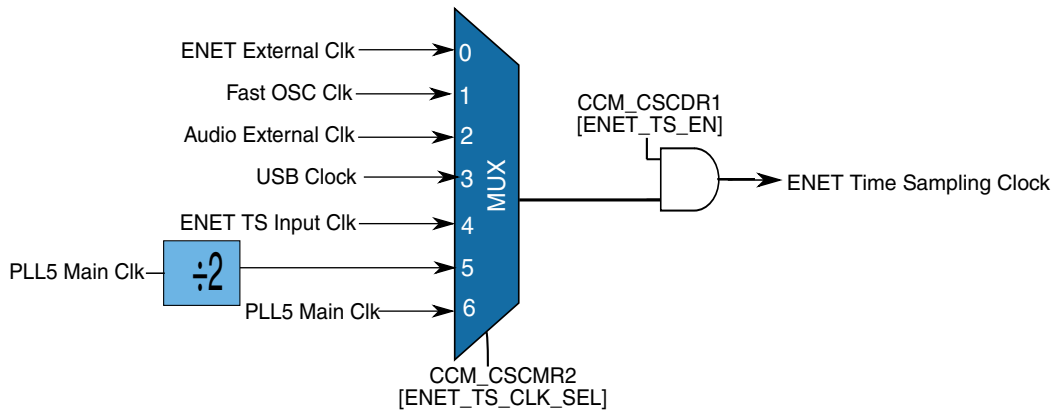

Figure 6-10. ENET Timer Clocking

### 6.1.11.8 eSDHC Clocking

This section shows eSDHC clocking.

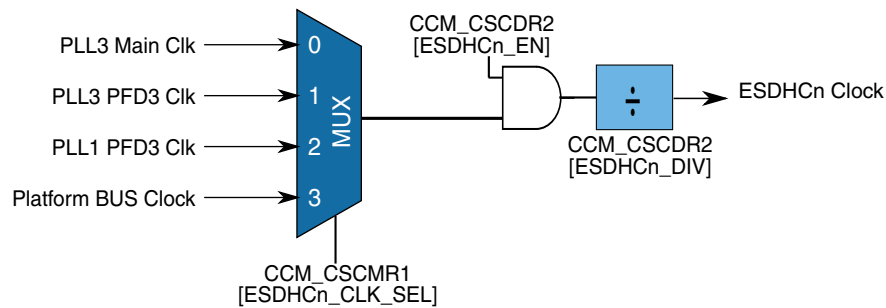

Figure 6-11. eSDHC Clocking

### 6.1.11.9 DCU clocking

This section shows DCU clocking.

Figure 6-12. DCU Clocking

### 6.1.11.10 ESAI clocking

This section shows ESAI clocking.

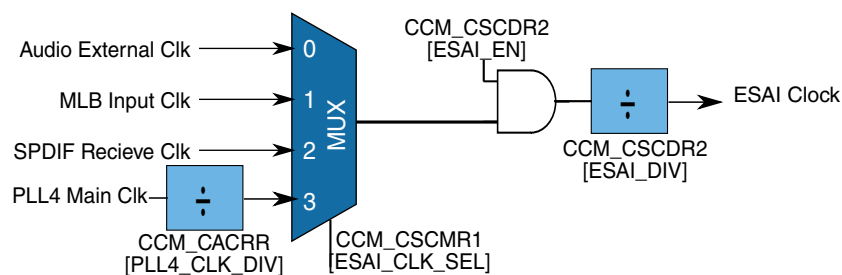

Figure 6-13. ESAI Clocking

### 6.1.11.11 SPDIF Clocking

SPDIF clocking is controlled from the SPDIF module itself, through [SPDIF\\_STC\[TxCk\\_Source\]](#). CCM has no direct control of SPDIF clock. SPDIF clock can be observed through CCM Clock Output Source Register (CCM\_CCOSR).

### 6.1.11.12 SAI clocking

This section shows SAI clocking.

## 6.1.12 Appendix

## 6.1.13 Maximum Frequencies Supported

### NOTE

Do not configure CCM to generate frequencies higher than those listed in the table below. Refer to the data sheets for maximum frequencies for a specific device.

**Table 6-10. Maximum frequencies**

Clock name	Output/Input	Frequency (MHz)	Notes
Platform Bus Clock	output	170	
Cortex-A5 Clock	output	500	400 MHz for R-Series
FlexCAN Clock	output	85	
Cortex-M4 Clock	output	170	
DAP Clock	output	170	
DCU Pixel Clock	output	240	When pix_div is to be confirmed at 45/90, CCM should give out 90 MHz
DDRC Clock	output	400	
ENET Clock	input	50	
ENET RMII Clock	output	50	PLL5
ENET MII TX/RX Clock	input	25	
ENET TS Clock	input	100	
ENET Clock	output	50	
eSDHC Clock	output	52	PLL3_PFD3 (Divider inside CCM at 480 MHz)
flex_root_clk	output	85	
GPU Core Clock (R-Series only)	output	400	PLL2 PFD2
1588 TIMER Clock	output	100	PLL5
IPG	output	85	
NFC Clock	output	80	
PLL1 Main Clock	input	528	
PLL1 PFD1 Clock	input	500	NFC Flash40
PLL1 PFD2 Clock	input	452	
PLL1 PFD3 Clock	input	396	
PLL1 PFD4 Clock	input	528	
PLL2 Main Clock	input	528	
PLL2 PFD1 Clock	input	500	

*Table continues on the next page...*

**Table 6-10. Maximum frequencies (continued)**

Clock name	Output/Input	Frequency (MHz)	Notes
PLL2 PFD2 Clock	input	396	
PLL2 PFD3 Clock	input	339	
PLL2 PFD4 Clock	input	413	
PLL3 Main Clock	input	480	
PLL3 PFD3 Clock	input	308	
PLL3 PFD4 Clock	input	320	
PLL4 Main Clock	input	1300	
PLL5 Main Clock	input	100	
PLL6 Main Clock	input	1064	
QSPI Serial Clock	output	80	
QSPI SerialX2 Clock	output	160	
QSPI SerialX4 Clock	output	320	
SWO Clock	output	44	
Trace Clock	output	170	
VADC Core Clock	output	133	PLL6 : 1064/8
VADC Div Clock	output	66	

## 6.2 Clock Controller Module (CCM)

### 6.2.1 Introduction

This document describes the Clock Controller Module (CCM). The CCM generates the clocks for all the peripherals.

#### 6.2.1.1 Overview

The Clock Controller Module controls the following functions:

- Uses the available clock sources to generate clock roots to various parts of the device
- Uses programmable bits to control frequencies of the clock roots
- Controls the low power mechanism
- Provides control signals to Low Power Clock Gating module (LPCG) for gating clocks
- Provides handshake with System Reset Controller (SRC) for reset performance
- Provides handshake with Global Power Controller (GPC) for low power mode operations

### 6.2.1.2 Features

The CCM includes the following features:

- Four clock sources: two internal RC oscillators and two crystal oscillators.
- Seven PLLs present in the processor.

**Table 6-11. PLL Definitions**

PLL	PLL Definition
PLL1	PLLSYS 528
PLL2	PLL 528
PLL3	USB0 PLL 480
PLL4	AUDIO PLL
PLL5	ENET PLL
PLL6	VIDEO PLL
PLL7	USB1 PLL

- Separate dividers and clock source selectors for core, bus, and each peripheral's clock.
- External clocks have option to bypass PLL clocks.
- Clock signals can be output on CKO1 and CKO2 pins for observation.
- Registers accessible via IP bus.
- Low Power modes management.
- Programmable clock gating of the peripheral clocks in low power modes.
- Frequency scaling management procedure for ARM core clock by shifting between PLL sources, without loss of clocks.
- Frequency scaling management procedure for peripheral root clock by programmable divider. The division is done on the fly without loss of clocks.

### 6.2.1.3 CCM Block Diagram

The CCM contains the following sub-blocks:

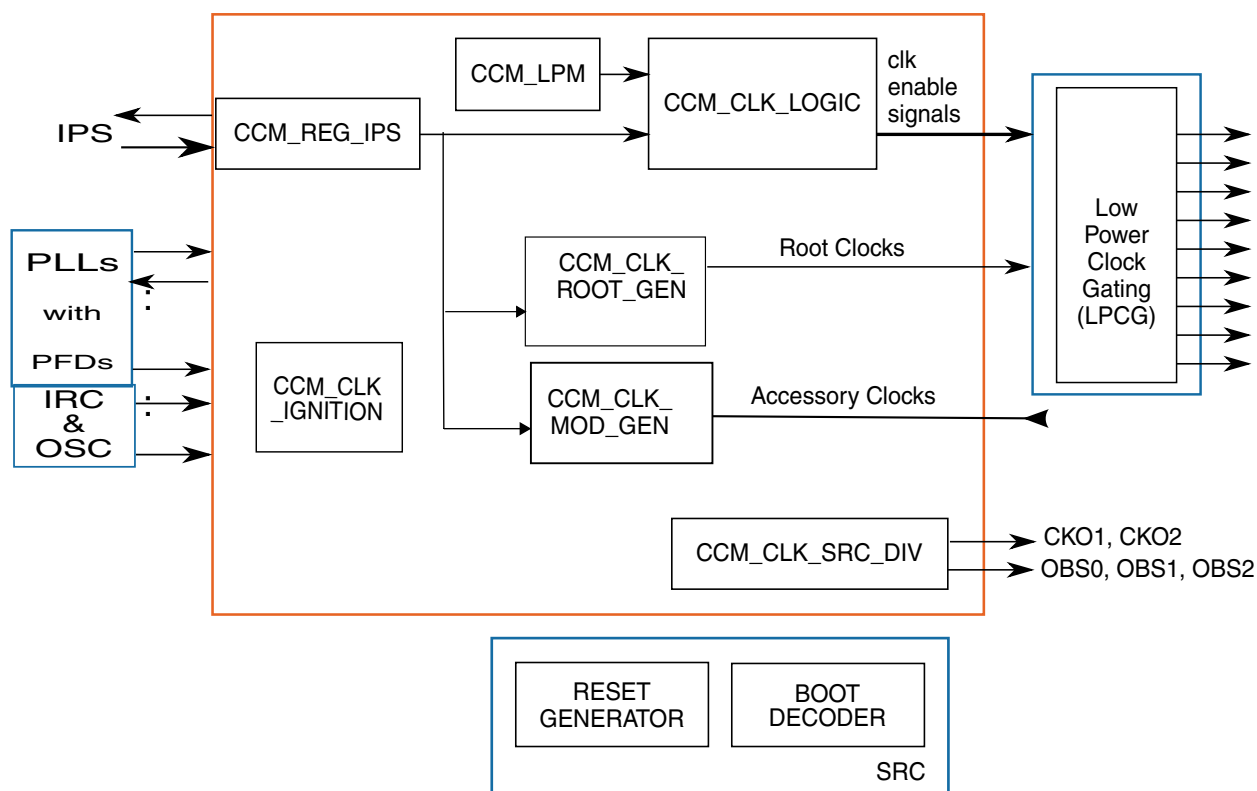

**Table 6-12. CCM Sub-blocks**

Name	Definition
CCM_CLK_IGNITION	Manages the ignition process. This module starts its functionality once CCM comes out of reset. It manages the process that begins with starting the osc, PLLs and finishes with creation of stable output root clocks after reset.

*Table continues on the next page...*

**Table 6-12. CCM Sub-blocks (continued)**

Name	Definition
CCM_CLK_SRC_DIV	Muxes different clocks and critical internal signals for observability. These output clocks are connected to the pads.
CCM_CLK_ROOT_GEN	Receives the main clocks and generates the output root clocks.
CCM_CLK_MOD_GEN	Generates the accessory clocks.
CCM_REG_IPS	The Register interface for configuring CCM and maintaining status.
CCM_LPM	Manages the low power mode entry and exit sequence.
CCM_CLK_LOGIC	Generates the clock enable signals based on info from CCM_LPM and CCM registers. The clock enables are used in LPCG to turn off and on the module clocks.

**Figure 6-18. Block Diagram**

## 6.2.2 Memory Map and Registers

CCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

### 6.2.2.1 CCM Control Register (CCM\_CCR)

The figure below represents the CCM Control Register (CCR), which contains bits to control general operation of CCM. The table below provides its field descriptions.

Address: 4006\_B000h base + 0h offset = 4006\_B000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															FIRC_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			FXOSC_EN	0				OSCNT							
W																
Reset	0	0	0	1	0	0	0	0	0	1	0	1	0	1	1	1

**CCM\_CCR field descriptions**

Field	Description									
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.									
16 FIRC_EN	On-Chip fast RC Oscillator enable bit  0    Disable on-chip RC oscillator 1    Enable on-chip RC oscillator									
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.									
12 FXOSC_EN	On-chip fast crystal oscillator (24 MHz FXOSC) enable bit. The system will start with on-chip oscillator enabled to supply source for the PLL's. Software can change this bit if a transition to the bypass PLL clocks was performed for all the PLLs. In cases that this bit is changed from '0' to '1' then CCM will enable the on-chip oscillator and after counting CCM_CCR[OSCNT] clock cycles it will notify that on-chip oscillator is ready by a interrupt FXOSC_RDY and by status bit FXOSC_RDY. The FXOSC_EN bit should be changed only when on-chip oscillator is not chosen as the clock source.  <b>Table 6-13. CCR[FXOSC_EN] and CLPCR[FXOSC_PWRDWN] behavior</b> <table><tr><th>FXOSC_EN</th><th>FXOSC_PWRDWN</th><th>Description</th></tr><tr><td>0</td><td>0</td><td>FXOSC clock and FXOSC_RDY are disabled.</td></tr><tr><td>1</td><td>0</td><td>FXOSC clock and FXOSC_RDY are enabled.</td></tr></table>	FXOSC_EN	FXOSC_PWRDWN	Description	0	0	FXOSC clock and FXOSC_RDY are disabled.	1	0	FXOSC clock and FXOSC_RDY are enabled.
FXOSC_EN	FXOSC_PWRDWN	Description								
0	0	FXOSC clock and FXOSC_RDY are disabled.								
1	0	FXOSC clock and FXOSC_RDY are enabled.								

Table continues on the next page...

CCM\_CCR field descriptions (continued)

Field	Description		
	Table 6-13. CCR[FXOSC_EN] and CLPCR[FXOSC_PWRDWN] behavior (continued)		
	FXOSC_EN	FXOSC_PWRDWN	Description
	Don't care	1	FXOSC is power down and clock is not coming. FXOSC_RDY is disabled.
11–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.		
OSCNT	Oscillator ready counter value. These bits define value of 32 KHz counter, that serve as counter for oscillator lock time. This is used for oscillator lock time. Current estimation is ~2.7ms. This counter will be used in ignition sequence and in wake from stop sequence if CCM_CLPCR[SBYOS] bit was defined, to notify that on-chip oscillator output is ready for use.		
	00000000	count 1 cycle of 32 KHz SXOSC clock	
	11111111	count 256 cycles of 32 KHz SXOSC clock	

### 6.2.2.2 CCM Status Register (CCM\_CSR)

The figure below represents the CCM status Register (CSR). The status bits are read only bits. The table below provides its field descriptions.

Address: 4006\_B000h base + 4h offset = 4006\_B004h

**CCM\_CSR field descriptions**

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 FXOSC_RDY	Status indication of on board oscillator. This bit will be asserted after CCR[OSCNT] cycles after the on-chip oscillator is powered on and enabled.  0 On board oscillator is not ready. 1 On board oscillator is ready.

*Table continues on the next page...*

## CCM\_CSR field descriptions (continued)

Field	Description
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
3–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 Reserved	This field is reserved. This bit is reserved. Writes to this bit have no effect.

## 6.2.2.3 CCM Clock Switcher Register (CCM\_CCSR)

The figure below represents the CCM Clock Switcher register (CCSR). The CCSR register contains bits to control the switcher sub module dividers and multiplexers. The table below provides its field descriptions.

## NOTE

When switching clock sources on GL MUX, both active and target clock sources must be active.

Address: 4006\_B000h base + 8h offset = 4006\_B008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 6.2.2.10 CCM Testing Observability Register (CCM\_CTOR)

The figure below represents the CCM Testing Observability Register (CTOR). CCM includes three muxes to mux between different critical signals for testing observability. The output of the three muxes is generated on the three output signals obs\_output\_0, obs\_output\_1, and obs\_output\_2. Those three output signals can be generated on the IC pads by configuring the IOMUXC. The CTOR register contains bits to control the data generated for observability on the three output signals above. The table below provides its field descriptions.

Address: 4006\_B000h base + 28h offset = 4006\_B028h

**6.2.2.11 CCM Low Power Control Register (CCM\_CLPCR)**

The CLPCR register contains bits to control the low power modes operation. The table below provides its field descriptions.

**NOTE**

Setting all the bits CLPCR[M\_CORE0\_WFI], CLPCR[M\_CORE1\_WFI], CLPCR[M\_SCU\_IDLE], and CLPCR[M\_L2CC\_IDLE] will result in stop mode or low power stop mode depending upon GPC.

## Memory Map and Registers

Address: 4006\_B000h base + 2Ch offset = 4006\_B02Ch

## CCM\_CLPCR field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 M_L2CC_IDLE	Mask L2CC IDLE for entering low power mode. 0 L2CC IDLE is not masked 1 L2CC IDLE is masked
24 M_SCU_IDLE	Mask SCU IDLE for entering low power mode. 0 SCU IDLE is not masked 1 SCU IDLE is masked
23 M_CORE1_WFI	Mask WFI of core1 for entering low power mode 1 WFI of core1 is masked 0 WFI of core1 is not masked
22 M_CORE0_WFI	Mask WFI of core0 for entering low power mode 0 WFI of core0 is not masked 1 WFI of core0 is masked
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 Reserved	This field is reserved. Unimplemented
18–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FXOSC_BYPSS	Bypass status of 24 MHz oscillator 0 24 Mhz oscialltor not bypassed 1 24 Mhz oscillator bypassed by external oscillator
11 FXOSC_PWRDWN	In run mode, software can manually control powering down of on-chip oscillator. If software manually powered down the on-chip oscillator, then standby oscillator functionality for on-chip oscillator will be bypassed.  The manual closing of on-chip oscillator should be performed only in case the reference oscillator (FXOSC) is not the source of all the clocks generation.  0 On-chip oscillator will not be powered down 1 On-chip oscillator will be powered down
10 FXOSC_BYPSEN	24 Mhz Oscillator bypass enable signal. 0 24 Mhz oscillator is not bypassed 1 24 Mhz oscillator is bypassed by external oscillator
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 ANADIG_STOP_MODE	Masks the ANADIG stop mode indicator. See <a href="#">ANADIG_ANA_MISC0[STOP_MODE_CONFIG]</a> . 0 Stop Mode indication is masked to Anatop 1 Stop Mode indication is sent to Anatop
7 DIS_REF_OSC	In run mode, software can manually control closing of external reference oscillator clock, i.e. generating '1' on ref_en_b signal. If software closed manually the external reference clock, then sbyos functionality will be bypassed.

*Table continues on the next page...*

## CCM\_CLPCR field descriptions (continued)

Field	Description
	<p>The manual closing of external reference oscillator should be performed only in case the reference oscillator (FXOSC) is not the source of any clock generation.</p> <p>0 External high frequency oscillator will be enabled, i.e. ref_en_b = '0'.(default)</p> <p>1 External high frequency oscillator will be disabled, i.e. ref_en_b = '1'</p>
6 SBYOS	<p>Standby clock oscillator bit. This bit defines whether the 24 MHz FXOSC will be powered down in stop mode. This bit is discarded if CCM_CLPCR[FXOSC_PWRDWN] is asserted.</p> <p>0 On-chip oscillator will not be powered down, after next entrance to stop mode.</p> <p>1 On-chip oscillator will be powered down, after next entrance to stop mode.</p>
5 ARM_CLK_LPM	<p>Define if ARM clocks (Cortex-A5 and Cortex-M4) will be disabled on wait mode. This is useful for debug mode, when the user still wants to simulate entering wait mode and still keep ARM clock functioning.</p> <p><b>NOTE:</b> Software should not enable ARM power gating in wait mode if this bit is cleared.</p> <p>0 ARM clock enabled on wait mode.</p> <p>1 ARM clock disabled on wait mode.</p>
4-3 Reserved	This field is reserved.
Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

### 6.2.2.12 CCM Interrupt Status Register (CCM\_CISR)

The figure below represents the CCM Interrupt Status Register (CISR). This is a write one to clear register. Once a interrupt is generated, software should write one to clear it. The table below provides its field descriptions.

Address: 4006\_B000h base + 30h offset = 4006\_B030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0								FXOSC_RDY LRF_PLL6 LRF_PLL5 LRF_PLL4 LRF_PLL3 LRF_PLL2 LRF_PLL1							
W									w1c w1c w1c w1c w1c w1c w1c							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**CCM\_CISR field descriptions**

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FXOSC_RDY	Status of on board oscillator ready, i.e. CCM_CCR[OSCNT] has finished counting. Interrupt will be generated when status is set.  0 On board oscillatory is not ready 1 On board oscillatory is ready
5 LRF_PLL6	Lock ready flag status of the PLL6  This is set only when the PLL6 is enabled and not when it is in bypass.

*Table continues on the next page...*

**CCM\_CISR field descriptions (continued)**

Field	Description
	0 Lock ready flag of PLL6 generates no interrupt 1 Lock ready flag of PLL6 generates interrupt
4 LRF_PLL5	Lock ready flag status of the PLL5  This is set only when the PLL5 is enabled and not when it is in bypass.  0 Lock ready flag of PLL5 generates no interrupt 1 Lock ready flag of PLL5 generates interrupt
3 LRF_PLL4	Lock ready flag status of the PLL4  This is set only when the PLL5 is enabled and not when it is in bypass.  0 Lock ready flag of PLL4 generates no interrupt 1 Lock ready flag of PLL4 generates interrupt
2 LRF_PLL3	Lock ready flag status of the PLL3  This is set only when the PLL3 is enabled and not when it is in bypass.  0 Lock ready flag of PLL3 generates no interrupt 1 Lock ready flag of PLL3 generates interrupt
1 LRF_PLL2	Lock ready flag status of the PLL2  This is set only when the PLL2 is enabled and not when it is in bypass.  0 Lock ready flag of PLL2 generates no interrupt 1 Lock ready flag of PLL2 generates interrupt
0 LRF_PLL1	Lock ready flag status of the PLL1  This is set only when the PLL1 is enabled and not when it is in bypass.  0 Lock ready flag of PLL1 generates no interrupt 1 Lock ready flag of PLL1 generates interrupt

### 6.2.2.13 CCM Interrupt Mask Register (CCM\_CIMR)

The figure below represents the CCM Interrupt Mask Register (CIMR). The table below provides its field descriptions.

Address: 4006\_B000h base + 34h offset = 4006\_B034h

**CCM\_CIMR field descriptions**

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6 M_FXOSC_READY	Mask interrupt generation due to on board oscillator ready 0 Interrupt is not masked 1 Interrupt is masked
5 M_LRF_PLL6	Mask interrupt generation due to lock ready flag of PLL6

*Table continues on the next page...*

## CCM\_CIMR field descriptions (continued)

Field	Description
	0 Interrupt is not masked 1 Interrupt is masked
4 M_LRF_PLL5	Mask interrupt generation due to lock ready flag of PLL5 0 Interrupt is not masked 1 Interrupt is masked
3 M_LRF_PLL4	Mask interrupt generation due to lock ready flag of PLL4 0 Interrupt is not masked 1 Interrupt is masked
2 M_LRF_PLL3	Mask interrupt generation due to lock ready flag of PLL3 0 Interrupt is not masked 1 Interrupt is masked
1 M_LRF_PLL2	Mask interrupt generation due to lock ready flag of PLL2 0 Interrupt is not masked 1 Interrupt is masked
0 M_LRF_PLL1	Mask interrupt generation due to lock ready flag of PLL1 0 Interrupt is not masked 1 Interrupt is masked

## 6.2.2.14 CCM Clock Output Source Register (CCM\_CCOSR)

The figure below represents the CCM Clock Output Source Register (CCOSR). The CCOSR register contains bits to control the clocks that will be generated on the output CKO1 and CKO2. The table below provides its field descriptions.

Address: 4006\_B000h base + 38h offset = 4006\_B038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	0					CKO2_EN	CKO2_DIV					CKO2_SEL

### 6.2.2.15 CCM General Purpose Register (CCM.CGPR)

The figure below represents the CCM General Purpose Register (CGPR). The table below provides its field descriptions.

Address: 4006\_B000h base + 3Ch offset = 4006\_B03Ch

**CCM.CGPR field descriptions**

Field	Description
31–5 Reserved	This field is reserved.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 QSPIn_ACCZ	Used for passing bus clock as source to QSPI. It overrides CCM_CSCMR1[QSPIn_CLK_SEL]. Both QSPI0 and QSPI1 will be switched to bus clock when this bit is set.  0 Clock source to QSPIn depends on CCM_CSCMR1[QSPIn_CLK_SEL] 1 QSPIn clock source is platform bus clock
0 FS_ENABLE (R-Series)	MLB 1024xFs enable <b>For R-Series:</b> <ul style="list-style-type: none"> <li>0 - 1024xFs MLB is disabled</li> <li>1 - 1024xFs is enabled</li> </ul> <b>For F-Series:</b> This field is reserved and read-only.

### 6.2.2.16 CCM Clock Gating Register (CCM\_CCGRn)

These registers define the clock gating for power reduction of each module as shown in [Table 6-14](#) (CG(i) bits). Each CG(i) field consists of two bits. There are 12 CGR registers. The number of registers required is according to the number of peripherals in the system.

#### NOTE

For modules on multiple AIPS slots, only the first address is used for clock gating.

**Table 6-14. CCGR mapping table**

Register	AIPS0/1 Slot #	Module Controlled
CCM_CCGR0[CG0]	AIPS0-Slot32	FlexCAN0
CCM_CCGR0[CG1]	AIPS0-Slot33	
CCM_CCGR0[CG2]	AIPS0-Slot34

**6.2.2.17 CCM Module Enable Override Register (CCM\_CMEOR<sub>n</sub>)**

The following figure represents the CCM Module Enable Override Register (CMEOR). The CMEOR register contains bits to override the clock enable signal from the module. These bits are applicable for only those modules whose clocks are enabled by clock enable signal.

MO(i) fields are used to override the clock enable signal from each module independently.

The register mapping (clock enabling conditions for each module) for the different MOR's is same as that for different CGR's, as shown in [Table 6-14](#)

**NOTE**

For modules on multiple AIPS slots, only the first address is used for module enabling.

**Table 6-16. MO Bitfield Descriptions**

MO Value	Description
0	Don't override module enable signal
1	Override module enable signal

**NOTE**

For description of individual field, refer to [Peripheral Bridge 0 \(AIPS-Lite 0\) Memory Map](#) and [Peripheral Bridge 1 \(AIPS-Lite 1\) Memory Map](#)

Address: 4006\_B000h base + 70h offset + (4d × i), where i=0d to 5d

3 PLL1_PFD4	Indicates the status of PLL1_PFD4 disable signal 0 PFD output is enabled 1 PFD output is disabled
2 PLL1_PFD3	Indicates the status of PLL1_PFD3 disable signal 0 PFD output is enabled 1 PFD output is disabled
1 PLL1_PFD2	Indicates the status of PLL1_PFD2 disable signal 0 PFD output is enabled 1 PFD output is disabled
0 PLL1_PFD1	Indicates the status of PLL1_PFD1 disable signal 0 PFD output is enabled 1 PFD output is disabled

### 6.2.2.19 CCM CORE Wakeup Register (CCM\_CCOWR)

The figure represents the CCM Core Wakeup Register (CCOWR).

Address: 4006\_B000h base + 8Ch offset = 4006\_B08Ch

**CCM\_CCOWR field descriptions**

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 AUX_CORE_WKUP	Wakes up the secondary (non-master) core. 0 Secondary core clock is gated 1 Secondary core clock is enabled
WAKEUP_KEY	This should be written with key 5A5Ah in order to write to the AUX_CORE_WKUP.

### 6.2.2.20 CCM Platform Clock Gating Register (CCPGR<sub>n</sub>)

The following figure represents the CCM Platform Clock Gating Register (CCPGR). The clock gating Registers define the clock gating for power reduction of each clock (PCG(i) bits). There are four CCPGR registers. The number of registers required is according to the number of peripherals in the system.

**Table 6-17. CCPGR mapping table**

Registers	AIPS0/1 Slot #	Module Controlled

Table continues on the next page...

**CCM\_CCPGR $n$  field descriptions (continued)**

Field	Description
3–2 PPCG1	Platform Peripheral gating definition bits
PPCG0	Platform Peripheral gating definition bits

**6.2.3 Sync Signals**

Sync signals are generated for edge alignment.

**Figure 6-19. Sync Signals**

**6.2.4 Accessory clocks**

For all the Accessory clock sources muxing it is assumed that clocks will not be switched while running.

**6.2.5 CKIL Synchronizing to ipg\_clk**

CKIL is synchronized to ipg\_clk when system is in functional mode. When system is in stop mode, i.e. when there is no ipg\_clk, the CKIL synchronizer will be bypassed, and raw ckil will be supplied to the system.

**6.2.6 Low Power Clock Gating module (LPCG)**

The LPCG module receives the root clocks and splits them to clock branches for each module. The clock branches are gated clocks. The enables for those gates can come from the following sources:

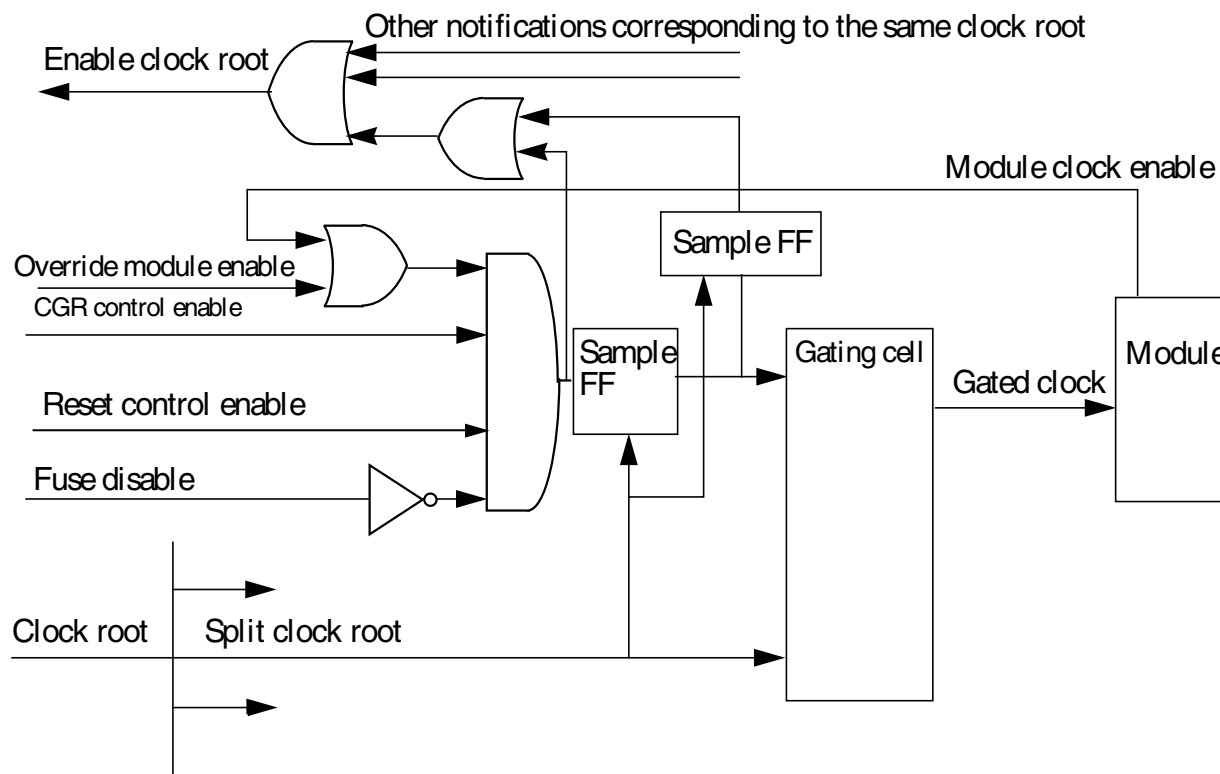

- Clock enable signal from CCM — this signal is generated by configuration of the CCM\_CCGR bits in CCM. It is based on the low power mode.
- Clock enable signal from the module — this signal is generated by the module based on internal logic of the module. Not every enable signal from the module is used. For clock enable signals from the module, that are used, CCM will generate override signal based on programable bit in CCM\_CMEOR.
- Clock enable signal from the System Reset Controller (SRC) — this signal will enable the clock during the reset procedure. See [System Reset Controller\(SRC\)](#) for details on the clock enable signal during reset procedure.
- Hard coded enable from fuse box.

The above possible enable signals are ANDed to generate the enable signal for the gating cell.

The enable signal for the gating cell is synchronized with the clock it needs to gate. This is done in order to prevent glitches on the gated clock.

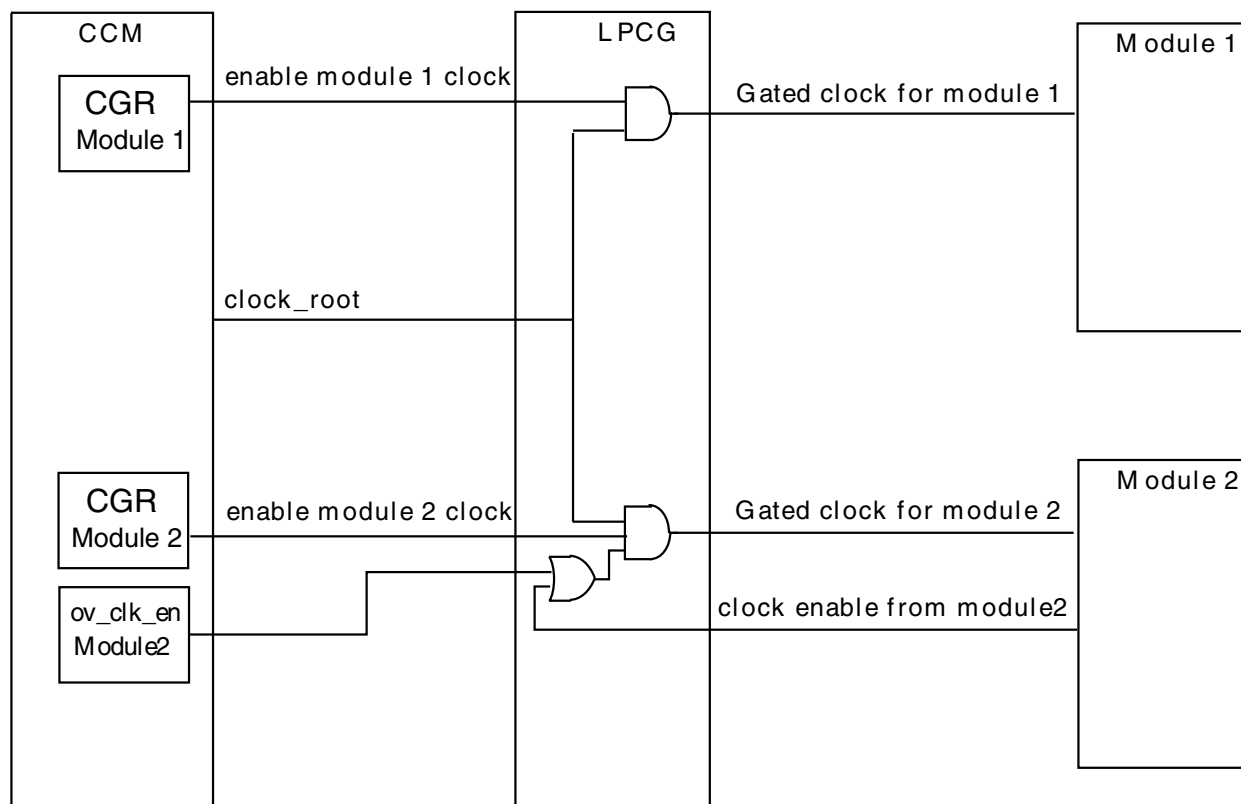

Notifications are generated for the CCM, to indicate when to close and to open the clock roots. All notifications that correspond to the same clock root will be ORed to generate one notification signal to CCM for clock root gating.

The following figure describes the implementation for each gating cell:

**Figure 6-20. Implementation for each gating cell**

## 6.2.7 Power modes

**Figure 6-21. Power Modes**

CCM supports three low power modes: RUN mode, WAIT mode, and STOP mode.

## 6.3 Slow Clock Source Controller Module (SCSC)

### 6.3.1 Introduction

The Slow Clock Source Controller (SCSC) module configures the SIRC and SOSC controls. It is alive in standby mode and also in case of power failure. Power Failure implies when VDDIO (3V3) or VDD\_SOC (1V2) are not available.

- SIRC- 128kHz controller:

XTAL_OK	Power Fail	SIRC CONTROL
0	0	SIRC_EN
1	0	SIRC_EN
0	1	SIRC_EN_ON_FAIL
1	1	0 - SIRC will be disabled

- RC trims coming from fuse box controller are latched to retain the value in standby.
- SOS - 32 KHz controller
  - Controls the enable signal.

## 6.3.2 Memory Map and Registers

### SCSC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_2000	SIRC Control Register (SCSC_SIRC_CTR)	32	R/W	0000_FF11h	<a href="#">6.3.2.1/715</a>
4005_2004	SOSC Control (SCSC_SOSC_CTR)	32	R/W	7CFF_0000h	<a href="#">6.3.2.2/716</a>

### 6.3.2.1 SIRC Control Register (SCSC\_SIRC\_CTR)

Address: 4005\_2000h base + 0h offset = 4005\_2000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	SIRC_DIV							0			SIRC_EN_ON_FAIL	0			SIRC_EN
W																
Reset	1	1	1	1	1	1	1	1	0	0	0	1	0	0	0	1

## SCSC\_SIRC\_CTR field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 SIRC_DIV	0000000: Divide by 1 0000001: Divide by 2 ... 1111110: Divide by 127 1111111: Divide by 128 - default  <b>NOTE:</b> This divider output is used as 1 KHz clock source for LPTIMER. SIRC clock is unaffected by this divider.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 SIRC_EN_ON_FAIL	This bit will have no effect when power (VDDIO or VDDSOC) is available. <b>NOTE:</b> If power fails and xtal32 clock is available - SIRC will be disabled by hardware to save power when running on battery supply.  1 If Power Fails and xtal32 is not available, enable SIRC 0 If Power Fails and xtal32 is not available. Disable SIRC
3–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 SIRC_EN	This bit has no effect in case Power Fail is 1. <b>NOTE:</b> The PLL lock detection circuit depends on this clock.  1 Enable SIRC 0 Disable SIRC

## 6.3.2.2 SOSC Control (SCSC\_SOSC\_CTR)

Figure represents the SOSC\_CTR Register (CSR).

Address: 4005\_2000h base + 4h offset = 4005\_2004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**SCSC\_SOSC\_CTR field descriptions**

Field	Description
31 Reserved	This field is reserved.
30–16 Reserved	This field is reserved.
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 SOSC_EN	-  0    Disable oscillator 32 KHz XOSC 1    Enable oscillator 32 KHz XOSC

## 6.4 Clock Monitor Unit (CMU)

### 6.4.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0\_RMN with CLKMN0\_RMT as the reference clock
- Monitors CLKMN0\_RMT frequency with CLKMT0\_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0\_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

#### NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0\_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event.

The CMU can monitor CLKMN0\_RMT, which must have a frequency higher than that of CLKMT0\_RMN divided by the factor shown in CMU\_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU\_HFREFR) and CMU Low Frequency Reference Register (CMU\_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0\_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

### **NOTE**

See the "Clocking" chapter for the number of CMU instances on this chip.

#### **6.4.1.1 Main features**

- CLKMT0\_RMN frequency measurement with CLKMN0\_RMT as reference clock.
- CLKMN0\_RMT monitoring with respect to  $\text{CLKMT0\_RMN} \div 2^{\text{CSR[RCDIV]}}$  clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to  $\text{CLKMT0\_RMN} \div 4$ .
- Event generation for various failures detected inside monitoring unit.

#### **6.4.2 Block diagram**

The block diagram of the CMU module(s) is shown in the "Clocking" chapter of this Reference Manual.

#### **6.4.3 Signals**

The table below describes the signals on the boundary of the CMU (in alphabetical order).

**Table 6-19. Signal description**

Signal	I/O	Description
CLKMNO_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

**NOTE**

See the "Clocking" chapter for device specific clock sources of each CMU.

## 6.4.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

**NOTE**

See "Clocking" chapter for register and field availability details.

**CMU memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4006_F000	CMU Control Status Register (CMU_CSR)	32	R/W	<a href="#">See section</a>	<a href="#">6.4.4.1/720</a>
4006_F004	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	<a href="#">6.4.4.2/721</a>
4006_F008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	<a href="#">6.4.4.3/722</a>
4006_F00C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	<a href="#">6.4.4.4/722</a>
4006_F010	CMU Interrupt Status Register (CMU_ISR)	32	w1c	<a href="#">See section</a>	<a href="#">6.4.4.5/723</a>
4006_F018	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	<a href="#">6.4.4.6/725</a>

### 6.4.4.1 CMU Control Status Register (CMU\_CSR)

Address: 4006\_F000h base + 0h offset = 4006\_F000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								SFM	0						
W																
Reset	0	0	0	0	0	0	0	0	0*	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						CKSEL1		0					RCDIV		CME
W																
Reset	0	0	0	0	0	0	0*	0*	0	0	0	0	0	0*	0*	0

\* Notes:

- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

#### CMU\_CSR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SFM	Start frequency measure.  The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR.  0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
22–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 CKSEL1	Frequency measure clock selection bit.  CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering.  Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details.  00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–1 RCDIV	CLKMT0_RMN division factor.

Table continues on the next page...

**CMU\_CSR field descriptions (continued)**

Field	Description
	These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ . This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature.  00 CLKMT0_RMN $\div$ 1 (No division) 01 CLKMT0_RMN $\div$ 2 10 CLKMT0_RMN $\div$ 4 11 CLKMT0_RMN $\div$ 8
0 CME	CLKMN1 monitor enable.  0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

**6.4.4.2 CMU Frequency Display Register (CMU\_FDR)**

The CMU\_FDR is used to determine the measured frequency of:

- CLKMT0\_RMN

with respect to the reference clock CLKMN0\_RMT.

**NOTE**

The CMU\_FDR should be read only when  
CMU\_CSR[SFM] = 0.

Address: 4006\_F000h base + 4h offset = 4006\_F004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												FD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**CMU\_FDR field descriptions**

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FD	Measured frequency bits.  This register displays the measured frequency ( $f_{\text{sel}}$ ) with respect to the reference clock ( $f_{\text{CLKMN0\_RMT}}$ ). The measured value is given by the following formula:  $f_{\text{sel}} = (f_{\text{CLKMN0\_RMT}} \times \text{CMU\_MDR[MD]}) \div \text{CMU\_FDR[FD]}$

6.4.4.3 CMU High Frequency Reference Register CLKMN1 (CMU\_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU\_HFREFR register.

NOTE

For correct synchronization of CMU\_HFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0\_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 4006\_F000h base + 8h offset = 4006\_F008h

CMU\_HFREFR field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
HFREF	High Frequency reference value.  These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: $(\text{HFREF} \div 16) \times (f_{\text{CLKMT0\_RMN}} \div 4)$ .

6.4.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU\_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU\_LFREFR register.

NOTE

For correct synchronization of CMU\_LFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0\_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 4006\_F000h base + Ch offset = 4006\_F00Ch

### CMU\_LFREFR field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
LFREF	Low Frequency reference value.  These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: $(\text{LFREF} \div 16) \times (f_{\text{CLKMT0\_RMN}} \div 4)$ .

#### 6.4.4.5 CMU Interrupt Status Register (CMU\_ISR)

##### NOTE

All flags in the CMU\_ISR are set asynchronously. This register must be read only after an interrupt is triggered by the CMU. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

##### NOTE

Before switching off a clock that is measured by a CMU, the clock frequency measurements in the CMU should be disabled. Failing to do so may result in spurious interrupts.

Address: 4006\_F000h base + 10h offset = 4006\_F010h

## Clock Monitor Unit (CMU)

\* Notes:

- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

### CMU\_ISR field descriptions

Field	Description
31–4 Reserved	This field is reserved.
3 Reserved	This field is reserved. <b>NOTE:</b> This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled .
2 FHHI	CLKMN1 frequency higher than high reference event status.  This bit is set by hardware when CLKMN1 frequency becomes higher than the high frequency reference value determined by CMU_HFREFR[HFREF] and CLKMN1 is 'ON'. It can be cleared by software by writing '1'.  0 No FHH event 1 FHH event occurred
1 FLLI	CLKMN1 frequency less than low reference event status.  This bit is set by hardware when CLKMN1 frequency becomes lower than the low frequency reference value determined by CMU_LFREFR[LFREF], and CLKMN1 is 'ON'. Software clears this field by writing a '1'.  <b>NOTE:</b> This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled .  0 No FLL event 1 FLL event occurred
0 OLRI	Oscillator frequency less than $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ event status.  This bit is set by hardware when the $f_{\text{CLKMN0\_RMT}}$ is less than $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ frequency and CLKMN0_RMT is 'ON' . It can be cleared by software by writing '1'.  0 No OLR event 1 OLR event occurred

### 6.4.4.6 CMU Measurement Duration Register (CMU\_MDR)

Address: 4006\_F000h base + 18h offset = 4006\_F018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												MD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**CMU\_MDR field descriptions**

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MD	Measurement duration bits  This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR[SFM] = 1.  <b>NOTE:</b> Only values that do not cause a CMU_FDR[FD] overflow shall be written to CMU_MDR[MD]. There is no internal status of a CMU_FDR[FD] overflow.

## 6.4.5 Functional description

### 6.4.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0\_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU\_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0\_RMT signal. The measurement starts when CMU\_CSR[SFM] = 1. The measurement duration is given by the contents of CMU\_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU\_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU\_FDR[FD]. The frequency of the selected clock ( $f_{sel}$ ) can be derived from the value loaded in the CMU\_FDR[FD] as shown in the following equation:

$$f_{sel} = f_{CLKMN0\_RMT} \times \frac{CMU\_MDR[MD]}{CMU\_FDR[FD]}$$

### 6.4.5.2 CLKMN0\_RMT supervisor

If frequency of CLKMN0\_RMT is smaller than the frequency of  $\text{CLKMTO\_RMN} \div 2^{\text{CMU\_CSR[RCDIV]}}$  and CLKMN0\_RMT is 'ON', then:

- The CMU writes 1 to CMU\_ISR[OLRI].
- The CMU asserts the OLR signal.

#### Note

$f_{\text{CLKMN0\_RMT}}$  must be greater than  $f_{\text{CLKMTO\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$  by at least 0.5 MHz in order to guarantee correct  $f_{\text{CLKMN0\_RMT}}$  monitoring.

### 6.4.5.3 CLKMN1 supervisor

The frequency of CLKMN1 ( $f_{\text{CLKMN1}}$ ) can be monitored by programming  $\text{CMU\_CSR[CME]} = 1$ . CLKMN1 monitoring starts as soon as  $\text{CMU\_CSR[CME]} = 1$ . This monitor can be disabled at any time by programming  $\text{CMU\_CSR[CME]} = 0$ .

If  $f_{\text{CLKMN1}}$  is greater than the reference value determined by fields  $\text{CMU\_HFREFR[HFREF]}$  and CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU\_ISR[FHHI].
- The CMU asserts the FHH signal.

If  $f_{\text{CLKMN1}}$  is less than a reference value determined by the bits  $\text{CMU\_LFREFR[LFREF]}$  and the CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU\_ISR[FLLI].
- The CMU asserts the FLL signal.

#### Note

An example of determining the  $\text{HFREF}_{\text{Actual}}$  is as follows.  
Assume a  $f_{\text{CLKMTO\_RMN}} = 16$  MHz with a accuracy of  $\pm 5\%$ . In order to monitor a  $f_{\text{CLKMN1}} = 200$  MHz, the ideal  $\text{HFREF}_{\text{Ideal}} = 800$ . The actual HFREF value will be 842 when the accuracy is taken into consideration ( $\text{HFREF}_{\text{Actual}} = (\text{HFREF}_{\text{Ideal}} \div 0.95)$ ). See this chip's Data Sheet for specific  $f_{\text{CLKMTO\_RMN}}$  and  $f_{\text{CLKMN1}}$  values.

The actual LFREF value will be 762 when accuracy is taken into consideration ( $\text{LFREF}_{\text{Actual}} = \text{LFREF}_{\text{Ideal}} \div 1.05$ ).

## 6.5 Power Management

### 6.5.1 Introduction

The power management system on this device has the following capabilities:

- Software-controlled clock gating of peripherals through the CCM module
- Software-controlled enabling/disabling of PLL source through the Anadig registers
- Lowest-power mode features power gating and disabling of all clock sources
- Two power domains (PD0 and PD1) and two voltage domains (1.1V SNVS logic and 1.2V)
- Option to retain 64K, 16K, or no memory for different power-gated (LPStop $n$ ) modes
- Multiple operating modes to optimize device performance and wake-up times, including
  - Run
  - Low Power Run (LPRun, ULPRun)
  - Stop
  - Low Power Stop (LPStop1, LPStop2, LPStop)

The following figure shows the modules in the power management system and their interaction. The power domains (PD $n$ ) are described in [Power domains](#).

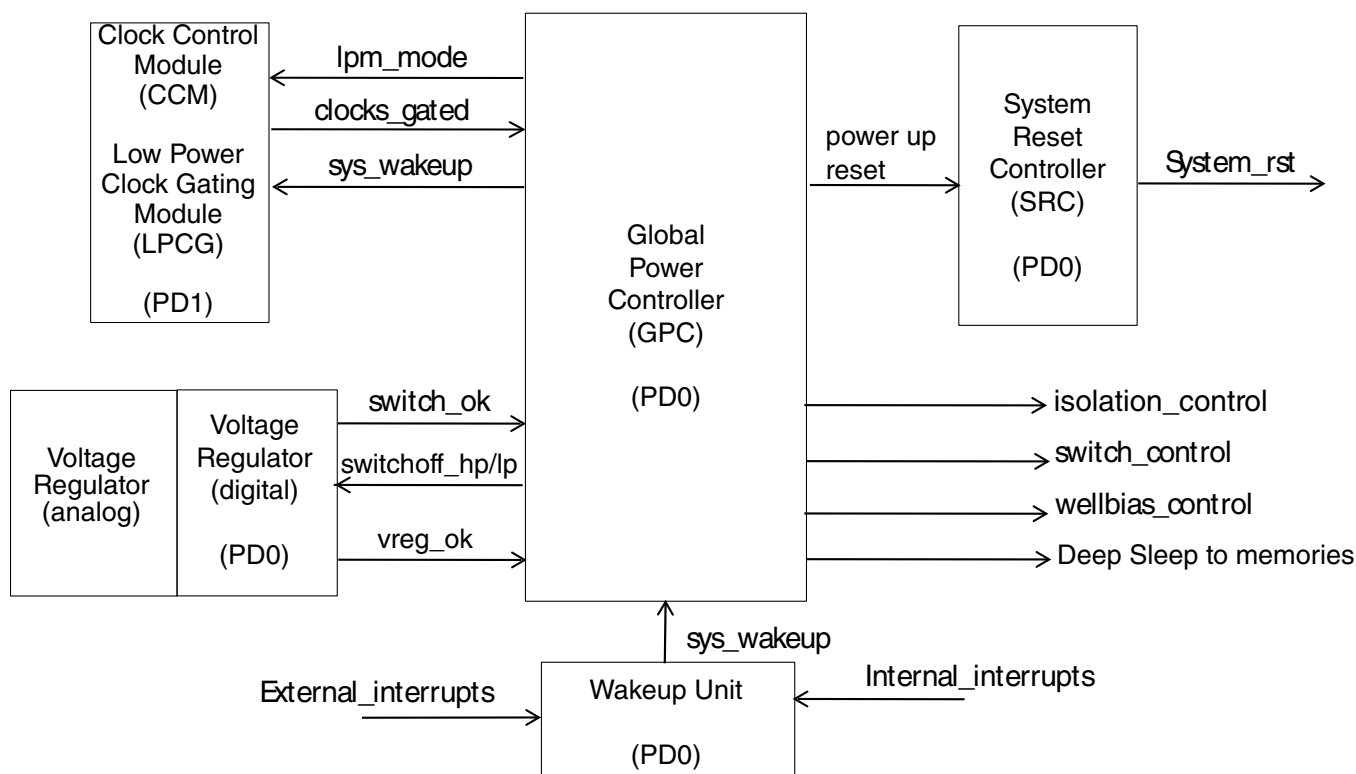

Figure 6-22. Power management modules

## 6.5.2 Power domains

The device's modules are partitioned into three logical power domains to allow the user to minimize power consumption by powering off certain functions while retaining only necessary functionality.

Table 6-20. Power domain descriptions

Power Domain	Description	Modules
PD1	Power-gated domain	All modules that are power-gated in LPStopn modes
PD0	Always-powered domain. Modules in this domain are operating in LPStopn mode.	LPTimer, SRC, VREG_DIG, GPC, WKPU, PMU, FIRC, ADC0, ADC1, LCD, 17 GPIO pads for wakeup
VBB (R-Series) VBAT (F-Series)	The modules in this domain are operational even if there is external supply failure. This domain derives its power from the coin cell.	Contains the SecureRTC, 32KHz XOSC, Tamper, and Monitors. It is powered by a coin cell when the main power supply is switched off.

### 6.5.3 Low-power modes

#### Warning

In order for certain low-power modes to operate as expected, unused TAMPER detection pins must be tied to ground.

The following table shows the device configuration for the various low-power modes. The table also indicates which modules are power-gated, clock-gated, or software configurable. See [Power domains](#) for details on what modules are included in the different power domains.

**Table 6-21. Power gating and clock gating overview**

Domain	Features	Power Gated Modes: SW save and restore <sup>1</sup>			LP Modes: Dynamic Power Saving and Clock Gating Modes <sup>1</sup>		
		LPStop1	LPStop2	LPStop3	Stop	ULPRun	LPRun
PD1	Platform	Off	Off	Off	On	On	On
PD1	Peripherals	Off	Off	Off	Off	Option	Option
PD1	PLLs	Off	Off	Off	Off	Off	Off
PD1	24M XOSC	Off	Off	Off	Off	Off	Option

1. Option denotes that the application can configure the feature to be On or Off. Recommended configurations are given below.

2. First 64K of SysRAM0
3. First 16K of SysRAM0
4. VBB (R-Series)/VBAT (F-Series) contains the RTC, 32kHz XOSC, and Tamper. It is powered by a coin cell when the main power supply is switched off.
5. There are 17 always alive pads which can be used to cause a wakeup event in LPStopn modes. See the Pin muxing section for details.

### 6.5.3.1 Run mode

In Run mode:

- Device operates at highest rated frequency.
- All device peripherals are operational.

### 6.5.3.2 LPRun mode

Low Power Run mode is a software-controlled, dynamic power-saving mode. On reset exit the device is in LPRun mode. All the Arm subsystem clocks are on Fast IRC clock, which is at 24MHz. All the PLLs are in bypassed (Off) state. All the running clocks are scaled down to lower frequencies, from high PLL frequencies to FIRC or FOSC. If some auxiliary clocks, for example the audio subsystem or nand flash clocks, are to be operated at the crystal oscillator clock, then PLLs may be configured to run in bypass mode by configuring the Anadig registers.

Other features of the LPRun mode include:

- The CCM\_CCGR register is configured to clock gate the peripherals.
- The PLL and PFD modules are disabled through Anadig.
- FXOSC24 is disabled through the CCM.
- FIRC24 is enabled through the CCM.

### 6.5.3.3 ULPRun mode

Ultra-Low Power Run mode is an extension of the LPRun mode allowing the Arm subsystem clock frequencies to be further scaled down to 32KHz or 128KHz.

### 6.5.3.4 Wait mode

Wait mode is entered when the GPC\_LPMR register is configured for Wait mode and the WFI (Wait For Interrupt) instruction is executed on the core. Wait mode is recommended for applications where the cores can be stalled and other peripherals can operate at a lower frequency.

WFI for an individual core can be executed and GPC\_LPMR may not be configured to enter into chip Wait mode. In dual-core configurations, the application can configure WFI to put a single core into halt. Other peripherals can continue operating at the configured frequencies if GPC\_LPMR is configured to 00b, i.e., Run mode.

In Wait mode

- CA5 and CM4 cores are halted.
- Normal recovery is from an interrupt.

### 6.5.3.5 Stop mode

All clocks to the peripherals are gated by the CCM. Applications should configure that module if any peripherals are to be clocked in Stop mode.

#### 6.5.3.5.1 Stop mode entry sequence (clock-gating mode)

The following steps must be performed to enter Stop mode.

1. Switch the system clock to 24MHz FIRC by performing the following two steps in order. This is done before disabling any of the primary clock sources (e.g., PLLs, SIRC, SOSC, FOSC) as the low-power state machine needs a running system clock.
  - a. Writing 00b to CCM\_CCSR[5:4]
  - b. Writing 00b to CCM\_CCSR[3:0]
2. Disable the PLLs by configuring these Anadig registers
  - Anadig\_PLL7\_CTRL
  - Anadig\_PLL3\_CTRL
  - Anadig\_PLL2\_CTRL
  - Anadig\_PLL4\_CTRL
  - Anadig\_PLL6\_CTRL
  - Anadig\_PLL5\_CTRL
  - Anadig\_PLL1\_CTRL
3. Write 1 to CCM\_CLPCR[ANATOP\_STOP\_MODE]
4. Write 10b to GPC\_LPMR[CLPCR] to enter Stop mode.
5. Execute the WFI instruction.

#### 6.5.3.5.2 Optional stop mode entry sequence

This section describes the recommended configuration for advanced power-saving in Stop mode.

When the main 2p5 regulator is disabled, the weak 2p5 regulator can be enabled to keep the 2.5V output at roughly 2.5V, depending on the value of VDDIO. To use this feature, perform the following steps.

1. Write 1 to Anadig\_reg\_2p5[enable\_linreg] to enable regulator output.
2. Write 1 to Anadig\_reg\_2p5[enable\_weak\_linreg] to enable the weak regulator.

In addition, the GPC provides several power-saving options in Stop mode. In Stop mode you can:

- Enable Well Bias by writing 1 to GPC\_PGCR[WB\_STOP].
- Turn off HPREG by writing 1 to GPC\_PGCR[HP\_OFF].
- Enable Deep Sleep for all memories by writing 1 to GPC\_PGCR[DS\_STOP]. Deep Sleep shuts down power to periphery and maintains memory contents. The outputs of the memory are pulled low.

Lowest-power Stop mode can be achieved by disabling all clock sources through the CCM and SCSC.

### 6.5.3.6 LPStopn modes

Low Power Stop modes are advanced power saving modes that switch off power to Power Domain 1 (PD1).

Using registers in the GPC, you can configure the device to enter into one of three LPStop modes:

- LPStop1: Lowest power stop mode with no SRAM retained
- LPStop2: 16K RAM is retained
- LPStop3: 64K RAM is retained

It is recommended to keep all the primary clock sources disabled and to wake up from external interrupt sources. Refer to [Wakeup Unit \(WKPU\)](#) for details. If the RTC is to be kept enabled, SOSC can be used as clock source.

#### 6.5.3.6.1 LPStopn mode entry sequence (power-gating mode)

The following steps must be performed to enter LPStopn mode.

1. Switch the system clock to 24MHz FIRC by performing the following two steps in order.
  - a. Writing 00b to CCM\_CCSR[4:5]
  - b. Writing 00b to CCM\_CCSR[3:0]
2. Disable the PLLs by configuring these Anadig registers
  - Anadig\_PLL7\_CTRL
  - Anadig\_PLL3\_CTRL
  - Anadig\_PLL2\_CTRL
  - Anadig\_PLL4\_CTRL
  - Anadig\_PLL6\_CTRL

- Anadig\_PLL5\_CTRL
  - Anadig\_PLL1\_CTRL
3. Write 1 to CCM\_CLPCR[ANATOP\_STOP\_MODE].
  4. Write 10b to GPC\_LPMR[CLPCR] to enter Stop mode.
  5. Write 1 to GPC\_PGCR[PG\_PD1] to enter into power gated mode for PD1.
  6. Execute the WFI instruction.

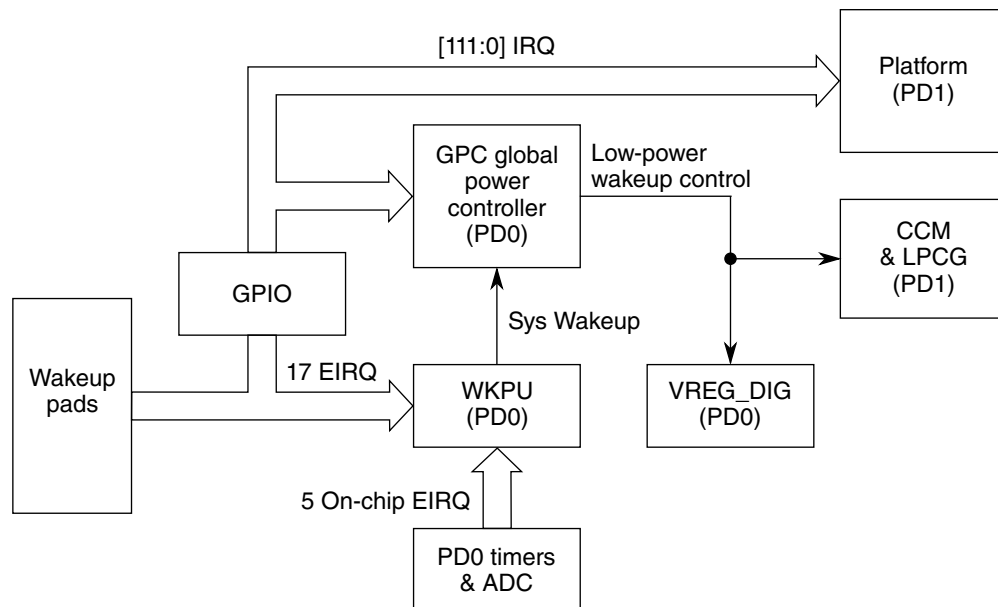

#### 6.5.3.6.2 Optional LPStop<sub>n</sub> mode entry sequence

The GPC provides several power-saving options in LPStop<sub>n</sub> mode. In LPStop<sub>n</sub> mode you can:

- Keep 64KB of System RAM on by writing 0 to GPC\_PGCR[PG\_16K] and to GPC\_PGCR[PG\_48K]. Clearing these two bits will cause device to enter LPStop<sub>3</sub> mode.
- Disable FIRC during LPStop<sub>n</sub> by writing 0 to CCM\_CCR[FIRC\_EN].

#### 6.5.3.7 Interrupt connectivity

This figure shows the interrupt connectivity of the device.

**Figure 6-23. Interrupt connectivity**

#### NOTE

- Refer to the GPC\_IMR configuration registers for interrupt configurations.
- System can exit from LPStop<sub>n</sub> only through interrupts routed by WKPU.

- All the external IRQs should be level-triggered to cause an exit from Stop mode.
- Refer to [Wakeup Unit \(WKPU\)](#) for on-chip and external wakeup interrupts.

## 6.6 Global Power Controller (GPC)

### 6.6.1 Introduction

The Global Power Controller (GPC) module generates the controls for power gated modes and low power modes. It generally does the isolation of power domain, power gating of power switches and initiates power down to the voltage regulator.

### 6.6.2 Features

Key features of the GPC include:

- Power shutdown controller
- Provides the ability to switch off power to a target subsystem.
- Generates power-up and power-down control sequences.
- Provides programmable registers to adjust the timing of the power control signals.

### 6.6.3 GPC Memory/Register Map

GPC memory map

### 6.6.3.1 Power Gating Control Register (GPC\_PGCR)

The GPC\_PGCR enables the response to a power-down request. It also allows to configure various power gated modes and Low Power modes. The following figure shows the register and table describes the register fields.

#### NOTE

Deep Sleep pin shut down power to periphery and maintain memory contents. The outputs of the memory are pulled low

Address: 4006\_C000h base + 0h offset = 4006\_C000h

#### GPC\_PGCR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

## GPC\_PGCR field descriptions (continued)

Field	Description
7 DS_STOP	- 0 Deep Sleep signal to memories is not asserted in STOP mode. 1 Deep Sleep signal to memories is asserted in STOP mode.
6 DS_LPSTOP	- 0 Deep Sleep signal to memories is not asserted in LPSTOP mode. 1 Deep Sleep signal to memories is asserted in LPSTOP mode.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WB_STOP	Enable Well Bias in STOP mode 0 Well Bias disabled in STOP mode. 1 Well Bias enabled in STOP mode.
3 HP_OFF	Turn OFF HPREG in STOP mode 0 HPREG ON in STOP mode. 1 HPREG OFF in STOP mode.
2 PG_48K	Power gate 64KRAM. This bit will take in effect if PGCR[PG_PD1] is set <b>NOTE:</b> If this bit is configured 0, PG_16K must also be configured to 0. This will enable LPSTOP3 mode 0 Do not switch off 64K RAM (16K and 48K RAM Power Switch) during LPSTOP3 mode. 1 Switch off 48K RAM Power Switch during LPSTOP2 or LPSTOP1 mode.
1 PG_16K	Power gate 16KRAM. This bit will take in effect if PGCR[PG_PD1] is set 0 Do not switch off 16K RAM Power Switch during LPSTOP3 and LPSTOP2 mode 1 Switch off 16K RAM Power Switch during LPSTOP1 mode.
0 PG_PD1	Power gate Power Domain 1. 0 Do not switch off power to power domain1. 1 Switch off power domain 1 (LPSTOP mode).

### 6.6.3.2 Power Gating Status Register (GPC\_PGSR)

The GPC\_PGSR provides the power-down status of the target subsystem. The following figure shows the register and table describes the register fields.

Address: 4006\_C000h base + Ch offset = 4006\_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0											PREV_LPM		CUR_LPM		PSR
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**GPC\_PGSR field descriptions**

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–3 PREV_LPM	Previous Low Power Mode. These bits indicate the previous state of the GPC.  00 RUN mode 01 WAIT mode 10 STOP mode 11 LPSTOPn mode
2–1 CUR_LPM	Current Low Power Mode  00 RUN mode 01 WAIT mode 10 STOP mode 11 LPSTOPn mode
0 PSR	Power status. When in functional (or software-controlled debug) mode, PGC hardware sets PSR as soon as any of the power control output changes its state to one. Write one to clear this bit. Software should clear this bit after power up; otherwise, PSR continues to reflect the power status of the initial power down.

### 6.6.3.3 Low Power Mode Register (GPC\_LPMR)

The GPC\_LPMR register allows the user to configure the low power mode. The following figure shows the register and the table describes the register fields.

**NOTE**

To enter into LPSTOP mode, CLPCR should be configured to 2'b10 and GPC\_PGCR[PG\_PD1, PG\_64K, PG\_16K] should be configured accordingly.

**NOTE**

When exiting from LPSTOP mode, FXOSC must be enabled before disabling pending interrupts to allow pending interrupts to propagate. To enable the oscillator set GPC\_LPMR[CLPCR] to '00' (RUN).

Address: 4006\_C000h base + 40h offset = 4006\_C040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**GPC\_IMR3 field descriptions (continued)**

<b>Field</b>	<b>Description</b>
25 SPDIF	Masks SPDIF interrupt  0 Enable SPDIF interrupt as source of wake-up from STOP mode 1 Ignore interrupt from SPDIF as source of wake-up from STOP mode
24 ESAI	Masks ESAI interrupt  0 Enable ESAI interrupt as source of wake-up from STOP mode 1 Ignore interrupt from ESAI as source of wake-up from STOP mode
23–20 UNIMPLEMENTED	This field is unimplemented. Read or write on this field has no effect.
19 NFC	Masks NFC interrupt  0 Enable NFC interrupt as source of wake-up from STOP mode 1 Ignore interrupt from NFC as source of wake-up from STOP mode
18 ESW	Masks ESW interrupt  0 Enable ESW interrupt as source of wake-up from STOP mode 1 Ignore interrupt from ESW as source of wake-up from STOP mode
17 1588T1	Masks 1588T1 interrupt  0 Enable 1588T1 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from 1588T1 as source of wake-up from STOP mode
16 1588T0	Masks 1588T0 interrupt  0 Enable 1588T0 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from 1588T0 as source of wake-up from STOP mode
15 ENET1	Masks ENET1 interrupt  0 Enable ENET1 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from ENET0 as source of wake-up from STOP mode
14 ENET0	Masks ENET0 interrupt  0 Enable ENET0 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from ENET0 as source of wake-up from STOP mode
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 USBC1	Masks USBC1 interrupt  0 Enable USBC1 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from USBC1 as source of wake-up from STOP mode
11 USBC0	Masks USBC0 interrupt  0 Enable USBC0 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from USBC0 as source of wake-up from STOP mode
10 I2C3	Masks I2C3 interrupt  0 Enable I2C3 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from I2C3 as source of wake-up from STOP mode

*Table continues on the next page...*

**GPC\_IMR3 field descriptions (continued)**

Field	Description
9 I2C2	Masks I2C2 interrupt 0 Enable I2C2 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from I2C2 as source of wake-up from STOP mode
8 I2C1	Masks I2C1 interrupt 0 Enable I2C1 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from I2C1 as source of wake-up from STOP mode
7 I2C0	Masks I2C0 interrupt 0 Enable I2C0 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from I2C0 as source of wake-up from STOP mode
6 DSPI3	Masks DSPI3 interrupt 0 Enable DSPI3 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from DSPI3 as source of wake-up from STOP mode
5 DSPI2	Masks DSPI2 interrupt 0 Enable DSPI2 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from DSPI2 as source of wake-up from STOP mode
4 DSPI1	Masks DSPI1 interrupt 0 Enable DSPI1 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from DSPI1 as source of wake-up from STOP mode
3 DSPI0	Masks DSPI0 interrupt 0 Enable DSPI0 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from DSPI0 as source of wake-up from STOP mode
2 UART5	Masks UART5 interrupt 0 Enable UART5 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from UART5 as source of wake-up from STOP mode
1 UART4	Masks UART4 interrupt 0 Enable UART4 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from UART4 as source of wake-up from STOP mode
0 UART3	Masks UART3 interrupt 0 Enable UART3 interrupt as source of wake-up from STOP mode 1 Ignore interrupt from UART3 as source of wake-up from STOP mode

### 6.6.3.7 Interrupt Mask Register (GPC\_IMR4)

This register is used to mask certain interrupts if they are not desired to be a source of wake up during STOP mode.

Address: 4006\_C000h base + 50h offset = 4006\_C050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## 6.6.4 Functional Description

### 6.6.4.1 Power Shutdown Controller

The Power Shutdown Controller takes control once all the clocks are successfully gated and GPC is configured for LPSTOPn modes. It initiates the power down request to Power Gating Controller (PGC) enabling PGC to start the power down sequence. It also monitors wake up request and accordingly generates power up request to PGC after HPREG stabilizes. The system can wake-up from the following sources

- External reset
- System wake-up from WKPU
- Level Trigger Interrupt (only for STOP mode)

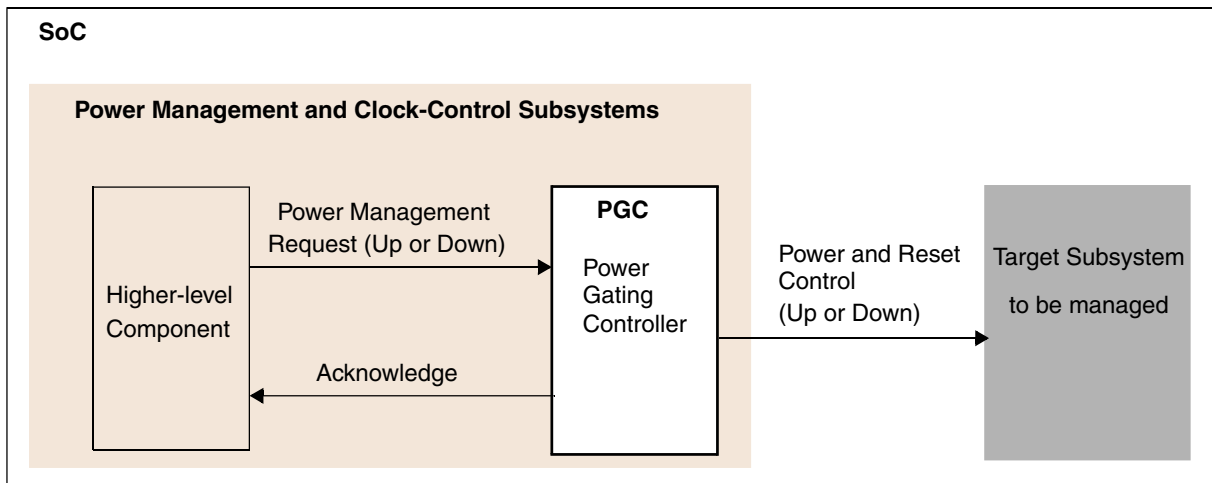

**NOTE**

During wake-up by interrupt, software should mask the corresponding interrupt in GPC\_IMR register which are not the source of wake-up during STOP mode.

**6.6.4.2 Power Gating Controller**

The Power Gating Controller (PGC) is a power management component that controls the power-down and power-up sequencing of individual subsystems. For subsystems to be completely powered down in low power modes, a specific sequence of power control signals must be followed. The sequence timing is programmable using the PGC control registers.

Figure 6-24 shows the PGC as part of the overall power management scheme in this device.

**Figure 6-24. PGC Top-Level Block Diagram**

**6.6.4.2.1 Functional Mode**

The following sections describe the power-control sequencing steps for various low power modes .

**6.6.4.2.1.1 LPSTOP Entry Sequence (PG Entry Sequence)**

These steps outline the power-down sequence:

1. Software sets the GPC\_PGCR[PG\_PD1] bit, see [Power Gating Control Register \(GPC\\_PGCR\)](#).
2. Software also configures the GPC\_LPMR[CLPCR] to STOP mode.

3. CCM stops the clocks to the target subsystem on receiving ARM\_DSM\_REQUEST after executing WFI instruction.
4. On receiving the stop clock indication from CCM, GPC put the memories into deep sleep if GPC\_PGCR[DS\_LPSTOP] is set to '1'.
5. GPC asserts *isolation* to isolate the outputs of power-gated domain.
6. GPC triggers SRC to assert reset to power gated domain(PD1) .
7. VREG\_DIG then power gated the power domains after 20  $\mu$ s.
8. VREG\_DIG also powered down HPREG and LPREG after 50  $\mu$ s.
9. FIRC is disabled if CCM\_CCR[FIRC\_EN] is configured to '0' after VREG\_DIG completely power down the regulators.

The figure below shows the power-down sequence.

**Figure 6-25. Power-Down Sequence Timing Diagram**

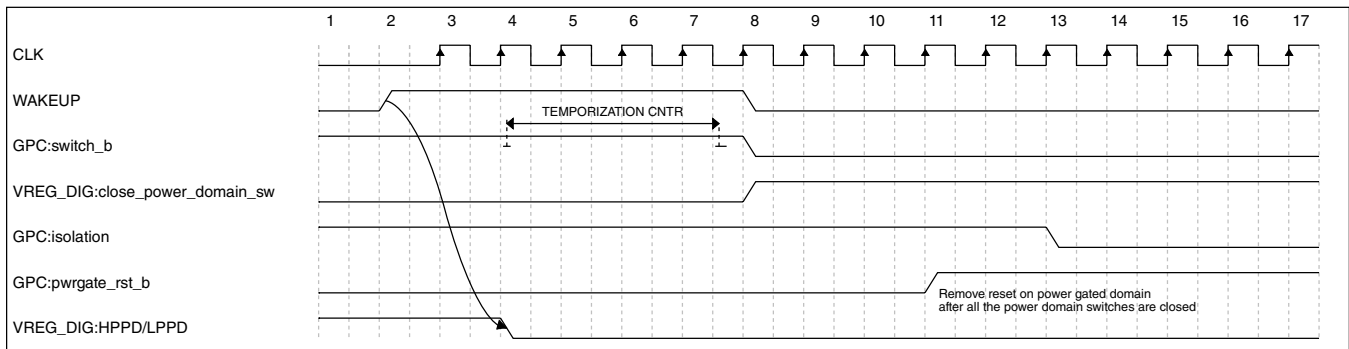

## 6.6.4.2.1.2 LPStop Mode Exit Sequence

The LPStop mode exit sequence is not interruptible and initiated only on receiving system wake up, or external reset.

These steps outline the LPStop exit sequence:

1. On exit, GPC first enables the FIRC and removes the deep sleep synchronously
2. VREG\_DIG enables the HPREG and LPREG on receiving wake-up indication from GPC
3. GPC, then enables all the power domain switches after HP regulator stabilizes.
4. GPC indicates SRC to remove the reset from power gated domain once all the power domain switches are closed.
5. GPC negates the isolation after two cycles.
6. CCM then starts enabling the clocks once the isolation is removed.

The figure below shows the power-up sequence.

**Figure 6-26. Power-Up Sequence Timing Diagram**

#### 6.6.4.2.1.3 Stop Mode Entry Sequence

The following steps outline the normal stop mode entry sequence:

1. Software ensures GPC\_PGCR[PG\_PD1] bit and GPC\_PGCR[WB\_STOP] bit are not set; see [Power Gating Control Register \(GPC\\_PGCR\)](#)
2. Software also configures the GPC\_LPMR[CLPCR] to STOP mode.
3. The clock-control subsystem stops the clocks to the target subsystem on receiving ARM\_DSM\_REQUEST after executing WFI instruction.
4. On receiving stop clock indicating from the CCM, HPREG is power-down and put the memories into deep-sleep based on GPC\_PGCR[HP\_OFF] and GPC\_PGCR[DS\_STOP] configurable bit.
5. FIRC is disabled, if CCM\_CCR[FIRC\_EN] is configured to '0'.

#### 6.6.4.2.1.4 Stop Mode Exit Sequence

The following steps outline the normal stop mode exit sequence on receiving system wake up, external reset or interrupt which are configured as source of wakeup:

1. The stop-mode exit is initiated by enabling the FIRC oscillator
2. HPREG is enabled synchronously and deep-sleep is removed
3. After the expiry of 10us (configurable through fuse), wakeup is generated to CCM to enable the clocks

#### 6.6.4.2.1.5 Well Bias Stop mode entry sequence

These steps outline the well bias stop mode sequence:

1. Software ensures GPC\_PGCR[PG\_PD1] bit is not set and GPC\_PGCR[WB\_STOP] bit is set; see [Power Gating Control Register \(GPC\\_PGCR\)](#)
2. Software also configures the GPC\_LPMR[CLPCR] to STOP mode.
3. The clock-control subsystem stops the clocks to the target subsystem
4. On receiving stop clock indicating from the CCM, well bias cell are isolated and put the memories in deep sleep based on GPC\_PGCR[DS\_STOP].
5. PMOS switch is then disabled after 2 clocks

6. After 5us, Well Bias Regulator is enabled.
7. HPREG is powered down after 5 us once the WB regulator is enabled. Also disabled FIRC if CCM\_CCR[FIRC\_EN] is configured to '0'.

Refer to [Voltage Regulators](#) for details.

#### 6.6.4.2.1.6 Well Bias Stop mode exit sequence

The well bias stop mode exit is initiated on receiving system wake up, or external reset. It also exits from well bias stop mode on interrupts which are configured as source of wake up from stop mode. The following outline the well bias stop mode exit sequence.

1. On well bias stop mode exit indication, GPC enables FIRC oscillator if it was configured to be off.
2. HPREG is then enabled synchronously and deep-sleep is also removed
3. Wakeup is generated to CCM after 300 ns
4. After 5us, Well Bias regulator is disabled
5. PMOS switch is enabled after the expiry of another 5us and then isolation is removed after 2 clocks
6. CCM sampled the wakeup signal once isolation is removed and enabled the clocks henceforth

#### 6.6.4.2.1.7 Inhibit Stop and FIRC Control

The inhibit stop signal from the platform prevents the entry into STOP mode. This is possible by overwriting the LPM mode provided to the CCM. During inhibit stop, the LPM mode exposed to CCM is RUN mode irrespective of other mode configured in GPC\_LPMR register. The inhibit stop signal is discarded if the GPC is configured for LPSTOP mode ( where GPC\_LPMR[CLPCR] = 2'b10 and GPC\_PGCR[PG\_PD1] = 1'b1. See [Low Power Mode Register \(GPC\\_LPMR\)](#) and [Power Gating Control Register \(GPC\\_PGCR\)](#)

The FIRC oscillator can be disabled during LPRUN and STOP mode to minimize power.

The setting of CCM\_CCR[FIRC\_EN] controls whether or not the FIRC will be disabled and GPC\_LPMR[CLPCR] defines the power mode to which this applies:

- When CCM\_CCR[FIRC\_EN]=1, FIRC is always enabled.
- When CCM\_CCR[FIRC\_EN]=0, and GPC\_LPMR[CLPCR]=2'b10 (STOP), FIRC will be disabled in a RUN mode, but not in a STOP mode.
- When CCM\_CCR[FIRC\_EN] = '0' and GPC\_LPMR[CLPCR] = 2'b10 (STOP) , FIRC is disabled after the hardware enters STOP mode.
- On exit of stop mode, FIRC is enabled again and remains ON until GPC\_LPMR[CLPCR] is set to RUN mode and CCM\_CCR[FIRC\_EN] is= '0'.

## 6.7 Voltage Regulators

### 6.7.1 Overview

The power blocks are used for providing 1.2 V digital supply to the Core logic of this device. The main/input supply voltage is 3.3 V. Digital/regulated output supply is 1.20 V - 1.26 V, for High Power/Run mode. Maximum load current supported is 1200 mA in high power mode. There are two other modes, namely "low power" and "ultra low power" with lower current driving capabilities and lower power consumption to support the device low power modes.

Power management for this device requires the following blocks described below:

- High power regulator HPREG
- Low Power Regulator LPREG
- Ultra Low Power Regulator ULPREG
- 1.1 V Regulator LDO\_IP1
- 2.5 V Regulator LDO\_2P5
- 3.0 V Regulator USB\_LDO
- SNVS Regulator
- Voltage reference for HPREG
- Voltage reference for LPREG, ULPREG, and Low Voltage Detectors (LVD)
- Low Voltage detector for 3.3 V supply
- Separate Low voltage detector for HPREG, LPREG, and ULPREG output voltages
- Separate High voltage detector (HVD) for HPREG
- Power on Reset (POR)
- Power-up sequencing
- N-well Bias circuit, which contains Well Bias Regulator (WBREG), to reduce leakage power in Low Power modes.

The voltage regulator digital interface provides the temporization delay of 300  $\mu$ s at initial power-up and during exit from LPSTOP mode. This, in conjunction with POR1 (which means ULPREG is powered-up), indicates the SRC to release the reset to the device and enter to the next phase, i.e, phase1. It provides trimming controls for regulators and LVDs. It also manages transition from run to low power mode and vice-versa. It generates interrupt on High Voltage Detection during RUN and STOP mode.

Various feature of the VREG digital interface are:

- Temporization counter of 300  $\mu$ s to get HPREG and HPBGAP up and stable during:
  - initial power up
  - LPSTOP mode exit
- Transition between different modes:
  - RUN to STOP
  - RUN to LPSTOP mode
  - STOP to RUN mode
  - LPSTOP to RUN mode
- Source of Power-On-Reset to Sytem Reset Controller.
- Interrupt on HVD (High Voltage Detection) during RUN and STOP mode
- Masking of HVD and HPLVD (High Power Low Voltage Detection) during LPSTOP mode
- Well Bias circuit control during STOP mode

### 6.7.1.1 Signal Description

The following signals connect off-chip. VDDREG, VSS, VDD are the Power supplies.

**Table 6-22. Signal Description**

Signal name	Direction	Description
VDDREG	In/Out	3.3 V supply for regulation
VSS	In/Out	Ground for Supplies
BCTRL	Out	Base control Pin for the external Ballast transistor.
VDD	In/Out	1.2V regulated supply from Ballast transistor.

### 6.7.1.2 Digital Interface Block Diagram

The following figure shows the block diagram for Voltage Regulator Digital Interface.

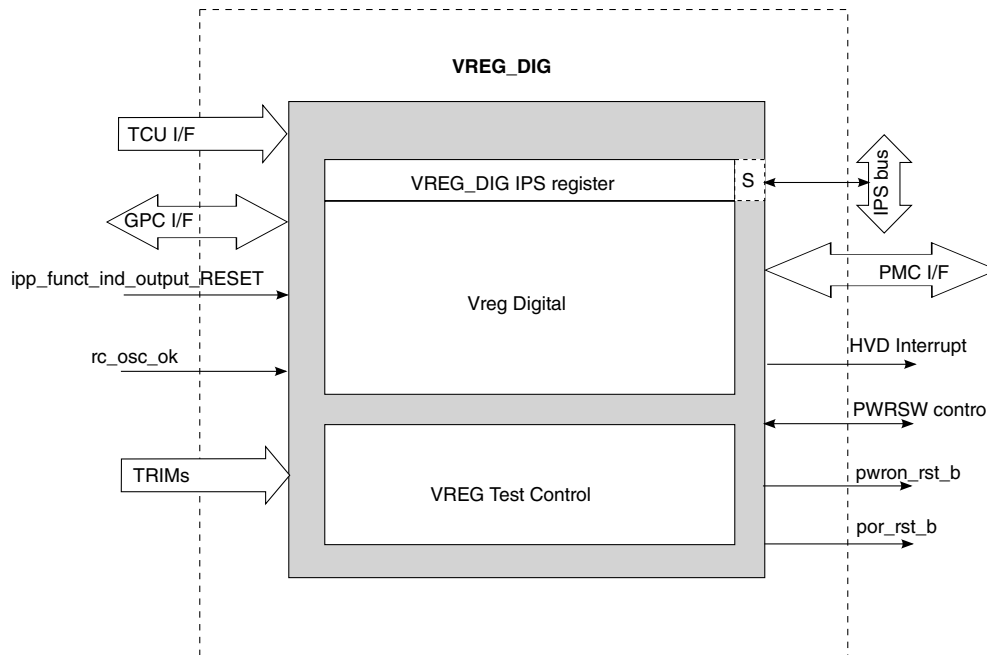

Figure 6-27. VREG\_DIG Block Diagram

## 6.7.2 Memory Map and Registers

### VREG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4006_D000	Control Register (VREG_CTRL)	32	R/W	0000_0003h	<a href="#">6.7.2.1/763</a>
4006_D004	Status register (VREG_STAT)	32	R/W	0000_0000h	<a href="#">6.7.2.2/765</a>

### 6.7.2.1 Control Register (VREG\_CTRL)

The lower bit (Mask) of this register controls the masking of the HVD interrupt. The reset value of this bit is such that it unmask the HVD interrupt.

The PORPU bit is used to control PORPU which is an input 1.2V level active high signal of the voltage regulator and is used to disable the POR-LVDMOKHV loop. The signal controls the zero/non-zero current consumption mode of the POR. The signal can control the POR only after LVDMOKHV is high. To save current consumption in low power mode (STOP/LPSTOP), this circuitry can be disabled by driving 0 on PORPU. This will disable the generation of POROUT. Whenever the High Power regulator is switched-off, POROUT circuitry can also be disabled by programming this register bit. This register can be programmed anytime by the software but the affect would only happen when the HPPD to voltage regulator is 1 (that is, HPREG is off). During RUN mode this circuitry is always ON as it does not provide considerable current consumption. The lower bit (Mask) of this register controls the masking of the HVD interrupt. The reset value of this bit is such that it unmask the HVD interrupt.

Address: 4006\_D000h base + 0h offset = 4006\_D000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**VREG\_STAT field descriptions**

Field	Description
31–1 Reserved	Reserved  This field is reserved. This read-only field is reserved and always has the value 0.
0 HVDSTAT	This bit status of HVD. It is read only and write 1 to clear. 1 : HVD interrupt is set 0 : HVD interrupt is cleared

**VREG\_STAT field descriptions (continued)**

Field	Description
-------	-------------

**6.7.3 Functional Description**

The voltage regulator consists of three internal regulators - HPREG, LPREG and ULPREG. These are designed keeping in mind that when in LPSTOP mode, the HPREG and LPREG are turned off; while in STOP mode, HPREG is turned off. The always-ON design works on ULPREG. In RUN mode, the main current is supplied from HPREG (trimmed at 1.20V) and the LPREG and ULPREG (trimmed at 1.15V) are unloaded.

**6.7.3.1 High Power or Main Regulator (HPREG)**

This section describes High Power Regulator (HPREG), which is used to convert 3.3 V input supply (VDDREG) to 1.23 V digital supply. HPREG is split into two parts:

- Regulator Controller
- The NPN bipolar transistor, which is placed external to the chip

The base of the bipolar transistor is driven by a control signal generated by the controller. The nominal target output is 1.23 V typical. The actual output will be in the range of 1.20 V - 1.26 V, post trimming. The stabilization for HPREG is achieved using an external capacitance. HPREG gets its reference voltage from a Bandgap reference circuit, which is internal to the module (LPBGAP, with a voltage of 1.2V post trim). This reference voltage is required to be trimmed to reduce the spread of the output supply.

**6.7.3.2 Low Power Regulator (LPREG)**

LPREG generates power for the device in STOP mode and has a drive strength of 200mA. The output of this regulator is tied to HPREG and in normal mode it does not supply any load current. The regulator is driven by VDDREG supply and provides the output supply of 1.22V in STOP mode, when HPREG is turned off. It has programmable output voltage in steps of 25mV.

Post trim output is in the range of 1.18 V to 1.24 V. Voltage level is selected during manufacturing and locked.

### 6.7.3.3 Ultra Low Power Regulator (ULPREG)

ULPREG generates power for the Low Power Stop modes when both HPREG & LPREG are turned off. Output of this regulator is tied those of HPREG & LPREG, but it does not supply current in normal or STOP mode. It has very low power consumption and has low load and line regulation requirements. It has output voltage programmability, but no offset programmability. Maximum drive current is 20mA.

Internal ballasts are also present in ULPREG.

### 6.7.3.4 LVDs and POR

Two types of LVDs are available:

- LVD\_MAIN for the 3.3V input supply with upper and lower thresholds at 2.770 V and 2.748 level.
- Three separate LVD\_DIG for the 1.2V common output voltage of HPREG, LPREG and ULPREG

LVD\_MAIN monitors the IO supply and one LVD\_DIG exists for each regulator: HPREG, LPREG, ULPREG. All LVD\_DIG can be programmed for different thresholds. Power-down pins are provided for all LVDs. The reference voltage used for all LVDs is from the trimmed LPBGAP.

When LVDs are powered down, their outputs are pulled high. When high power and low power regulators are OFF, the LVD\_DIG placed in the main domain should also be in power-down state.

### 6.7.3.5 Power Up Sequencing

During supply ramp-up, POR1P2 is used to mask all 1.2V control signals and initialize the LVDOKs to '0' output level. At start-up, all regulators and LVDs are turned ON after 3.3V supply POR3P3 is released. The 1.2V control bit masking is released once:

- POR1P2 is released for 1.2V supply which is after 1.2V supply is stable
- ULVDDOKHV, MLVDDOKHV, and ULVDMOKHV are '1'

During start-up or LPSTOP exit mode, load should be applied only after waiting for a time equal to the start-up time of HPREG. During the normal operation, all of the three regulators HPREG, LPREG and ULPREG will be simultaneously on, but the load current will be supplied by HPREG only. Similarly, when the device enters STOP mode, HPREG

will be off, but LPREG and ULPREG will be simultaneously on, and the load current will be supplied by LPREG. During LPSTOP mode, only ULPREG will be on and LPREG and HPREG will be turned off.

The following sections provides the functional information of VREG\_DIG and how the voltage regulator should be controlled during various low-power modes.

#### **6.7.3.6 STOP Mode**

When the device is operating in RUN mode, HPREG and LPREG both are ON, but current is supplied by the HPREG. In the Stop mode, device is powered up but there is not much activity (clock) happening inside the device. Therefore, in the Stop mode, LPREG is sufficient to provide the required device current and hence, HPREG is switched off. On system wakeup, it enables the HPREG and switch to RUN mode.

#### **6.7.3.7 Low Power Stop Mode (LPSTOP)**

In LPSTOP mode, a small part of the device is ON and the remaining part is not powered. In this mode, ULPREG supplies the core current (leakage) while HPREG and LPREG is OFF. VREG\_DIG also opens all the power switches (PD1, 16K and 48K) based on the configuration provided in GPC power gate control register before powering off the HPREG and LPREG. On system wakeup, it enables the transition to RUN mode by enabling the HPREG and LPREG. All the power switches are closed after HPREG stabilizes.

#### **6.7.3.8 Well Bias STOP Mode**

It enables the system to enter into lowest power STOP mode. In this mode, the device current is provided by WBREG regulator while HPREG is switched off. On system wakeup, it enables the HPREG and disables the WBREG.

## 6.8 Analog Components Control Digital Interface (ANADIG)

### 6.8.1 Overview

ANADIG is collection of digital interfaces and controllers of analog components, which include control registers described below for controlling analog components and analog interfaces. ANADIG can be accessed through the IPS bus interface.

#### NOTE

For the ANADIG PLL (including USB PLL), regulator, and miscellaneous registers, the fields are preprogrammed for a configuration and are read-only from a customer perspective.

#### NOTE

The registers described in this chapter will be referred to from different sections of this Reference Manual.

#### NOTE

The device has to run on the IRC to detect a BO event on the LDO1p1.

### 6.8.2 Memory Map and Registers

#### 6.8.2.1 Anadig Registers

### 6.8.2.1.1 PLL3 Control register (ANADIG\_PLL3\_CTRL)

This register defines the control bits for 480 MHz PLL of USB0.

Address: 4005\_0000h base + 10h offset = 4005\_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	0														BYPASS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	BYPASS_CLK_SRC	ENABLE	POWER	0				EN_USB_CLKS	0				DIV_SELECT	Reserved	
W																
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

**ANADIG\_PLL3\_CTRL field descriptions**

Field	Description
31 LOCK	Lock bit. 0 PLL is not currently locked. 1 PLL is currently locked.
30–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 BYPASS	Bypass the PLL. 0 Disable bypass 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source selection. 0 24 MHz XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the PLL output clock. 0 PLL output clock is gated, so disabled. 1 PLL output clock is enabled.
12 POWER	Powers up the USB0 PLL. 0 Not powered up 1 Powered up
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 EN_USB_CLKS	Clock Gating for 8 Phase clock of USB0 PHY. 0 8-phase PLL outputs for USB0 PHY are powered down. 1 8-phase PLL outputs for USB0 PHY are powered up.
5–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DIV_SELECT	Select PLL multiplication factor (MFI), $F_{out} = F_{ref} * 20$ to generates $F_{out} = 480$ MHz when $F_{ref} = 24$ MHz. 0 $F_{out} = F_{ref} * 20$ (default value) 1 $F_{out} = F_{ref} * 22$
0 Reserved	This field is reserved.

### 6.8.2.1.2 PLL7 Control register (ANADIG\_PLL7\_CTRL)

This register defines the control bits for the 480 MHz PLL of USB1.

Address: 4005\_0000h base + 20h offset = 4005\_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	0														BYPASS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	BYPASS_CLK_SRC	ENABLE	POWER	Reserved				EN_USB_CLKS	0				DIV_SELECT	Reserved	
W																
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

**ANADIG\_PLL7\_CTRL field descriptions**

Field	Description
31 LOCK	Lock bit. 0 PLL is not currently locked. 1 PLL is currently locked.
30–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 BYPASS	Bypasses the PLL. 0 Disable bypass 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 Clock output not enabled 1 Enable clock output
12 POWER	Powers up the USB1 PLL 0 Not powered up 1 Powered up
11–7 Reserved	This field is reserved.
6 EN_USB_CLKS	Clock Gating for 8 Phase clock of USB0 PHY. 0 8-phase PLL outputs for USB1 PHY are powered down. 1 8-phase PLL outputs for USB1 PHY are powered up.
5–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DIV_SELECT	Select PLL multiplication factor (MFI), $F_{out} = F_{ref} * 20$ to generates $F_{out} = 480$ MHz when $F_{ref} = 24$ MHz. 0 $F_{out} = F_{ref} * 20$ (default value) 1 $F_{out} = F_{ref} * 22$
0 Reserved	This field is reserved.

### 6.8.2.1.3 PLL2 Control register (ANADIG\_PLL2\_CTRL)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 30h offset = 4005\_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	0												PFD_OFFSET_EN	DITHER_ENABLE	BYPASS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	BYPASS_CLK_SRC	ENABLE	POWERDOWN	Reserved					0					DIV_SELECT	
W																
Reset	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	1

**ANADIG\_PLL2\_CTRL field descriptions**

Field	Description
31 LOCK	<p>Lock bit.</p> <p>Shows whether the PLL is locked on the required frequency.</p> <p>0 PLL is not currently locked.</p> <p>1 PLL is currently locked.</p>

*Table continues on the next page...*

**ANADIG\_PLL2\_CTRL field descriptions (continued)**

Field	Description
30–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_EN	Enables an offset in the phase frequency detector. 0 Offset in the phase frequency detector is not enabled 1 Enable an offset in the phase frequency detector
17 DITHER_ENABLE	Enables dither in the fractional modulator calculation. 0 Dither in the fractional modulator calculation is not enabled 1 Enable dither in the fractional modulator calculation.
16 BYPASS	Bypasses the PLL The frequency that is at the input of the PLL circumvents the PLL and is routed directly to the output of the PLL, i.e., the PLL has no affect on the frequency. If this bit is set, the output will be either 24 MHz xtal clock or external clock through LVDS pad depending on the BYPASS_CLK_SOURCE bit. 0 Disable bypass 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the PLL output clock. 0 PLL output clock is gated, so disabled. 1 PLL output clock is enabled.
12 POWERDOWN	Powers down the PLL. 0 PLL is not powered down. 1 Power down the PLL.
11–7 Reserved	This field is reserved.
6–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DIV_SELECT	Frequency multiplier selection (MFI). 0 $F_{out} = F_{ref} * 20$ 1 $F_{out} = F_{ref} * 22$ . If PLL frequency is to be 528MHz, $F_{out} = 528 \text{ MHz} = 24 \text{ MHz xtal} * 22$ .

### 6.8.2.1.4 PLL2 Spread Spectrum definition register (ANADIG\_PLL2\_SS)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 40h offset = 4005\_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STOP															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	ENABLE	STEP														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ANADIG\_PLL2\_SS field descriptions

Field	Description
31–16 STOP	<p>STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula).</p> <p>Modulation Depth = (STOP / MFD) * Fref, where MFD is the MFD field value in <a href="#">PLL2 Denominator definition register (ANADIG_PLL2_DENOM)</a> register. Recommended: Modulation Depth = 2%, Modulation Frequency = 30K</p> <p>Modulation Frequency = (STEP / (2 * STOP)) * Fref, where Fref = 24MHz..</p>
15 ENABLE	<p>This bit enables the spread spectrum modulation.</p> <p>0 Spectrum modulation is disabled 1 Spectrum modulation is enabled</p>
STEP	<p>STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula).</p> <p>Modulation Depth = (STOP / MFD) * Fref, where MFD is the MFD field value in <a href="#">PLL2 Denominator definition register (ANADIG_PLL2_DENOM)</a> register. Recommended: Modulation Depth = 2%, Modulation Frequency = 30K</p> <p>Modulation Frequency = (STEP / (2 * STOP)) * Fref, where Fref = 24MHz..</p>

### 6.8.2.1.5 PLL2 Numerator definition register (ANADIG\_PLL2\_NUM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 50h offset = 4005\_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		MFN																													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ANADIG\_PLL2\_NUM field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFN	30-bit numerator of the fractional loop divider (unsigned integer).  <b>NOTE:</b> These bits are preset to required values that are within the range of the PLL. <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

### 6.8.2.1.6 PLL2 Denominator definition register (ANADIG\_PLL2\_DENOM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 60h offset = 4005\_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ANADIG\_PLL2\_DENOM field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFD	30-bit denominator of the fractional loop divider (unsigned integer).  <b>NOTE:</b> These bits are preset to required values that are within the range of the PLL. <b>NOTE:</b> Zero is an invalid value. <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

### 6.8.2.1.7 PLL4 Control register (ANADIG\_PLL4\_CTRL)

This register defines the control bits for the audio PLL.

Address: 4005\_0000h base + 70h offset = 4005\_0070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
R	LOCK		0										0		PFD_OFFSET_EN		DITHER_ENABLE	BYPASS
W																		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1		

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	BYPASS_CLK_SRC		ENABLE	POWERDOWN	0			DIV_SELECT							
W																
Reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	0	1

**ANADIG\_PLL4\_CTRL field descriptions**

Field	Description
31 LOCK	Lock bit.  0 PLL is not currently locked. 1 PLL is currently locked.
30–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## ANADIG\_PLL4\_CTRL field descriptions (continued)

Field	Description
20–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_EN	Enables an offset in the phase frequency detector. 0 PFD offset is disabled 1 Enable PFD offset
17 DITHER_ENABLE	Enables dither in the fractional modulator calculation. 0 Dither is disabled 1 Enable dither
16 BYPASS	Bypasses the PLL. 0 Disable bypass, PLL will drive its own Clock 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Colock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 PLL output clock is disabled. 1 PLL output clock is enabled.
12 POWERDOWN	Powers down the PLL. 0 No Power Down 1 PLL Power Down
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV_SELECT	Frequency multiplier factor selection.  Freq = InputFreq (24 MHz for Xtal) * DIV_SELECT  <b>NOTE:</b> This PLL can function from 600 MHz to 1300 MHz.  <b>NOTE:</b> Zero is an invalid value.

## 6.8.2.1.8 PLL4 Numerator register (ANADIG\_PLL4\_NUM)

This register defines the control bits for the audio PLL.

Address: 4005\_0000h base + 80h offset = 4005\_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ANADIG\_PLL4\_DENOM field descriptions**

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFD	This is the 30-bit denominator of the fractional loop divider.  <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

6.8.2.1.10 PLL6 Control register (ANADIG\_PLL6\_CTRL)

This register defines the control bits for the video PLL.

Address: 4005\_0000h base + A0h offset = 4005\_00A0h

ANADIG\_PLL6\_CTRL field descriptions

Field	Description
31 LOCK	Lock bit.  0 PLL is not currently locked. 1 PLL is currently locked.
30–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

**ANADIG\_PLL6\_CTRL field descriptions (continued)**

Field	Description
20–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_EN	Enables an offset in the phase frequency detector. 0 PFD offset is disabled 1 Enable PFD offset
17 DITHER_ENABLE	Enables dither in the fractional modulator calculation. 0 Dither is disabled 1 Enable dither
16 BYPASS	Bypasses the PLL. 0 Bypass is disabled 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 Clock output is not enabled 1 Enable clock output
12 POWERDOWN	Powers down the PLL. 0 Power down is not enabled 1 Enable power down
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV_SELECT	Frequency multiplier factor selection.  Freq = InputFreq (24MHz for Xtal) * DIV_SELECT. This PLL can function from 600 MHz to 1300 MHz. <b>NOTE:</b> Zero is an invalid value.

**6.8.2.1.11 PLL6 Numerator register (ANADIG\_PLL6\_NUM)**

This register defines the control bits for the video PLL.

Address: 4005\_0000h base + B0h offset = 4005\_00B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																MFN															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ANADIG\_PLL6\_NUM field descriptions**

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFN	This is the 30-bit numerator of the fractional loop divider.  <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

**6.8.2.1.12 PLL6 Denominator register (ANADIG\_PLL6\_DENOM)**

This register defines the control bits for the video PLL.

Address: 4005\_0000h base + C0h offset = 4005\_00C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ANADIG\_PLL6\_DENOM field descriptions**

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFD	This is the 30-bit denominator of the fractional loop divider.  <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

### 6.8.2.1.13 PLL5 Control register (ANADIG\_PLL5\_CTRL)

This register defines the control bits for the ENET PLL. The raw VCO output frequency is 500 MHz. This PLL produces a reference clock for the Ethernet block. Ref\_Ethernet is configurable based on the DIV\_SELECT field.

Address: 4005\_0000h base + E0h offset = 4005\_00E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK						0									
W														PFD_OFFSET_EN	DITHER_ENABLE	BYPASS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						0					0				
W		BYPASS_CLK_SRC	ENABLE	POWERDOWN												DIV_SELECT
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1

**ANADIG\_PLL5\_CTRL field descriptions**

Field	Description
31 LOCK	Lock bit.

*Table continues on the next page...*

**ANADIG\_PLL5\_CTRL field descriptions (continued)**

Field	Description
	0 PLL is not currently locked. 1 PLL is currently locked.
30–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_EN	Enables an offset in the phase frequency detector. 0 PFD offset is not enabled 1 Enable PFD offset
17 DITHER_ENABLE	Enables dither in the fractional modulator calculation. 0 Dither is not enabled 1 Enable dither
16 BYPASS	Bypasses the PLL.. 0 Bypass is not enabled 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 Clock output is not enabled 1 Enable clock output
12 POWERDOWN	Powers down the PLL. 0 Power down is not enabled 1 Enable power down
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV_SELECT	Controls the frequency of the Ethernet reference clock. Only setting 01 (50MHz) is valid. 01 50 MHz

**6.8.2.1.14 ANADIG PLL3 PFD definition register (ANADIG\_PLL3\_PFD)**

This register defines the control bits for the PFD clocks derived from PLL3 for USB0.

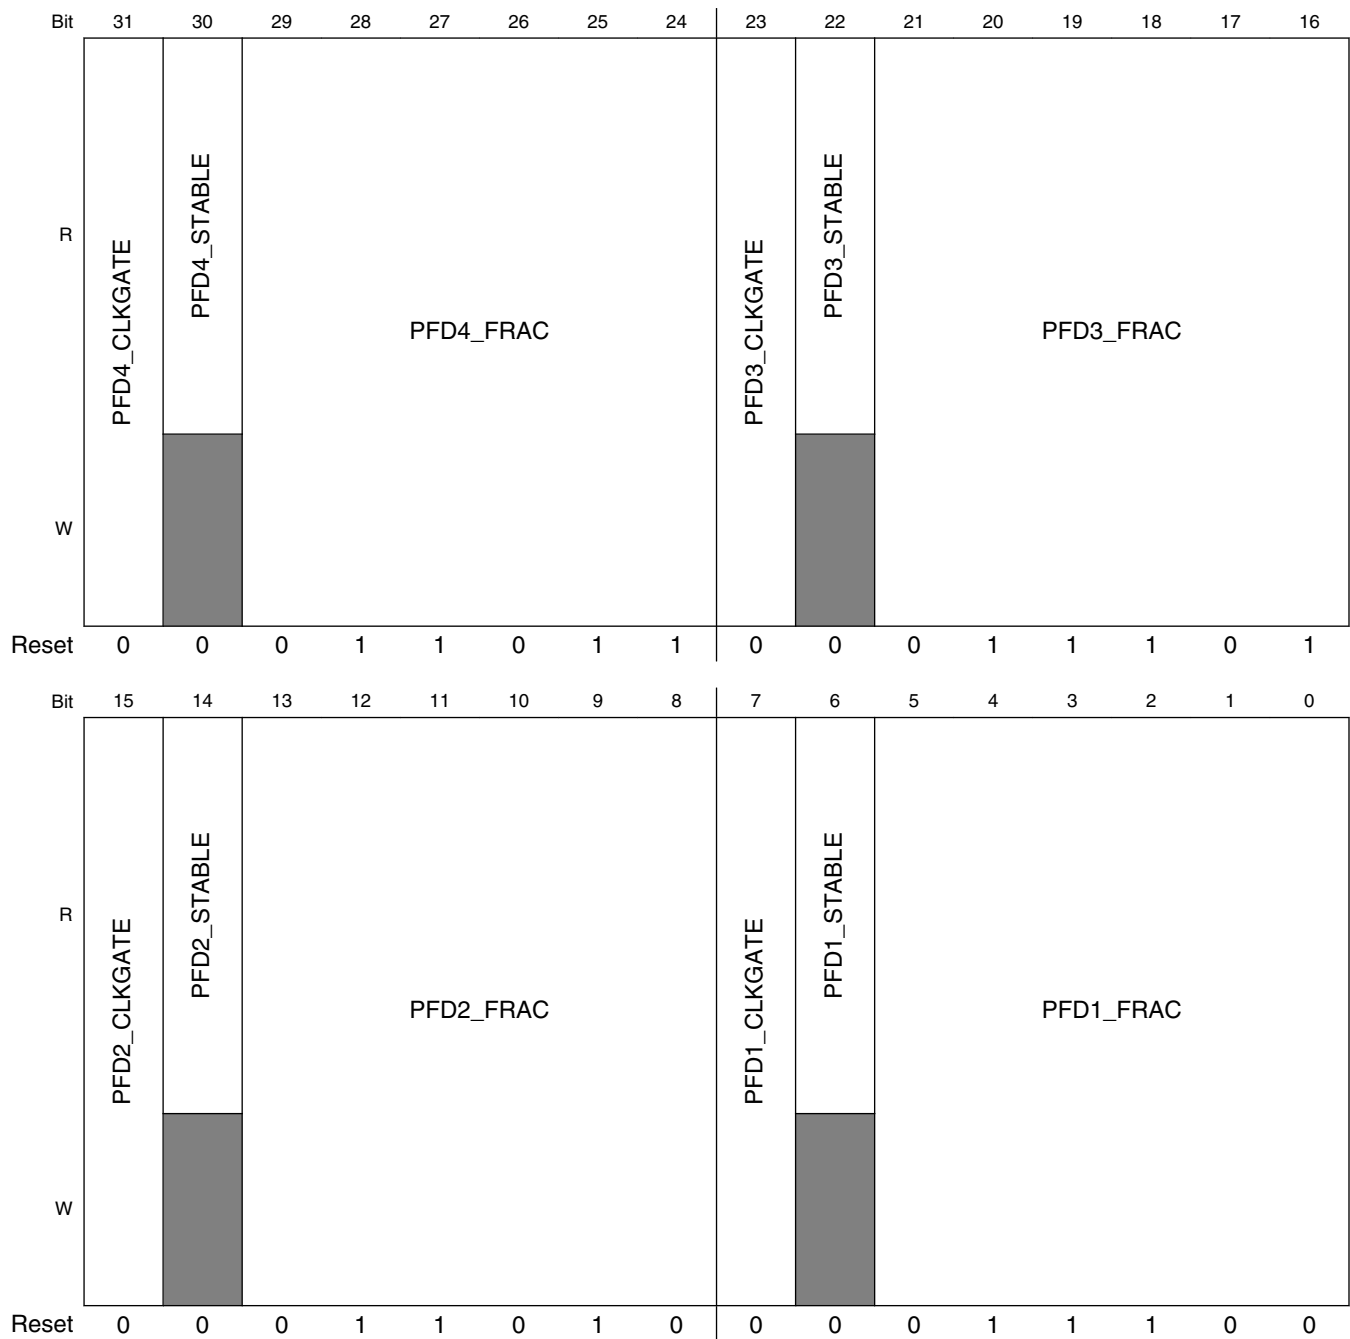

**NOTE**

It is recommended that PFD setting are kept between 18 and 35 for all PFDs.

**NOTE**

PLL7 for USB1 does not have PFDs.

Address: 4005\_0000h base + F0h offset = 4005\_00F0h

**ANADIG\_PLL3\_PFD field descriptions**

Field	Description
31 PFD4_CLKGATE	This bit controls the generation of PFD4.

Table continues on the next page...

## ANADIG\_PLL3\_PFD field descriptions (continued)

Field	Description
	0 ref_pfd4 fractional divider clock is enabled. 1 ref_pfd4 fractional divider clock is disabled for power savings.
30 PFD4_STABLE	This read-only field is for diagnostic purpose only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable.  <b>NOTE:</b> Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
29–24 PFD4_FRAC	This field controls the fractional divide value. The resulting frequency is $480 \times 18 / \text{pfd4\_frac}$ where the value of pfd4_frac ranges between 12 and 35.
23 PFD3_CLKGATE	This bit controls the generation of PFD3. 0 ref_pfd3 fractional divider clock is enabled. 1 ref_pfd3 fractional divider clock is disabled for power savings.
22 PFD3_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable.  <b>NOTE:</b> Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
21–16 PFD3_FRAC	This field controls the fractional divide value. The resulting frequency shall be $480 \times 18 / \text{pfd3\_frac}$ where the value of pfd3_frac ranges from 12 to 35.
15 PFD2_CLKGATE	This bit controls the generation of PFD2. 0 ref_pfd2 fractional divider clock is enabled. 1 ref_pfd2 fractional divider clock is disabled for power savings.
14 PFD2_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable.  <b>NOTE:</b> Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
13–8 PFD2_FRAC	This field controls the fractional divide value. The resulting frequency is $480 \times 18 / \text{pfd2\_frac}$ where the value of pfd2_frac ranges from 12 to 35.
7 PFD1_CLKGATE	This bit controls the generation of PFD1. 0 ref_pfd1 fractional divider clock is enabled. 1 ref_pfd1 fractional divider clock is disabled for power saving.
6 PFD1_STABLE	This read-only bitfield is for diagnostic purposes only since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable.  <b>NOTE:</b> Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
PFD1_FRAC	This field controls the fractional divide value.  The resulting frequency shall be $480 \times 18 / \text{pfd1\_frac}$ , where the value of pfd1_frac ranges from 12 to 35.

Table continues on the next page...

**ANADIG\_PLL3\_PFD field descriptions (continued)**

Field	Description
	<b>NOTE:</b> It is recommended that PFD setting is kept between 18 and 35 for all PFDs.

**6.8.2.1.15 ANADIG PLL2 PFD definition register (ANADIG\_PLL2\_PFD)**

This register defines the control bits for the core PLL.

**NOTE**

It is recommended that PFD setting is kept between 18 and 35 for all PFDs.

Address: 4005\_0000h base + 100h offset = 4005\_0100h

**ANADIG\_PLL2\_PFD field descriptions**

Field	Description
31 PFD4_CLKGATE	This bit controls the generation of PFD4. 0 ref_pfd4 fractional divider clock is enabled. 1 ref_pfd4 fractional divider clock is disabled for power savings.
30 PFD4_STABLE	This read-only field is for diagnostic purpose only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
29–24 PFD4_FRAC	This field controls the fractional divide value. The resulting frequency is $528 \times 18 / \text{pfd4\_frac}$ where the value of pfd4_frac ranges between 12 and 35.
23 PFD3_CLKGATE	This bit controls the generation of PFD3. 0 ref_pfd3 fractional divider clock is enabled. 1 ref_pfd3 fractional divider clock is disabled for power savings.
22 PFD3_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
21–16 PFD3_FRAC	This field controls the fractional divide value. The resulting frequency shall be $528 \times 18 / \text{pfd3\_frac}$ where the value of pfd3_frac ranges from 12 to 35.
15 PFD2_CLKGATE	This bit controls the generation of PFD2. 0 ref_pfd2 fractional divider clock is enabled. 1 ref_pfd2 fractional divider clock is disabled for power savings.
14 PFD2_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The

Table continues on the next page...

Field	Description
	value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
13–8 PFD2_FRAC	This field controls the fractional divide value. The resulting frequency is $528 \times 18 / \text{pfd2\_frac}$ where the value of pfd2_frac ranges from 12 to 35.
7 PFD1_CLKGATE	This bit controls the generation of PFD1. 0 ref_pfd1 fractional divider clock is enabled. 1 ref_pfd1 fractional divider clock is disabled for power saving.
6 PFD1_STABLE	This read-only bitfield is for diagnostic purposes only since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
PFD1_FRAC	This field controls the fractional divide value.  The resulting frequency shall be $528 \times 18 / \text{pfd1\_frac}$ where the value of pfd1_frac ranges from 12 to 35.  <b>NOTE:</b> It is recommended that PFD setting is kept between 18 and 35 for all PFDs.

6.8.2.1.16 ANADIG Regulator 1P1 definition register (ANADIG\_REG\_1P1)

This register defines the control and status bits for the 1.1 V regulator. This regulator is designed to power the digital portions of the analog cells.

Address: 4005\_0000h base + 110h offset = 4005\_0110h

ANADIG\_REG\_1P1 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

**ANADIG\_REG\_1P1 field descriptions (continued)**

Field	Description
17 OK_VDD1P1	This status bit signals that the regulator output is ok.  0 Regulator output is not ok. 1 Regulator output is ok.
16 BO_VDD1P1	This is the status bit that shows if the regulator Brown-out is asserted or not.  Brown out is the point when regulator is unable to hold its output above the configured voltage.  0 Brown-out is not detected on the regulator output. 1 Brown-out is detected on the regulator output.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ENABLE_PULLDOWN	Control bit to enable the pull-down circuitry in the regulator.  0 Pull-down circuitry in the regulator is disabled 1 enable the pull-down circuitry in the regulator.
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator input power.  Once, this bit is asserted, regulator will not sync more current then its limit.  0 Current-limit circuitry in the regulator is disabled 1 Enable the current-limit circuitry in the regulator.
1 ENABLE_BO	Control bit to enable the brown-out circuitry in the regulator.  0 Brown-out circuitry in the regulator is disabled 1 Enable the brown-out circuitry in the regulator.
0 ENABLE_LINREG	Control bit to enable the regulator output.  0 Regulator output is disabled 1 Enable the regulator output.

**6.8.2.1.17 ANADIG Regulator 3P0 definition register (ANADIG\_REG\_3P0)**

This register defines the control and status bits for the 3.0 V regulator powered by the host USB  $V_{BUS}$  pin. The regulator will automatically use the VBUS pin with 5.0 V.

**NOTE**

The regulator will only be enabled when at least one of the VBUS\_DETECT pins is at a valid VBUS level (>4.4 V)

## Anadig Registers

Address: 4005\_0000h base + 120h offset = 4005\_0120h

### ANADIG\_REG\_3P0 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 OK_VDD3P0	This status bit signals that the regulator output is ok. It will only turn on when LINREG enable is set and one of the VBUS_DETECT pins is at a valid VBUS level. 0 Regulator output is not ok 1 Regulator output is ok
16 BO_VDD3P0	This is the status bit that shows if the regulator Brown-out is asserted or not. Brown out is the point when regulator is unable to hold its output above the configured voltage. 0 Brown-out is not detected on the regulator output. 1 Brown-out is detected on the regulator output.

Table continues on the next page...

**ANADIG\_REG\_3P0 field descriptions (continued)**

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 REG_3P0_ VBUS_SEL	If both $V_{BUS}$ host and $V_{BUS}$ otg are detected present, then this bit determines which source is utilized for generating reg_3p0.  0 Utilize host power. 1 Utilize OTG power.
6–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator input power.  Once, this bit is asserted, regulator will not supply more current then its limit.  0 Current-limit circuitry in the regulator is not enabled 1 Enable the current-limit circuitry in the regulator
1 ENABLE_BO	Control bit to enable the brown-out circuitry in the regulator.  0 Brown-out circuitry in the regulator is not enabled 1 Enable the brown-out circuitry in the regulator
0 ENABLE_ LINREG	Control bit to enable the regulator.  0 Regulator output is not enabled 1 Enable the regulator.

6.8.2.1.18 ANADIG Regulator 2P5 definition register (ANADIG\_REG\_2P5)

This register defines the control and status bits for the 2.5 V regulator.

Address: 4005\_0000h base + 130h offset = 4005\_0130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**ANADIG\_REG\_2P5 field descriptions**

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ENABLE_ WEAK_LINREG	Enables the weak 2p5 regulator. This regulator is used when the main 2p5 regulator is disabled to keep the 2.5 V output roughly at 2.5 V. It depends directly on the value of VDDIO. The same enable is also used to enable the weak 1p1 regulator. This regulator is used when the main 1p1 regulator is disabled to keep the 1.1 V output roughly at 1.1 V.  <b>NOTE:</b> Setting this bit is mandatory for wake-up from USB in stop mode when main regulators (1p1 and 2p5) are turned off. Weak Linreg (1p1 and 2p5) are enabled in stop mode to support wake-up from USB.  0 Weak 2p5 regulator is not enabled 1 Enable the weak 2p5 regulator
17 OK_VDD2P5	Status bit that signals when the regulator output is ok.  0 Regulator output is not ok. 1 Regulator output is ok.
16 BO_VDD2P5	This is the status bit that shows if the regulator Brown-out is asserted or not.  Brown out is the point when regulator is unable to hold its output above the configured voltage.  0 Brown-out is not detected on the regulator output. 1 Brown-out is detected on the regulator output.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ENABLE_ PULLDOWN	Control bit to enable the pull-down circuitry in the regulator.  0 Pull-down circuitry in the regulator is not enabled 1 Enable the pull-down circuitry in the regulator
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator.  0 Current-limit circuitry in the regulator is not enabled 1 Enable the current-limit circuitry in the regulator
1 ENABLE_BO	Control bit to enable the brown-out circuitry in the regulator.  0 Brown-out circuitry in the regulator is not enabled 1 Enable the brown-out circuitry in the regulator
0 ENABLE_ LINREG	Control bit to enable the regulator output.  0 Enable the regulator output. 1 Regulator output is not enabled

### 6.8.2.1.19 ANADIG Analog Miscellaneous definition register (ANADIG\_ANA\_MISC0)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 4005\_0000h base + 150h offset = 4005\_0150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
R	0			0													OSC_XTALOK_EN	OSC_XTALOK
W																		
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0		

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	0		CLK_24M_IRC_XTAL_SEL	STOP_MODE_CONFIG	0				REFTOP_VBGUP	0				REFTOP_SELBIASOFF	REFTOP_LOWPPOWER	REFTOP_PWDVBGUP	REFTOP_PWD
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**ANADIG\_ANA\_MISC0 field descriptions**

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 OSC_XTALOK_EN	Oscillator Crystal Lock Enable 0 Oscillator crystal lock is not enabled 1 Enable the oscillator crystal lock
16 OSC_XTALOK	Status bit which signals that the output of the 24 MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency. 0 Output of the 24 MHz crystal oscillator is not stable 1 Output of the 24 MHz crystal oscillator is stable
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CLK_24M_IRC_XTAL_SEL	Select internal 24M IRC clock or External 24M xtal clock as a source of 24MHz. 0 External 24Mhz Xtal Clock. 1 24MHz Internal IRC. It is recommended to not use internal IRC for enabling PLLs.
12 STOP_MODE_CONFIG	Configure the analog behavior in stop mode. 0 All analog except rtc powered down on stop mode assertion. 1 On the device AnatoP, just the Reftop (reference bias circuit) can be kept alive in Stop mode. <b>NOTE:</b> To support wake-up from USB (Device Mode) , this bit must be set to '1' if 'analog_stop_mode' is used in stop mode (i.e if 'analog_stop_mode' bit is set '1' in CCM Low Power Control Register).
11–8 Reserved	This read-only field is reserved and always has the value 0.
7 REFTOP_VBGUP	This field signals that the analog bandgap voltage is up and stable. 0 Analog bandgap voltage is not up and stable 1 Analog bandgap voltage is up and stable
6–4 Reserved	This read-only field is reserved and always has the value 0.
3 REFTOP_SELBIASOFF	Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This field should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap. 0 Self-bias circuit in the analog bandgap is not disabled 1 Disable the self-bias circuit in the analog bandgap
2 REFTOP_LOWPOWER	Control bit to enable the low-power mode in the analog bandgap. 0 Low-power mode in the analog bandgap is not enabled 1 Enable the low-power mode in the analog bandgap
1 REFTOP_PWDVBGUP	Control bit to power-down the VBG-up detection circuitry in the analog bandgap. 0 VBG-up detection circuitry in the analog bandgap is not powered down 1 Power-down the VBG-up detection circuitry in the analog bandgap

*Table continues on the next page...*

**ANADIG\_ANA\_MISC0 field descriptions (continued)**

Field	Description
0 REFTOP_PWD	Control bit to power-down the analog bandgap reference circuitry.  0 Analog bandgap reference circuitry is not powered down 1 Powerdown the analog bandgap reference circuitry

**6.8.2.1.20 ANADIG Analog Miscellaneous definition register (ANADIG\_ANA\_MISC1)**

This register defines the control and status bits for miscellaneous analog blocks. The lvds1 and lvds2 controls below control the behavior of the anack1/1b and anack2/2b lvds IOs.

Address: 4005\_0000h base + 160h offset = 4005\_0160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	IRQ_ANA_BO	IRQ_TEMPSENSE	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			LVDSCLK1_IBEN	0	LVDSCLK1_OBEN	0				0					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ANADIG\_ANA\_MISC1 field descriptions**

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 IRQ_ANA_BO	This status bit is set to one when when any of the analog regulator brownout interrupts assert. Check the regulator status bits to discover which regulator interrupt asserted. To clear this bit write a 1 in Clear SCT mode.  0 None of the analog regulator brownout interrupts is asserted 1 Set to one when when any of the analog regulator brownout interrupts is asserted
29 IRQ_TEMPSENSE	This status bit is set to one when when the temperature sensor interrupt asserts. To clear this bit write a 1 in Clear SCT mode.

Table continues on the next page...

**ANADIG\_ANA\_MISC1 field descriptions (continued)**

Field	Description
	0 Temperature sensor interrupt is not asserted 1 Set to one when the temperature sensor interrupt is asserted
28–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LVDSCLK1_ IBEN	This enables the lvds input buffer for AnaClock. Do not enable input and output buffers simultaneously. 0 LVDs input buffer not enabled for AnaClock 1 Enable the LVDs input buffer for AnaClock
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 LVDSCLK1_ OBEN	This bit enables the lvds output buffer for selected internal clock. <b>NOTE:</b> Do not enable input and output buffers simultaneously. 0 LVDs output buffer is not enabled for driving internal clock 1 Enable the LVDs output buffer for driving internal clock
9–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

6.8.2.1.21 PLL1 Control register (ANADIG\_PLL1\_CTRL)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 270h offset = 4005\_0270h

ANADIG\_PLL1\_CTRL field descriptions

Field	Description
31 LOCK	Lock bit.  Shows whether the PLL is locked on the required frequency.  0    PLL is not currently locked. 1    PLL is currently locked.

Table continues on the next page...

**ANADIG\_PLL1\_CTRL field descriptions (continued)**

Field	Description
30–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_EN	Enables an offset in the phase frequency detector. 0 Offset in the phase frequency detector is not enabled 1 Enable an offset in the phase frequency detector
17 DITHER_ENABLE	Enables dither in the fractional modulator calculation. 0 Dither in the fractional modulator calculation is not enabled 1 Enable dither in the fractional modulator calculation.
16 BYPASS	Bypasses the PLL The frequency that is at the input of the PLL circumvents the PLL and is routed directly to the output of the PLL, i.e., the PLL has no affect on the frequency. If this bit is set, the output will be either 24MHz xtal clock or external clock through LVDS pad depending on the BYPASS_CLK_SOURCE bit. 0 Disable bypass 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source. 0 24M XTAL clock is selected as clock source for the PLL 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the PLL output clock. 0 PLL output clock is disabled. 1 PLL output clock is enabled.
12 POWERDOWN	Powers down the PLL. 0 PLL is not powered down 1 Power down the PLL
11–7 Reserved	This field is reserved.
6–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DIV_SELECT	Frequency multiplier selection. 0 $F_{out} = F_{ref} * 20$ 1 $F_{out} = F_{ref} * 22$

### 6.8.2.1.22 PLL1 Spread Spectrum register (ANADIG\_PLL1\_SS)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 280h offset = 4005\_0280h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STOP

#### ANADIG\_PLL1\_SS field descriptions

Field	Description
31–16 STOP	<p>STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula).</p> <p>Modulation Depth = <math>(\text{STOP} / \text{B}) * \text{Fref}</math>, where B is the B field value in <a href="#">PLL2 Denominator definition register (ANADIG_PLL2_DENOM)</a> register. Recommended: Modulation Depth = 2%, Modulation Frequency = 32K</p> <p>Modulation Frequency = <math>(\text{STEP} / (2 * \text{STOP})) * \text{Fref}</math>, where Fref = 24MHz..</p>
15 ENABLE	<p>This bit enables the spread spectrum modulation.</p> <p>0 Spread spectrum modulation is not enabled 1 Enable spread spectrum modulation</p>
STEP	<p>STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula).</p> <p>Modulation Depth = <math>(\text{STOP} / \text{B}) * \text{Fref}</math>, where B is the B field value in <a href="#">PLL2 Denominator definition register (ANADIG_PLL2_DENOM)</a> register. Recommended: Modulation Depth = 2%, Modulation Frequency = 32K</p> <p>Modulation Frequency = <math>(\text{STEP} / (2 * \text{STOP})) * \text{Fref}</math>, where Fref = 24MHz..</p>

### 6.8.2.1.23 PLL1 Numerator register (ANADIG\_PLL1\_NUM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 290h offset = 4005\_0290h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		MFN																													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ANADIG\_PLL1\_NUM field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFN	This is the 30-bit numerator of the fractional loop divider.  <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

### 6.8.2.1.24 PLL1 Denominator register (ANADIG\_PLL1\_DENOM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005\_0000h base + 2A0h offset = 4005\_02A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		MFD																													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0

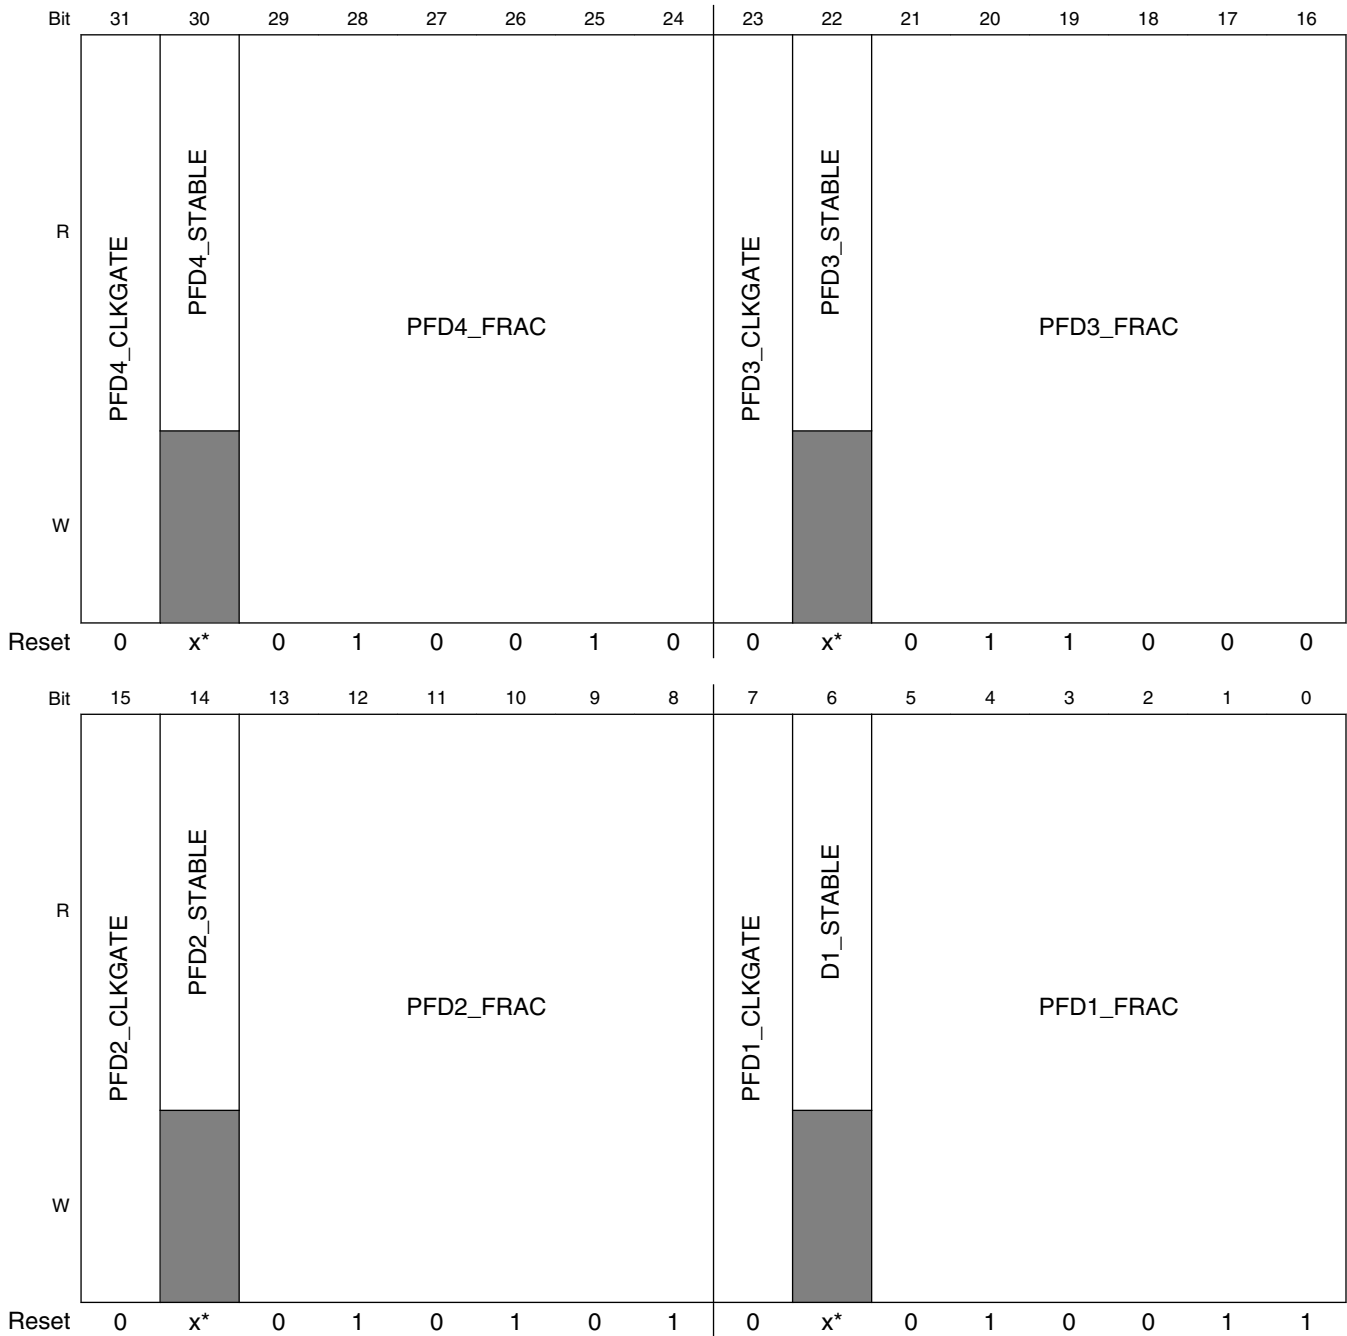

#### ANADIG\_PLL1\_DENOM field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MFD	This is the 30-bit denominator of the fractional loop divider.  <b>NOTE:</b> The value of the numerator must always be configured to be less than the value of the denominator.

6.8.2.1.25 ANADIG PLL1\_PFD definition register (ANADIG\_PLL1\_PFD)

This register defines the control bits for the core PLL.

Address: 4005\_0000h base + 2B0h offset = 4005\_02B0h

\* Notes:  
• x = Undefined at reset.

## ANADIG\_PLL1\_PFD field descriptions

Field	Description
31 PFD4_CLKGATE	This bit enables the fractional divider clock. 0 ref_pfd4 fractional divider clock is enabled. 1 ref_pfd4 fractional divider clock is disabled for power savings.
30 PFD4_STABLE	This read-only bitfield is for diagnostic purpose only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
29–24 PFD4_FRAC	This field controls the fractional divide value. The resulting frequency will be $528 \times 18 / \text{pfd4\_frac}$ where the value of pfd4_frac ranges from 12 to 35.
23 PFD3_CLKGATE	This bit enables the fractional divider clock. 0 ref_pfd3 fractional divider clock is enabled. 1 ref_pfd3 fractional divider clock is disabled for power savings.
22 PFD3_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
21–16 PFD3_FRAC	This field controls the fractional divide value. The resulting frequency shall be $528 \times 18 / \text{pfd3\_frac}$ where the value of pfd3_frac ranges from 12 to 35.
15 PFD2_CLKGATE	This bit controls the generation of PFD2. 0 ref_pfd2 fractional divider clock is enabled. 1 ref_pfd2 fractional divider clock is disabled for power savings.
14 PFD2_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
13–8 PFD2_FRAC	This field controls the fractional divide value. The resulting frequency is $480 \times 18 / \text{pfd2\_frac}$ where the value of pfd2_frac ranges from 12 to 35.
7 PFD1_CLKGATE	This bit enables the fractional divider clock. 0 ref_pfd1 fractional divider clock is enabled. 1 ref_pfd1 fractional divider clock is disabled for power saving.
6 D1_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
PFD1_FRAC	This field controls the fractional divide value. The resulting frequency shall be $528 \times 18 / \text{pfd1\_frac}$ where the value of pfd1_frac ranges from 12 to 35.

### 6.8.2.1.26 ANADIG PLL Lock register (ANADIG\_PLL\_LOCK)

This register give lock status of different PLLs controlled by ANADIG.

Address: 4005\_0000h base + 2C0h offset = 4005\_02C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0									PLL1	PLL2	PLL4	PLL6	PLL5	PLL3	PLL7
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ANADIG\_PLL\_LOCK field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 PLL1	This bit shows if PLL1 (528) is locked. 0 PLL1 not locked yet. 1 PLL1 locked.
5 PLL2	This bit shows id PLL2 (528) is locked. 0 PLL2 not locked yet. 1 PLL2 (528) locked.
4 PLL4	This bit shows if PLL4 (Audio) is locked. 0 PLL4 not locked yet. 1 PLL4 locked.
3 PLL6	This bit shows if PLL6 (Video) is locked. 0 PLL6 not locked yet. 1 PLL6 locked.
2 PLL5	This bit shows if PLL5 (ENET)is locked. 0 PLL5 not locked yet. 1 PLL5 locked.
1 PLL3	This bit shows if PLL3 (USB0) is locked. 0 PLL3 not locked yet. 1 PLL3 locked.
0 PLL7	This bit shows if PLL7 (USB1) is locked. 0 PLL7 not locked yet. 1 PLL7 locked.

## **Chapter 7**

# **SNVS, Reset, eFuse, and Boot**

## **7.1 Secure Non-Volatile Storage (SNVS)**

### **7.1.1 SNVS overview**

The low-power (battery-backed) section incorporates a secure real time counter, a monotonic counter, and a general-purpose register. This portion of the block is powered by a battery that maintains the state of the SNVS\_LP registers when the chip is powered off.

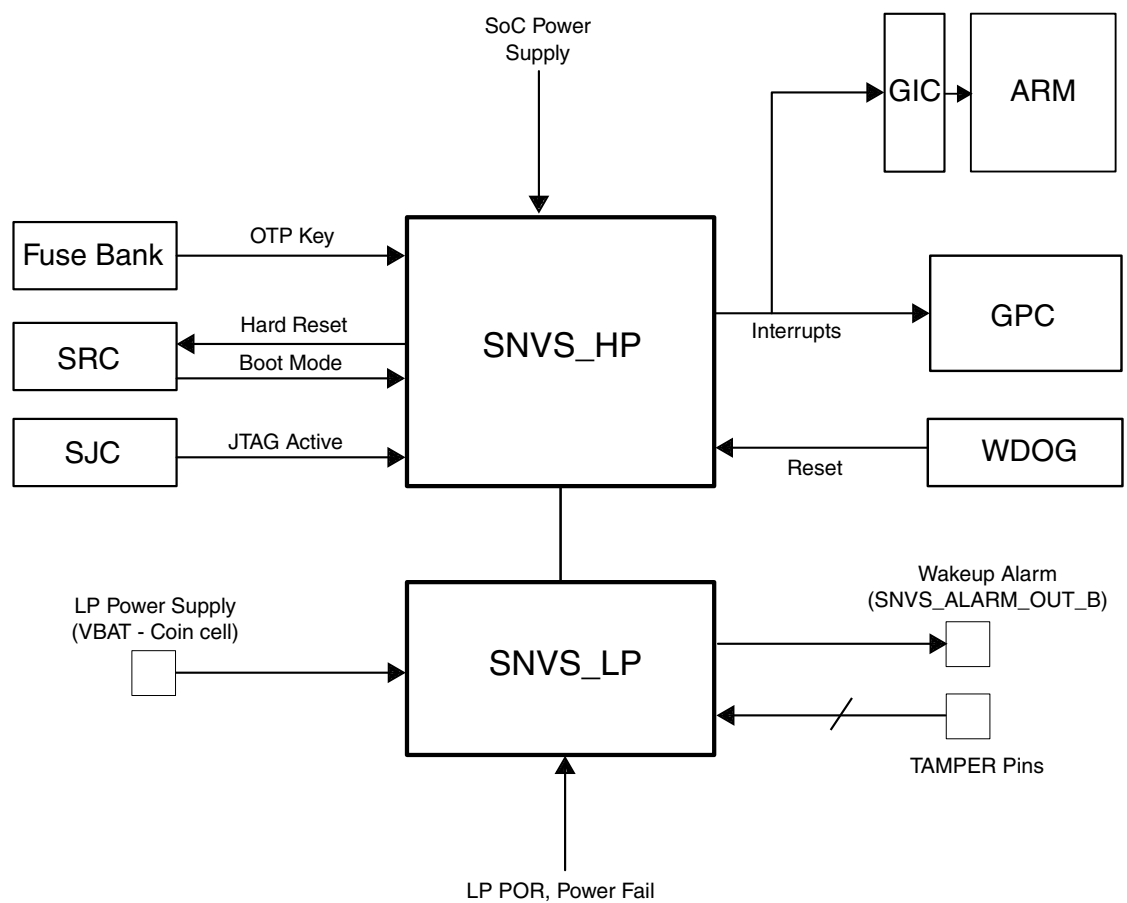

Figure 7-1. Example SNVS connectivity

NOTE

For the security features of the SNVS available on some F-Series devices, see the *Vybrid Security Reference Manual*.

7.1.1.1 SNVS features

This table summarizes the features:

Table 7-1. SNVS feature summary

Feature	What it does
Non-secure real-time counter (HPRTC)	<ul style="list-style-type: none"><li>• The counter is driven by a dedicated clock which is off when the system power is down</li><li>• Programmable time alarm interrupt</li><li>• Periodic interrupt can be generated with different frequencies</li></ul>
Monotonic counter	<ul style="list-style-type: none"><li>• The monotonic counter state is non-volatile</li><li>• The counter can only increment</li><li>• The counter is a non-rollover counter</li><li>• The counter value is invalidated in case of security violation</li></ul>

Table continues on the next page...

**Table 7-1. SNVS feature summary (continued)**

Feature	What it does
General-purpose register	<ul style="list-style-type: none"> <li>The general-purpose register state is non-volatile</li> </ul>
Register access protection	<ul style="list-style-type: none"> <li>Privileged software access policy</li> <li>Registers can be programmed only when the system security monitor is in a functional state</li> <li>Some registers/values can only be programmable once per a boot cycle</li> </ul>

### 7.1.1.2 Modes of operation

The SNVS operates in either the system power-down or the system power-up mode of operation.

During system power-down, the SNVS\_HP is powered down. The SNVS\_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode, the SNVS\_LP retains the state of its registers .

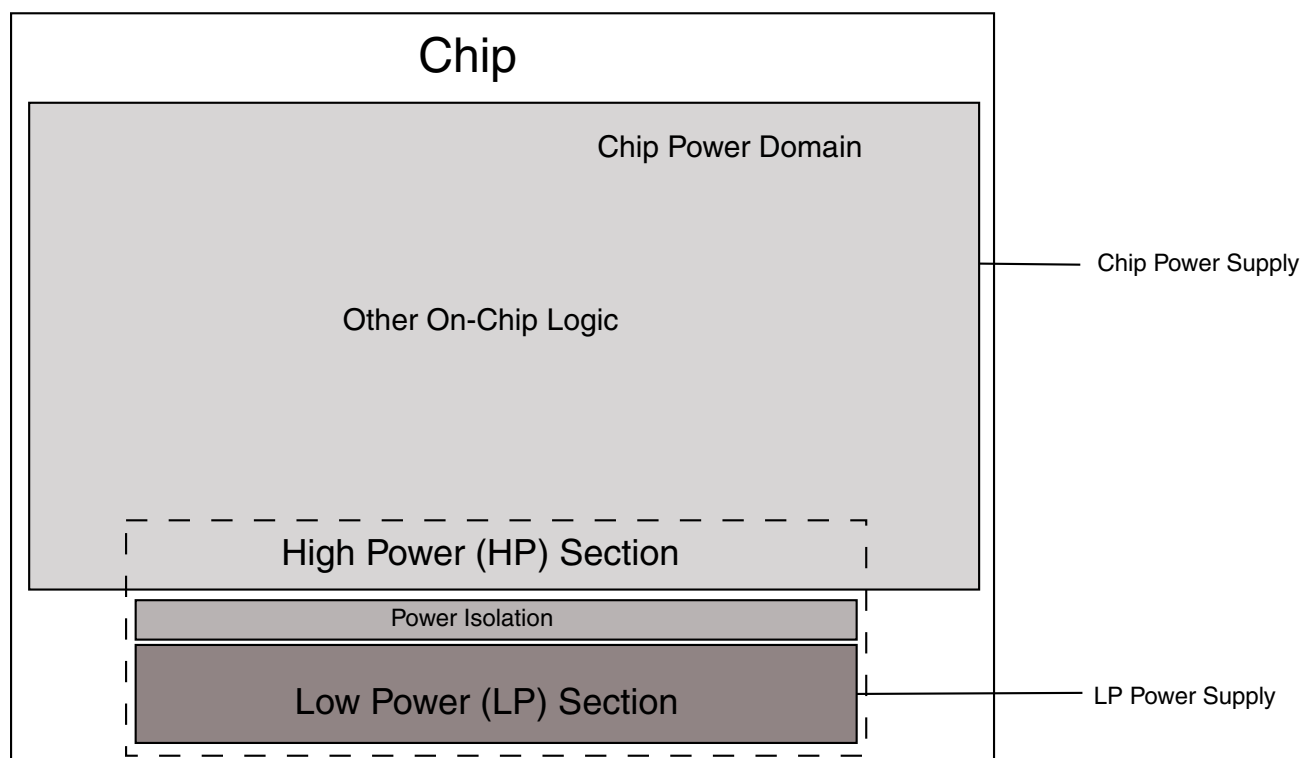

During the system power-up, the SNVS\_HP and SNVS\_LP are both powered up and all SNVS functions are operational.

### 7.1.2 SNVS structure

The SNVS block is divided into two major submodules based on power supply: the high power domain (SNVS\_HP) and the low power domain (SNVS\_LP). They are powered as follows:

- SNVS\_LP - dedicated always-powered-on domain
- SNVS\_HP - system (chip) power domain

The following figure illustrates the low power and chip power domains of SNVS.

**Figure 7-2. SNVS Power Domains**

The SNVS\_HP section implements all features that enable system communication and provisioning of the SNVS\_LP section.

The SNVS\_LP section provides hardware that enables secure storage and protection of sensitive data.

### 7.1.2.1 SNVS\_HP (high-power domain)

The SNVS\_HP is partitioned into these functional units:

- IP bus interface
- SNVS\_LP interface
- Real-time counter with alarm
- Control and status registers

The SNVS\_HP is in the chip's power-supply domain and thus receives the power along with the rest of the chip. The SNVS\_HP provides an interface between the SNVS\_LP and the rest of the system; there is no way to access the SNVS\_LP registers except through the SNVS\_HP. For access to the SNVS\_LP registers, the SNVS\_HP must be powered up. It uses a register access permission policy to determine whether the access to the particular registers is permitted.

### 7.1.2.2 Non-secure real-time counter

The SNVS\_HP has an autonomous non-secure real-time counter. The counter is not active and is reset when the system is powered down. The HP RTC can be used by any application; it has no privileged software access restrictions. The counter can be synchronized with the SNVS\_LP SRTC by writing to a specific bit in the SNVS\_HP control register.

#### 7.1.2.2.1 Calibrating the time counter

The RTC accuracy may suffer from a drift in the clock, which is used to increment the RTC register. To compensate for this drift, a clock calibration mechanism can adjust the RTC value. It is up to the system processor to decide whether the calibration is required or not. If the RTC correction is required, enable the mechanism and set the calibration value in the control register. The calibration value is a 5-bit value including the sign bit, which is implemented in the 2's complement.

If the calibration mechanism is enabled, the calibration value is added or subtracted from the RTC on a periodic basis, once per 32768 cycles of the RTC clock.

This table shows the available correction range:

**Table 7-2. Time counter calibration settings**

Calibration value setting	Correction in counts per 32768 cycles of the counter clock
01111	+15
:	:
00010	+2
00001	+1
00000	0
11111	-1
11110	-2
:	:
10001	-15
10000	-16

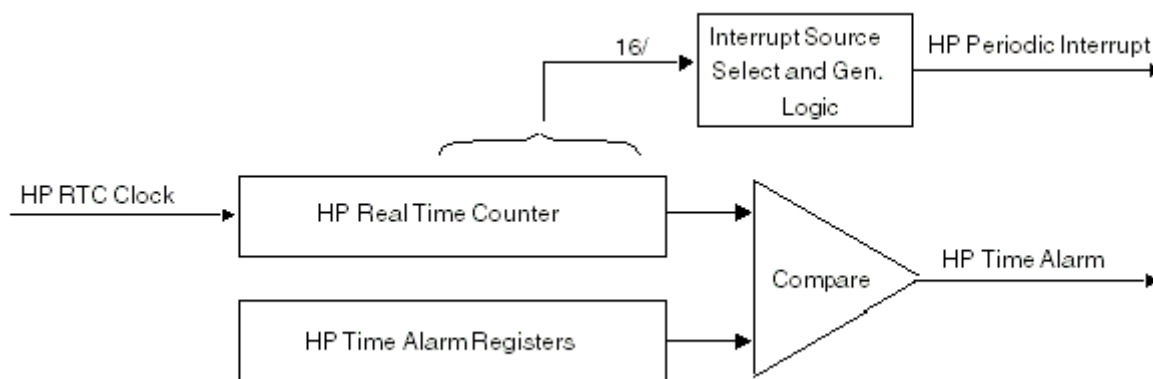

### 7.1.2.2.2 Time counter alarm

The SNVS\_HP non-secure RTC has its own time-alarm register. Any application can update this register. The SNVS\_HP time alarm can generate interrupts to alert the host processor and can wake up the host processor from one of its low-power modes. Note that this alarm can't wake up the entire system if it is powered off because this alarm would also be powered off.

### 7.1.2.2.3 Periodic interrupt

The SNVS\_HP non-secure RTC incorporates a periodic interrupt. The periodic interrupt is generated when a zero-to-one or one-to-zero transition occurs on the selected bit of the RTC. The periodic interrupt source is chosen from the 16 bits of the HP RTC according to the PI\_FREQ field setting in the HP control register. This bit selection also defines the frequency of the periodic interrupt.

This figure shows the SNVS\_HP RTC and its interrupts:

**Figure 7-3. SNVS\_HP RTC, alarm, and interrupts**

## 7.1.3 SNVS\_LP (low-power domain)

The SNVS\_LP has these functional units:

- Non-rollover monotonic counter
- General-purpose register
- Control and status registers

The SNVS\_LP is a data storage subsystem. Its purpose is to store and protect system data, regardless of the main system power state.

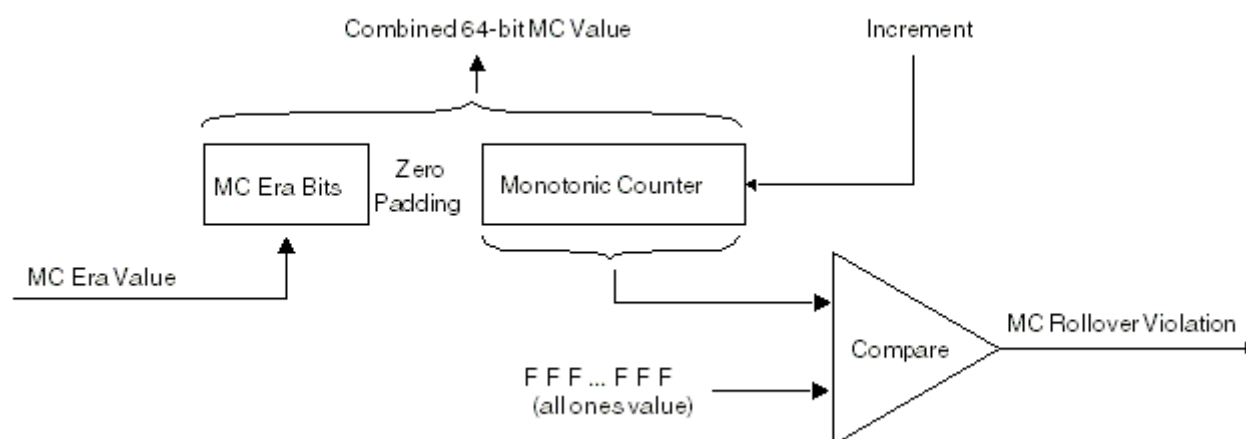

The SNVS\_LP is in the always-powered-up domain, which is a separate power domain with its own power supply.

### 7.1.3.1 Behavior during system power down

When the chip power-supply domain loses power, the The SNVS\_LP continues to operate normally and ignores all inputs from the SNVS\_HP.

### 7.1.3.2 Monotonic Counter (MC)

This figure shows the MC and its rollover security violation:

**Figure 7-4. SNVS\_LP monotonic counter**

Some security applications require the Monotonic Counter (MC) that can't be exhausted or returned to any previous value during the product's lifetime. Because the MC can never repeat a number, it can't be reset or cycled back to its starting count. If it reaches its maximum value, it does not rollover. Instead, a monotonic counter rollover indication is generated to the SNVS\_LP tamper monitor. This generates an interrupt to the host processor.

The SNVS uses an ERA value derived from the OTP elements as a mechanism to recover from an MC failure (for example, due to a failure of the LP power) where the MC value was compromised or cleared. The ERA value is prepended to the MC to form its most significant bits. Once any of the ERA value bits are set, the MC can count up from any value, including zero. This guarantees that any future value of the combined monotonic counter is greater than any of its past values.

## 7.1.4 SNVS reset and system powerup

This table describes the reset actions for the SNVS.

**Table 7-3. Reset summary**

Reset	Source	Characteristics	Internally resets
HP hard	ipg_hard_async_reset_b	active-low, asynchronous	All SNVS_HPSNVS_LP registers and flops.
LP Power On Reset (POR)	lp_por_b	active-low, asynchronous	All SNVS_LP registers and flops.
LP software reset	software	active-high, synchronous, one cycle	All SNVS_LP registers and flops. The LP software reset can be asserted if not disabled.

## 7.1.5 SNVS interrupts and alarms

SNVS provides these interrupt and alarm lines:

- Functional interrupt (active-low)
- Real-time clock period interrupt

This table summarizes all SNVS interrupts and alarm sources.

**Table 7-4. Interrupts and alarms summary**

Interrupt	Source	Default configuration <sup>1</sup>	Configuration options
SNVS functional interrupt	RTC time alarm	Disable	Enable/Disable
	RTC periodic interrupt	Disable	Enable/Disable

1. Default behavior refers to the setting after the LP/HP reset.

## 7.1.6 Programming guidelines

This section provides the initialization and application information for the SNVS module.

### 7.1.6.1 RTC control bits setting

All SNVS registers are programmed from the register bus. Therefore, any changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC clock after they are programmed. To avoid IP clock and RTC clock synchronization issues, these values can only be programmed when the corresponding function is disabled. This table presents the list of these values with the control bit setting required for programming:

**Table 7-5. RTC synchronized values list**

Function	Value/register	Control bit setting
HP section		
HP real-time counter	HPRTCMR and HPRTCLR registers	RTC_EN = 0—HPRTCMR/HPRTCLR can be programmed RTC_EN = 1—HPRTCMR/HPRTCLR can't be programmed
HP time alarm	HPTAMR and HPTALR registers	HPTA_EN = 0—HPTAMR/HPTALR can be programmed HPTA_EN = 1—HPTAMR/HPTALR can't be programmed
HP time calibration value	HPCALB_VAL value	HPCALB_EN = 0—HPCALB_VAL can be programmed HPCALB_EN = 1—HPCALB_VAL can't be programmed

Perform these steps to program the synchronized values:

1. Check the enable bit value. If it is set, clear it.
2. Verify that the enable bit is cleared.

There are two reasons to verify the enable bit's setting:

- The enable bit clearing does not happen immediately. It takes three IPclock cycles and two RTC clock cycles to change the enable bit's value.
  - If the enable bit is locked for programming, it can't be cleared.
3. Program the desired value.
  4. Set the enable bit. It takes three IP clock cycles and two RTC clock cycles for the bit to set.

#### NOTE

Incrementing the value programmed into the RTC registers by two compensates for the two RTC clock cycle delays that are required to enable the counter.

### 7.1.6.2 RTC value read

There are two scenarios when the software can read the corrupted values from the RTC (HPRTCMR and HPRTCLR) registers:

- The RTC counters are incremented by the slow 32-kHz clock, which is asynchronous to the system clock. The counter value is synchronized to the system clock before the software reads that. The synchronization register can capture the counter value in the middle of the counter update. In this case, it is not guaranteed that all bits are properly sampled by the synchronization register; the value read by the software can be wrong.
- The RTC value is longer than the single bus read transaction of 32 bits. Therefore, the software reads two registers with each holding a portion of the counter value. After reading one of these registers but before reading the second register, both registers can update their values. In this case, the value combined by the software is incorrect.

To avoid these issues, it is strongly recommended that the software performs two consecutive reads of the RTC value:

- If the two consecutive reads are similar, the value is correct.
- If the two consecutive reads are different, perform two more reads.

The worst-case scenario can require three sessions of two consecutive reads.

### **7.1.6.3 General initialization guidelines**

Perform these steps to properly initialize the module:

1. Enable the interrupts in the SNVScntrl and configuration registers.
2. Program the SNVS general functions/configurations.
3. User-specific: Set the lock bits.

## **7.1.7 SNVS memory map/register definition**

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and a register table. The register table provides detailed descriptions of the register bit and field functions in the bit order.

The SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

The privileged read/write accessible registers can only be accessed for read/write by the privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. The non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS\_HPcommand register.

- Non-secure
- Trusted
- Secure

The non-privileged read/write accessible registers are read/write accessible by any software.

The following table shows the SNVS memory map. The LP register values are set only on the LP POR and are unaffected by the system (HP) POR. The HP registers are set only on the system POR and are unaffected by the LP POR.

**SNVS memory map**

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

### 7.1.7.12 SNVS\_LP Secure Monotonic Counter MSB Register (SNVS\_LPSMCMR)

The SNVS\_LP secure monotonic counter MSB register contains the monotonic counter era bits and the most-significant 16 bits of the monotonic counter. The monotonic counter is incremented by one if there is a write command to the LPSMCMR register or the LPSMCLR register.

Address: 400A\_7000h base + 5Ch offset = 400A\_705Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### SNVS\_LPSMCMR field descriptions

Field	Description
31–16 MC_ERA_BITS	Monotonic Counter Era Bits These bits are the inputs to the module and are typically connected to the fuses.
MON_COUNTER	Monotonic Counter Most-Significant 16 Bits The MC is incremented by one when: <ul style="list-style-type: none"> <li>• A write transaction to the LPSMCMR register or the LPSMCLR register is detected.</li> <li>• The MC_ENV bit is set.</li> <li>• The MC_SL and MC_HL bits are not set.</li> </ul>

### 7.1.7.13 SNVS\_LP Secure Monotonic Counter LSB Register (SNVS\_LPSMCLR)

The SNVS\_LP secure monotonic counter LSB register contains the 32 least-significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR register or the LPSMCLR register.

Address: 400A\_7000h base + 60h offset = 400A\_7060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**7.1.7.14 SNVS\_LP General-Purpose Register (SNVS\_LPGPR)**

The SNVS\_LP general-purpose register is a 32-bit read/write register located in the low-power domain. Because the LPGPR is located in the battery-backed power domain, the LPGPR can be used by any application for retaining data during the SoC power-down mode.

Address: 400A\_7000h base + 68h offset = 400A\_7068h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SNVS\_HPVIDR2 field descriptions**

Field	Description
31–24 IP_ERA	Era of the IP design 00h - Era 1 or 2 03h - Era 3 04h - Era 4 05h - Era 5
23–16 INTG_OPT	SNVS Integration Option
15–8 ECO_REV	SNVS ECO Revision
CONFIG_OPT	SNVS Configuration Option

## 7.2 Reset

### 7.2.1 Introduction

This chapter describes the Reset architecture for this device.

### 7.2.2 Reset Sources

The possible sources of reset on this device are as follows:

- POR (Power On Reset)
- External hardware reset via the /RESET pin ( ext\_reset\_b pin) - Active Low
- Software JTAG
- Watchdog Reset
- Security Reset (CSU\_RESET\_B)
- Clock Monitor Reset (CMU). The CMU is used to monitor the main 24MHz crystal oscillator.
- PMU Low Voltage Detection. LVDs on the 3.3V Main supply and the 1.2V core supplies will trigger a reset event. HVDs on the supplies do not trigger a reset but will optionally trigger an interrupt.
- CPU Exception Error Check (illegal opcode or other CPU exception error)

### 7.2.3 Reset Functions

The following table shows the action on the SoC of each of the possible reset sources. Although the LDOs do not generate resets they are listed in the table. Only the main PMU can generate a reset based on its LVDs.

The various 'targets' for reset are grouped as follows:

- A -> All device Configurations (Trimbits, fuse shadow bits), Boot configuration & reset vectors, CCM, OCOTP, ANADIG.
- B -> SJC, TAP registers
- C -> Security Logic
- D -> SRTC
- E -> DDR Logic
- F -> All other logic on SoC

**Table 7-6. Reset Functionality**

	<b>A</b>	<b>B</b>	<b>D</b>	<b>E</b>	<b>F</b>	
<b>Reset Source</b>	<b>Configs</b>	<b>SJC/TAP</b>	<b>RTC</b>	<b>DDR Logic</b>	<b>All other</b>	<b>Comments</b>
POR	Reset	Reset	Reset	Reset	Reset	Reset all with POR

WDOG	No	No	No	Reset	Reset	
CMU	Reset	Reset	Reset	Reset	Reset	CMU monitors loss of 24MHz XTAL
LVD (PMU)	Reset	Reset	Reset	Reset	Reset	
HVD (PMU)	No	No	No	No	No	Configurable interrupt, no reset
LDO-OK (3.3/1.1-analog)	No	No	No	No	No	Configurable interrupt, no reset
LDO-OK (3.3/2.5-analog)	No	No	No	No	No	Configurable interrupt, no reset
LDO-OK (3.3/1.1-coin)	No	No	No	No	No	No interrupt relevant as only VBB (R-Series)/VBAT (F-Series) domain alive
LDO-OK (5.0/3.3-USB)	No	No	No	No	No	Configurable interrupt, no reset
CPU Exception	No	No	No	Reset	Reset	

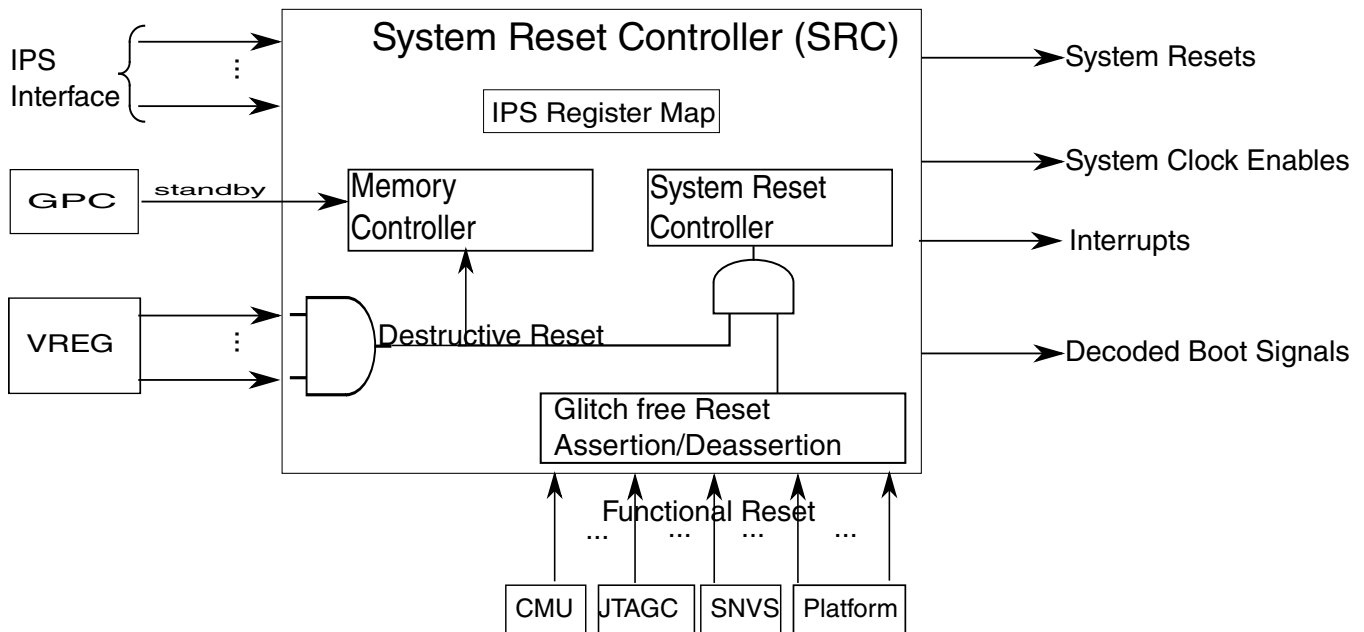

## 7.2.4 Clock Monitor

The Clock Monitor Unit (CMU) is used to monitor the main 24MHz crystal oscillator. Upon failure of the crystal the CMU should reset the system.

## 7.3 System Reset Controller (SRC)

### 7.3.1 Introduction

The System Reset Controller (SRC) generates the resets for the device. The functional reset sources are programmable as either reset or interrupt. The block also generates interrupts for various device events.

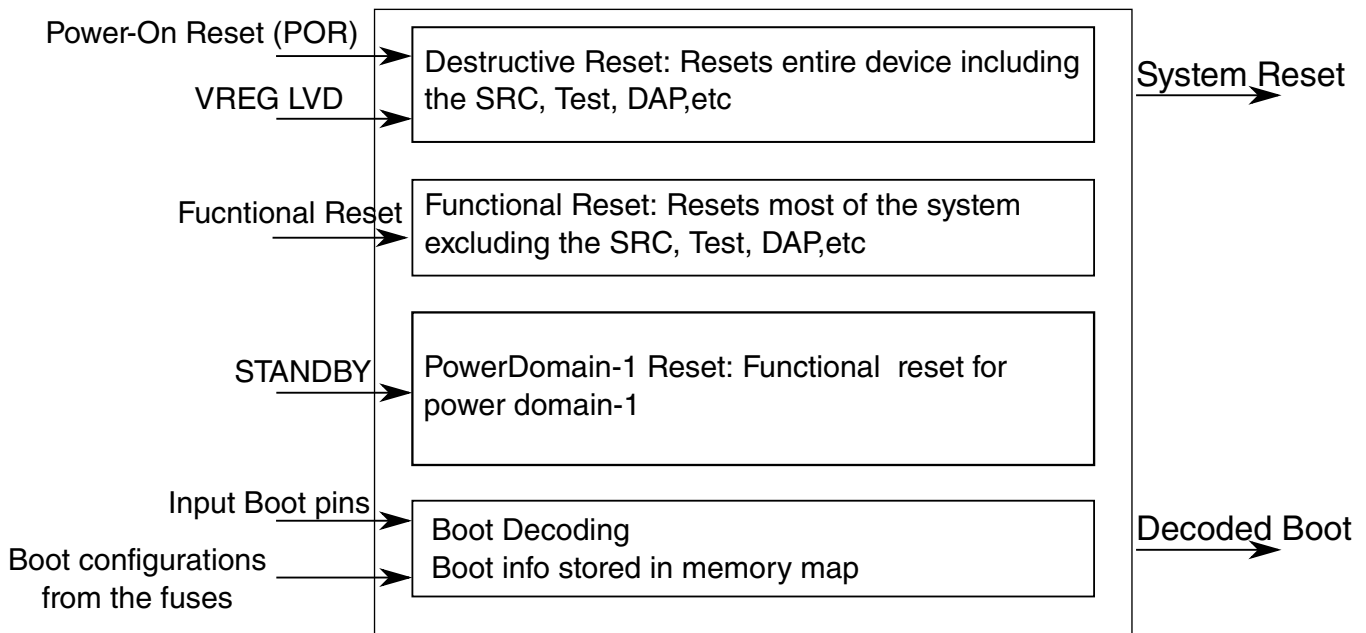

**Figure 7-5. Functional reset sequence**

### 7.3.2 SRC Overview

The SRC generates the reset signals for the device. The SRC controls the bringup of the device from all of the destructive and functional resets. The SRC handles three types of resets

- **Destructive reset:** These resets are caused by LVD(s) and poweron reset. It causes the whole device to reset.
- **Functional reset:** These resets are caused by different events. They cause most of the system to reset except the modules resettable only by destructive reset like SRC, DAP, WDOG, etc.
- **Standby reset:** This reset is triggered by programming the GPC. The power domain 1 of the system is reset.

**Figure 7-6. SRC High Level Diagram**

### 7.3.2.1 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the reset sources and the nature of the reset
- Latches the BMOD pins and common configuration signals from the internal fuses
- Provides user flexibility to choose the events as functional reset or interrupt
- Latches all reset/interrupt events in the SRC\_SRSR

## 7.3.3 Memory Map and Register Definition

### 7.3.3.1 Register Descriptions

This section consists of register descriptions in address order. All registers are reset on POR sequence.

## SRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_E000	SRC Control Register (SRC_SCR)	32	R/W	0000_050Ah	<a href="#">7.3.3.2/844</a>

4006_E058	MISC3 (SRC_MISC3)	32	R/W	0000_0000h	<a href="#">7.3.3.13/860</a>

### 7.3.3.2 SRC Control Register (SRC\_SCR)

The following figure presents the Reset control register (SRC), which contains bits that control operation of the reset controller and the table provides its field descriptions.

Address: 4006\_E000h base + 0h offset = 4006\_E000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			0	0	CM4_WDGRST_MASK				0			CA5_WDGRST_MASK			
W				SW_RST												
Reset	0	0	0	0	0	1	0	1	0	0	0	0	1	0	1	0

**SRC\_SCR field descriptions**

Field	Description
31–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 SW_RST	Software reset. Initiates Functional reset sequence  0 Software reset not requested 1 Software reset requested Self clearing, Always read 0
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–7 CM4_WDGRST_MASK	Mask CM4 WDOG reset. If these 4 bits are coded from A to 5 ,then CM4 WDOG reset input to SRC will be masked and will not create reset to the device. Any other code will be coded to 1010 and CM4 WDOG reset will not be masked.  0101 CM4 WDOG reset is masked 1010 CM4 WDOG reset is not masked (default) Write of anyvalue other than 01010 will set the field to 1010
6–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CA5_WDGRST_MASK	Mask CA5 WDOG reset. If these 4 bits are coded from A to 5 then, CA5 WDOG reset input to SRC will be masked and will not reset the device. Any other code will be coded to 1010 and CA5 WDOG reset will not be masked  <b>NOTE:</b> During the time the WDOG event is masked using SRC logic, it is likely that WDOG Reset Status Register (WRSR) bit 1 (which indicates WDOG timeout event) will get asserted. SW / OS developer must prepare for this case. Re-enable WDOG is possible, by un-mask it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module. (HW reset is the only mean to cause de-assertion of that bit).

*Table continues on the next page...*

**SRC\_SCR field descriptions (continued)**

Field	Description
0101	A5 EWDOG reset is masked
1010	CA5 WDOG reset is not masked (default)

**7.3.3.3 SRC Boot Mode Register 1 (SRC\_SBMR1)**

The following presents the Boot Mode register (SBMR1), which contains bits that reflect the status of Boot Mode Pins of the chip. The default values for those bits depend on the values of pins/fuses during reset sequence. The boot configuration signals are sampled once fuses are read. The boot configuration can either be sampled from OCOTP or GPIO based on the boot mode selected. The table provides its field descriptions.

**NOTE**

When sampled from GPIO, these bits are only updated on a Power On Reset (POR).

Address: 4006\_E000h base + 4h offset = 4006\_E004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BOOT_CFG4								BOOT_CFG3								BOOT_CFG2								BOOT_CFG1							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SRC\_SBMR1 field descriptions**

Field	Description
31–24 BOOT_CFG4	Please refer to <a href="#">OCOTP_CFG4</a> .
23–16 BOOT_CFG3	Please refer to <a href="#">OCOTP_CFG3</a> .
15–8 BOOT_CFG2	Please refer to <a href="#">OCOTP_CFG2</a> .
BOOT_CFG1	Please refer to <a href="#">OCOTP_CFG1</a> .

**7.3.3.4 SRC Status Register (SRC\_SRSR)**

The SRSR is a status register that records the source of the reset events for the chip. The SRSR register bit is set when the event occurs.

**NOTE**

On a Power on Reset, the register will read 0x00FEFF65. The recommendation is to clear all reset sources after a POR event to read the proper reset status for future reset events.

NOTE

When using a debugger, the RESETB bit will also be set due to the debugger asserting reset.

NOTE

The following bits are expected to be valid after a power on reset.

- SRSR[POR\_RST]
- SRSR[CA5\_WDG\_RST]
- SRSR[WDOG\_RST]
- SRSR[RESET\_B] - due to debugger
- SRSR[POR1P2]
- SRSR[HP\_LVD]
- SRSR[ULP\_LVD]
- SRSR[LVD\_P3P]
- SRSR[LP\_LVD]
- SRSR[MDM\_SYS\_RST]

At bootup the SW can mask-read all the other SRSR bits i.e. ignore other bits. All bits should be cleared by writing '1' to them after bootup for proper status setting.

Address: 4006\_E000h base + 8h offset = 4006\_E008h

## SRC\_SRSR field descriptions

Field	Description
31 CM4_LCK	Indicates when CM4 is in lockup. 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset .
30 SOSC_OK	Indicates no clock is detected on SOSC 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 CMU_FLL_FHH	Indicates CMU event when BUS frequency clock is out of range 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset .
27 CMU_OLR	Indicates CMU event of FOSC frequency less than 40 Mhz 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
26 REG_3P0_OK	Indicates Anadig regulator 3.0V unstable event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
25 REG_2P5_OK	Indicates Anadig regulator 2.5V unstable event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
24 REG_1P1_OK	Indicates Anadig regulator 1.1V unstable event 1 The SRSR register bit is set when the event occurs. 0 The SRSR register bit is reset.
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

**SRC\_SRSR field descriptions (continued)**

Field	Description
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SRC_SW_RST	Indicates SRC_SCR[SW_RST] is set 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 MDM_SYS_RST	Indicates the MDM-AP[SYSRESETREQ] is set 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LP_LVD	Indicates LP regulator's LVD event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
11 LVD_P3P	Indicates 3.3V main supply is unstable 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
10 ULP_LVD	Indicates ULP regulator's LVD event 1 The SRSR register bit is set when the event occurs 0 reset.set when the event occurs
9 HP_LVD	Indicates HP regulator's LVD event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
8 POR1P2	Indicates 1.2V supply goes below 0.7V event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
7 RESETB	Indicates external reset event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 JTAG_RST	Indicates HIGH-Z JTAG event 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
4–3 WD0G_RST	Indicates watchdog Time-out event. WDOG_RST_F[1] - CM4 core WDOG_RST_F[0] - CA5 core 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.

*Table continues on the next page...*

**SRC\_SRSR field descriptions (continued)**

Field	Description
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 CA5_WDG_RST	Indicates event from internal CA5 watchdog timer 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.
0 POR_RST	Indicates event POR1- power on reset. 1 The SRSR register bit is set when the event occurs 0 The SRSR register bit is reset.

**7.3.3.5 SRC\_SECR**

Address: 4006\_E000h base + Ch offset = 4006\_E00Ch

**SRC\_SECR field descriptions**

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WRLOCK	Once writeable. Once written the SPIDEN and SPNIDEN can't be written
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SPIDEN	Secure invasive debug enable. Can be set by user running device in secure mode. Refer to <a href="#">Additional Authentication Interface</a>
0 SPNIDEN	Secure non-invasive debug enable. Can be set by user running device in secure mode.

### 7.3.3.6 SRC Reset Interrupt Configuration Register (SRC\_SICR)

The SICR is a reset event configuration register. The event mentioned in the bitfield is configured as interrupt, when field is '1' and as reset when the bitfield value is '0'.

Address: 4006\_E000h base + 14h offset = 4006\_E014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CM4_LCK	0	FOSC_OK_CFG	CMU_FLL_FHH	CMU_OLR	1	REG_2P5	REG_1P1	RESERVED					0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

**SRC\_SICR field descriptions**

Field	Description
31 CM4_LCK	Configures when CM4 is in lockup 1 The bitfield is configured as interrupt 0 The bitfield is reset.
30 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
29 FOSC_OK_CFG	Configure ANADIG_ANA_MISC0[OSC_XTALOK_EN] register to 1 to support no_fosc clock as interrupt/reset event.
28 CMU_FLL_FHH	Configures CMU event when BUS frequency clock is out of range 1 The bitfield is configured as interrupt 0 The bitfield is reset.
27 CMU_OLR	Configures CMU event of FOSC frequency less than 40 Mhz 1 The bitfield is configured as interrupt 0 The bitfield is reset.
26 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 1.
25 REG_2P5	Configures Anadig regulator 2.5V unstable event

Table continues on the next page...

**SRC\_SICR field descriptions (continued)**

Field	Description
	1 The bitfield is configured as interrupt 0 The bitfield is reset.
24 REG_1P1	Configures Anadig regulator 1.1V unstable event 1 The bitfield is configured as interrupt 0 The bitfield is reset.
23–20 RESERVED	This field is reserved. Reserved for future use
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	Reserved  This field is reserved. This read-only field is reserved and always has the value 0.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 RESERVED	This field is reserved. Reserved for future use
5 JTAG_RST	Configures HIGH-Z JTAG event 1 The bitfield is configured as interrupt 0 The bitfield is reset.
4–3 WD OG_RST	Configures watchdog Time-out event. WDOG_RST_F[1] - CM4 core WDOG_RST_F[0] - CA5 core 1 The bitfield is configured as interrupt 0 The bitfield is reset.
2 RESERVED	This field is reserved. Reserved for future use
1 CA5_WDG_RST	Configures event from internal CA5 watchdog timer 1 The bitfield is configured as interrupt 0 The bitfield is reset.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 7.3.3.7 SRC Interrupt Masking Register (SRC\_SIMR)

The SIMR is a interrupt masking register. The event configured in the SCR\_SICR as interrupt can be masked in this register. Once the interrupt is masked it will not reflect in SCR\_SRSR. Interrupts are masked when the bitfield representing the event is '0'.

Address: 4006\_E000h base + 18h offset = 4006\_E018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## 7.3.4 Functional Description

### 7.3.4.1 Reset Sources

The Reset control logic receives event requests from all the potential reset sources. All the "functional Reset/ Interrupt" events are qualified based on the SRC\_SICR either as interrupt or reset. All the events are latched in the SRC\_SRSR register unless masked by SRC\_SIMR register. The reset sources are described in the following table.

**Table 7-7. Reset\_Table**

Reset Source	Reset Type
POR1 - power on reset	Destructive reset
POR1P2: 1.2V supply goes below 0.7V event	Destructive reset
HP LVD: HP regulator's LVD event	Destructive reset
ULP LVD: ULP regulator's LVD event	Destructive reset

*Table continues on the next page...*

**Table 7-7. Reset\_Table (continued)**

Reset Source	Reset Type
LVD_P3P: 3.3V main supply is unstable	Destructive reset
LP_LVD: LP regulator's LVD event	Destructive reset
CA5 internal WDOG Time-out	Functional Reset / Interrupt
Platform WDOG[CA5 core] Time out	Functional Reset / Interrupt
Platform WDOG[CM4 core] Time out	Functional Reset / Interrupt
JTAGC Reset	Functional Reset / Interrupt
External Reset, RESETB	Functional reset
MDM_AP_CTRL[SYSRESETREQ]	Functional Reset / Interrupt
SNVS_HP: Hard Fail state	Default reset.Generated from SNVS_HP
SRC_SCR[SW_RST]	Functional Reset / Interrupt
CSU Alram reset	Functional Reset / Interrupt
Anadig1.1V regulator unstable	Functional Reset / Interrupt
Anadig 2.5V regulator unstable	Functional Reset / Interrupt
Anadig 3.3V regulator unstable	Functional Reset / Interrupt
CMU: FOSC frequency is < 24MHz	Functional Reset / Interrupt
CMU: Bus frequency clock out of range	Functional Reset / Interrupt
No FOSC clock	Functional Reset / Interrupt
No SOSC clock	Functional Reset / Interrupt
CM4 is in lockup	Functional Reset / Interrupt

- If a destructive reset occurs during a functional reset deassertion sequence, the destructive reset sequence will start without completing the current reset sequence.
- If a functional reset occurs during a functional reset deassertion sequence. The reset sequence will re-initiate.
- System Reset deassertion sequence will not start until all the resets are deasserted.

#### 7.3.4.2 Destructive reset sequence

The resets from SRC to device are asserted immediately on any destructive reset event. While the clock enables are deasserted at the same time. The RESETB is deasserted to indicate that the device is under reset.

**Figure 7-7. Destructive reset sequence**

**The SRC follows the sequence below on deassertion of poweron or any LVD resets :**

1. The stable VREG and FIRC is indicated by VREG by de-asserting the o\_por\_rst\_b.
2. The deassertion of EARLY\_RESET wakes the CCM and the OCOTP.
3. Once the CCM indicates that the clocks are stable by asserting the CLOCK\_READY the memory repair is initiated.
4. After the memory repair is over the fuses clock is enabled for latching fuses.
5. The latched fuses are decoded by SRC and stored in internal registers.
6. The SYNC\_FLOP\_RST\_CLK\_EN is asserted to enable clocks to initialize all non-resettable flops in the device.
7. The deassertion of system reset is held till the external reset RESETB is not released. this is to give controllability to the user on the boot up of the core.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery

### 7.3.4.3 Functional reset sequence

On the assertion of the functional reset the clocks are gated on the edge of the IPG clock to ensure glitch free stop of ongoing transactions. The SRC resets are asserted after the clocks are gated. The RESETB is deasserted to indicate that the device is under reset. The memory repair is not initiated.

**Figure 7-8. Functional reset sequence**

**The SRC follows the below mentioned sequence on deassertion of any functional reset:**

1. The clock enables are deasserted on IPG clock.
2. The SRC resets are asserted after a few FIRC clocks to ensure all clocks are properly gated.
3. The deassertion of EARLY\_RESET wakes the CCM and the OCOTP.
4. Once the CCM indicates that the clocks are stable by asserting the CLOCK\_READY the clock for the fuse latching is enabled.
5. The latched fuses are decoded by SRC and stored in internal registers.
6. The SYNC\_FLOP\_RST\_CLK\_EN is asserted to enable clocks to initialize all non-resettable flops in the device.
7. The deassertion of system reset is held till the external reset RESETB is not released. This is to give controllability to the user on the boot up of the core.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

## 7.3.4.4 External reset sequence

On the assertion of the RESETB the clocks are gated on the edge of the IPG clock to ensure glitch free stop of ongoing transactions. The SRC resets are asserted after the clocks are gated. The memory repair is not initiated.

**Figure 7-10. Standby reset sequence (Exit by Standby Exit)**

**The SRC follows the below mentioned sequence on assertion of standby reset :**

1. The clocks are gated immediately.
2. The SRC power domain 1 resets are asserted immediately.
3. The deassertion of EARLY\_RESET wakes the CCM and the OCOTP
4. Once the CCM indicates that the clocks are stable by asserting the CLOCK\_READY, initiating the memory repair sequence.
5. The clock for the fuse latching is enabled after the memory repair.
6. The latched fuses are decoded by SRC and stored in internal registers.
7. The SYNC\_FLOP\_RST\_CLK\_EN is asserted to enable clocks to initialize all non-resettable flops in the device.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

**Figure 7-11. Standby reset sequence (Abort by External Reset)**

The SRC follows the below mentioned sequence on assertion of standby reset :

1. The clock enables are deasserted immediately.
2. The SRC power domain 1 resets are asserted immediately.
3. The SRC power domain 0 resets are asserted on the assertion of external reset, RESETB. The standby mode is exited.
4. The deassertion of EARLY\_RESET wakes the CCM and the OCOTP.
5. Once the CCM indicates that the clocks are stable by asserting the CLOCK\_READY, initiating the memory repair sequence.
6. The clock for the fuse latching is enabled after the memory repair.
7. The latched fuses are decoded by SRC and stored in internal registers.
8. The SYNC\_FLOP\_RST\_CLK\_EN is asserted to enable clocks to initialize all non-resettable flops in the device.
9. The deassertion of system reset is held till the external reset RESETB is not released. This is to give controllability to the user on the boot up of the core.
10. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

### 7.3.4.6 Memory Repair

The memory repair function can be seen as a memory self test that runs after a memory power-on. The whole process is transparent to the user. There is nothing to be configured and it can be bypassed if desired.

The memory repair is done after every powerdown of Memory. The two triggering reset events are destructive reset and Standby. The memory repair is initiated after CCM indicates the clocks are stable. The memory repair can be bypassed by assertion signal.

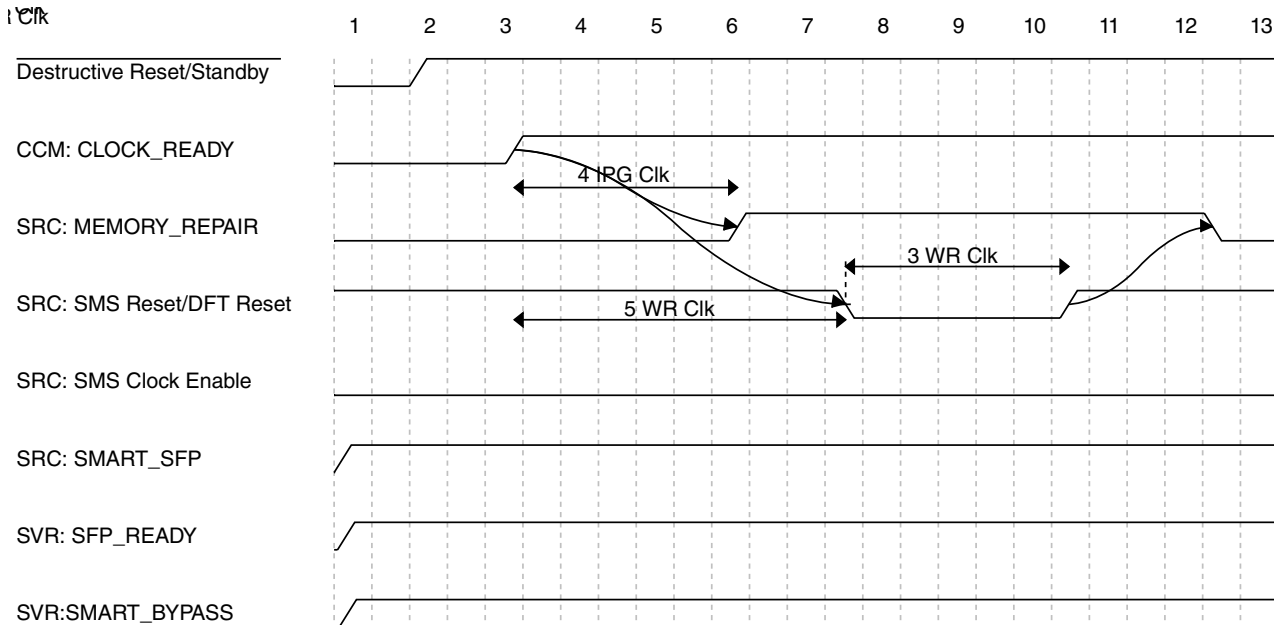

Figure 7-12. Memory Repair Sequence (Bypass = '0')

The memory repair follows the following sequence when SMART\_BYPASS = '0' :

1. The memory repair is initiated after the CCM indicates the clocks are ready.

2. The SMS reset are asserted for few memory repair clock cycles.
3. Once the SMS resets are deasserted the memory repair clocks are enabled, for proper clean reset recovery.
4. The SMART\_SFP is deasserted.
5. On the assertion of SFP\_READY, the SMART\_SFP is asserted.
6. The memory repair clock enables are deasserted along with the MEMORY\_REPAIR indicator.

**Figure 7-13. Memory Repair Sequence (Bypass = '1')**

The memory repair follows following sequence when SMART\_BYPASS = '1' :

1. The memory repair is initiated after the CCM indicates the clocks are ready.
2. The SMS reset are asserted for few memory repair clock cycles.
3. The SMS resets are deasserted along with the MEMORY\_REPAIR indicator.

### 7.3.4.7 BOOTMOD Pin Latching

The exact boot sequence is controlled by the values of the BOOTMOD pins on this device.

All the boot pins will be sampled at deassertion of EARLY\_RST.

The value of the BOOTMOD pins will be latched after the IIM asserts the fuse read completion flag. After latching, the values of the BOOTMOD pins are used to determine the booting options of the core as given in the SBMR register.

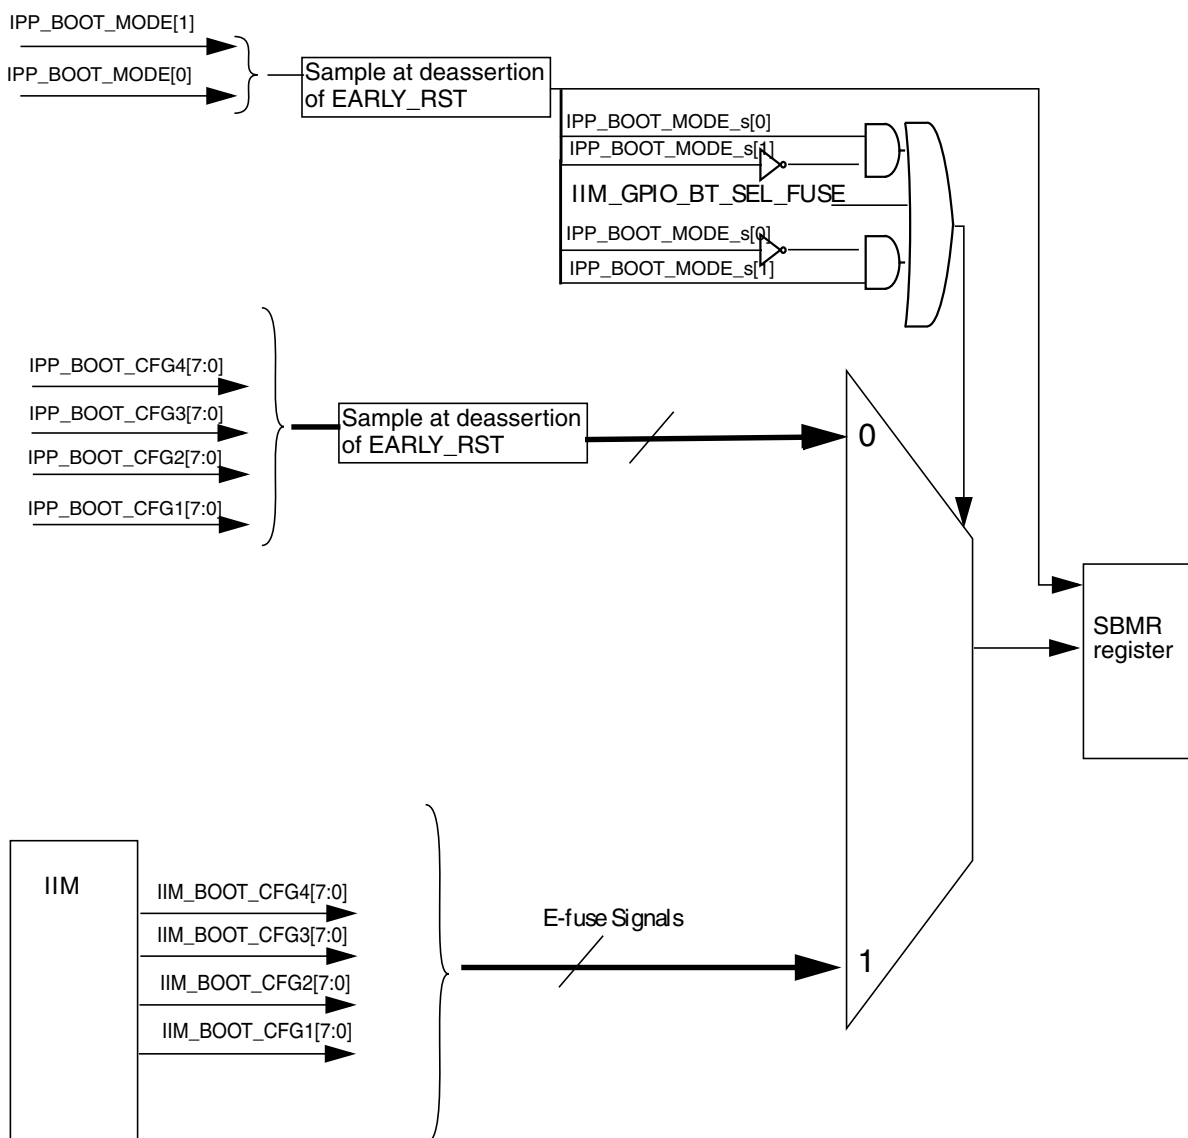

The Boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals (RCON). The `gpio_bt_sel` e-fuse defines the source to be used to derive the boot information. When `gpio_bt_sel` is set, e-fuses are used. When cleared, GPIO signals are used.

When RCON mode is chosen (10 for `BOOTMOD[1:0]`) then the GPIO signals are used.

When Internal Production Boot Mode is chosen (00 for `BOOTMOD[1:0]`) then e-fuses signals are used, independent of the `gpio_bt_sel` e-fuse value.

The Boot information is provided in SBMR register. The figure below shows the selection of Boot mode information.

**Figure 7-14. Boot Mode Information**

## 7.4 On-Chip One Time Programmable Controller (OCOTP)

### 7.4.1 Introduction

The OCOTP controller provides the primary mechanism for interfacing with on-chip fuses. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, security configuration, boot characteristics and various control signals requiring permanent non-volatility. For security purposes, the fuses protect the confidentiality or integrity of critical security data against both software attacks and board-level hardware attacks.

This chapter describes the on-chip One Time Programmable (OTP) Controller. It describes the block functionality and implementation in detail. In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

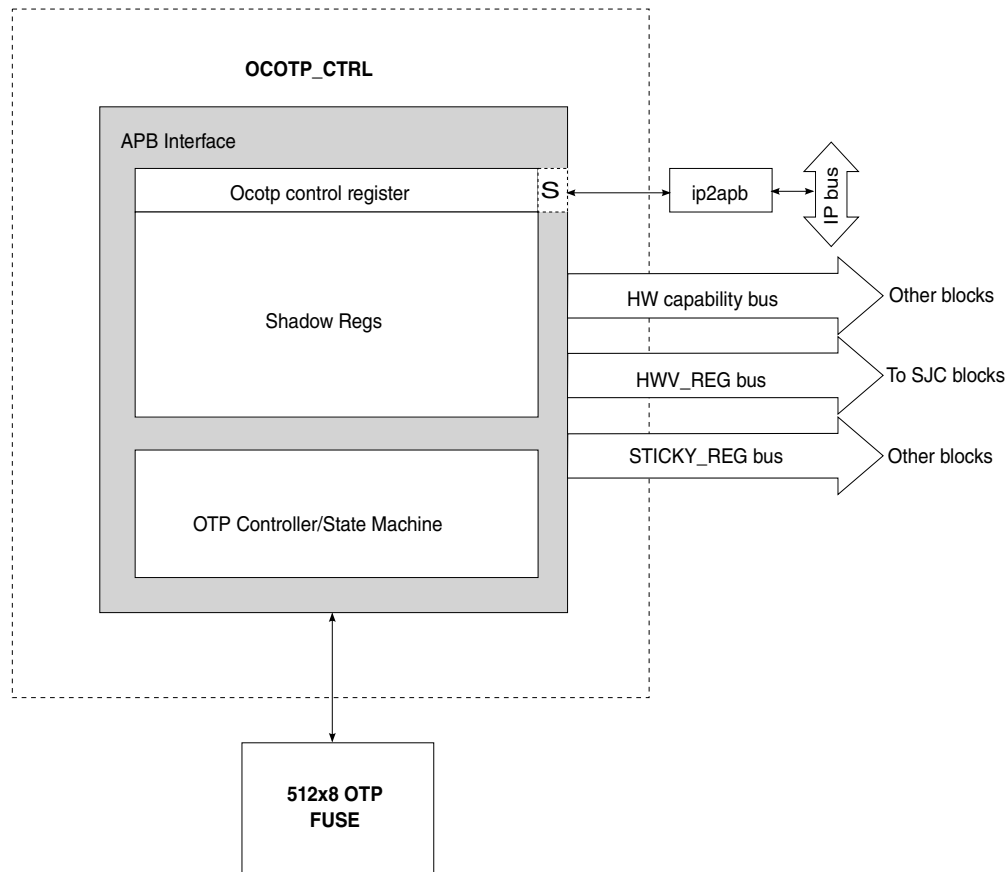

### 7.4.2 Overview of On-Chip OTP (OCOTP) controller

The OCOTP controller provides the following features :

- Shadow cache of fuse values loaded at reset prior to system boot.
- Ability to read and override fuse values in shadow cache (doesn't affect fuse element).
- Ability to read fuses directly (ignoring shadow cache).
- Ability to write (program) fuses by the software
- Fuses and shadow cache bits enforcing read-protect, override-protect, and write-protect.
- Scan protection
- Provide program-protect and read-protect efuse.
- Provide override and read protection of shadow register.
- CRC32 test for read-lock fuse content.

### 7.4.3 Top-level symbol and functional overview

The figure below shows the OCOTP system level diagram.

**Figure 7-15. OCOTP system level diagram**

### 7.4.3.1 Operation

The OCOTP provides two functions:

- Configure control registers for programming and a reading fuse word.
- Override and read shadow registers.

For an efuse, programming can only be performed on a bit and reading is based on a byte. OCOTP configuration for program and read are performed on 32-bit words for software convenience. For writes, the 32-bit word reflects the "write-mask". Bits are set to 0 by default, and when blown, are permanently set to 1. The OCOTP will program bit with 1 in the fuse word one bit by one bit. For reads, OCOTP will read four times to get 4 bytes in the fuse word in order.

This device uses seven banks of fuses for functional and CRC remaining nine are used for ECC and redundant fuses. Each bank is made up of eight fuse words. Physically, there are 4k fuse bits (16 banks) present in one 512x8 efuse box.

### 7.4.3.1.1 Fuse shadow memory footprint

The OTP memory footprint is shown in the figure below. It has 16 banks of 256 fuses (4 KB fuses in total). Each bank is arranged in 8 rows (32-bit words) with 32 fuses per row. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

#### NOTE

Out of 16 banks, 9 banks are used; remaining banks are reserved.

#### 7.4.3.1.1.1 Fuse map address table

Table 7-8. Fuse map address table

Bank	Word	Fuse Address	Base Address	Description
Bank0	Word0	0x00	0x400a5400	Lock controls
Bank0	Word1	0x01	0x400a5410	Secure JTAG Challenge

Bank15	Word7	0x7F	0x400A_5CF0	CRC7

#### 7.4.3.1.2 Fuse values

- All fuses are read and stored in a shadow register before the reset is de-asserted.
- It is possible to re-write, override these shadow register values based on the protection offered by the corresponding fuse locks.
- Fuse values can be read through shadow registers or by initiating a read sequence on the fuse location.

#### 7.4.3.1.3 Fuse protection and overrides

- The first 32 bits of the fuse box define different locks. These locks are associated with rest of the fuses in the fuse box. These locks define the property of the fuses they are associated with.
- The lock bits are used to disable the fuses and the corresponding shadow registers.
- Except lock word, all the fuse words and shadow registers can be prohibited from programming or writing by programming corresponding lock bit in lock word.
- There are different types of locks defined and associated with various fuses. These fuses offer the following capabilities:
  - Override protect (OP): Fuse values cannot be overridden by writing into shadow registers
  - Write Protect (WP): Fuse writes are blocked
  - Read Protect (RP): Fuses values cannot be read by software (shadow registers).

#### 7.4.3.1.4 Fuse blowing

Fuse blow is a simple procedure. Simple code is already available with Validation. Sophisticated drivers can be had from i.MX which will be taking care of the fuse and corresponding lock blow as well. It does not need any extra hardware/supply. High voltage needed to blow the fuse is already available within the device.

#### 7.4.3.1.5 Fuse and shadow register read

All shadow registers are always readable through the APB bus except some secret key regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA. In addition OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new write, read, or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully.

To read fuse word directly from fusebox correctly, complete the following steps:

1. Program OCOTP\_TIMING[STROBE\_READ] and OCOTP\_TIMING[RELAX] fields with timing values to match the current frequency of the ipg\_clk. OTP read will work at maximum bus frequencies as long as the OCOTP\_TIMING parameters are set correctly.
2. Check that OCOTP\_CTRL[BUSY] and OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested address to OCOTP\_CTRL[ADDR].
4. Set OCOTP\_READ\_CTRL[READ\_FUSE] to 1. OCOTP will auto read 4 bytes in requested word address in fusebox one by one. Then put read value into OCOTP\_READ\_FUSE\_DATA register.
5. Once complete, the controller will clear OCOTP\_CTRL[BUSY]. A read request to a protected or locked region will result in no OTP access and no setting of OCOTP\_CTRL[BUSY]. In addition OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read the OCOTP\_READ\_FUSE\_DATA register to get fuse word value. OCOTP\_READ\_FUSE\_DATA will be 0xBADABADA when OCOTP\_CTRL[ERROR] is set.

#### 7.4.3.1.6 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The OCOTP\_LOCK register also has no shadow or fuse lock bits but it is always read only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank correctly complete the following steps:

1. Program OCOTP\_TIMING[STROBE\_PROG] and OCOTP\_TIMING[RELAX] fields with timing values to match the current frequency of the ipg\_clk. OTP writes will work at maximum bus frequencies as long as the OCOTP\_TIMING parameters are set correctly.
2. Check that OCOTP\_CTRL[BUSY] and OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested fuse address to OCOTP\_CTRL[ADDR] and program the unlock code into OCOTP\_CTRL[WR\_UNLOCK]. This must be programmed for each write access. The lock code is documented in the OCOTP\_CTRLn register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the OCOTP\_DATA register. This will automatically set OCOTP\_CTRL[BUSY] and clear OCOTP\_CTRL[WR\_UNLOCK]. To protect programming same OTP bit twice, before a program the OCOTP will automatically read the fuse value and use it to mask program data. The controller will use masked program data to program a 32-bit word in the OTP per the address in OCOTP\_CTRL[ADDR]. Field with 1's will result in that OTP bit being programmed. Field with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of OCOTP\_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to OCOTP\_CTRL[ADDR] will not affect an active write operation. It should also be noted that during the programming OCOTP\_DATA will shift right (with zero fill). This shifting is required to program the OTP serially. During the write operation, OCOTP\_DATA cannot be modified.
5. Once complete, the controller will clear OCOTP\_CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of OCOTP\_CTRL[BUSY]. In addition OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are scaled at 10  $\mu$ s per word. Write latencies will be based on the number of bits being set to 1. For example, if half the fuse bits in one word are programmed, the latency is 10  $\mu$ s x 16.

For further details of OTP read/write operations see [eFUSE].

OCOTP\_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while OCOTP\_CTRL[RELOAD\_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.

- A write is performed to a shadow register that has been locked.
- A read is performed to from a shadow register which has been read locked.
- A program is performed to a fuse word which has that locked.
- A read is performed to from a fuse word which has that read locked.

#### 7.4.3.1.7 Write postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2  $\mu$ s after the clearing of OCOTP\_CTRL\_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes. A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY.
- Once BUSY is clear, wait for defined efuse time.
- Perform the next OTP operation.

#### 7.4.3.2 OTP read/write timing parameters

Three timing fields in the OCOTP\_TIMING register specify counter limit values that are used to time how long the state machine remains in the various states and also specify the STROBE signal timing. All are specified in ipg\_clk cycles. Since the ipg\_clk frequency is configurable, these timing parameters must be adjusted to yield the appropriate delay.

The OCOTP\_TIMING[RELAX] field specifies how long to remain in states to meet setup and hold timing requirements. This parameter should be set by the following equation:

$$t_{RELAX} = t_{HP\_PG} = (OCOTP\_TIMING[RELAX] + 1) / ipg\_frequency > 12 \text{ ns (shouldn't be less than 2 cycles)}$$

The OCOTP\_TIMING[RELAX] field is used to calculate other setup and hold timing delays in addition to tHP\_PG. For all timing to be met, this is the max delay that must be programmed.

Except for setup and hold timing delays, there are two timing parameters for the STROBE signal pulse width.

The OCOTP\_TIMING[STROBE\_PROG] field specifies the period of the STROBE signal during fuse writes and is given in units of ipg\_clk cycles. The STROBE signal, tPGM, should be asserted high for a value for 12  $\mu$ s. Even though a range is given for tPGM, it is advised to use a value of 12  $\mu$ s. Therefore, this field should be set according to the following equation:

$t_{PGM} = ((OCOTP\_TIMING[STROBE\_PROG]+1) - (2*OCOTP\_TIMING[RELAX]+1))/ipg\_frequency = 12\ \mu s$

The `OCOTP_TIMING[STROBE_READ]` field specifies the period of the STROBE signal for fuse reads and is given in units of `ipg_clk` cycles. This field should be set according to the following equation:

$t_{RD} = ((OCOTP\_TIMING[STROBE\_READ]+1) - (2*OCOTP\_TIMING[RELAX]+1))/ipg\_frequency > 170\ ns.$

The figure below illustrates the relationship between the STROBE signal in programming and reading mode and the timing register fields that affect it. The implementation uses one counter to generate the STROBE waveform within one period and a second counter counts the number of cycles to create for programming the designated word.

Figure 7-16. STROBE signal creation and timing

### 7.4.3.3 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time `OCOTP_CTRL_BUSY` is set. The load time is similar to that of a "reload shadow" operation.

### 7.4.3.4 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources. Four JTAG security levels are shown in the table below.

**Table 7-9. JTAG security level control bits**

Security Mode	JTAG_SMODE	SEC_CONFIG	Description
No Debug	2'b11	x	The highest security level.
Secure JTAG	2'b01	x	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	1'b1	Low Security, all JTAG features are enabled.
SCC JTAG	2'b00	1'b0	No security.

JTAG debug access may be semi-permanently enabled by blowing the jtag\_bp bit (JTAG Bypass Security). This, however, can be overridden by blowing the jtag\_re bit (JTAG Security Re-enable). Blowing the jtag\_bp bit effectively changes the security level from 'Secure JTAG' to 'JTAG Enable', without actually modifying the JTAG\_SMODE fuses.

## 7.4.4 OCOTP memory map/register definition

Some registers in this module are accessible in 4 different ways:

- Reg. Addr + 0x0 generic: Use generic address to read/write entire content of the register.
- Reg. Addr + 0x4 \_SET: Use set address space to set bits of the register. All the bits, which are marked 1 in the write, get set.
- Reg. Addr + 0x8 \_CLR: Use clear address space to clear bits of the register. All the bits, which are marked 1 in the write, get cleared.
- Reg. Addr + 0xC \_TOG: Use toggle address space to toggle bits of the register. All the bits, which are marked 1 in the write, get toggled.

This additional functionality allows for performing atomic operations on the register content.

### 7.4.4.1 OTP Controller Control Register (OCOTP\_CTRLn)

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP. The control fields such as WR\_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the OCOTP\_DATA register to perform write operations. Read operations to the OCOTP involve the ADDR and BUSY/ERROR bit fields, and the OCOTP\_READ\_CTRL register. The read value is saved in the OCOTP\_READ\_FUSE\_DATA register.

Address: 400A\_5000h base + 0h offset + (4d × i), where i=0d to 3d

OCOTP\_CTRLn field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY).  0x3E77 <b>KEY</b> — Key needed to unlock OCOTP_DATA register.
15–13 Reserved	This field is reserved. Reserved
12 CRC_FAIL	Set by controller when the calculated CRC value is not equal to appointed CRC fuse word
11 CRC_TEST	Set this bit to calculate the CRC according to the start address and the end address in the CRC_ADDR register. It compares this with the CRC fuse word selected by the CRC address in the CRC_ADDR register, and generates the value for the CRC_FAIL flag.
10 RELOAD_SHADOWS	Set to force re-loading the shadow registers (Hardware/Software capability and LOCK). This operation will automatically set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	Set by the controller when an access to a locked region (OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface is active and software requests an access to the OTP. In this instance, the

Table continues on the next page...

**OCOTP\_CTRL $n$  field descriptions (continued)**

Field	Description
	ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a one to the SCT clear address space and not by a general write.
8 BUSY	OTP controller status bit. When active, no new write access or read access to OTP (including RELOAD_SHADOWS) can be performed. It is cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the Hardware/Software and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7 Reserved	This field is reserved. Reserved
ADDR	OTP write and read access address register. Specifies one of 128 word address locations (0x00 - 0x7f). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not update until the access is complete.

**7.4.4.2 OTP Controller Timing Register (OCOTP\_TIMING)**

This register specifies [OTP Read/Write Timing Parameters](#)

Address: 400A\_5000h base + 10h offset = 400A\_5010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				WAIT							STROBE_READ				RELAX				STROBE_PROG												
W																																
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0

**OCOTP\_TIMING field descriptions**

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–22 WAIT	This count value specifies time interval between auto read and write access while programming the fuse. It is given in number of ipg_clk periods.
21–16 STROBE_READ	This count value specifies the strobe period in one time read OTP. $Trd = ((STROBE\_READ+1) - 2*(RELAX+1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.
STROBE_PROG	This count value specifies the strobe period in one time write OTP. $Tpgm = ((STROBE\_PROG+1) - 2*(RELAX+1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.

**7.4.4.3 OTP Controller Write Data Register (OCOTP\_DATA)**

The OCOTP Data Register is used for OTP Programming.

This register is used in conjunction with OCOTP\_CTRL to perform one-time writes to the OTP. Please see the "Software Write Sequence" section for operating details.

## On-Chip One Time Programmable Controller (OCOTP)

Address: 400A\_5000h base + 20h offset = 400A\_5020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### OCOTP\_DATA field descriptions

Field	Description
DATA	Used to initiate a write to OTP. Please see the "Software Write Sequence" section for operating details.

## 7.4.4.4 OTP Controller Read Control Register (OCOTP\_READ\_CTRL)

The OCOTP Register is used for OTP Read.

This register is used in conjunction with OCOTP\_CTRL to perform one time read to the OTP. Please see the "FusSoftware read Sequence" section for operating details.

The OCOTP Register is used for OTP Read

Address: 400A\_5000h base + 30h offset = 400A\_5030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### OCOTP\_READ\_FUSE\_DATA field descriptions

Field	Description
DATA	The data read from OTP

### 7.4.4.6 Software Controllable Set Register (OCOTP\_SCSn)

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after POR.

Address: 400A\_5000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	SPARE														
W

R	SPARE															HAB_JDE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### OCOTP\_SCSn field descriptions

Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through software programming. This bit is only reset after a POR is issued.

*Table continues on the next page...*

**OCOTP\_SCS<sub>n</sub> field descriptions (continued)**

Field	Description
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	<p>HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properplay signed command to do so is found and validated by the HAB.</p> <p>The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled.</p> <p>Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR.</p> <p>0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms).</p> <p>1 JTAG debugging is enabled by the HAB (though this signal may be gated off)</p>

**7.4.4.7 OTP Controller CRC address (OCOTP\_CRC\_ADDR)**

This register is used to calculate as part of the CRC validation.

Address: 400A\_5000h base + 70h offset = 400A\_5070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R														CRC_ADDR																		
W	Reserved													CRC_ADDR			DATA_END_ADDR								DATA_START_ADDR

#### OCOTP\_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

### 7.4.4.10 Value of OTP Bank0 Word0 (Lock controls) (OCOTP\_LOCK)

Copied from the OTP automatically after reset. Can be re-loaded by setting \_OCOTP\_CTRL[RELOAD\_SHADOWS]

On-Chip One Time Programmable Controller (OCOTP)

This register shadowed the OTP fuse BANK 0, word 0(ADDR 0x00). This register is always read/write lock. The corresponding fuse word is always read lock.

Address: 400A\_5000h base + 400h offset = 400A\_5400h

OCOTP\_LOCK field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–28 CRC_GP_HI_LOCK	Status of shadow register write and read, OTP program and read lock for upper 128 bits CRC region. When bit 1 is set, the reading and writing of this region's OTP fuse and reading of shadow register are blocked. When bit 0 is set, the writing of this region's shadow register and OTP fuse are blocked.
27–26 CRC_GP_LO_LOCK	Status of shadow register write and read, OTP program and read lock for lower 128 bits CRC region. When bit 1 is set, the reading and writing of this region's OTP fuse and reading of shadow register are blocked. When bit 0 is set, the writing of this region's shadow register and OTP fuse are blocked.
25–23 Reserved	This field is reserved. Reserved
22 MISC_CONF_LOCK	Status of shadow register and OTP write lock for misc_conf region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
21–20 PMU_LOCK	Status of shadow register and OTP write lock for PMU region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
19–18 ANALOG_LOCK	Status of shadow register and OTP write lock for analog region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

Table continues on the next page...

**OCOTP\_LOCK field descriptions (continued)**

Field	Description
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–15 Reserved	This field is reserved. Reserved
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–12 GP2_LOCK	Lock for General Purpose fuse register #2 (GP2)  Status of shadow register and OTP write lock for GP2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
11–10 GP1_LOCK	Lock for General Purpose fuse register #1 (GP1)  Status of shadow register and OTP write lock for GP1 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
9–8 MAC_ADDR_LOCK	Lock MAC_ADDR fuses.  Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
7 Reserved	Reserved.  This field is reserved. Reading this bit will get a 1.
6 SJC_RESP_LOCK	Status of shadow register read and write, OTP read and write lock for sjc_resp region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
5–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 BOOT_CFG_LOCK	Perform lock on BOOT related fuses.  Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
Reserved	This field is reserved.

**7.4.4.11 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP\_CFG0)**

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

This register shadows the OTP fuse BANK 0, word 1 (ADDR 0x01). This register is read-only after TESTER\_LOCK[1] is set. The corresponding fuse word is also read-only after TESTER\_LOCK[0] is set.

Address: 400A\_5000h base + 410h offset = 400A\_5410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### 7.4.4.14 Value of OTP Bank0 Word6 (Configuration and Manufacturing Info.) (OCOTP\_CFG5)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

This register shadowed the OTP fuse BANK 0, word 6 (ADDR 0x06). This register is read-only after BOOT\_CFG\_LOCK [1] is set. The corresponding fuse word is also read-only after BOOT\_CFG\_LOCK [0] is set.

## On-Chip One Time Programmable Controller (OCOTP)

Address: 400A\_5000h base + 460h offset = 400A\_5460h

### OCOTP\_CFG5 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 JTAG_HEO	JTAG HAB Enable Override.  Disallows HAB JTAG enabling. The HAB may normally enable JTAG debugging by means of the HAB_JDE-bit in the OCOTP SCS register. The JTAG_HEO-bit can override this behavior.  0 HAB may enable JTAG debug access 1 HAB JTAG enable is overridden (HAB may not enable JTAG debug access)
26 KTE	Kill Trace Enable.  Enables tracing capability on ETM, and other modules.  0 Bus tracing is allowed 1 Bus tracing is allowed in case security state as defined by Secure JTAG allows it (for example, JTAG_ENABLE or NO_DEBUG)
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–22 JTAG_SMODE	JTAG Security Mode.  Controls the security mode of the JTAG debug interface.  00 JTAG enable mode 01 Secure JTAG mode 11 No debug mode
21 WDOG_ENABLE	Watchdog Enable.  Used to specify whether to enable / not watchdog at boot.  0 Watch-Dog is disabled. 1 Watch-Dog is enabled.

Table continues on the next page...

**OCOTP\_CFG5 field descriptions (continued)**

Field	Description
20 SJC_DISABLE	Secure JTAG Controller module.  This fuse is used to create highest JTAG security level, where JTAG is totally blocked.  0 Secure JTAG Controller is enabled 1 Secure JTAG Controller is disabled
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 Reserved	This field is reserved.
17–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 BT_FUSE_SEL	Determines, whether using fuses for boot configuration, or GPIO /Serial loader.  0=Boot mode configuration is taken from GPIOs. 1=Boot mode configuration is taken from fuses. 0 - Boot using Serial Loader (USB) 1- Boot mode configuration is taken from fuses. If boot_mode="00" (Development) If boot_mode="10" (Production)
3 DIR_BT_DIS	Direct Boot Disable.  0 Enable 1 Disable
2 Reserved	This field is reserved.
SEC_CONFIG	Security Configuration  00 FAB (Open) 01 Open - allows any code to be flashed and executed, even if it has no valid signature. 1x Closed (Security On)

**7.4.4.15 Value of Bank1 Word6 (Temperature Sensor calibration OCOTP\_ANA\_TEMPSENSE) (OCOTP\_TEMPSENSE)**

The temperature is calculated from the ADC reading (tempsensor\_count ), using the calibration data, as follows: Current temperature =  $25 + ((\text{tempsensor\_count} - \text{ROOM\_TEMPSENSOR\_CNT}) * (\text{HOT\_TEST\_TEMPERATURE} - 25) / (\text{HOT\_TEMPSENSOR\_CNT} - \text{ROOM\_TEMPSENSOR\_CNT}))$

Address: 400A\_5000h base + 4E0h offset = 400A\_54E0h

### OCOTP\_RNG field descriptions

Field	Description
31–24 RNG_TRIM	Trims bits for RNG in CAAM. 6-bits of the field control the entropy delay value, freq_count_max and freq_count_min; 2-bits control the oscillator output divider.
23–16 Reserved	This field is reserved.
15–12 ADC1_CAL	ADC1 Calibration value
11–8 ADC0_CAL	Calibration 0 for ADC0
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
VADC_ BANDGAP	Trim values for VADC bandgap.

#### 7.4.4.26 Value of OTP Bank7 Word7 (Memory Related Info.) (OCOTP\_VTMON)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

This register shadowed the OTP fuse BANK 7, word 7 (ADDR 0x3F). This register is read-only after ANALOG\_LOCK[1] is set. The corresponding fuse word is also read-only after ANALOG\_LOCK[0] is set.

Address: 400A\_5000h base + 8F0h offset = 400A\_58F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 7.5 System Boot

### 7.5.1 Introduction

The boot process begins at Power On Reset (POR) where the hardware reset logic forces the ARM core to begin execution starting from the on-chip Boot ROM. The Boot ROM code uses the state of the internal register `BOOT_MODE` [1:0] as well as the state of various eFUSES and/or GPIO settings to determine the boot flow behavior of the device.

The main features of the ROM include:

- Support for booting from various boot devices
- Serial Downloader support (USB and UART)
- Device Configuration Data (DCD)
- Wakeup from low-power modes
- Wakeup secondary core
- HAB Re-authentication on Low Power Standby exit

Boot ROM supports the following boot devices:

- NOR Flash
- NAND Flash
- FlexCAN
- SD/MMC
- QuadSPI
- Serial ROM devices (through I2C and SPI interfaces)

The boot process can be summarized in the following steps.

1. Reset the device.
2. Begin execution of Boot ROM code. The boot process depends on the reset type, `HAB_REAUTH` setting, CPU ID, `BOOT_MODE`[1:0], and the `RCON` register.
3. Read the Image Vector Table and boot data structures. Optionally, download image to memory.
4. Execute image, i.e., the user code.

In normal operation, the Boot ROM uses the state of the BOOT\_MODE register and eFUSES to determine the boot device. For development purposes, there is also an option to use GPIO pin inputs to override the fuse values to determine the boot device.

### NOTE

BOOT\_MODE and and GPIO Pins are sampled on a Power On Reset event.

The Boot ROM code also allows for programs to be downloaded and executed on the device. An example is a provisioning program that can make further use of the serial connection to program a boot device with a new image. Typically, the provisioning program is downloaded to internal RAM and programs the boot devices such as a NAND Flash. The ROM Serial Downloader can use either the high speed USB or UART interface in non-stream mode connection.

The Boot ROM allows waking from low power modes and waking up secondary core (either Cortex-A5 or Cortex-M4 depending on configuration). On reset the Boot ROM checks the CPU ID and power gating status register. The primary core (with ID = 0), on waking up from low power mode, and, secondary core (with ID=1) in all power modes, will skip downloading the image from the boot device. It will jump to the address saved in the PERSISTENT\_ENTRY [Persistent Bits](#) register.

The Device Configuration Data (DCD) feature allows the Boot ROM code to obtain system configuration data from an external Program Image residing on the boot device. As an example, the DCD can be used to program the SDRAM controller for optimal settings to improve the boot performance. DCD configuration options are restricted to memory areas and peripheral addresses that are considered essential for boot purposes.

The remainder of this chapter provides the details on how to configure and use the boot features of the device.

## 7.5.2 Boot Modes

On reset, the device checks the CPU ID in the MSCM CPxNUM register and Power Gating Controller status register.

On normal boot, the Primary Core behavior is defined by the Boot Mode pins settings as described in [Boot Mode Pin Settings](#). On waking up from low power boot mode, the Primary Core skips configuring the clocks. The Boot ROM checks that PERSISTENT\_ENTRY0 (see [Persistent Bits](#)) is a pointer to a valid address space (internal SRAM, DDR, FlexBus, and QuadSPI). If PERSISTENT\_ENTRY0 is a pointer

to a valid range, it starts execution using the entry point from the PERSISTENT\_ENTRY0 register. If PERSISTENT\_ENTRY0 is a pointer to an invalid range, the Primary Core performs a system reset.

**Note**

Only wake-up to internal SRAM is supported as clocks to other modules are disabled.

For the Secondary Core, the Boot ROM checks that the PERSISTENT\_ENTRY is a pointer to a valid address space ( Internal SRAM, DDR, FlexBus, and QuadSPI). If PERSISTENT\_ENTRY is a pointer to a valid range, it starts execution using the entry point from the PERSISTENT\_ENTRY register. If PERSISTENT\_ENTRY is a pointer to invalid range, it sets error status registers (see [Persistent Bits](#)), sends a wakeup error interrupt, and performs a Wait-For-Interrupt instruction. The Interrupt Service routine of primary core must reconfigure the system and reset the secondary core.

**Note**

SW that enables secondary core is not part of ROM. It must be part of upper level SW.

**7.5.2.1 Boot Mode Pin Settings**

The device has four boot modes (one is reserved for Freescale use). Boot mode is selected based on the binary value stored in the internal BOOT\_MODE register. BOOT\_MODE is initialized by sampling the BOOT\_MODE0 and BOOT\_MODE1 pins on the rising edge of RESET\_B after POR. After these pins are sampled, their subsequent state does not affect the contents of the BOOT\_MODE internal register. The state of the internal BOOT\_MODE register may be read from the BMOD[1:0] field of the SRC Boot Mode Register (SRC\_SBMR2). The available boot modes are: Boot From Fuses, serial boot via USB or UART, Boot from RCON and FSL Test mode. See the table below for settings.

**Table 7-10. Boot MODE Pin Settings**

BOOT_MODE[1:0]	Boot Type
00	Boot From Fuses
01	Serial Downloader
10	Boot from RCON

## 7.5.2.2 High Level Boot Sequence

The figure below shows the High Level boot ROM code flow in this device.

Figure 7-17. BOOT Flow

### Note

For FlexBus (NOR) and QuadSPI boot devices, downloading initial load region to iRAM is skipped. IVT is read from FlexBus/QuadSPI address space respectively (see [Image Vector Table and Boot Data](#)). Copying initial load region and the rest of the program image is done only if the absolute start address of the image is not equal to FlexBus/QuadSPI start address.

#### 7.5.2.3 Boot From Fuses Mode (BOOT\_MODE [1:0] = 0b00)

A value of 0b00 in the BOOT\_MODE [1:0] register selects the Boot From Fuses mode. This mode is similar to the Boot from RCON mode, with one difference. In this mode the GPIO boot override pins are ignored. The boot ROM code uses the boot eFUSE settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT\_FUSE\_SEL eFUSE value. If BT\_FUSE\_SEL = 0, indicating that the boot device (for example, Flash, SD/MMC) has not yet been programmed, the boot flow jumps directly to the Serial Downloader. If BT\_FUSE\_SEL = 1, then the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFUSES may be configured incorrectly for the hardware on the platform. In such a case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using Boot From Fuses mode solves this problem. The first time the BT\_FUSE\_SEL eFuse is encountered, it is not blown (thus BT\_FUSE\_SEL=0). This forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded, which can then provision the boot device with a Program Image, and blow the BT\_FUSE\_SEL and the other boot configuration eFUSES. After reset, the Boot ROM code determines that BT\_FUSE\_SEL is blown (BT\_FUSE\_SEL = 1) and the ROM code performs internal boot according to the new eFUSE settings. This allows a user to set BOOT\_MODE [1:0] = 0b00 on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without changing the value of BOOT\_MODE [1:0] or pull-ups/pull-downs on the BOOT\_MODE pins.

#### 7.5.2.4 Mode: Serial Downloader Mode (BOOT\_MODE [1:0] = 0b01)

The serial downloader is invoked if the external Flash device is not programmed, when a failure is encountered during the boot flow process, or any of the following conditions are met:

- `BOOT_MODE[1:0] = 0b01` (serial downloader mode)
- `BOOT_MODE[1:0] = 0b00` (boot from fuses) and the `eFUSE BT_FUSE_SEL = 0`
- `BOOT_MODE[1:0] = 0b00` or `0b10` (Boot From Fuses or Boot From RCON) and there is not a valid image in the external boot
- Internal failure
- Runtime exception occurs
- Error is returned by the HAB functions while in a Closed security configuration. Errors are ignored in an Open security configuration (see [Boot Security Settings](#)).

To determine the USB/UART connection, the Boot ROM polls the USB/UART status register.

If `WDOG_ENABLE` eFUSE is 1 and there is no activity on USB/UART port within the predefined polling time, then the ROM program will power down the SoC using the Watchdog Timer (either `WDOG-A5` or `WDOG-M4` depending on the primary core). When the serial bootloader is active, the Watchdog is serviced periodically. If the communication between the serial Host and this device is idle for more than 90 seconds, or the processor goes into an endless loop, then the watchdog expires and powers down the device. For details on the Serial Downloader see [Serial Downloader \(BOOT\\_MODE \[1:0\] = 0b01\)](#).

#### 7.5.2.5 Boot from RCON (BOOT\_MODE [1:0] = 0b10)

A value of 10 in the `BOOT_MODE [1:0]` register selects the Boot from RCON. In this mode, the processor continues to execute boot code from the internal boot ROM. The boot code performs hardware initialization, loads the Program Image from the chosen boot device, performs image validation using the HAB library (see [Boot Security Settings](#)), and then jumps to an address derived from the Program Image. If any error occurs during internal boot, the boot code jumps to the Serial Downloader (see [Serial Downloader \(BOOT\\_MODE \[1:0\] = 0b01\)](#)). A secure boot using the HAB is possible in all the three boot modes.

When set to Boot from RCON, the boot flow may be controlled by a combination of eFUSE settings with an option of overriding the fuse settings using GPIO General Purpose I/O (GPIO) pins. Whether the ROM uses GPIO pins for a select number of configuration parameters or eFUSES in this mode is determined by the GPIO Boot Select (`BT_FUSE_SEL`) eFUSE.

- If BT\_FUSE\_SEL = 1, all boot options are controlled by the eFUSEs described in [Table 7-11](#).
- If BT\_FUSE\_SEL = 0, specific boot configuration parameters may be set using GPIO pins rather than eFUSEs. The fuses that can be overridden when in this mode are indicated in the GPIO column of [Table 7-11](#). [Table 7-12](#) provides the details on the GPIO pins.

The use of GPIO overrides is intended for development since these pads are used for other purposes in deployed products. Freescale recommends controlling the boot configuration by eFUSEs in deployed products and reserving the use of the GPIO mode for development and testing purposes only.

### 7.5.3 Device Configuration

This section describes the external inputs that control the behavior of the Boot ROM code. This includes boot device selection (NAND, NOR, MMC), boot device configuration (NAND address cycles), and so on. In general, the source for this configuration comes from eFUSEs embedded in this device. However, certain configuration parameters can be sourced from GPIO pins allowing further flexibility during the development process.

#### 7.5.3.1 Boot eFUSE Descriptions

The table below is a comprehensive list of the configuration parameters that the device ROM uses.

**Table 7-11. BOOT eFuse Descriptions**

Fuse	Config	Definition	GPIO <sup>1</sup>	Shipped Value	Settings <sup>2</sup>
DIR_BT_DIS	OEM	Reserved FSL Test/WDOG-1 Reset boot Mode Disable	NA	0	0 Reserved FSL Test/Watchdog Reset Boot Mode is allowed 1 Reserved FSL Test/Watchdog Reset Boot Mode is not allowed
BT_FUSE_SEL	OEM	In Boot from RCON, the BT_FUSE_SEL fuse determines whether the boot settings indicated by a Yes in the GPIO column are controlled by either GPIO pins or eFUSE settings in the IC Identification Module	NA	0	If BOOT_MODE[1:0] = 0b10 0 Bits of SBMR are overridden by GPIO pins. 1 Specific bits of SBMR are controlled by eFUSE settings.  If BOOT_MODE[1:0] = 0b00

4. Bank0 Word7 Field[31:24]

### 7.5.3.2 GPIO Boot Overrides

The table below provides a list of GPIO boot overrides. These input pins are sampled at POR, and can be used to override corresponding eFUSE values, depending on the setting of the BT\_FUSE\_SEL fuse. The GPIO override feature is only available when BT\_FUSE\_SEL is 0 (fuse is un-blown) and BOOT\_MODE [1:0] = 10.

**Table 7-12. GPIO Override Contact Assignments**

### 7.5.3.3 Device Configuration Data

See [Device Configuration Data \(DCD\)](#) for more details on Device Configuration Data.

## 7.5.4 Device Initialization

This section describes the details on the device ROM and provides initialization details. This includes details on the following:

- The iROM Memory Map
- The iRAM Memory Map
- On-chip blocks that the ROM should make use of or change POR register default values

- Clock initialization
- Enabling the MMU/L2 cache when performing a secure boot (SEC\_CONFIG = Closed)
- Exception handling, error logging, and interrupt handling

7.5.4.1 Internal ROM / RAM Memory Map

The figure below shows the internal ROM and internal RAM memory map for the device.

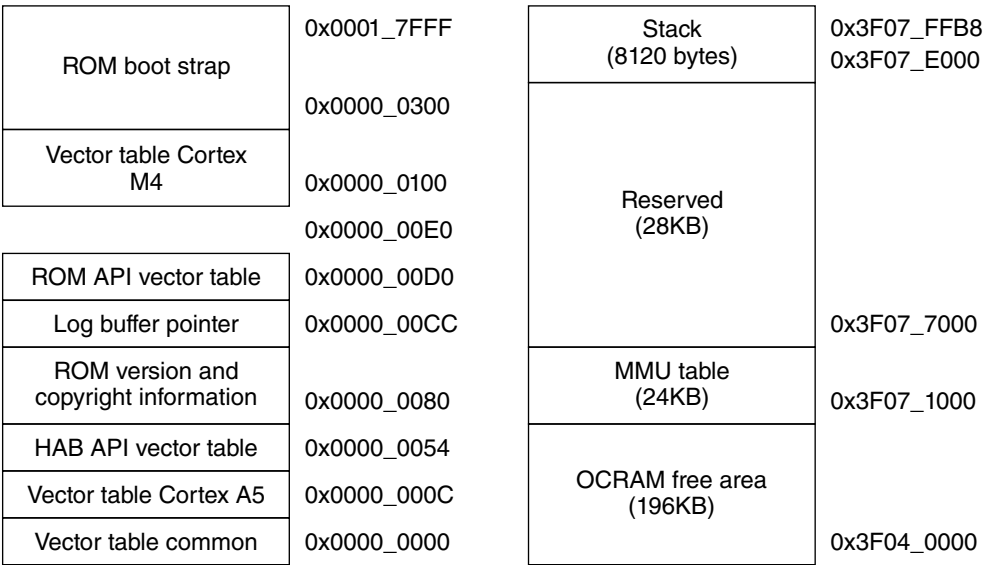

Figure 7-18. Internal ROM and RAM Memory Map

NOTE

RAM Areas will be overwritten by the BOOTROM.  
Application can use this area after the control is transferred.

7.5.4.2 Boot Block Activation

The device Boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow. The ROM configures and uses the following blocks during the boot process. Note that the blocks actually used depend on the boot mode and boot device selection:

- ANADIG - Analog module. The ANADIG contains PLLs and USB PHY.

- MSCM — Miscellaneous System Configuration Module
- SRC - System Reset Controller
- CCM - Clock Control Module
- OCOTP - On-Chip OTP Controller. The OCOTP contains the eFUSES.
- GPIO — GPIO Controller
- PIT — Programmable Interrupt Timer
- IOMUXC - I/O Multiplexer Control allows GPIO use to override eFUSE boot settings GPIO - used to choose tests in FSL Test Mode
- SPI — Serial Peripheral Interface
- FlexBus Controller - External Memory Interface. Used for NOR devices
- QuadSPI — Quad SPI controller
- I2C - Inter IC Controller
- NFC - NAND Flash controller pin interface
- USB - Used for serial download of a boot device provisioning program
- ESDHC — Enhanced Secure Digital Host Controller
- FlexCAN — CAN Controller
- UART — To Support Serial Boot
- WDOG-A5 - Watchdog Cortex-A5 Timer
- WDOG-M4 — Watchdog Cortex-M4 Timer

### 7.5.4.3 Clocks at Boot Time

Boot ROM provides facility to bypass external oscillator. This can be used by blowing OSC\_BYPASS efuse. Refer to [Boot eFUSE Descriptions](#)

Boot ROM also allows customer to override the reset value of CCM\_CCR[OSCNT] field by programming OSC\_TUNED eFuse (Refer to [Boot eFUSE Descriptions](#)) when OSC\_BYPASS eFuse is not blown. This can be helpful when the crystal startup time is more. Boot ROM performs a timed poll for CCM\_CSR[FXOSC\_RDY] to be asserted.

The time is computed by the formula: Wait Time = 1.5\*(CCM\_CCR[OSCNT]/SIRC) if CCM\_CSR[FXOSC\_RDY] is not set within the time computed, then BOOTROM enters fail safe mode (serial download from UART).

The table below shows the various clocks and their sources used by ROM.

**Table 7-13. Normal Frequency Clocks Configuration**

Clock	CCM Signal	Source	Frequency(MHz)
Cortex-A5 Clock	ca5_mux_out_clk	PLL1_PFD4	264
Cortex-M4 Clock (Platform Bus Clock)	cm4_div_out_clk	PLL1_PFD4	132
IPG Clock	Bus_div_out_clk	PLL1_PFD4	66
FlexBUS Clock		Platform Bus Clock	33 (Configurable by Application)
NFC Clock	nfc_clk_root	PLL3_PFD1 PLL1_PFD2	30.85 (Normal Frequency) 45.25 (Fast Frequency)
QSPI0 Clock	qspi0_serial_b_clk qspi0_serial_clk qspi0_serialx2_b_clk qspi0_serialx2_clk qspi0_serialx4_b_clk qspi0_serialx4_clk	PLL3_PFD4 PLL3_MAIN PLL3_PFD4	18.62 (INIT) 60 74.5
QSPI1 Clock	qspi1_serial_b_clk qspi1_serial_clk qspi1_serialx2_b_clk qspi1_serialx2_clk qspi1_serialx4_b_clk qspi1_serialx4_clk	PLL3_PFD4 PLL3_MAIN PLL3_PFD4	18.62 (INIT) 60 74.5
eSDHC0 Clock	esdhc0_clk_root	Platform Bus Clock PLL1_PFD3 PLL1_PFD3 PLL3_PFD3 PLL3_PFD3	400KHz (INIT) 24.75 MHz (SD Operating) 49.5 MHz (SD High) 18.62 MHz(MMC Operating) 42.5 MHz (MMC High)
eSDHC1 Clock	esdhc1_clk_root	Platform Bus Clock PLL1_PFD3 PLL1_PFD3 PLL3_PFD3 PLL3_PFD3	400KHz (INIT) 24.75MHz (SD Operating) 49.5MHz (SD High) 18.62MHz(MMC Operating) 42.5MHz (MMC High)
USB Clock	usb_clk		
CAN0 Bus Clock		External Oscillator Clock	1 MHz
CAN1 Bus Clock		External Oscillator Clock	1 MHz
I2C0 Bus Clock		IPG Clock	353 KHz (ipg_clk = 24MHz) 342 KHz (ipg_clk = 66MHz)

Table continues on the next page...

**Table 7-13. Normal Frequency Clocks Configuration (continued)**

Clock	CCM Signal	Source	Frequency(MHz)
I2C1 Bus Clock		IPG Clock	353KHz (ipg_clk = 24MHz)
I2C2 Bus Clock		IPG Clock	342KHz (ipg_clk = 66MHz)
I2C3 Bus Clock		IPG Clock	353KHz (ipg_clk = 24MHz)
SPI0 Bus Clock		IPG Clock	EEPROM ~5MHz FLASH - ~20MHz
SPI1 Bus Clock		IPG Clock	EEPROM ~5MHz FLASH - ~20MHz
SPI2 Bus Clock		IPG Clock	EEPROM ~5MHz FLASH - ~20MHz
SPI3 Bus Clock		IPG Clock	EEPROM ~5MHz FLASH - ~20MHz
UART0 Baud Rate		IPG Clock	115200bps
UART1 Baud Rate		IPG Clock	115200bps
UART2 Baud Rate		IPG Clock	115200bps
UART3 Baud Rate		IPG Clock	115200bps

On reset the processor has access to all peripherals. ROM code will disable the clocks listed in [Table 7-14](#), except for the boot devices listed in the second column.

**Table 7-14. List of Disabled Clocks**

Clock Name	Enabled for BOOT Device
CCGR0_FLEXCAN_0	FlexCAN0

CCPGR1_FLEXBUS	FlexBus

#### 7.5.4.4 Enabling MMU and Caches

The Boot ROM includes a feature of enabling the Memory Management Unit (MMU) and caches to improve the boot speed when performing a secure boot with SEC\_CONFIG = Closed ([High Assurance Boot \(HAB\)](#)). L1 data cache, L2 cache and MMU are enabled during image authentication.

By default L1 I-Cache is enabled.

The MMU feature is controlled by the BT\_MMU\_DISABLE eFUSE. By default the BT\_MMU\_DISABLE eFUSE is not blown meaning the ROM uses MMU, L1 Data and L2 caches of the Cortex-A5 core. The ROM establishes a page table in the MMU Page Table area of iRAM. The ROM also configures the L1 and L2 cache as write through. This improves the performance of the HAB signature verification software.

During normal boot, enabling the MMU and setting the CSF pointer in the Image Vector Table to NULL has no impact on the boot performance. When SEC\_CONFIG=Open is the final configuration, it is recommended to blow the BT\_MMU\_DISABLE fuse. The Table below describes the relationship between BT\_MMU\_DISABLE and L2\_CACHE\_DISABLE fuse bits and its impact on BOOTROM implementation for Cortex-A5 and Cortex-M4 cores:

**Table 7-15. Impact of BT\_MMU\_DISABLE & L2\_CACHE\_DISABLE on BOOTROM Implementation**

Booting Core	BT_MMU_DISABLE	L2_CACHE_DISABLE	Remarks
Cortex-A5	0	0	L1-DCache, MMU & L2 Cache enabled
	0	1	L1-DCache, MMU Enabled & L2 Cache disabled
	1	X	L1-Dcache, MMU & L2 Cache Disabled
Cortex-M4	X	X	L1-DCache enabled

### Note

If the Cortex-M4 is the primary core, the MMU and L2 Cache Controller are not supported.

#### 7.5.4.5 WDOG\_ENABLE eFUSE

WDOG\_ENABLE eFUSE is used to enable Watchdog during Boot. By default this fuse will not be blown (0). Watchdog is configured to generate System Reset instead of Interrupt during boot. However this can be changed by application code after leaving the BootROM. Watchdog, once started, cannot be stopped or disabled, hence, it becomes application's responsibility to service watchdog before it expires.

If the fuse is 1, then the BootROM sets WDOG\_WCR[WDE] to 1 with a timeout of 90 seconds. This gives 90 seconds to download, authenticate, and jump to application code. If this fails to happen, then a system reset will be issued. Note that the watchdog is serviced before jumping to application code, giving the user code 90 seconds to service the watchdog again.

In case of plugin download, watchdog is serviced before and after plugin is executed. This will mean that plugin code has to ensure that the watchdog is serviced every 90 seconds (to prevent watchdog trigger) during the period application code is downloaded to the internal memory. In case of Serial Download (USB & UART) and FLEXCAN boot modes, BOOTROM periodically services watchdog, allowing 90 seconds window for every transmission/reception of command and data

#### 7.5.4.6 Watchdog Reset Boot Mode

To change the boot mode without altering the BOOTMOD pins' states, e.g., for testing purposes, the PERSIST\_SBMR\_SHADOW register and software watchdog reset can be used.

To override the regular boot-mode settings, software configures the PERSIST\_SBMR\_SHADOW register with the required boot-mode settings and sets the PERSIST\_WDOG\_BOOT bit (see the “Persistent Bits” table). Then, when software reset is performed, the Boot ROM code uses the PERSIST\_SBMR\_SHADOW register settings instead of the regular ones.

This mode is disabled if DIR\_BT\_DIS eFUSE is blown.

#### 7.5.4.7 Exception Handling

The exception vectors located at the start of iROM (see [Internal ROM / RAM Memory Map](#) for vector table location) are used to map all the ARM exceptions.

During boot phase of primary core, all exception vectors other than reset vector point to Serial Downloader in iROM. In case of exceptions after low power exit, system will reboot by triggering Watchdog.

During the boot phase of secondary core, the exception vectors point to function that sets error status registers (see [Persistent Bits](#)), sends wakeup error interrupt and performs Wait-For-Interrupt instruction. Interrupt Service routine of primary core must reconfigure system and reset the secondary core.

#### 7.5.4.8 Interrupt Handling during Boot

No special interrupt handling routines are required during the boot process. Interrupts are disabled during boot ROM execution and may be enabled later in application code.

### 7.5.4.9 Persistent Bits

Some modes of Boot ROM require registers that keep their values after warm reset. SRC General Purpose registers are used for this purpose. These bits are cleared only during Power On Reset. See the table below for persistent bits list and description.

**Table 7-16. Persistent Bits**

Bit Name	Bit Location	Description
PERSISTENT_ENTRY0[31:0]	SRC_GPR0[31:0]	Holds entry function for primary core for waking-up from low power mode.
PERSISTENT_ARG0[31:0]	SRC_GPR1[31:0]	Holds argument of entry function for primary core for waking-up from low power mode.
PERSISTENT_ENTRY1[31:0]	SRC_GPR2[31:0]	Holds entry function for secondary core.
PERSISTENT_ARG1[31:0]	SRC_GPR3[31:0]	Holds argument of entry function for secondary core.
PERSIST_SECONDARY_BOOT	SRC_ROM4[30]	This bit identifies which image must be used - primary and secondary. Used only for boot modes that support redundant boot.
PERSIST_BLOCK_REWRITE	SRC_ROM4[29]	Not used
PERSIST_WDOG_BOOT	SRC_ROM4[28]	This bit is set for enabling SBMR shadow register during Watchdog Reset Boot Mode. See <a href="#">Watchdog Reset Boot Mode</a> for more details.
CPU1_ERROR_STATUS	SRC_ROM4[25]	Secondary core error status bit
PERSIST_SBMR_SHADOW	SRC_ROM3[31:0]	These bits are used as shadow SBMR registers during Watchdog Reset Boot Mode. See <a href="#">Watchdog Reset Boot Mode</a> for more details.

### 7.5.5 Boot Devices (Internal Boot)

This device supports the following boot Flash devices/interfaces:

- Quad SPI Flash Memory
- NOR Flash with FlexBus, located on CS0 or CS1, 8, 16 or 32 bit multiplexed or non-multiplexed bus widths. (32bit non-multiplexed is not supported)
- Nand Flash memory (MLC or SLC NAND Devices), Pages sizes ranging from 2K – 8K supported.
- SD/MMC/eSD/eMMC4.3 via ESDHC interface, supporting high capacity cards

- EEPROM boot via SPI (Serial Flash) or I2C (via SPI and I2C blocks respectively).
- FlexCAN Boot.

The selection of Boot Device type is controlled by BOOT\_CFG1[7:4] eFUSES.

See the table below for more details:

**Table 7-17. BOOT Device Selection**

BOOT_CFG1[7:4]	Boot Device
0000	QSPI Serial Flash Memory
0001	NOR Flash (FlexBus Interface)
0010	Serial-ROM (SPI or I2C)
0011	FlexCAN Boot
0100	Reserved
0101	Reserved
0110	SD/eSD
0111	MMC/eMMC
1XXX	NAND Flash

## 7.5.5.1 QuadSPI Serial Flash Memory Boot

### 7.5.5.1.1 QuadSPI eFUSE Configuration

Fuse	Config	Definition	GPIO <sup>3</sup>	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0000 – Boot from QuadSPI
BOOT_CFG1[1]	OEM	QuadSPI Interface selection	Yes	0	0 – QuadSPI0 selected 1 – QuadSPI1 selected

3. Setting can be overridden by GPIO settings when BT\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

### 7.5.5.1.2 QuadSPI Serial Flash BOOT Operation

The Boot ROM will attempt to boot from QuadSPI flash if the "BOOT\_CFG1[7:4]" fuses are programmed to "0000" as shown in the QuadSPI eFUSE Configuration table. The ROM will initialize the QuadSPI Interface as selected in Fuse bit BOOT\_CFG1[1] in the [QuadSPI eFUSE Configuration](#). QuadSPI interface initialization is a two step process. The ROM expects the QuadSPI configuration parameters as explained in the [QuadSPI Configuration Parameters](#) to be present in the Serial Flash memory from the starting

location of serial flash to the 318 byte offset. The ROM reads these configuration parameters using the default read command configured in the LUT of the QuadSPI interface with SCLOCK operating at 18Mhz.

In the second step, ROM configures the selected QuadSPI interface with the configuration parameters read from the serial flash and starts the boot procedure. Refer to [Table 7-21](#) for details regarding QuadSPI configuration parameters and to the [QuadSPI boot flow chart](#) for detailed boot flow chart of QuadSPI.

Both booting an XIP and non XIP image is supported from serial flash. For XIP boot, the image has to be built for QuadSPI address space and for non XIP the image can be built to execute from DDR or SRAM.

For QUAD mode boot, the Boot ROM expects the Quad Enable bit inside the QSPI Flash to be already set before booting starts. Therefore, the QUAD enable bit must be set in the non-volatile register of the flash at the time of programming.

### Note

In Case of Cortex-M4 Boot, with QSPI0, the application image entry pointer in IVT must point to QSPI0 memory region (0x2000\_0000-0x2FFF\_FFFF) instead of Code Alias Region (0x1000\_0000-0x17ff\_ffff). Application can jump to alias region for execution internally. In case of Low Power Standby Exit (for Both Cortex-A5 and Cortex-M4), Application must program STBY Exit routine in iRAM. QSPI clocks will be disabled.

#### 7.5.5.1.3 IOMUX Configuration for QuadSPI

The table below shows QuadSPI IOMUX pin configuration.

**Table 7-18. QuadSPI IOMUX Pin Configuration**

Signal	QSPI0			QSPI1		
	Signal Name	Pin	Mux Mode	Signal Name	Pin	Mux Mode
A_SCK	QSPI0_A_SCK	PTD0	ALT1	QSPI1_A_SCK	PTA19	ALT7
A_CS0	QSPI0_A_CS0	PTD1	ALT1	QSPI1_A_CS0	PTB0	ALT7
A_CS1	QSPI0_A_CS1	PTB6	ALT3	-	-	-
A_DATA[3]	QSPI0_A_DAT A[3]	PTD2	ALT1	QSPI1_A_DAT A[3]	PTB1	ALT7
A_DATA[2]	QSPI0_A_DAT A[2]	PTD3	ALT1	QSPI1_A_DAT A[2]	PTB2	ALT7
A_DATA[1]	QSPI0_A_DAT A[1]	PTD4	ALT1	QSPI1_A_DAT A[1]	PTB3	ALT7

*Table continues on the next page...*

**Table 7-18. QuadSPI IOMUX Pin Configuration

**7.5.5.1.5 QuadSPI Configuration Parameters**

Table below lists various QuadSPI Configuration Parameters.

**Table 7-21. QuadSPI Configuration Parameters**

Name	Offset	Size in Bytes	Description		
Reserved	0	4	Reserved to 0 <b>NOTE:</b> Any other value may result in undefined operation		
Hold Delay	4	1	Hold Delay for A/B		
			Value	QSPI0 B	QSPI0 A/QSPI1 A
			00	Disable	Disable
			01	Disable	Enable
			02	Enable	Disable
			03	Enable	Enable
Half Speed Phase Selection	5	1	Half Speed Phase Selection 0 Select sampling at non-inverted clock 1 Select sampling at inverted clock		
Half Speed Delay Selection	6	1	Half Speed Delay Selection 0 One Clock cycle delay 1 Two Clock cycle delay		
Reserved1	7	1	This word is reserved		
Reserved2	8	4	This word is reserved		
Reserved3	12	4	This word is reserved		
Reserved4	16	4	This word is reserved		
Chip Select hold time	20	4	This is chip select hold time in terms of Serial clock (For Example 1 serial clock cycle).		
Chip Select setup time	24	4	Chip select setup time in terms of Serial clock (For example 1 serial clock).		
Serial Flash A1 size	28	4	Serial Flash A1 size in units of Bytes		
Serial Flash A2 size	32	4	Serial Flash A2 size in units of bytes		
Serial Flash B1 size	36	4	Serial Flash B1 size in units of bytes		
Serial Flash B2	40	4	Serial Flash B2 size in units of bytes		
Serial Clock Frequency	44	4	This is serial clock frequency select parameter.		
			Value	Clock	
			00	18 MHz	
			01	60 MHz	
			02	74 MHz (only SDR mode)	
Reserved5	48	4	This field is reserved		

Table continues on the next page...

**Table 7-21. QuadSPI Configuration Parameters (continued)**

Name	Offset	Size in Bytes	Description								
Mode of operation of serial Flash	52	1	This field describes the mode of operation of Serial flash								
			<table><tr><th>Value</th><th>Mode</th></tr><tr><td>01</td><td>Single (1-bit data)</td></tr><tr><td>02</td><td>Dual (2-bit data)</td></tr><tr><td>04</td><td>Quad (4-bit data)</td></tr></table>	Value	Mode	01	Single (1-bit data)	02	Dual (2-bit data)	04	Quad (4-bit data)
			Value	Mode							
			01	Single (1-bit data)							
			02	Dual (2-bit data)							
04	Quad (4-bit data)										
Serial Flash Port B Selection	53	1	Port A is always available. This field informs the device ROM the availability of Port B.  0 – Port B is not used 1 – Port B is used								
Dual Data Rate mode enable	54	1	This field enables the device ROM to enable DDR mode in QSPI.  0 – DDR mode is disabled 1 – DDR mode is enabled								
Data Strobe Signal enable in Serial Flash	55	1	This field enables Data Strobe signal in Serial Flash which supports it.  0 – Disable DQS 1 – Enable DQS								
Parallel Mode enable	56	1	This field enables the device ROM to configure the QSPI interface in parallel mode. Data will be read from serial Flash in parallel mode. Refer to QSP chapter for detail.  0 – Disable Parallel mode in QSPI 1 – Enable Parallel Mode in QSPI								
CS1 on Port A	57	1	This field helps ROM to enable CS1 on port A  0 – Disable CS1 on Port A 1 – Enable CS1 on Port A								
CS1 on Port B	58	1	This field helps ROM to enable CS1 on port B  0 – Disable CS1 on Port B 1 – Enable CS1 on Port B								
Full Speed Phase Selection	59	1	Select the edge of the sampling clock valid for full speed commands:  0: Select sampling at non-inverted clock 1: Select sampling at inverted clock  This bit is also used to shift the dqs_enable when DQS mode is selected								
Full Speed Delay Selection	60	1	Select the delay w.r.t. the reference edge for the sample point valid for full speed commands:  0: One clock cycle delay 1: Two clock cycles delay  This bit is also used to shift the dqs_enable when DQS mode is selected								
DDR Sampling Point	61	1	Select the sampling point for incoming data when serial flash is in DDR mode.  <b>NOTE:</b> Valid Values are (b000-b111)								

Table continues on the next page...

**Table 7-21. QuadSPI Configuration Parameters (continued)**

Name	Offset	Size in Bytes	Description
LUT program sequence	62	256	256 Bytes of Look up table program sequence. ROM programs the LUT of QuadSPI with this parameter supplied.  It assumes that the optimize read command sequence which will be used to read data from Serial flash and fill the AHB buffer is programmed at index 0.

The table below shows the available frequency in System Boot for booting through QuadSPI0 with multiple configuration (SDR, DDR modes):

**Table 7-22. QuadSPI SCK frequency limitation in Boot ROM**

	QuadSPI0 in DDR Mode	QuadSPI0 in SDR Mode
SCK frequency options in MHz	18	18, 60, 74

#### 7.5.5.1.6 QuadSPI boot flow chart

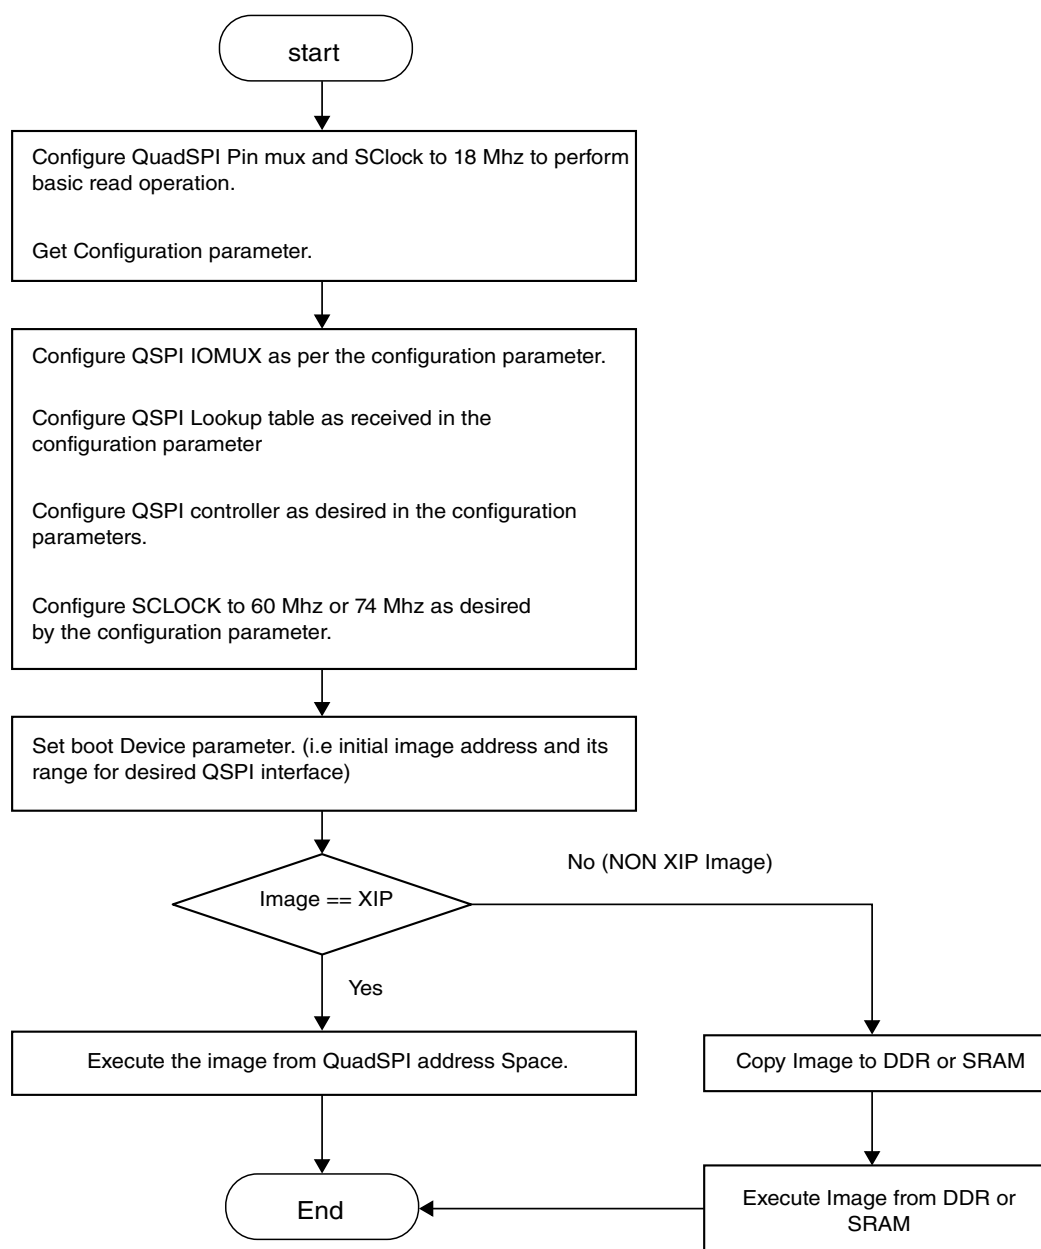

Figure 7-19. QuadSPI boot flow chart

**NOTE**

If flash is configured for "High performance mode (where command is generated only once)" in LUT program sequence. then external reset should be routed to flash reset to allow rebooting in case of any device reset other than Power On Reset. Also this high performance mode must be exited by application before any Low power mode entry where the device is supposed to reboot from QSPI flash on Low power mode exit. In general, any preserved configuration in external flash will not be understood by device after reset.

### 7.5.5.1.7 QuadSPI register boot ROM reset values

All reset values for the QuadSPI registers that are device specific are shown in the following table. All other register reset values are shown in the module memory map.

#### NOTE

The boot ROM initializes BUF3CR to all\_master (bit 31 =1) and all other to a dummy\_master (MSTRID = 0xE). The register reset values after the boot ROM initialization are listed below.

**Table 7-23. QuadSPI Buffer Configuration Register Reset Values**

Register	Reset Value
Buffer0 Configuration Register (QuadSPI_BUF0CR)	0000_0000h
Buffer1 Configuration Register (QuadSPI_BUF1CR)	0000_0000h
Buffer2 Configuration Register (QuadSPI_BUF2CR)	0000_000Eh
Buffer3 Configuration Register (QuadSPI_BUF3CR)	8000_2000h

**Table 7-24. Serial Flash A1 Top Address Reset Values**

Register	Reset Value
QuadSPI0_SFA1AD	2400_0000h
QuadSPI1_SFA1AD	6400_0000h

**Table 7-25. Serial Flash A2 Top Address Reset Values**

Register	Reset Value
QuadSPI0_SFA2AD	2800_0000h
QuadSPI1_SFA2AD	6400_0000h

**Table 7-26. Serial Flash B1 Top Address Reset Values**

Register	Reset Value
QuadSPI0_SFB1AD	2C00_0000h
QuadSPI1_SFB1AD	6C00_0000h

**Table 7-27. Serial Flash B2 Top Address Reset Values**

Register	Reset Value
QuadSPI0_SFB2AD	3000_0000h
QuadSPI1_SFB2AD	6C00_0000h

### 7.5.5.2 NOR Flash Boot using FlexBus Interface

### 7.5.5.2.1 NOR Flash eFUSE Configuration

The FlexBus module works in the asynchronous mode, and supports muxed, Address/Data, or non-muxed schemes based on fuse settings:

**Table 7-28. FlexBus BOOT eFUSE Descriptions**

Fuse	Config	Definition	GPIO <sup>4</sup>	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0001 – Boot from FlexBus
BOOT_CFG1[3]	OEM	Chip Select	Yes	0	0 – Boot from FB_CS0 1 – Boot from FB_CS1
BOOT_CFG1[2:1]	OEM	Port Size Select	Yes	00	1X – 16 bit 01 – 8 bit 00 – 32 bit
BOOT_CFG1[0]	OEM	Multiplexed/Non-Multiplexed configuration	Yes	0	0 – Non Muxed Mode 1 – Muxed Mode
BOOT_CFG2[4:5]	OEM	Address Select	Yes	00	00 – Assert FB_CS <sub>n</sub> on the first rising clock edge after the address is asserted.  01 – Assert FB_CS <sub>n</sub> on the second rising clock edge after the address is asserted.  10 – Assert FB_CS <sub>n</sub> on the third rising clock edge after the address is asserted.  11 – Assert FB_CS <sub>n</sub> on the fourth rising clock edge after the address is asserted.
BOOT_CFG2[3]	OEM	Extended Latch Enable	Yes	0	0 – FB_TS/ALE assert for one cycle 1 – FB_TS/ALE asserted until the first positive edge after FB_CS0
BOOT_CFG2[1]	OEM	Byte Enable	Yes	0	0 – No Byte enable asserted for Read 1 – Byte enable asserted for Read
BOOT_CFG2[0]	OEM	Transfer Acknowledge	Yes	0	0 – Internal Transfer ACK 1 – External Transfer ACK

4. Setting can be overridden by GPIO settings when BT\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

### 7.5.5.2.2 NOR Flash Boot Operation

Booting from the NOR Flash is supported via FlexBus interface. The FlexBus interface clock is fixed to **33MHz**. The device ROM reads NOR Flash Configuration Block (see [NOR Flash Configuration Block](#)) directly from Flash. Thereafter configures FlexBus Controller parameters for optimized operation. The FlexBus IO interface clock can be increased by programming the Clock divider in FlexBus Configuration Block. Subsequently, Image Vector Table and Boot Data structures are read to determine if the image can be executed directly from FlexBus address space or should be copied to other memory. The start field of Boot Data Structure specifies the final location of the image (see [Image Vector Table and Boot Data](#)).

#### NOTE

In Case of Cortex-M4 Boot, the application image entry pointer in IVT must point to the FlexBus memory region (0x3000\_0000-0x3FFF\_FFFF) instead of the Code Alias Region (0x1800\_0000-0x1eff\_ffff). Application can jump to alias region for execution internally.

In case of Low Power Standby Exit (for Both Cortex-A5 & Cortex-M4), Application must program STBY Exit routine in iRAM. FlexBus clocks will be disabled.

### 7.5.5.2.3 NOR Flash Configuration Block

NOR Flash Configuration Block is present at an offset of **0x00**, from the start of Flash memory. The block contains information for programming the FlexBus Controller.

Details of the NOR Flash Configuration Block:

Name	Start Byte	Size in Bytes	Description
Finger Print	0	4	32 bit word with a value of "0x11223344"
Flash Size	4	4	Size of NOR Flash connected
Write Protect	8	1	Flash Write Protect 0 – Disable 1 – Enable
Secondary Wait State Enable Flag	9	1	Flash Secondary Wait State 0 – Disable 1 – Enable
Secondary Wait State Value	10	1	Secondary Wait state Value. Used only when Secondary Wait State Enable Flag is Set.

*Table continues on the next page...*

Name	Start Byte	Size in Bytes	Description
Address Setup	11	1	Controls the Assertion of chip-select with respect to assertion of a valid address and attributes. The address and attributes are considered valid at the same time FB_ALE asserts.  00 Assert FB_CS <sub>n</sub> on first rising clock edge after address is asserted. (Default FB_CS <sub>n</sub> )  01 Assert FB_CS <sub>n</sub> on second rising clock edge after address is asserted.  10 Assert FB_CS <sub>n</sub> on third rising clock edge after address is asserted.  11 Assert FB_CS <sub>n</sub> on fourth rising clock edge after address is asserted. (Default FB_CS <sub>0</sub> )
Read Address Hold	12	1	This field controls the address and attribute hold time after the termination during a read cycle that hits in the chip-select address space. The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.  The number of cycles the address and attributes are held after FB_CS <sub>n</sub> negation depends on the value of CSCR <sub>n</sub> [AA] as shown below.
Write Address Hold	13	1	Write address hold or deselect. This field controls the address, data, and attribute hold time after the termination of a write cycle that hits in the chip-select address space. The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.  00 Hold address and attributes one cycle after FB_CS <sub>n</sub> negates on writes. (Default FB_CS <sub>n</sub> )  01 Hold address and attributes two cycles after FB_CS <sub>n</sub> negates on writes.  10 Hold address and attributes three cycles after FB_CS <sub>n</sub> negates on writes.  11 Hold address and attributes four cycles after FB_CS <sub>n</sub> negates on writes. (Default FB_CS <sub>0</sub> )
Wait State	14	1	The number of wait states inserted after FB_CS <sub>n</sub> asserts and before an internal transfer acknowledge is generated (WS = 0 inserts zero wait states, WS = 0x3F inserts 63 wait states). If AA is reserved, FB_TA must be asserted by the external system regardless of the number of generated wait states. In that case, the external transfer acknowledge ends the cycle. An external FB_TA supersedes the generation of an internal FB_TA.
Clock Divider	15	1	The value between (1 & 8). This is used to configure the Flexbus Divider in CCM. $CLK_{FBUS} = \text{Platform Bus Clock} / (\text{Clock Divider} - 1)$
Burst-read enable.	16	1	Specifies whether burst reads are used for memory associated with each FB_CS <sub>n</sub> .  0 Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a longword read from an 8-bit port is broken into four 8-bit reads.  1 Enables data burst reads larger than the specified port size, including longword reads from 8- and 16-bit ports, word reads from 8-bit ports, and line reads from 8, 16-, and 32-bit ports.
Burst-write enable	17	1	Specifies whether burst writes are used for memory associated with each FB_CS <sub>n</sub> .

Table continues on the next page...

Name	Start Byte	Size in Bytes	Description
			0 Break data larger than the specified port size into individual, port-sized, non-burst writes. For example, a longword write to an 8-bit port takes four byte writes.  1 Enables burst write of data larger than the specified port size, including longword writes to 8 and 16-bit ports, word writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.

### 7.5.5.3 Serial ROM Boot using SPI/I2C Interface

The device supports boot from serial memory devices such as EEPROM and Serial Flash, using SPI (SPI 1, SPI 2, SPI 3, SPI 4), and I2C Controller (I2C 1, I2C 2, I2C 3, and I2C 4) interfaces.

### 7.5.5.3.1 Serial ROM eFUSE Configuration

The boot ROM code determines the type of device using the following parameters, either provided by eFUSE settings or sampled on the I/O pins, during boot (See the table below for details):

**Table 7-31. Serial ROM BOOT eFUSE Descriptions**

Fuse	Config	Definition	GPIO <sup>5</sup>	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0010 – Boot from Serial ROM
BOOT_CFG4[5:4]	OEM	CS Select (SPI Only)	Yes	00	00 – CS#0 01 – CS#1 10 – CS#2 11 – CS#3
BOOT_CFG4[3]	OEM	SPI Addressing (SPI Only)	Yes	0	0 – 2 bytes (16 bit) 1 – 3 bytes (24 bit)
BOOT_CFG4[2:0]	OEM	Port Select	Yes	000	000 – SPI0 001 – SPI1 010 – SPI2 011 – SPI3 100 – I2C0 101 – I2C1 110 – I2C2 111 – I2C3

5. Setting can be overridden by GPIO settings when BT\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

The I2C-0/I2C-1/I2C-2/I2C-3 block can be used as boot device using I2C interface, for serial ROM boot. The I2C interface is configured to operate at 343.75 Kbps. The boot ROM will copy 4Kbyte of data from Serial ROM device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the Rom code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

#### Note

The Initial 4K of Program Image must contain the IVT, DCD and the Boot Data structures.

### 7.5.5.3.2 SPI Boot

The Serial Peripheral Interface (SPI) interface is configured in Master mode and the EEPROM device is connected to SPI interface as slave. The boot ROM code copies 4 Kbyte data from EEPROM device to the internal RAM. If DCD verification is successful,

the ROM code copies the initial 4 Kbyte data as well as the rest of image directly to application destination extracted from application image. The SPI can read data from EEPROM using 2 or 3 byte addressing and its burst length is 32 bytes. The Clock Polarity (CPOL) and Clock Phase (CPHA) bits setting of the SPI block SPIx\_CTARn register are set as below during boot –

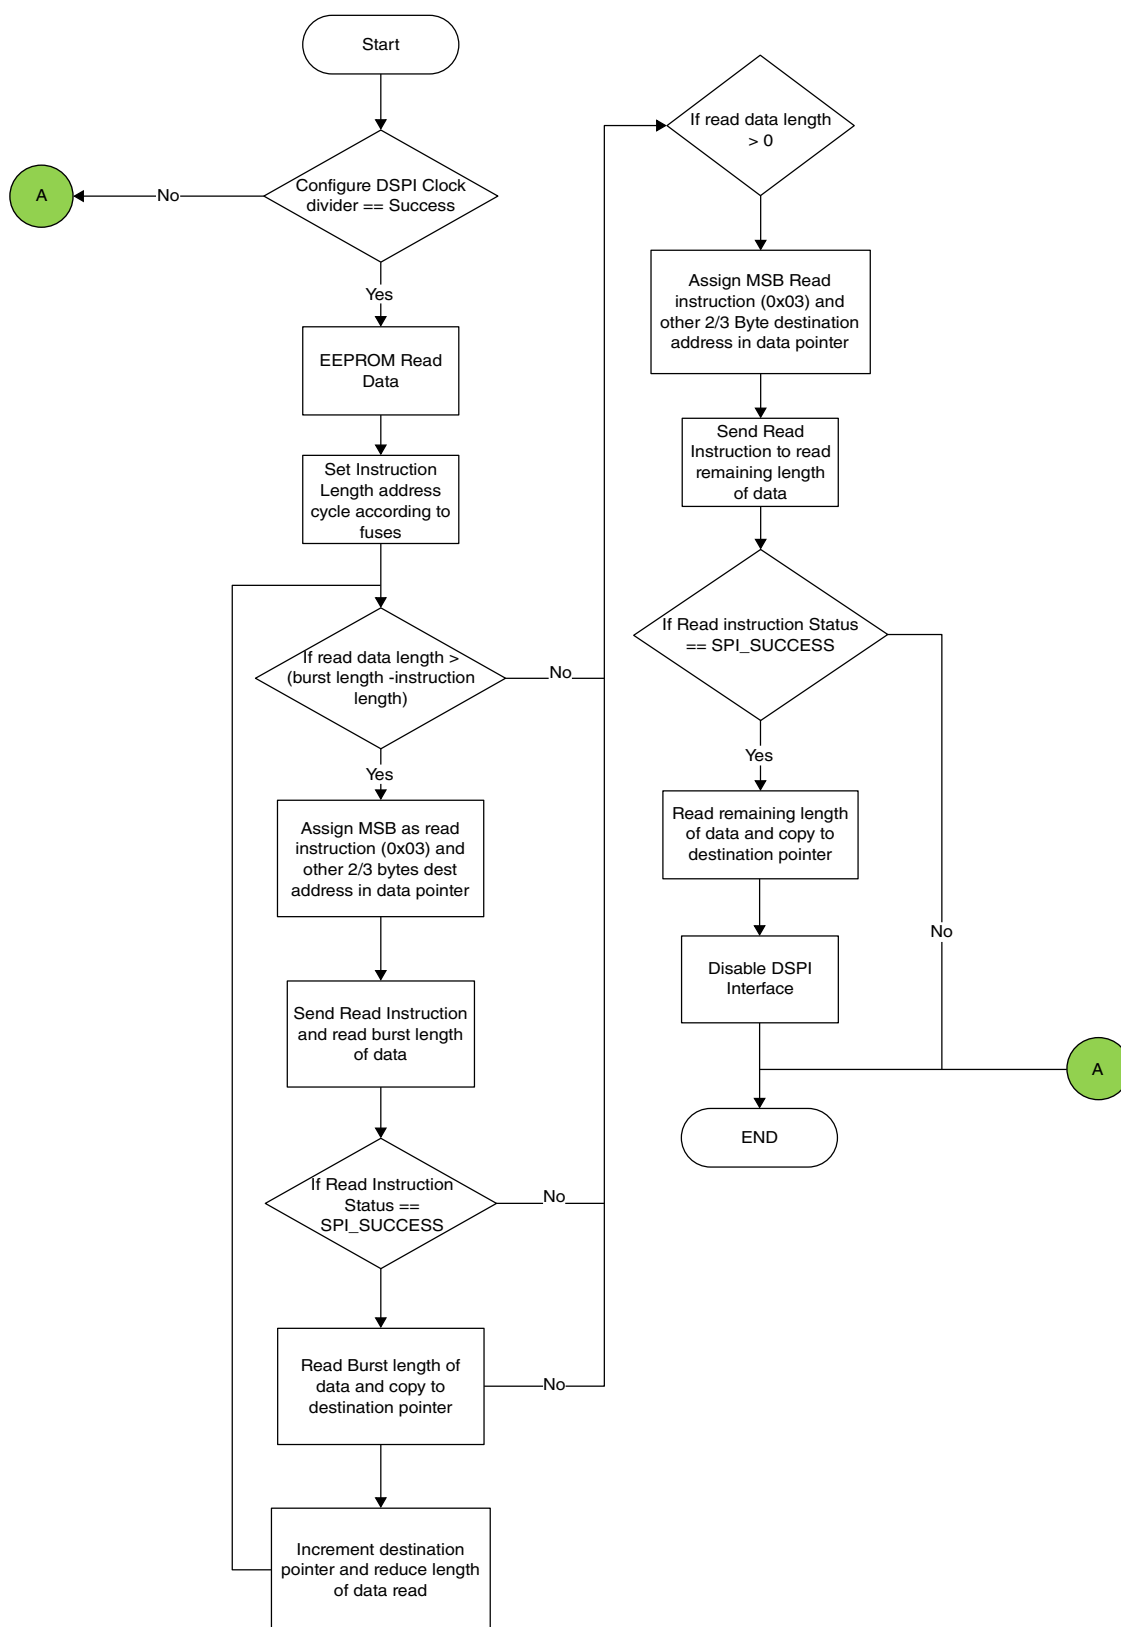

$\text{SPIx\_CTARn[CPOL]} = 0$

$\text{SPIx\_CTARn[CPHA]} = 0$

### Note

The Serial ROM Chip Select Number is determined by BOOT\_CFG4 [5:4] (Chip Select) fuse.

When using the SPI as boot device, the VFxxx Controller supports booting from both Serial EEPROM and Serial Flash devices. The boot code determines which device is being used by reading the appropriate eFUSE/I/O values at boot (See [Table 7-31](#) for details).

### Figure 7-20. SPI Boot Flow Diagram

### 7.5.5.3.3 IOMUX Configuration for SPI

The table below shows SPI IOMUX pin configuration.

**Table 7-32. SPI Pin Configuration**

Signal	Pad Name			
	SPI0	SPI1	SPI2	SPI3
CS3	SAI1_RX_DATA	QSPI0_A_DATA[3]	-	-
CS2	SAI1_TX_DATA	QSPI0_A_DATA[2]	-	-
CS1	SPI0_PCS1	QSPI0_A_DATA[1]	FB_AD[31]	QSPI0_B_DATA[3]
CS0	SPI0_PCS0	QSPI0_A_DATA[0]	FB_AD[30]	QSPI0_B_DATA[2]
SIN	SPI0_SIN	QSPI0_A_DQS	FB_AD[29]	QSPI0_B_DATA[1]
SOUT	SPI0_SOUT	QSPI0_B_SCK	FB_AD[28]	QSPI0_B_DATA[0]
SCK	SPI0_SCK	QSPI0_B_CS0	FB_AD[27]	QSPI0_B_DQS

### 7.5.5.3.4 I2C Boot

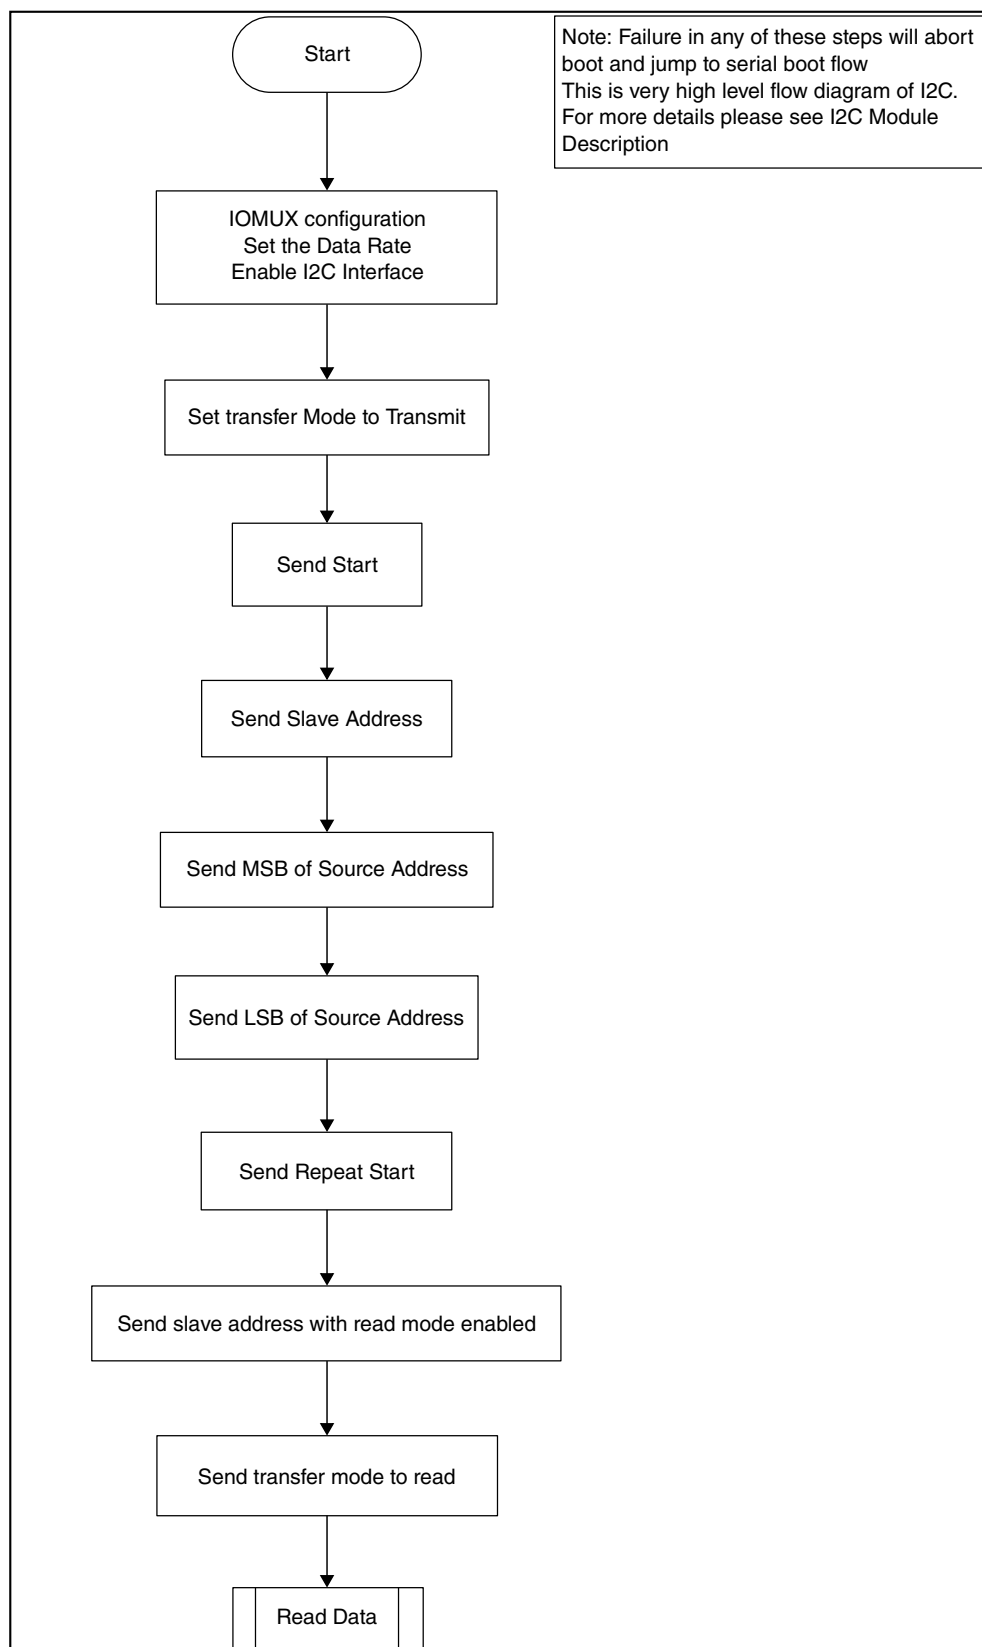

The boot flow when booting from an I2C device is shown in [Figure 7-21](#). The boot ROM code reads the fuses BOOT\_CFG4[2:0] (Boot Device Selection) and BOOT\_CFG1 [7:4] (Port select) to detect EEPROM device type. The ROM program copies 4K data from the EEPROM device to internal RAM. The boot ROM code next copies the initial 4Kbyte of data as well as rest of image directly to application destination extracted from application image.

The device uses the Device Select Code/Device Address in [Table 7-33](#) to boot from an EEPROM.

**Table 7-33. EEPROM via I2C Device Select Code**

Bits	Device Type Identifier				Chip Enable Address <sup>6</sup>			R/W
	7	6	5	4	3	2	1	0
Device Select Code	1	0	1	0	0	0	0	R/W

6. These address bits, should be configured at the memory device, to match this '000' value.

**Figure 7-21. I2C Boot Flow Diagram**

### 7.5.5.3.5 IOMUX Configuration for I2C

The table below shows I2C IOMUX pin configuration.

**Table 7-34. I2C Pin Configuration**

Signal	Pad Name			
	I2C0	I2C1	I2C2	I2C3
SCL	TRACECK	TRACED[1]	TRACED[6]	TRACED[14]
SDA	TRACED[0]	TRACED[2]	TRACED[7]	TRACED[15]

### 7.5.5.4 FlexCAN Boot

This device supports boot from CAN interfaces, either from FlexCAN0 or FlexCAN1 ports.

#### 7.5.5.4.1 FlexCAN eFUSE Configuration

BOOTROM code determines the type of device using the following parameters; either provided by eFUSE settings or sampled on the I/O pins, during boot (See the table below for details):

**Table 7-35. BOOT Device Selection**

Fuse	Config	Definition	GPIO <sup>1</sup>	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0011 – Boot From FlexCAN
BOOT_CFG1[0]	OEM	FlexCAN Port Selection	Yes	0	0 – Boot From FlexCAN0 1 – Boot From FlexCAN1

1. Setting can be overridden by GPIO settings when GPIO\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

#### 7.5.5.4.2 FlexCAN Configuration Parameters

Either FlexCAN0 or FlexCAN1 ports can be used to download the image from an external CAN host. The FlexCAN interface is configured to operate at 1 Mbps.

**Table 7-36. Bit timing parameters in FlexCAN**

FlexCAN Parameter	Value (in Time Quanta)	CAN2.0 Parameter	Value (in Time Quanta)
SYNC_SEG	1	SYNC_SEG = FlexCAN SYNC_SEG	1
PROP_SEG	3	PROP_SEG = FlexCAN PROP_SEG+1	4

*Table continues on the next page...*

**Table 7-36. Bit timing parameters in FlexCAN (continued)**

FlexCAN Parameter	Value (in Time Quanta)	CAN2.0 Parameter	Value (in Time Quanta)
PSEG1	2	PHASE_SEG1 = FlexCAN PSEG1+1	3
PSEG2	3	PHASE_SEG2 = FlexCAN PSEG2+1	4

### 7.5.5.4.3 FlexCAN Boot Operation

FlexCAN operates as a device, which is to be connected to an external CAN Host. The Host transfers the application image as per Serial Download Protocol. BOOTROM configures device ID as 0x04 and responds to Host with ID 0x14.

Before downloading the image, Host and device have to be associated. During this phase, the device waits for a pattern (0x67898967) from the host. After the pattern is received, it then responds with same pattern back to the host. This completes the ASSOCIATION Phase. BOOTROM waits for a period of 60 seconds for the ASSOCIATION Phase before switching to Serial Download Mode (using UART/USB).

After Association phase is completed, the Host can download the application image using the Serial Download protocol. The Serial Download Protocol has the capability of DCD\_WRITE before the image is downloaded to destination memory. Once the image is downloaded, CAN host must issue a JUMP command to the VFxxx Controller CAN device so that BOOTROM can authenticate and the jump to the entry point of the downloaded image.

A data flow control mechanism is required between the host and device for downloading image over FlexCAN interface. A software flow control mechanism has been developed below SDP protocol layer as shown in the following figure:

**Figure 7-22. FlexCAN Boot Protocol**

From Bottom up, the CAN boot architecture is similar to OSI layer architecture consisting of Physical, Data Link/flow control, Transport and Application layers only.

On top of FlexCAN controller, BOOTROM implements an echo-retry flow control mechanism in software. This mechanism has a concept of echoing back the data by the receiver which has been sent by a sender. In this architecture, a sender is an entity who has some data to send (as an originator) as per the upper layer protocol, which is SDP here. For example, SDP commands are always sent by Host, so the host will be called a sender, whereas VFxxx Controller device will be called a receiver. Again, as the SDP responses are always sent back by VFxxx Controller device, so the device will be a sender in this case, and host being a receiver, Echo back mechanism assures the sender doesn't send the next data to the receiver as it has to wait to receive the echo data of the last data sent to the intended receiver, which is VFxxx Controller device here.

Only Echo back mechanism is not enough for stable flow control, as SDP protocol has data flowing from both Host (command, data) and Devices (response, data). So in cases (especially when there is a switch between the sender and receiver functions between the host and device, e.g., sending command to receiving response or otherwise), either entity may miss a data. So a Retry mechanism is implemented to take care of this scenario. To be able to download the image properly, the host application has to implement the layered application as described above.

### **NOTE**

ECC detection and correction operation of FlexCAN internal RAM Memory is enabled by default. Boot Code thus initializes FlexCAN internal RAM area only if FlexCAN is selected for boot operation. During boot operation, if any un-correctable Errors detected, FlexCAN port is put into Freeze mode and the boot through FlexCAN is failed (and then may jump to recovery interface or serial downloader, as the case may be).

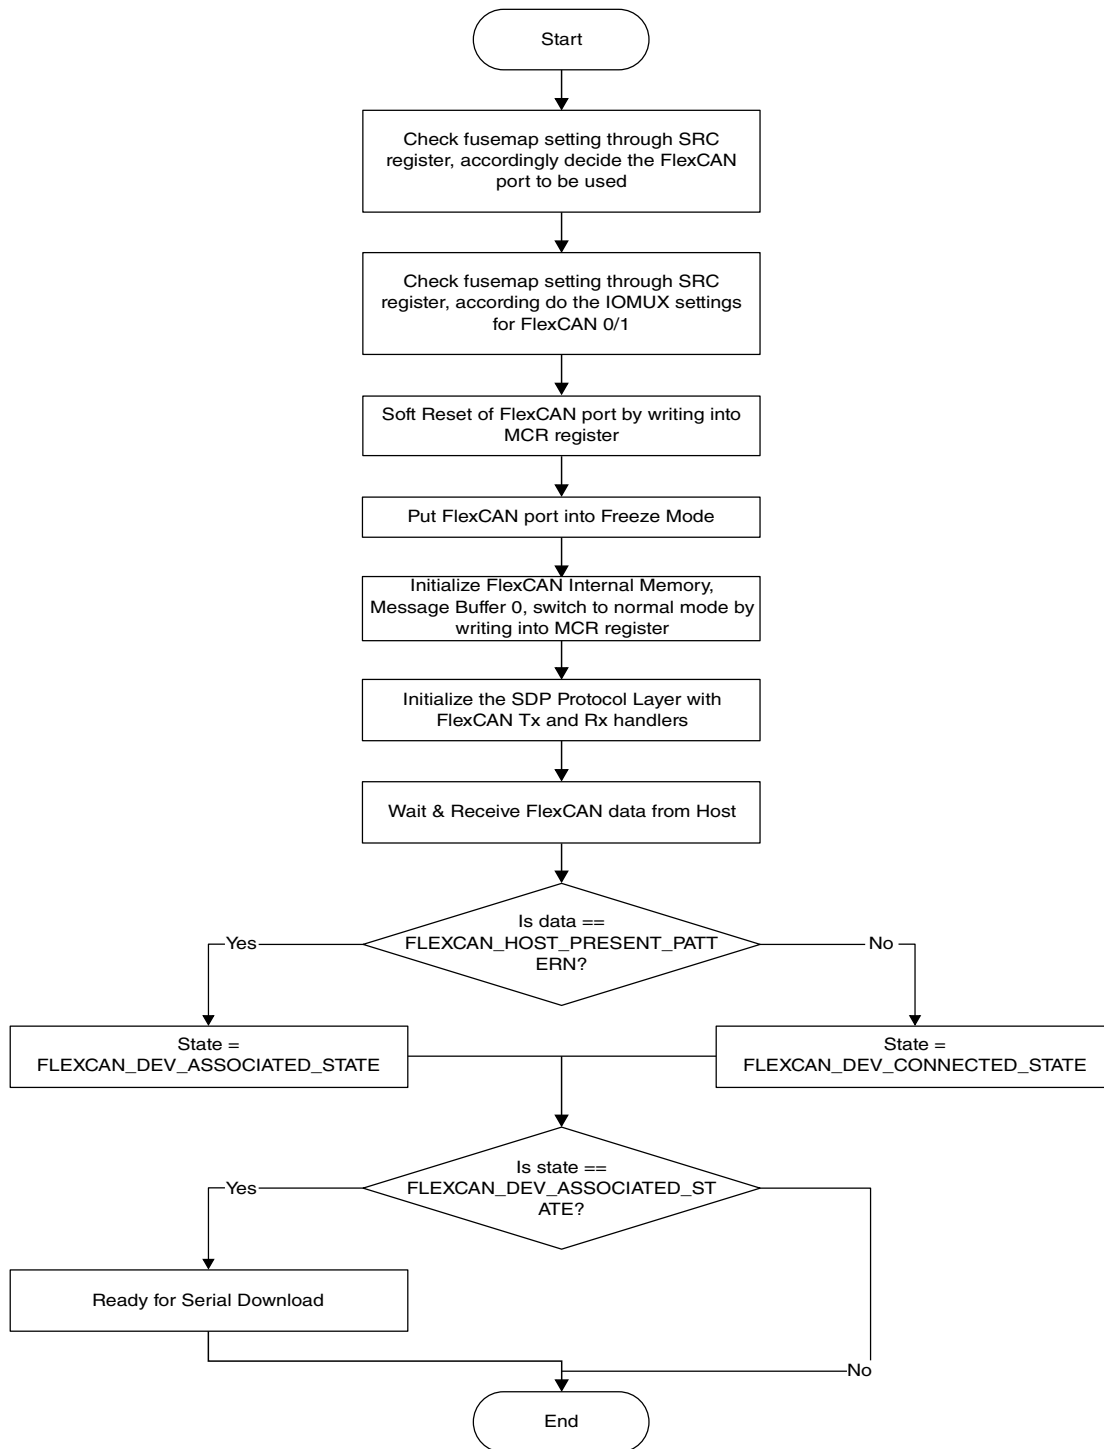

Figure 7-23. FlexCAN Flow Chart

#### 7.5.5.4.4 IOMUX Configuration for FlexCAN

The table below shows FlexCAN IOMUX pin configuration.

**Table 7-37. FlexCAN Pin Configuration**

Signal	Pad Name	
	FlexCAN0	FlexCAN1
RX	CAN0_RX	CAN1_RX
TX	CAN0_TX	CAN1_TX

### 7.5.5.5 SD/MMC Boot

The device ROM supports booting from MMC/eMMC and SD/eSD compliant devices.

#### 7.5.5.5.1 SD/MMC eFUSE Configuration

SD/MMC/eSD/eMMC boot can be performed using either ESDHC-0, ESDHC-1 ports, based on setting of the BOOT\_CFG2 [3] (Port Select) fuse or its associated GPIO input value at boot. All eSDHC ports support eMMC4.3 and fast boot. See the table below for details.

**Table 7-38. ESDHC BOOT eFUSE Descriptions**

Fuse	Config	Definition	GPIO <sup>7</sup>	Shipped Value	Settings
BOOT_CFG1[7:5]	OEM	Boot Device Selection	Yes	000	011 – BOOT from eSDHC interface
BOOT_CFG1[4]	OEM	SD/MMC Selection	Yes	0	0 – SD/eSD 1 – MMC/eMMC
BOOT_CFG1[3]	OEM	Fast Boot Enable	Yes	0	0 – Fast Boot Enable 1 –Fast Boot Disable
BOOT_CFG1[1]	OEM	SD /MMC Speed	Yes	0	1 – Normal 0 – High
BOOT_CFG2[7:5]	OEM	Bus Width/SD Calibration Step	Yes	000	SD/eSD (BOOT_CFG1[5]=0) Bus Width xx0 - 1-bit xx1 - 4-bit MMC/eMMC (BOOT_CFG1[5]=1) x00 - 1-bit x01 - 4-bit x10 - 8-bit Else - reserved.
BOOT_CFG2[3]	OEM	Port Select	Yes	0	0 – ESDHC0

*Table continues on the next page...*

**Table 7-38. ESDHC BOOT eFUSE Descriptions  
(continued)**

Fuse	Config	Definition	GPIO <sup>7</sup>	Shipped Value	Settings
					1 – ESDHC1
BOOT_CFG2[1]	OEM	Fast Boot Acknowledge Disable (eMMC Only)	Yes	0	0 - Boot Acknowledge Enabled. 1 - Boot Acknowledge Disabled.
BOOT_CFG2[0]	OEM	Override Pad Settings	Yes	0	0 - Use default values 1 - Use PAD_SETTINGS values

7. Setting can be overridden by GPIO settings when BT\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

Boot code supports following standards.

- MMCv4.3 or less
- eMMCv4.3 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST\_BOOT.

MMC/SD/eSD/eMMC can be connected to any of ESDHC-0, 1 block and can be booted by copying 4Kbyte of data from MMC/SD/eSD/eMMC device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the ROM code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

### Note

The Initial 4Kbyte of Program Image must contain the IVT, DCD and the Boot Data structures.

**Table 7-39. SD/MMC Frequencies**

	SD	MMC
Identification (KHz)	400 KHz	
Normal Speed Mode (MHz)	22 MHz	18.62 MHz
High Speed Mode (MHz)	44 MHz	42.56 MHz

## Note

BOOTROM code reads application image length and application destination pointer from image.

### 7.5.5.5.2 MMC and eMMC Boot

The following table provides MMC and eMMC boot details.

**Table 7-40. MMC and eMMC Boot Details**

Normal Boot Mode	<p>During initialization (normal boot mode) the MMC frequency is set to 400 KHz. When the MMC card enters the identification portion of the initialization, voltage validation is performed and the ROM boot code checks high voltage settings and card capacity. The ROM boot code supports both high capacity and low capacity MMC/eMMC cards. After initialization phase is complete, the ROM boot code switches to a higher frequency (18.62 MHz in Normal boot mode or 42.56 MHz in High Speed mode). eMMC is also interfaced via eSDHC and follows the same flow as MMC.</p> <p>The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD [179] to get the boot partition to be set. If there is no boot partition mentioned in BOOT_PARTITION_ENABLE field or the user partition has been mentioned, ROM boots from the user partition.</p>
eMMC4.3 Device Supporting Special Boot Mode	<p>If using an eMMC4.3 device supporting special boot mode, it can be initiated by pulling the CMD line low. If BOOT ACK is enabled, the eMMC4.3 device sends the BOOT ACK via DATA lines and ROM can read the BOOT ACK [S010E] to identify the eMMC4.3 device. If BOOT ACK is enabled ROM waits 50 ms to get the BOOT ACK and if BOOT ACK is received by ROM. If BOOT ACK is disabled ROM waits 1 second for data. If BOOT ACK or data was received then eMMC4.3 is booted in "Boot mode", otherwise eMMC4.3 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by BOOT_CFG1 [3] (Fast Boot) fuse. BOOT ACK is selected by BOOT_CFG2 [1].</p>

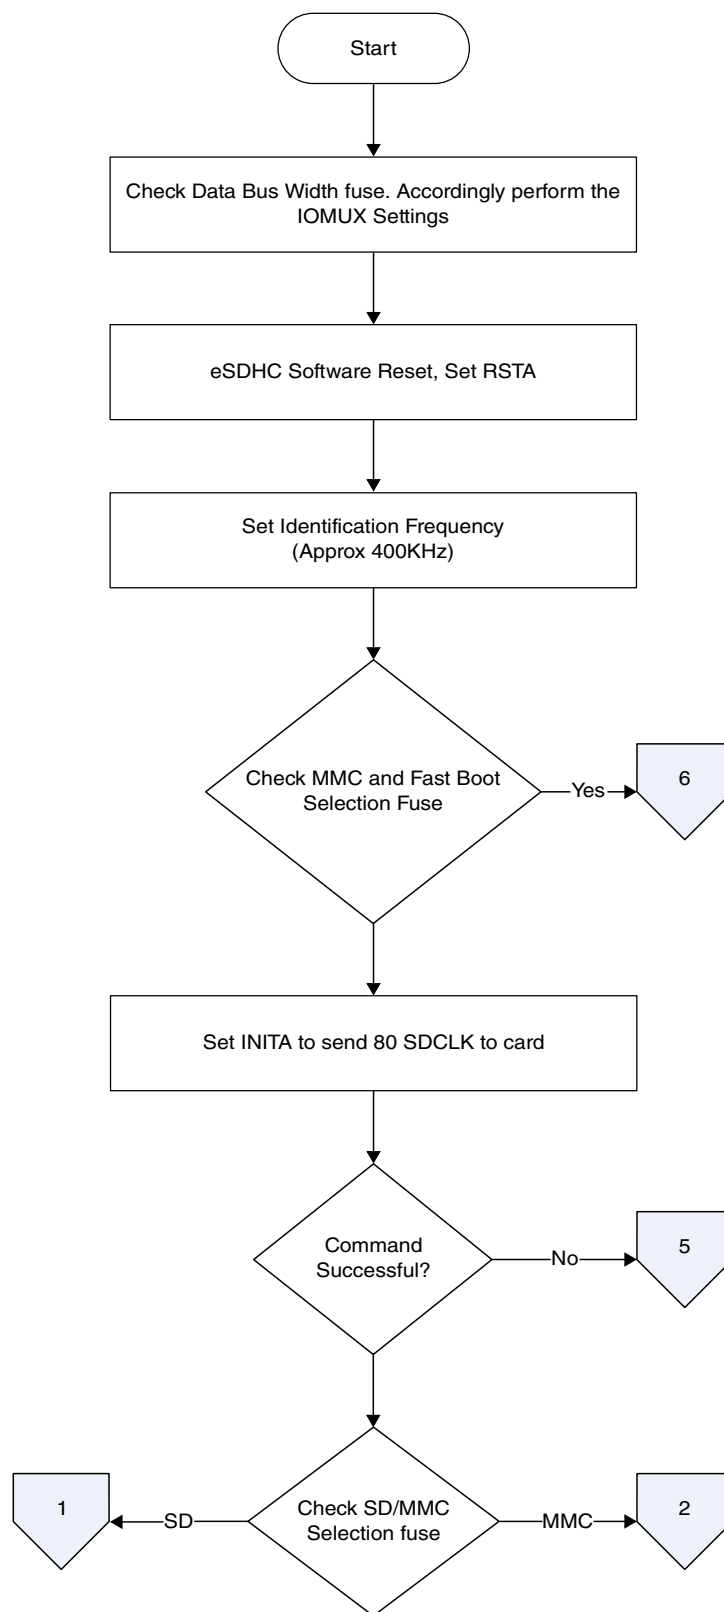

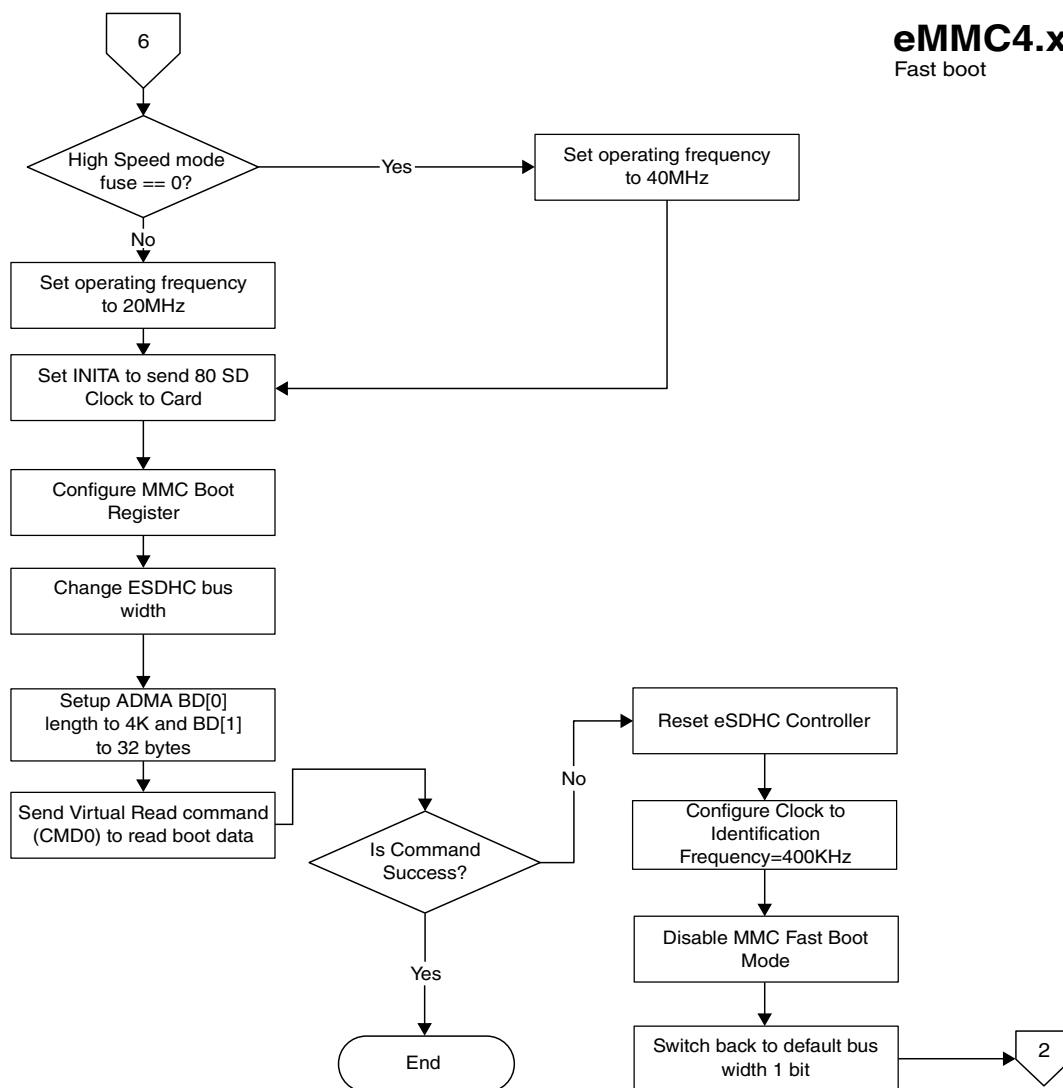

Figure 7-24. Expansion Device Boot Flow (1/7)

**eMMC4.x Boot**

Fast boot

**Figure 7-25. Expansion Device Boot Flow (2/7)**

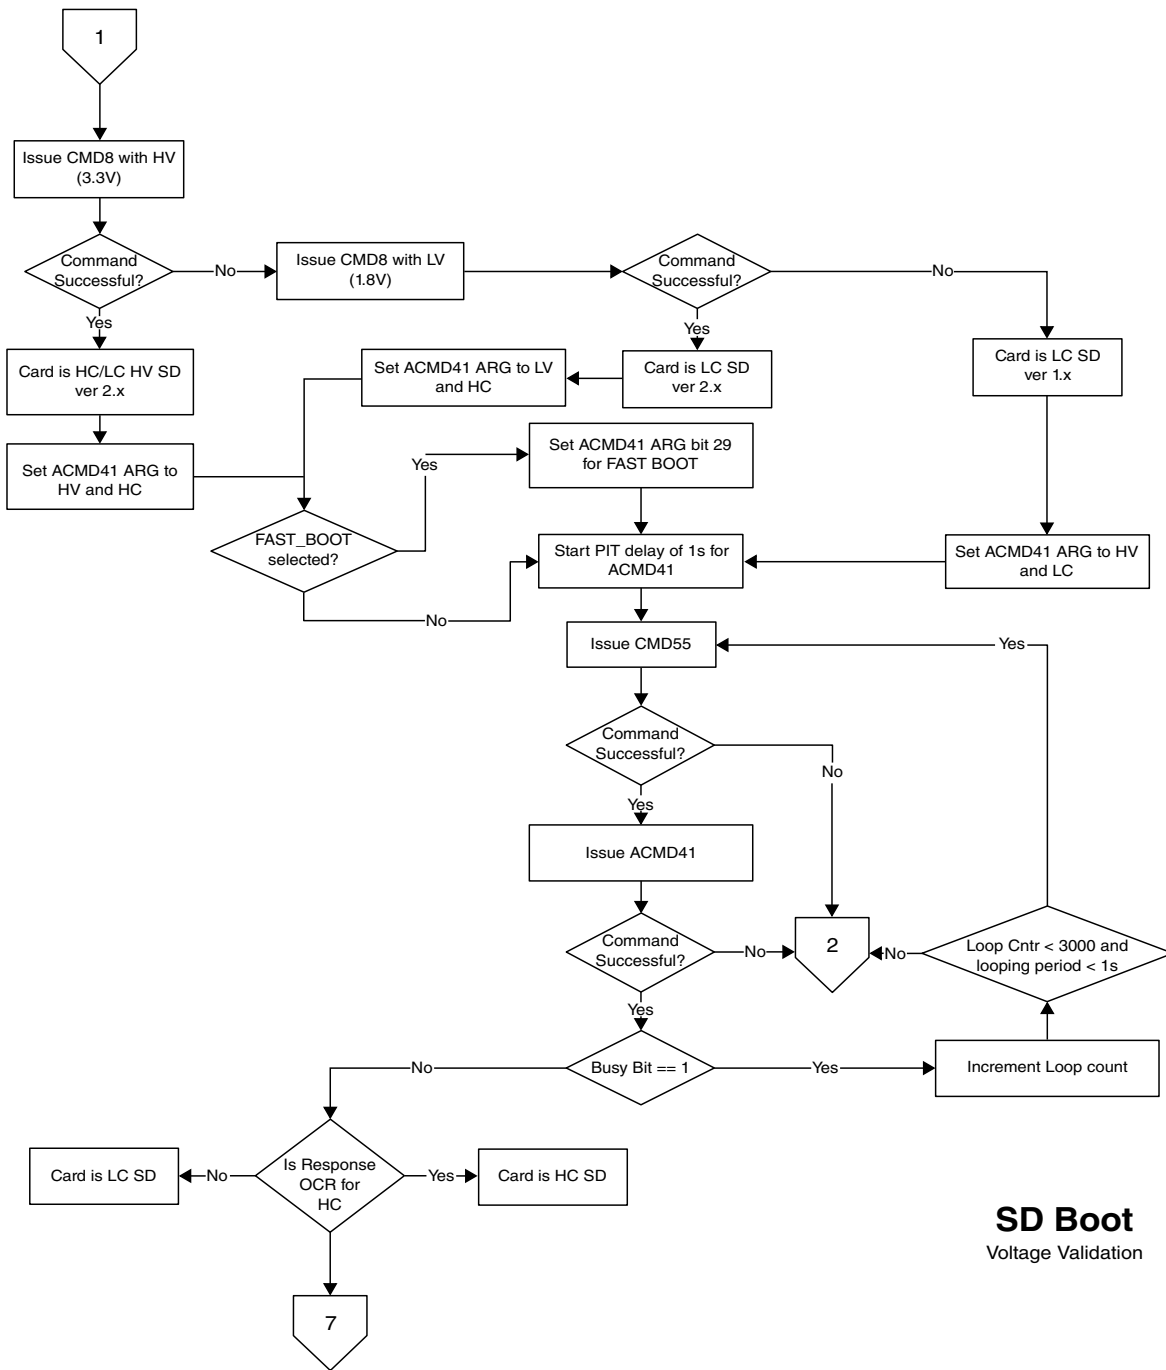

Figure 7-26. Expansion Device Boot Flow (3/7)

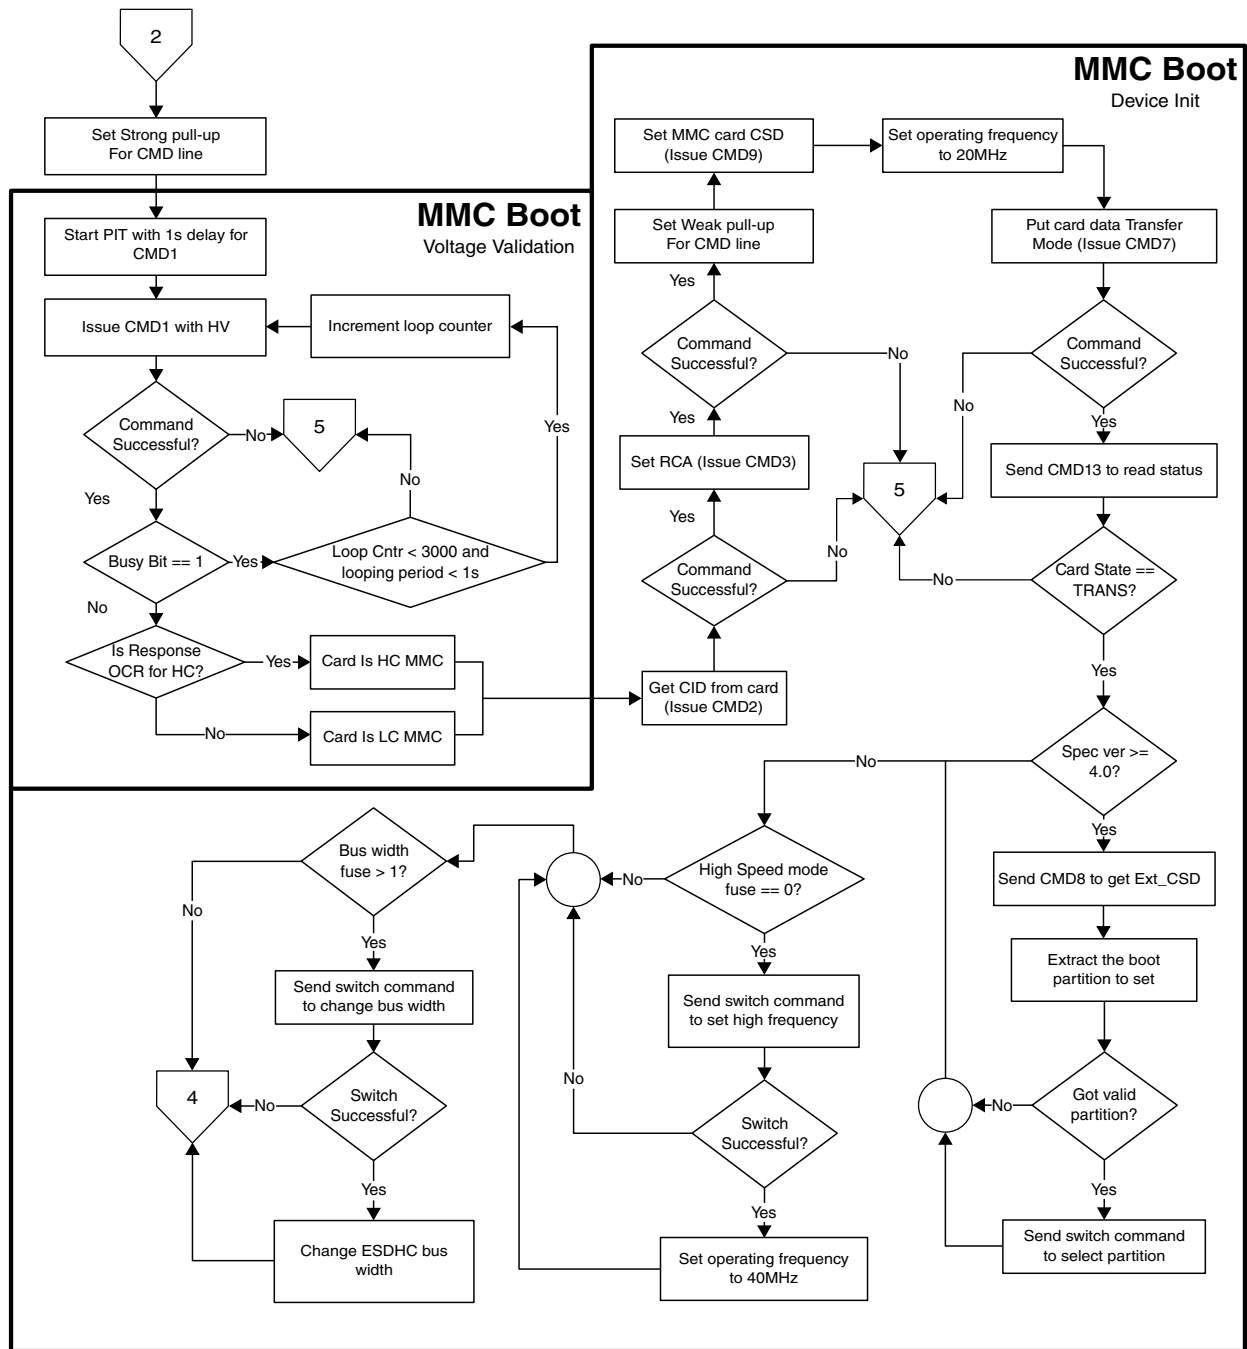

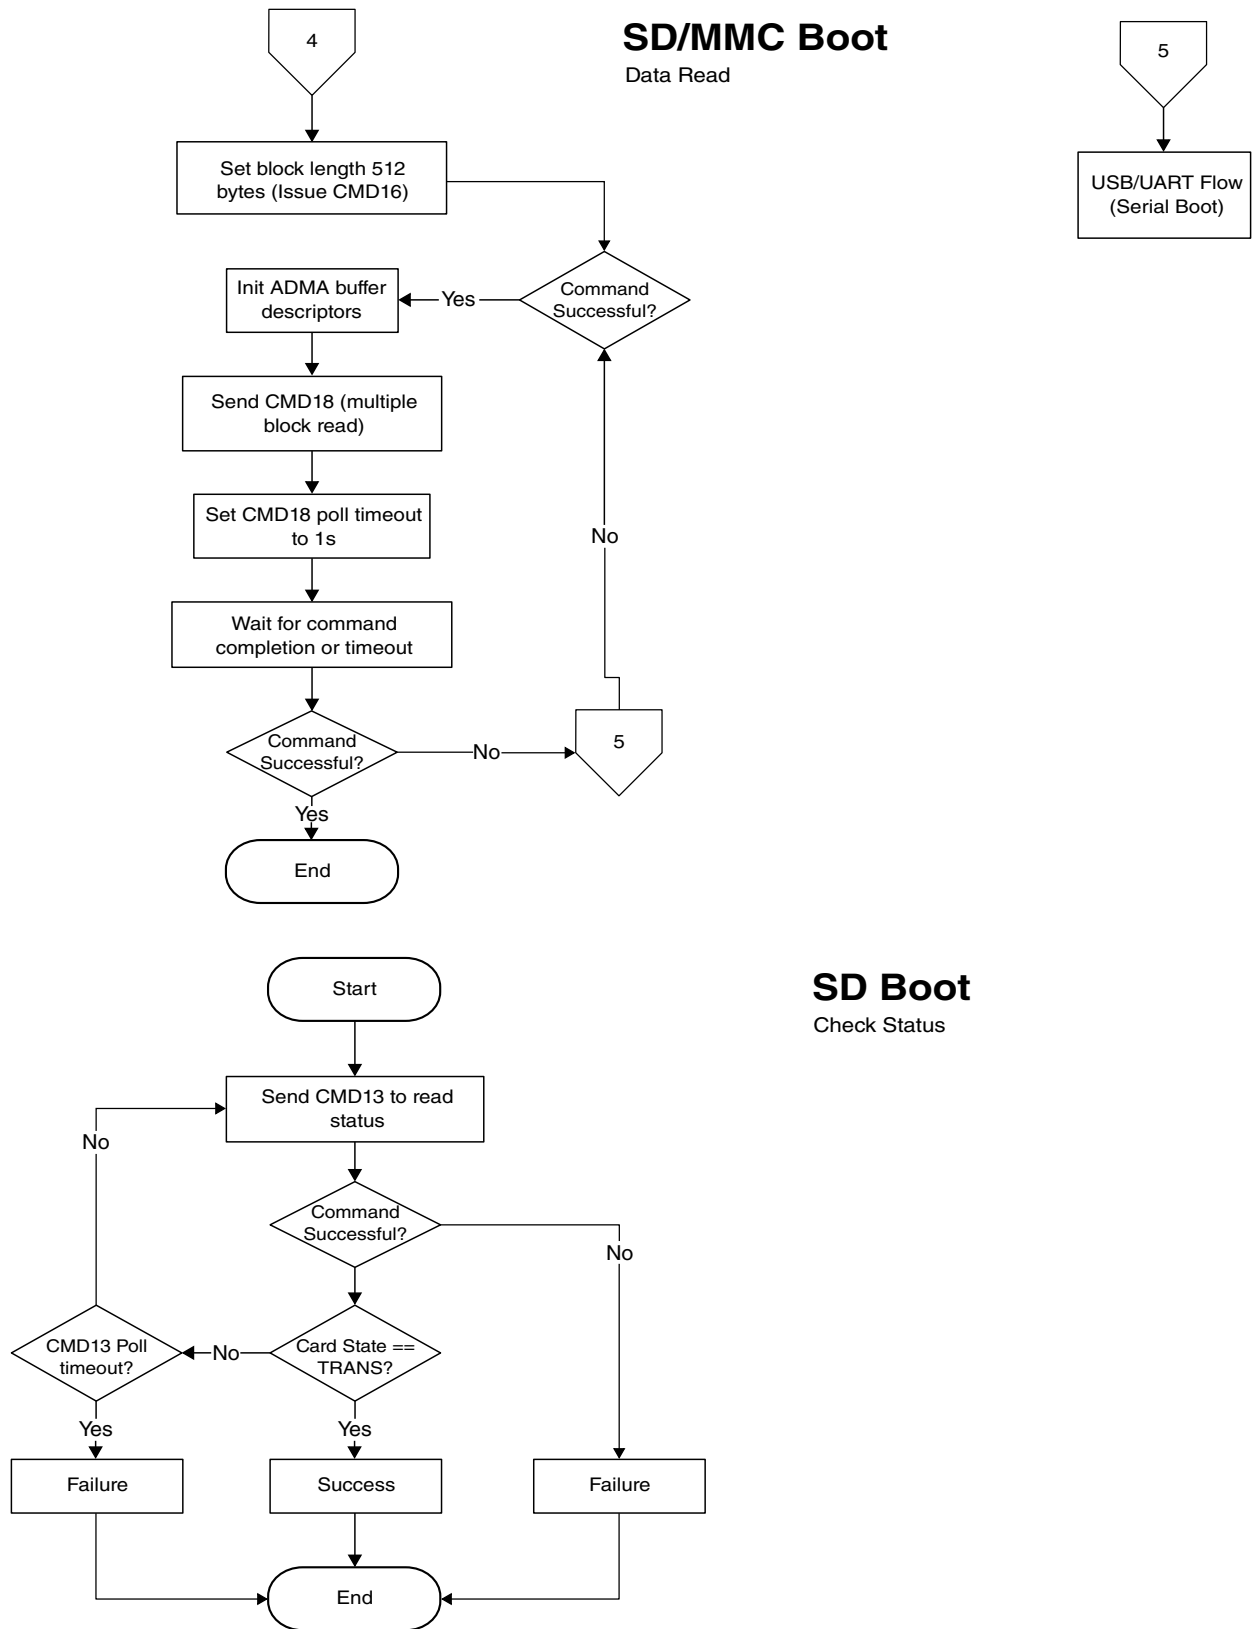

Figure 7-27. Expansion Device Boot Flow (4/7)

## MMC Boot

Switch Command

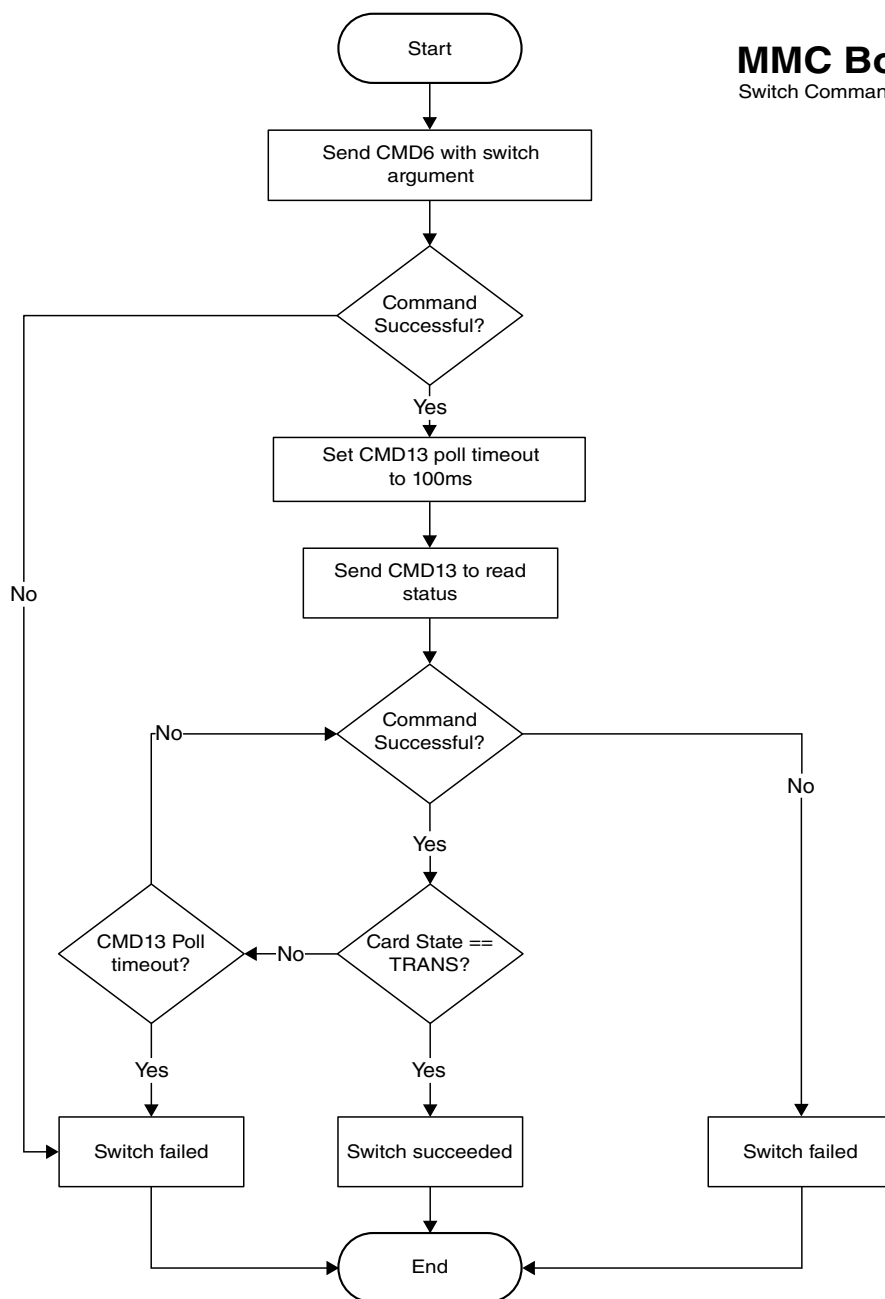

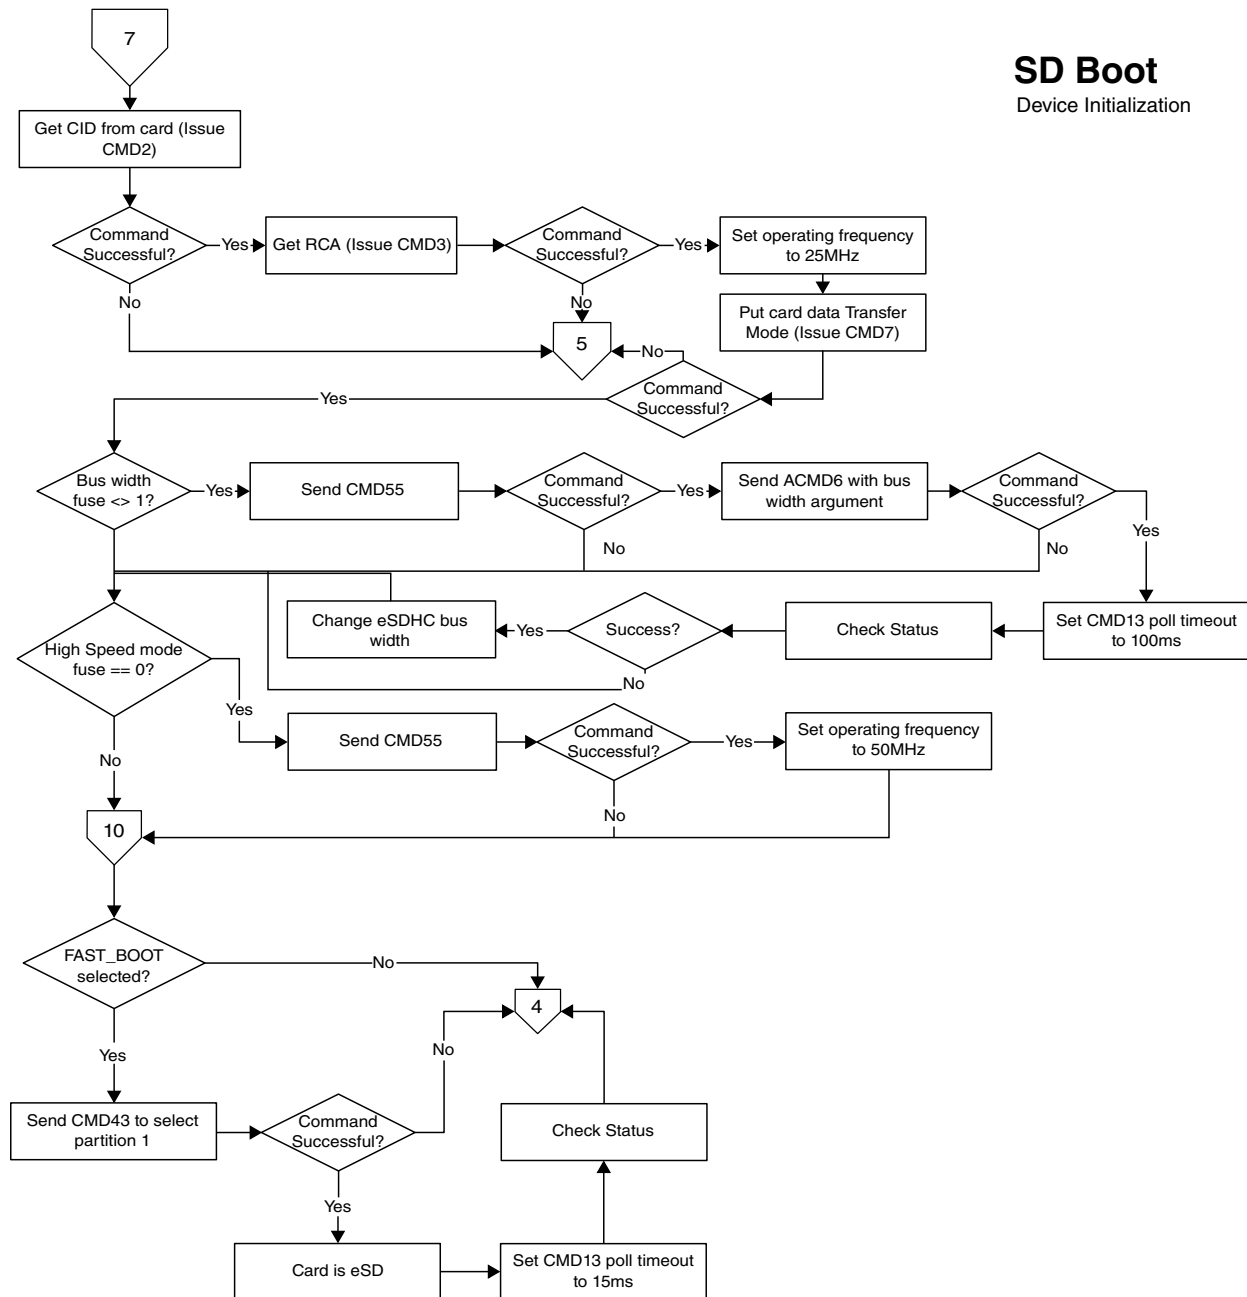

Figure 7-29. Expansion Device Boot Flow (6/7)

**SD Boot**

Device Initialization

**Figure 7-30. Expansion Device Boot Flow (7/7)****7.5.5.5.3 SD, eSD Boot**

After the normal boot mode initialization begins, the SD/eSD frequency is set to 400 KHz. During the identification phase, SD/eSD card voltage validation is performed. During voltage validation, boot code first checks with high voltage settings; if that fails, it checks with low voltage settings. The capacity of the card is also checked. Boot code supports high capacity and low capacity SD/eSD cards after voltage validation card initialization is done.

During card initialization, the ROM boot code attempts to set the boot partition for all SD and eSD devices. If this fails, the boot code assumes the card is a normal SD card. If it does not fail, the boot code assumes it is an eSD card. After the initialization phase is over, boot code switches to a higher frequency (22 MHz in Normal Speed mode or 44 MHz in High Speed Mode).

The SD clock speed can be selected by BOOT\_CFG1 [1].

#### 7.5.5.5.4 IOMUX Configuration for SD/MMC

The table below shows ESDHC IOMUX pin configuration.

**Table 7-41. ESDHC Pin Configuration**

Signal	Pad Name

#### 7.5.5.5.6 Redundant Boot Support for Expansion Device

The device ROM supports redundant boot for expansion device. Primary or Secondary image is selected depending on PERSIST\_SECONDARY\_BOOT setting (see [Table 7-16](#)).

If PERSIST\_SECONDARY\_BOOT is 0, the boot ROM uses address 0x0 for primary image.

If PERSIST\_SECONDARY\_BOOT is 1, the boot ROM will read secondary image table from address 0x200 on boot media and will use address specified in the table.

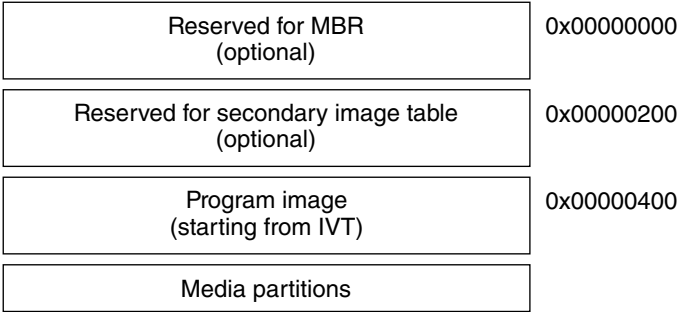

**Table 7-44. Secondary Image Table Format**

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- tag: used as indication of valid secondary image table. Must be 0x00112233.
- firstSectorNumber is the first 512B sector number of the secondary image.

For secondary image support, the primary image must reserve space for secondary image table. See the figure below for typical structures layout on expansion device.

**Figure 7-31. Expansion Device Structures Layout**

For Closed mode, if there are failures during primary image authentication, the BOOTROM will set PERSIST\_SECONDARY\_BOOT bit (see Table 7-16) and perform software reset. (After software reset, secondary image will be used.)

For Unsecured chip, if invalid Image Vector Table is read, then BOOTROM will set PERSIST\_SECONDARY\_BOOT bit (see Table 7-16) and perform software reset. (After software reset, secondary image will be used.)

**NOTE**

PERSIST\_SECONDARY\_BOOT bit can be cleared by application after boot or will be cleared automatically during Power On Reset.

### 7.5.5.6 NAND Flash Boot using NFC Interface

A number of MLC/SLC NAND Flash devices from different vendors are supported by the boot ROM. The Error Correction and Control (ECC) sub-block is used to detect the errors.

#### 7.5.5.6.1 NAND Flash eFUSE Configuration

The boot ROM determines the configuration of external the NAND flash by parameters, either provided by eFUSE, or sampled on GPIO pins, during boot. See the table below for parameters details.

**Table 7-45. NAND Boot eFUSE Descriptions**

Fuse	Config	Definition	GPIO <sup>8</sup>	Shipped Value	Settings
BOOT_CFG1[7]	OEM	Boot Device Selection	Yes	0	1 – BOOT from Nand Interface
BOOT_CFG1[6]	OEM	Nand Interface Frequency Select	Yes	0	1 – Normal Mode 33MHz 0 – Fast Mode 40MHz

*Table continues on the next page...*

**Table 7-45. NAND Boot eFUSE Descriptions  
(continued)**

Fuse	Config	Definition	GPIO <sup>8</sup>	Shipped Value	Settings
BOOT_CFG1[5]	OEM	Fast Boot Acknowledge	Yes	0	1 – Fast flash timing 0 – Slow flash timing
BOOT_CFG1[3]	OEM	Nand Chip Enable	Yes	0	0 – Use Chip Enable 0 1 – Use Chip Enable 1
BOOT_CFG1[2]	OEM	Nand Interface Data Width	Yes	0	0 – 8 Bit Interface 1 – 16 Bit interface
BOOT_CFG1[1:0]	OEM	Address Cycles	Yes	00	00 – 3 Address Cycles 01 – 2 Address Cycles 1X – Reserved
BOOT_CFG2[4:3]	OEM	Boot Search Count	Yes	00	0X – 2 10 – 4 11 – 8
BOOT_CFG2[2:1]	OEM	Pages in a Block	Yes	00	00 – 128 01 – 64 10 – 32 11 – Reserved
BOOT_CFG2[0]	OEM	Override Pad Settings	Yes	0	0 – use Default Settings 1 – Use Pad setting values
NAND_READ_CMD_CODE1[7:0] <sup>2</sup>	OEM	Read Command Code 1	No	0	Read Command Code 1
NAND_READ_CMD_CODE2[7:0] <sup>3</sup>	OEM	Read Command Code 2	No	0	Read Command Code 2

8. Setting can be overridden by GPIO settings when BT\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

2. Bank0 Word7 Field[7:0]

3. Bank0 Word7 Field[15:8]

## NOTE

Nand Flash Read Command Codes are read from fuses. If Command Code 2 is 0x00 then Command Code 0x30 is used in BOOTROM.

### 7.5.5.6.2 NAND Flash Boot Flow and BOOT Control Blocks (BCB)

There are two BCB data structures: FCB and DBBT. As part of the NAND media initialization, the ROM driver searches for a Firmware Configuration Block (FCB) that contains the page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

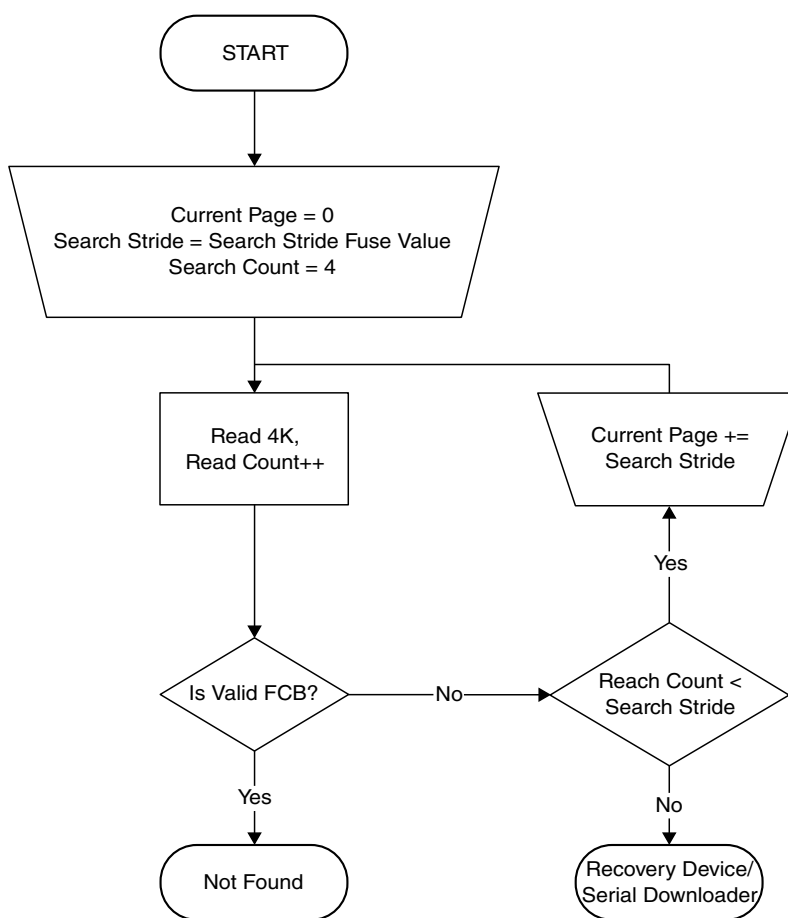

The hardware ECC level to use is embedded inside FCB block. The FCB data structure is itself protected using software ECC (SEC-DED Hamming Codes). Driver reads raw 2112 bytes of first sector and runs through software ECC engine that determines whether FCB data is valid or not.

If FCB is not found or ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the BOOTROM enters into serial download mode.

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. DBBT is searched in DBBT Search Area just like how FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using starting page address from FCB.

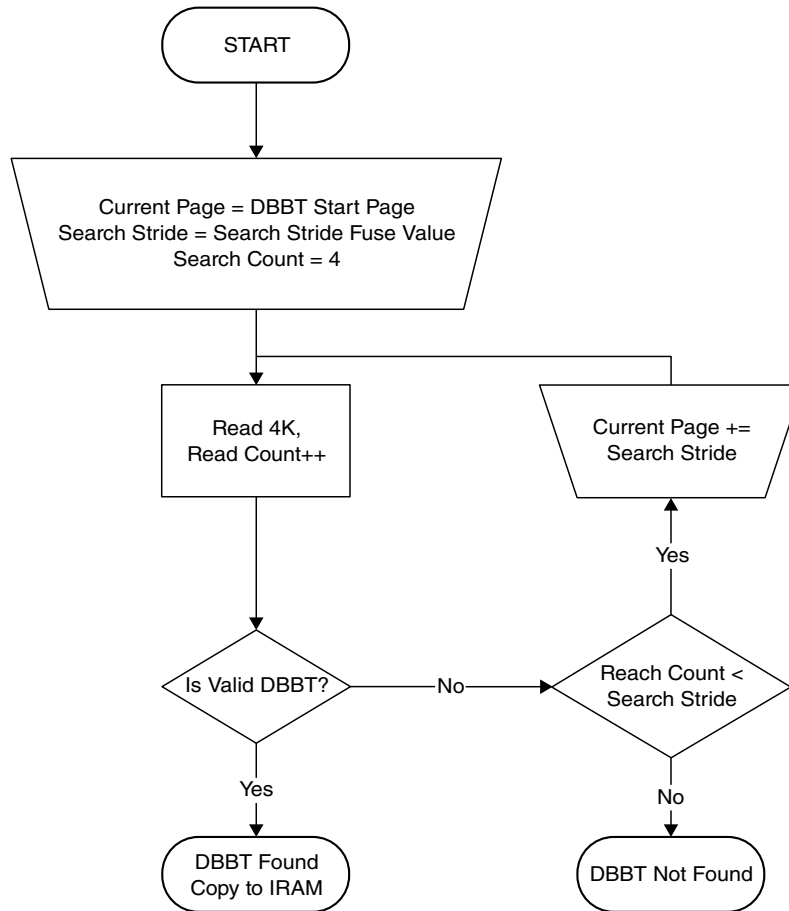

See the flow of FCB search in the figure below.

**Figure 7-32. FCB Search Flow**

Once FCB found the BOOTROM starts searching for Discovered Bad Blocks Table (DBBT). If DBBT Search Area is 0 in FCB, then ROM assumes that there are no bad blocks on NAND device. See the figure below for DBBT search flow.

**Figure 7-33. DBBT Search Flow**

If during primary image read there was a page with number of errors higher than ECC can correct, the BOOTROM will turn on PERSIST\_SECONDARY\_BOOT bit and perform SW reset. (After SW reset secondary image will be used).

If during secondary image read there was a page with number of errors higher than ECC can correct, the BOOTROM will go to serial loader.

#### NOTE

PERSIST\_SECONDARY\_BOOT bit can be cleared by application after boot or will be cleared automatically during Power On Reset.

### 7.5.5.6.3 Firmware Configuration Block (FCB)

The FCB is the first sector in the first good block. The FCB should be present at each search stride of the search area. The search area contains copies of the FCB at each stride distance, so in case the first NAND block becomes corrupted, the ROM will find its copy in the next NAND block. The search area should span over at least two NAND blocks. The location information for DBBT search area, FW1, and FW2 are all specified in the FCB. Flash Control Block Structure is as shown in the table below.

**Table 7-46. Flash Control Block Structure**

Name	Start Byte	Size in Bytes	Description
Reserved	0	4	Reserved for Fingerprint #1(Checksum)
FingerPrint	4	4	32 bit word with a value of 0x46434220, in ASCII "FCB"
Version	8	4	32-bit version number; this version of FCB is 0x00000001
Reserved	12	8	Not used by ROM
DataPageSize	20	4	Number of bytes of data in a page. Typically, this is 2048 bytes for 2112 bytes page size or 4096 bytes for 4314 bytes page size
TotalPageSize	24	4	Total number of bytes in page. Typically, 2112 for 2 K page or 4224 or 4314 for 4 K page.
SectorsPerBlock	28	4	Number of pages per block. Typically 64 or 128 or depending on NAND device type.
Reserved	32	24	Not used by ROM
EccBlock0EccType	56	4	Value from 0 to 7 used to set Error Correction Type for Block of ECC page
Reserved	60	44	Not used by ROM
Firmware1_startingSector	104	4	Page number address where first copy of bootable firmware is located
Firmware2_startingSector	108	4	Page number address where second copy of bootable firmware is located
Reserved	112	8	Not used by ROM
DBBTSearchAreaStartAddress	120	4	Page address for bad block table search area
Reserved	124	8	Not used by ROM
BBMarkerPhysicalOffset	132	4	This is the offset where manufacturer leaves bad block marker on a page
Reserved	136	36	Not used by ROM
DISBBM	172	4	If 0 ROM will swap BadBlockMarkerByte with SpareArea[0] after reading a page. If the value set is 1 then ROM will not do swapping
Reserved	176	40	Not used by ROM
DISBB_Search	216	4	Disable the bad block search function when reading the firmware, only using DBBT.
Bad Block Search Limit	220	4	Number of Blocks to be searched when a Bad Block is found. By Default the value of this field is 2.

**NOTE**

Firmware1\_startingSector, Firmware2\_startingSector and DBBTSearchAreaStartAddress must point to a page in a good Block. For performing Bad Block marker check, firmware 1 and 2 starting sectors must be block aligned.

**7.5.5.6.4 Discovered Bad Block Table (DBBT)**

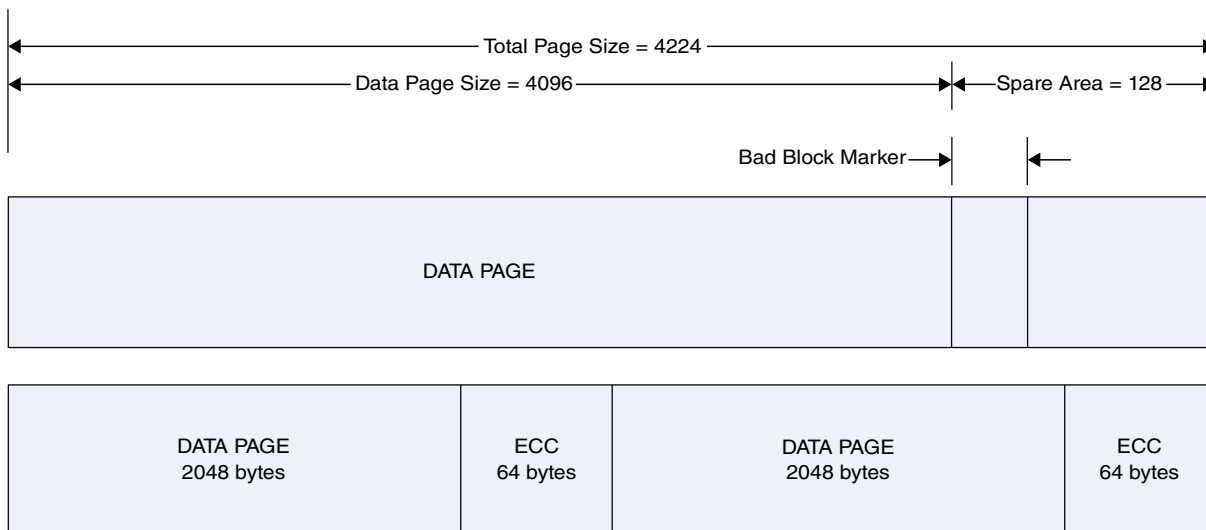

See the table below for DBBT format.

**Table 7-47. DBBT Structure**

Name	Start Byte	Size in Bytes	Description
Reserved	0	4	-
FingerPrint	4	4	32-bit word with a value of 0x44424254, in ASCII "DBBT"
Version	8	4	32-bit version number; this version of DBBT is 0x00000001
Reserved	12	4	-
DBBT_NUM_OF_PAGES	16	4	Size of DBBT in pages
Reserved	20	4*PageSize -20	-
Reserved	4*PageSize	4	-
Number of Entries	4*PageSize + 4	4	Number of Bad Blocks
Bad Block Number	4*PageSize + 8	4	First Bad Block number
Bad Block Number	4*PageSize + 12	4	Second Block number
.....	....	....	....
.....	....	....	....
Last Bad Block Number	....	....	Last Bad Block number

**7.5.5.6.5 Typical NAND Page Organization**

Nand Page is divided into multiple data blocks each of size 2048 bytes. Figure below shows a typical layout of NAND page of size 4224 bytes.

**Figure 7-34. Valid Layout for 4224 bytes Sized Page**

There are 2 data blocks of 2048 bytes each in a page of a 4k page sized NAND. The values of ECC should be such that above calculation should not result in a value greater than the size of a page in a 4k page NAND.

For NAND Boot, with page size restriction and data block size restricted to 2048 bytes, only a few combinations of ECC for block.

#### 7.5.5.6.6 Bad Block Handling in the ROM

During firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block. If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

If Bad Block table start page is null, check the manufactory made Bad Block marker. The location of Bad Block maker is at the first 3 or last 3 pages in every block of the NAND flash. Nand manufacturers normally use one byte in the spare area of certain pages within a block to mark a block is bad or not. 0xFF means good block, otherwise means bad block.

In order to preserve the BI (bad block information), flash updater or gang programmer applications need to swap Bad Block Information (BI) data (1 byte in length) to appropriate place in DATA Area for every page before programming NAND flash.

This is calculated using the following formula.

Total Page Size ->  $T_{\text{NAND}}$  bytes

Data Page Size ->  $D_{\text{NAND}}$  bytes

Bad Block Marker Offset from start of Page ->  $BB_{\text{Offset}}$

Total Spare Area Size ->  $TSP_{NAND} = T_{NAND} - D_{NAND}$

No of Virtual Pages ->  $NVP = D_{NAND} / 2048$

Spare Area Page Size per Virtual Page ->  $VSP_{NAND} = TSP_{NAND} / NVP$

Virtual Page Size ->  $VP_{Size} = 2048 + VSP_{NAND}$

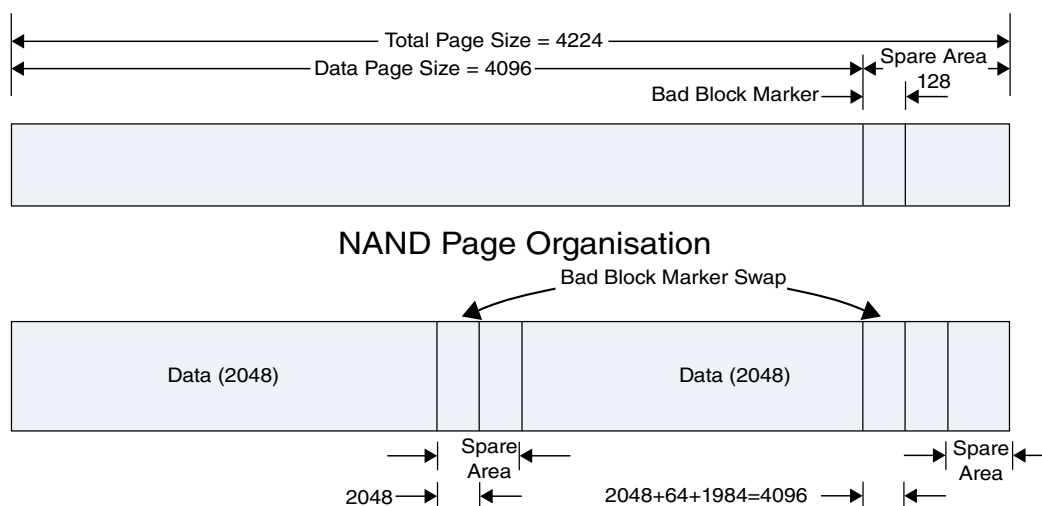

**Bad Block Marker Offset in Virtual Page ( $BBOFF_{VP}$ )**

**$BBOFF_{VP} = MOD(BB_{Offset}, VP_{Size})$**

**Bad Block Marker in Virtual Page count ( $BBOFF_{NVP}$ )**

**$BBOFF_{NVP} = BB_{Offset} / VP_{Size}$**

ROM when loading firmware copies back 1 byte from the Virtual Page to BI offset in page data. The figure below shows how the factory bad block marker is preserved.

**Figure 7-35. Factory Bad Block Marker Preservation**

In the FCB structure, there is `BBMarkerPhysicalOffset` to indicate Bad Block Marker place in the page data, that manufacturer uses to mark bad block.

Table Below show typical values for different NAND Page Sizes:

**Table 7-48. Bad Block Marker Position in NAND Page Layout**

$T_{NAND}$	$D_{NAND}$	$BB_{OFFSET}$	$TSP_{NAND}$	$NVP$	$VSP_{NAND}$	$VP_{SIZE}$	$BBOFF_{VP}$	$BBOFF_{NVP}$
2112	2048	2048	64	1	64	2112	2048	0
4224	4096	4096	128	2	64	2112	1984	1
4304	4096	4096	208	2	104	2152	1944	1
8640	8192	8192	448	4	112	2160	1712	3

NOTE: Data Page Size = 2048 bytes

### 7.5.5.6.7 Setup DMA for DDR Transfers

In DMA descriptors NAND Flash Controller is configured to read page data at double data rate, the word length is set to 16 and transfer count to half of page size.

### 7.5.5.6.8 IOMUX Configuration for NFC

The table below shows the Nand Flash Controller IOMUX pin configuration.

**Table 7-49. NAND IOMUX Pin Configuration**

Signal	Pad Name
NF_ALE	SAI1_RX_BCLK
NF_CLE	SAI1_RX_DATA
NF_CE0_b	SAI0_RX_DATA
NF_CE1_b	SAI0_TX_DATA
NF_IO[15]	FB_AD[31]
NF_IO[14]	FB_AD[30]
NF_IO[13]	FB_AD[29]
NF_IO[12]	FB_AD[28]
NF_IO[11]	FB_AD[27]
NF_IO[10]	FB_AD[26]
NF_IO[9]	FB_AD[25]
NF_IO[8]	FB_AD[24]
NF_IO[7]	FB_AD[23]
NF_IO[6]	FB_AD[22]
NF_IO[5]	FB_AD[21]
NF_IO[4]	FB_AD[20]
NF_IO[3]	FB_AD[19]
NF_IO[2]	FB_AD[18]
NF_IO[1]	FB_AD[17]
NF_IO[0]	FB_AD[16]
NF_R/B_b	SAI1_TX_BCLK
NF_RE_b	SAI0_RX_SYNC
NF_WE_b	SAI0_RX_BCLK

### 7.5.5.6.9 CCM Settings in various modes

**Table 7-50. NFC CCM Settings**

NFC		
Resgisters	Normal Mode	Fast Mode
Clock Source	PLL3_PFD1	PLL3_PFD1
CCSR	0x1004_0824	0x1004_0824
CSCMR1	0x0000_0200	0x0000_0200
CSCDR2	0x0000_2010	0x0000_2010
CSCDR3	0x0000_6000	0x0000_4000

## 7.5.6 Program Image

This section describes the data structures that are required to be included in a user's Program Image. A Program Image consists of:

- Image Vector Table- A list of pointers located at a fixed address that the ROM examines to determine where other components of the Program Image are located.
- Boot Data- A table indicating the Program Image Location, Program Image size in bytes and plugin flag.
- Device Configuration Data- IC configuration data.
- Data used by HAB- CSF command data, signatures and certificates
- User code and data

### 7.5.6.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot. The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process. The ROM locates the IVT at a fixed address that is determined by the boot device connected to VFxxx Controller. The IVT offset from the base address and initial load region size for each boot device type is defined in the table below. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

**Table 7-51. Image Vector Table Offset and Initial Load Region Size**

Boot Device Type	Image Vector Table Offset	Initial Load Region Size
NOR	4 Kbyte = 0x1000 bytes	Entire Image Size
NAND	1 Kbyte = 0x400 bytes	4 Kbyte
SD/MMC/eSD/eMMC	1 Kbyte = 0x400 bytes	4 Kbyte
I2C/SPI EEPROM	1 Kbyte = 0x400 bytes	4 Kbyte
Quad SPI	1 Kbyte = 0x400 bytes	Entire Image Size

**Figure 7-36. Image Vector Table**

### 7.5.6.1.1 Image Vector Table Structure

The IVT has the following format where each entry is a 32 bit word:

**Table 7-52. IVT Format**

Header (See table 30 below)
entry: Absolute address of the first instruction to execute from the image
reserved1: Reserved and should be zero
dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See <a href="#">Device Configuration Data (DCD)</a> for further details on DCD.
boot data: Absolute address of the Boot Data
self: Absolute address of the IVT. Used internally by the ROM
csf: Absolute address of Command Sequence File (CSF) used by the HAB library. See <a href="#">High Assurance Boot (HAB)</a> for details on secure boot using HAB. This field must be set to NULL when not performing a secure boot
reserved2: Reserved and should be zero

The IVT header has the following format:

**Table 7-53. IVT Header Format**

Tag	Length	Version
-----	--------	---------

Where:

Tag: A single byte field set to 0xD1

Length: a two byte field in big endian format containing the overall length of the IVT, in bytes, including the header. (The length is fixed and must have a value of 32 bytes)

Version: A single byte field set to 0x41

### 7.5.6.1.2 Boot Data Structure

The Boot Data must follow the format defined in the table below; each entry is a 32-bit word.

**Table 7-54. Device BOOT Data Format**

start	Absolute Address of Image
length	Size of Program Image
plugin	Plug-in Flag

### 7.5.6.2 Device Configuration Data (DCD)

Upon reset, the device uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving optimal system performance and there are even some peripherals that must be configured before they can be used. The DCD is configuration information contained in a Program Image, external to the ROM that the ROM interprets to configure various peripherals on this device. Some components such as SDRAM require some sequence of register programming as part of configuration before it is ready to be used. The DCD feature can be used to program DDRMC registers to the optimal settings.

The ROM determines the location of the DCD table based on information located in the Image Vector Table (IVT). See [Image Vector Table and Boot Data](#) for more details. The DCD table shown below is a big endian byte array of the allowable DCD commands. The maximum size of the DCD limited to 3028 bytes.

Table 7-55. DCD Data Format

Header
[CMD]
[CMD]
[CMD]
....

The DCD header is 4 bytes with the following format:

Table 7-56. DCD Header

Tag	Length	Version
-----	--------	---------

Where:

Tag: A single byte field set to 0xD2  
Length: a two byte field in big endian format containing the overall length of the DCD, in bytes, including the header.  
Version: A single byte field set to 0x40

7.5.6.2.1 Write Data Command

The Write Data Command is used to write a list of given 1, 2 or 4-byte values or bitmasks to a corresponding list of target addresses. The format of Write Data Command, again a big endian byte array, is shown in the table below.

Table 7-57. Write Data Command Format

Tag	Length	Parameter
	Address	
	Value/Mask	
	[Address]	
	[Value/Mask]	
	....	
	[Address]	
	[Value/Mask]	

Where:

Tag: A single byte field set to 0xCC  
Length: A two byte field in big endian format containing the length of the Write Data Command, in bytes, including the header  
Address: target address to which data should be written

Value/Mask: data value or bitmask to be written to preceding address

The Parameter field is a single byte divided into bitfields as follows:

**Table 7-58. Write Data Command Parameter field**

7	6	5	4	3	2	1	0
flags					bytes		

Where:

bytes: width of target locations in bytes. Either 1, 2 or 4

flags: control flags for command behavior.

Data Mask = bit 3: if set, only specific bits may be overwritten at target address (otherwise all bits may be overwritten)

Data Set = bit 4: if set, bits at the target address overwritten with this flag (otherwise it is ignored)

One or more target address and value/bitmask pairs can be specified. The same bytes and flags parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

**Table 7-59. Interpretation of Write Data Command Flags**

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write Value
0	1	*address = val_msk	Write Value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address  = val_msk	Set bitmask

### Note

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values is larger or any of the bitmask is wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within an allowed region, none of the values are written. The list of blocks and target addresses allowed for this device are given below.

**Table 7-60. Valid DCD Memory Address Ranges**

Memory Region	Address Range	Cortex-A5	Cortex-M4
SDRAM0	0x8000_0000 - 0xDFFF_FFFF	YES	YES
TCML	0x1F80_0000 - 0x1FFF_FFFF	YES	YES
QSPI0	0x2000_0000 - 0x2FFF_FFFF	YES	YES
FlexBUS	0x3000_0000 - 0x3EFF_FFFF	YES	YES
OCRAM - Sys RAM	0x3F00_0000 - 0x3F3F_FFFF	YES	YES
OCRAM - gfx RAM	0x3F40_0000 - 0x3F7F_FFFF	YES	YES
TCMU	0x3F80_0000 - 0x3FFF_FFFF	YES	YES
QSPI1	0x5000_0000 - 0x5FFF_FFFF	YES	YES
SDRAM1	0xE000_0000 - 0xFFFF_FFFF	YES	NO
Cortex-M4 Code Alias Region	0x0080_0000 - 0x1F7F_FFFF	NO	YES

**Table 7-61. Valid DCD Peripheral Address Ranges**

Peripheral	Address Range	Cortex-A5	Cortex-M4
DDRMC	0x400A_E000 - 0x400A_EFFF	YES	YES
IOMUX	0x4004_8000 - 0x4004_8FFF	YES	YES
FlexBUS Controller	0x4001_E000 - 0x4001_EFFF	YES	YES
Clock Control Module	0x4006_B000 - 0x4006_BFFF	YES	YES
ANADIG	0x4005_0000 - 0x4005_0FFF	YES	YES

### 7.5.6.2.2 Check Data Command

The Check Data Command is used to test for a given 1, 2 or 4-byte bitmasks from a source address. The Check Data Command is a big endian byte array with format shown in the table below.

**Table 7-62. Check Data Command Format**

Tag	Length	Parameter
	Address	
	Mask	
	[Count]	

Where:

Tag: A single byte field set to 0xCF

Length: A two byte field in big endian format containing the length of the Check Data Command, in bytes, including the header

Address: source address to test

Mask: bit mask to test

Count: optional poll count. If count is not specified this command will poll indefinitely until the exit condition is met. If count = 0, this command behaves as for NOP.

The Parameter field is a single byte divided into bitfields as follows:

**Table 7-63. Check Data Command Parameter field**

7	6	5	4	3	2	1	0
flags				bytes			

Where:

bytes: width of target locations in bytes. Either 1, 2 or 4

flags: control flags for command behavior.

Data Mask = bit 3: if set, only specific bits may be overwritten at target address (otherwise all bits may be overwritten)

Data Set = bit 4: if set, bits at the target address overwritten with this flag (otherwise it is ignored)

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

**Table 7-64. Interpretation of Check Data Command Flags**

"Mask"	"Set"	Action	Interpretation
0	0	$(*\text{address} \& \text{mask}) == 0$	All bits clear
0	1	$(*\text{address} \& \text{mask}) == \text{mask}$	All bits set
1	0	$(*\text{address} \& \text{mask}) != \text{mask}$	Any bit clear
1	1	$(*\text{address} \& \text{mask}) != 0$	Any bit set

### Note

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

#### 7.5.6.2.3 NOP Command

This command has no effect. The format of NOP Command is a little endian four byte array as shown in table below.

Table 7-65. NOP Command Format

Tag	Length	Undefined
-----	--------	-----------

Where:

Tag: A single byte field set to 0xC0  
Length: A two byte field containing the length of the NOP Command in bytes. Fixed to a value of 4.  
Undefined: This byte is ignored and can be set to any value.

7.5.7 Plugin Image

The device ROM supports a limited number of boot devices. To boot from other devices (for example, Ethernet), a supported boot device must be used (typically serial ROM) that includes firmware for the desired boot device.

The Boot ROM will detect the image type by using the plugin flag in the Boot Data Structure. If the plugin flag is 1, then the ROM will use the image as a plugin function. The function must initialize the boot device and copy the program image to the final location. At the end, the plugin function must return with the parameters of the program image.

The boot ROM will authenticate the plugin image prior to running the plugin function and then will authenticate the program image.

The plugin function must follow the API described below:

```
typedef unsigned char (*) plugin_download_f(void **start, size_t *bytes, UINT32 *ivt_offset)
```

ARGUMENTS PASSED:

- start - Image load address on exit.
- bytes - Image size on exit.
- ivt\_offset - Offset in bytes of the IVT from the image start address on exit.

RETURN VALUE:

- 1 - on success
- 0 - on failure

### 7.5.8 Serial Downloader (BOOT\_MODE [1:0] = 0b01)

The Serial Downloader provides a means to download a Program Image to the device over the USB/UART connection. In this mode, the ROM programs either WDOG-A5 or WDOG-M4 for a 32-second time-out if WDOG\_ENABLE eFUSE is 1, and then continuously polls for USB connection and UART activity. If no activity is found on USB or UART and the watchdog timer expires, then the ARM core is reset.

#### Note

The downloaded application image must continue to service the watchdog timer to avoid an undesired reset from occurring.

The USB/UART boot flow is shown in the figure below.

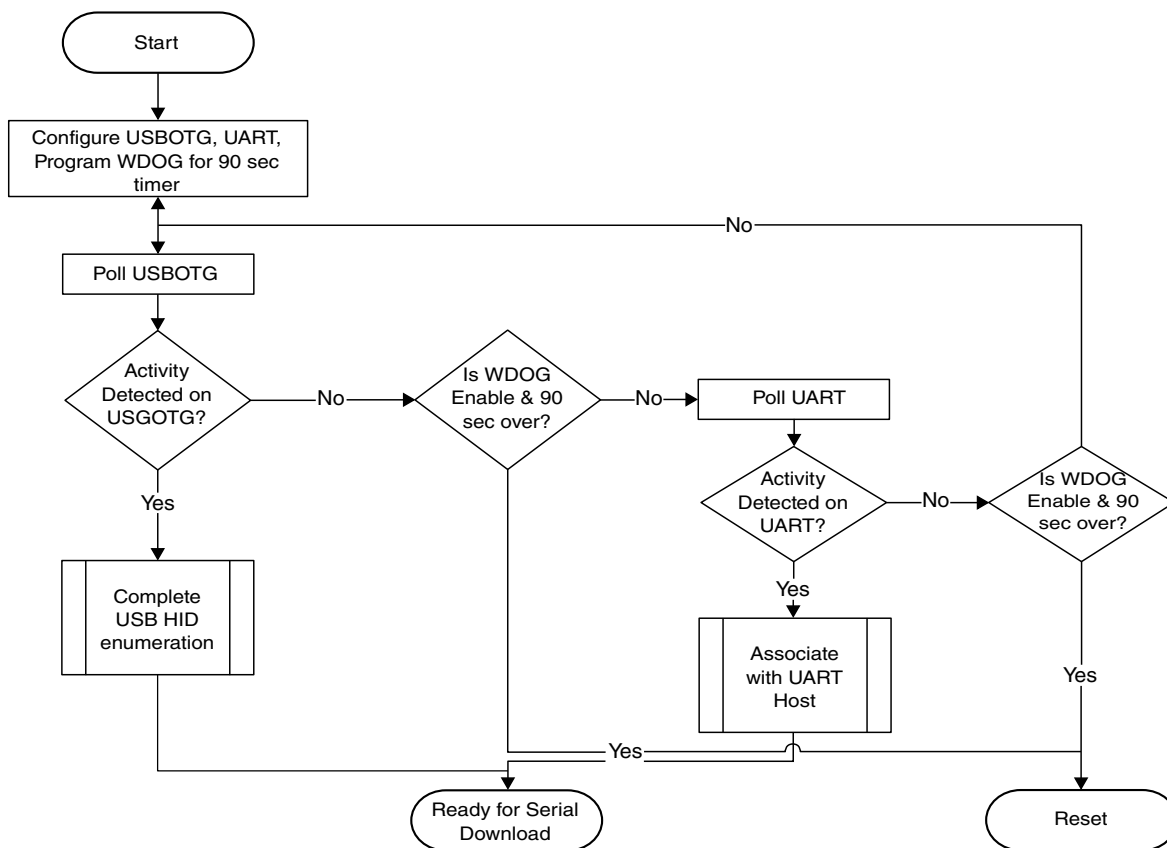

Figure 7-37. USB/UART Boot Flow

### 7.5.8.1 USB Boot Flow

USB support in this device is composed of the USB OTG core controller, compliant with the USB 2.0 specification and the USBPHY (HS USB transceiver). The device ROM supports the USB0 port for boot purposes. The other USB port on the device is not supported for boot purposes.

#### NOTE

Only USB0 is supported as a boot device. USB1 cannot be used.

The device USB Driver is implemented as a USB HID class. A collection of 4 HID reports are used to implement SDP protocol for data transfers:

- Report 1 transfer over Control OUT endpoint, 16-byte SDP command from host to device. Total bytes are 17 with first byte reserved for Report ID set to 1.
- Report 2 transfer over control OUT endpoint from host to device data associated with report 1 SDP command. Max report size is 1025 bytes with first byte reserved for Report ID set to 2.
- Report 3 transfer over interrupt endpoint from device to host to send HAB security state. Max size of this report is 5 bytes with first byte reserved for Report ID set to 3.
- Device sends 0x12343412 in production mode and 0x56787856 in engineering mode in the remaining 4 bytes of this report.
- Report 4 transfer over interrupt endpoint from device to host to send data in response to SDP command in report 1. Max size of this report is 65 with first byte reserved for Report ID set to 4.

#### 7.5.8.1.1 USB Configuration Details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for USB device driver are listed in the table below.

**Table 7-66. VID/PID and Strings for USB Device Driver**

Descriptor	Value
VID	0x15A2 (Freescale Vendor ID)
PID <sup>9</sup>	0x006A

*Table continues on the next page...*

**Table 7-66. VID/PID and Strings for USB Device Driver (continued)**

Descriptor	Value
String Descriptor1 (manufacturer)	Freescale Semiconductor Inc.
String Descriptor2 (product)	
String Descriptor4	Freescale Flash
String Descriptor5	Freescale Flash

9. Allocation based on BPN (Before Part Number)

### 7.5.8.1.2 IOMUX Configuration for USB

The interface signals of the UTMI PHY are not configured in the IOMUX. The UTMI PHY interface uses dedicated contacts on the IC. See the device data sheet for details.

## 7.5.8.2 UART Boot Flow

UART support in the device is composed of the UART controller(called as Host). The device ROM supports UART0, UART1, UART2 or UART3 ports for serial download.

Initially, the selected UART port for booting waits for a data pattern (0x23454523) from the UART host. After receiving this pattern, the device sends the same pattern back to the host. This phase of of pattern exchange is called Association phase.

Once the association phase is over, the host and device UART device implements SDP protocol of data transfers:

- 16 bytes SDP Commands are sent by the UART host
- Optionally more data bytes are sent by the UART host to the device UART device
- The device UART port sends 4 bytes of HAB security state, which is 0x12343412 in production mode and 0x56787856 in engineering mode.

If required, the device UART device sends data to UART host in response to the certain SDP commands.

### 7.5.8.2.1 UART eFUSE Configuration

The boot ROM determines the configuration of UART, either provided by eFUSE, or sampled on GPIO pins, during boot. See the table below for parameters details.

**Table 7-67. UART eFUSE Descriptions**

Fuse	Config	Definition	GPIO <sup>1</sup>	Shipped Value	Settings
BOOT_CFG3[5:4]	OEM	UART Boot Device Selection	Yes	00	00 – UART0 01 – UART1 10 – UART2 11 – UART3

1. Setting can be overridden by GPIO settings when BT\_FUSE\_SEL fuse is intact. See [Table 1](#) for corresponding GPIO pin.

### 7.5.8.2.2 IOMUX Configuration for UART

The table below shows the UART IOMUX pin configuration.

**Table 7-68. UART IOMUX Pin Configuration**

Signal	Pad Name			
	UART0	UART1	UART2	UART3
TX	SCI0_TX	SAI0_TX_BCLK	QSPI0_A_SCK	TRACED[14]
RX	SCI0_RX	SAI0_RX_BCLK	QSPI0_A_CS0	TRACED[15]
RTS	SCI0_RTS	SAI0_RX_DATA	QSPI0_A_DATA[3]	SAI0_TX_BCLK
CTS	SCI0_CTS	SAI0_TX_DATA	QSPI0_A_DATA[2]	SAI0_RX_BCLK

### 7.5.8.3 Serial Download protocol

The 16 byte SDP command from host to device is sent using HID report 1. The table below describes 16 byte SDP command data structure:

**Table 7-69. 16 Byte SDP Command Structure**

BYTE Offset	Size	Name	Description
0	2	COMMAND TYPE	Following commands are supported for the device ROM: <ul style="list-style-type: none"> <li>• 0x0101 READ_REGISTER</li> <li>• 0x0202 WRITE_REGISTER</li> <li>• 0x0404 WRITE_FILE</li> <li>• 0x0505 ERROR_STATUS</li> <li>• 0x0A0A DCD_WRITE</li> <li>• 0x0B0B JUMP_ADDRESS</li> </ul>
2	4	ADDRESS	Only relevant for following commands:

*Table continues on the next page...*

**Table 7-69. 16 Byte SDP Command Structure (continued)**

BYTE Offset	Size	Name	Description
			READ_REGISTER, WRITE_REGISTER, WRITE_FILE, DCD_WRITE, and JUMP_ADDRESS.  For READ_REGISTER and WRITE_REGISTER commands, this field is address to a register. For WRITE_FILE and JUMP_ADDRESS commands, this field is an address to internal or external memory address.
6	1	FORMAT	Format of access, 0x8 for 8-bit access, 0x10 for 16-bit and 0x20 for 32-bit access. Only relevant for READ_REGISTER and WRITE_REGISTER commands.
7	4	DATA COUNT	Size of data to read or write. Only relevant for WRITE_FILE, READ_REGISTER, WRITE_REGISTER and DCD_WRITE command. For WRITE_FILE and DCD_WRITE commands DATA COUNT is in byte units.
11	4	DATA	Value to write. Only relevant for WRITE_REGISTER command.
15	1	RESERVED	Not used in the device ROM

### 7.5.8.3.1 SDP Command

SDP commands are described in the following sections.

#### 7.5.8.3.1.1 READ REGISTER

The transaction for command READ\_REGISTER consists of following: 16 bytes (carried through Report1 in case of USB OTG interface) for command, HAB mode (carried through Report3 in case of USB OTG interface) and response or register value (carried through Report 4 in case of USB OTG interface). The register to read is specified in ADDRESS field of SDP command. First device sends HAB mode (through report-3 in case of USB OTG) followed by data bytes (carried through report-3 in case of USB OTG interface) read at given address. In case of USB OTG interface in use, if count is greater than 64 then multiple reports with report id 4 are sent until entire data requested by host is sent, while in case of other interfaces, the whole data is sent continuously. The STATUS is either 0x12343412 for production parts and 0x56787856 for development parts.

Command, Host to Device (carried through Report1 in case of USB-OTG):

## System Boot

Report ID(For USB Only)	16 Bytes SDP Command
1	Valid values for READ_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT

### Response, Device to Host:

	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

### Response, Device to Host: first response report

Report ID(For USB Only)	Response, Device to Host: first response
4	Register Value

If number of bytes requested is less than 4 then remaining bytes should be ignored by host.

In case of USB OTG only, multiple reports of Report ID 4 are sent until entire data requested is sent

### Report4, Response, Device to Host: Last response report

Report ID(For USB Only)	Response, Device to Host: Last response report
4	Register Value

If number of bytes requested is less than 64 then remaining bytes should be ignored by host.

## 7.5.8.3.1.2 WRITE REGISTER

The transaction for command WRITE\_REGISTER consists of following: 16 bytes (carried through Report1 in case of USB OTG interface) for command, HAB mode (carried through Report3 in case of USB OTG interface) and write status (carried through Report4 in case of USB OTG interface). Host sends WRITE\_REGISTER command (using Report1 in case of USB OTG interface). The register to write is specified in ADDRESS field of SDP command, with FORMAT field set to data type (number of bits to write 8, 16 or 32) and value to write in DATA field of SDP command. Device writes

the DATA to register address and returns WRITE\_COMPLETE response code (using Report4 in case of USB OTG interface) and Development/Engineering part status (using Report3 in case of USB OTG interface) to complete the transaction.

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	Valid values for WRITE_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT and DATA

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	WRITE_COMPLETE (0x128A8A12) status

On failure device will report HAB error status.

### 7.5.8.3.1.3 WRITE\_FILE

The transaction for command WRITE\_FILE consists of following reports: 16 bytes (carried through Report1 in case of USB OTG interface) for command, HAB mode (carried through Report3 in case of USB OTG interface) and write status (carried through Report4 in case of USB OTG interface). Host sends WRITE\_FILE command (through Report1 in case of USB OTG interface). The address to write is specified in ADDRESS field of SDP command (of Report1 in case of USB OTG interface), with FORMAT field set to data type (number of bits to write 8, 16, or 32). The data to be written to the address specified in SDP ADDRESS field then follows, from Host to Device (through Report2 in case of USB OTG interface). Device then returns COMPLETE code (using Report4 in case of USB OTG interface) and Development/Engineering part status (using Report3 in case of USB OTG interface) to complete the transaction:

Report1, Command, Host to Device:

## System Boot

Report ID(For USB only)	Command, Host to Device
1	Valid values for WRITE_FILE COMMAND, ADDRESS, DATA_COUNT

=====Optional Begin=====

Host sends ERROR\_STATUS command to query if HAB rejected the address

===== Optional End=====

Data, Host to Device:

Report ID(For USB Only)	Data, Host to Device
2	File Data

In case of USB OTG interface, Data will be sent through Max 1024 bytes data per report. In case of DATA\_COUNT more than 1024 bytes, host sends more Report2, Data, Host to Device:

Report2, Data, Host to Device:

Report ID(For USB only)	Data, Host to Device
2	File Data

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	COMPLETE (0x88888888) status

On failure device will report HAB error status.

#### 7.5.8.3.1.4 ERROR\_STATUS

The transaction for SDP command ERROR\_STATUS consists of three parts. Host sends the command (through Report1 in case of USB OTG interface); device sends global error status in 4 bytes (using Report4 in case of USB OTG interface) after returning Development/Engineering status code (through Report3 in case of USB OTG interface). When device receives ERROR\_STATUS command it will return global error status that is updated for each command. This command is useful to find out if last command resulted in device error or succeeded.

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	ERROR_STATUS COMMAND

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	4 bytes Error Status

#### 7.5.8.3.1.5 DCD WRITE

The SDP command DCD\_WRITE is used by host to send multiple register writes together. This command is provided to speed up the process of programming register writes such as to configure external RAM device. The command (sent through Report1 in case of USB OTG interface) goes with COMMAND TYPE set to DCD\_WRITE, ADDRESS which is used for temporary location of DCD data and DATA\_COUNT to number of bytes sent in data out phase. In data phase, host sends data for number of registers (using Report2 in case of USB OTG interface). Device completes the transaction (with Report3 in case of USB OTG interface) indicating Development/Production STATUS and WRITE\_COMPLETE (with report 4 in case of USB OTG interface) code 0x12828212.

Command, Host to Device:

## System Boot

Report ID(For USB only)	Command, Host to Device
1	DCD_WRITE COMMAND, ADDRESS, DATA_COUNT

Data, Host to Device:

Report ID(For USB only)	Datam Host to Device
2	DCD binary data

Max 1024 bytes per report in case of USB OTG only.

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	WRITE_COMPLETE (0x128A8A12) status

On failure device will report HAB error status.

See [Device Configuration Data \(DCD\)](#) for DCD format description.

### 7.5.8.3.1.6 JUMP ADDRESS

The SDP command JUMP\_ADDRESS will be the last command host can send to the device, after this command device will jump to the address specified in the ADDRESS field of SDP command and start executing. This command should typically follow after WRITE\_FILE command. The command is sent by host in command-phase of transaction (using Report1 in case of USB OTG interface), there is no data phase for this command but device send status (through report3 in case of USB OTG interface) to complete the transaction. And if HAB authentication fails then it will also send HAB error status (through report 4 in case of USB OTG interface).

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	JUMP_ADDRESS COMMAND

### Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Device sends a response only in case of an error jumping to the given address; device reports error with Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	4 bytes HAB Error Status

## 7.5.9 Recovery Devices

The device ROM supports recovery devices. If primary boot device fails, boot ROM will try to boot from recovery device using one of I2C or SPI ports.

For enabling recovery device BOOT\_CFG4 [6] fuse must be set. Additionally Serial EEPROM fuses must be set as described in [Serial ROM Boot using SPI/I2C Interface](#).

## 7.5.10 HAB Re-Authentication at Low Power Standby Exit

This feature allows Boot code to be re-authenticated when silicon wakes up after entering low power standby. This Feature is controlled by BOOT\_CFG3[0]. When fuse is set then this feature is enabled. During development stage this bit can be controlled using RCON16 (when BOOT\_MODE[1:0]=0b10). When BT\_FUSE\_SEL efuse is blown, then the configuration setting is read from eFUSE. When enabled, the boot code is downloaded again from the boot interface (either Primary or Secondary) based on settings of PERSIST\_SECONDARY\_BOOT. After downloading the code is then re-authenticated using HAB based on settings of SEC\_CONFIG[1:0] eFuse. Authenticated code is then allowed to execute. In case the authentication fails, the Boot ROM tries to download the image from the Recovery Device (depending on settings of

BOOT\_CFG4[6]). This feature is targeted to prevent execution of any malicious code or accidental modification of boot code that was introduced when the system was under STANDBY state.

## 7.5.11 Running Secondary Core

To start execution in the secondary (Cortex-M4) core, an application entry address must be established and the auxiliary core clock must be enabled. The auxiliary core begins execution in the Boot ROM code. The Boot ROM code checks the validity of the application entry address pointed to by SRC\_GPR2 and, if valid, jumps to the address.

1. Set SRC\_GPR2[PERSISTENT\_ENTRY1] to the entry point for the application to be executed by the secondary core. Ensure that this address is odd because the Cortex-M4 supports only Thumb Mode. For example,

```
SRC.GPR2[PERSISTENT_ENTRY1] = 0x3f040410+1;
```

2. Set SRC\_GPR3[PERSISTENT\_ARG1] to the argument to be passed to the application.
3. Enable the auxiliary core clock by setting CCM\_CCOWR to the key number 0x15a5a.

```
CCM_CCOWR = 0x15a5a;
```

## 7.5.12 Appendix

### 7.5.12.1 IOMUX and GPIO Pad Settings for BOOT Interfaces

To view the IOMUX and GPIO Pad settings of Boot interfaces, refer to the BOOT\_IOMUX\_GPIO\_SETTINGS excel file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it.

### 7.5.12.2 Fuse RCON Mapping

To view the RCON pins and Port pin mapping of BOOT interfaces, refer to Fuse\_RCON\_Mapping excel file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it.

### 7.5.12.3 PLL Configuration after BOOT

**Table 7-70. PLL Configuration After Boot**

PLL	Main		Fractional Divider 1		Fractional Divider 2		Fractional Divider 3		Fractional Divider 4	
	Mul	Freq (MHz)	Div	Freq (MHz)	Div	Freq (MHz)	Div	Freq (MHz)	Div	Freq (MHz)
PLL1	22	528	19	500.21	21	452.57	24	396	18	528
PLL2	22	528	19	500.21	24	396	28	339.42	23	413.21
PLL3	20	480	28	308.57	26	332.3	29	297.93	31	297.93

#### NOTE

PLL2 will be disabled after boot. PLLSYS and PLL3 are enabled during boot.

### 7.5.12.4 Basic CCM Settings

**Table 7-71. CCM\_Settings**

Register	Value	Description
CCR	0x0001_10FF	FIRC_EN = 1, FXOSC_EN = 1, OSCNT = 0xFF
CSR	0x0000_0030	FXOSC_READY = 1
CCSR	0x0004_0824	PLL1_PFD_CLK_SEL = 0x4, PLL1_PFD4_EN = 1, FAST_CLK_SEL = 1, SYS_CLK_SEL = 0x4
CACRR	0x0060_0809	FLEX_CLK_DIV = 1, PLL6_CLK_DIV = 1, IPG_CLK_DIV = 1, BUS_CLK_DIV = 1, ARM_CLK_DIV = 1
CIMR	0xFFFF_FFFF	M_FXOSC_READY = 1, M_LRF_PLL4 = 1, M_LRF_PLL3 = 1, M_LRF_PLL2 = 1, M_LRF_PLL1 = 1

## 7.6 Fusemap

### 7.6.1 Boot Fusemap

The following section details the various modes and selection of the required boot devices.

**Table 7-72. Boot Device Select**

Boot Device	BOOT_CFG1[7]	BOOT_CFG1[6]	BOOT_CFG1[5]	BOOT_CFG1[4]
QuadSPI	0	0	0	0
NOR Flash	0	0	0	1
Serial-ROM (SPI/IIC)	0	0	1	0
FlexCAN	0	0	1	1
SD/eSD	0	1	1	0
MMC/eMMC	0	1	1	1
NAND	1	x	x	x

### 7.6.2 Fusemap Descriptions Table

**Table 7-73. Fusemap Descriptions**

Fuse Address	Fuses Name	# of Fuses	Fuses Function	Settings	Locked by
0x400[1:0]	TESTER_LOCK	2	Provides Locking of various fuse bits.	00 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded.  1x - Override Protect (OP) x1 - Write Protect (WP)  11 - Both OP and WP	N/A
0x400[3:2]	BOOT_CFG_LOCK	2	Perform lock on BOOT related fuses.	00 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded.  1x - Override Protect (OP) x1 - Write Protect (WP)	N/A

*Table continues on the next page...*

0x400	Reserved		CRC-GP_HI_LOCK  '1x' – WP + Read Protect (CRC locking)  'x1' – WP + OP (General Purpose use)		CRC-GP_LO_LOCK  '1x' – WP + Read Protect (CRC locking)  'x1' – WP + OP (General Purpose use)		Reserved (LOCK_PIN)	Reserved

## Chapter 8

# Analog and Misc Control

## 8.1 12-bit Digital-to-Analog Converter (DAC)

### 8.1.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

### 8.1.2 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from  $1/4096 V_{in}$  to  $V_{in}$ , and the step is  $1/4096 V_{in}$ , where  $V_{in}$  is the input voltage.
- $V_{in}$  can be selected from two reference sources
- Static operation in Normal Stop mode
- 16-word data buffer supported with configurable watermark and multiple operation modes
- DMA support

### 8.1.3 Block diagram

The block diagram of the DAC module is as follows:

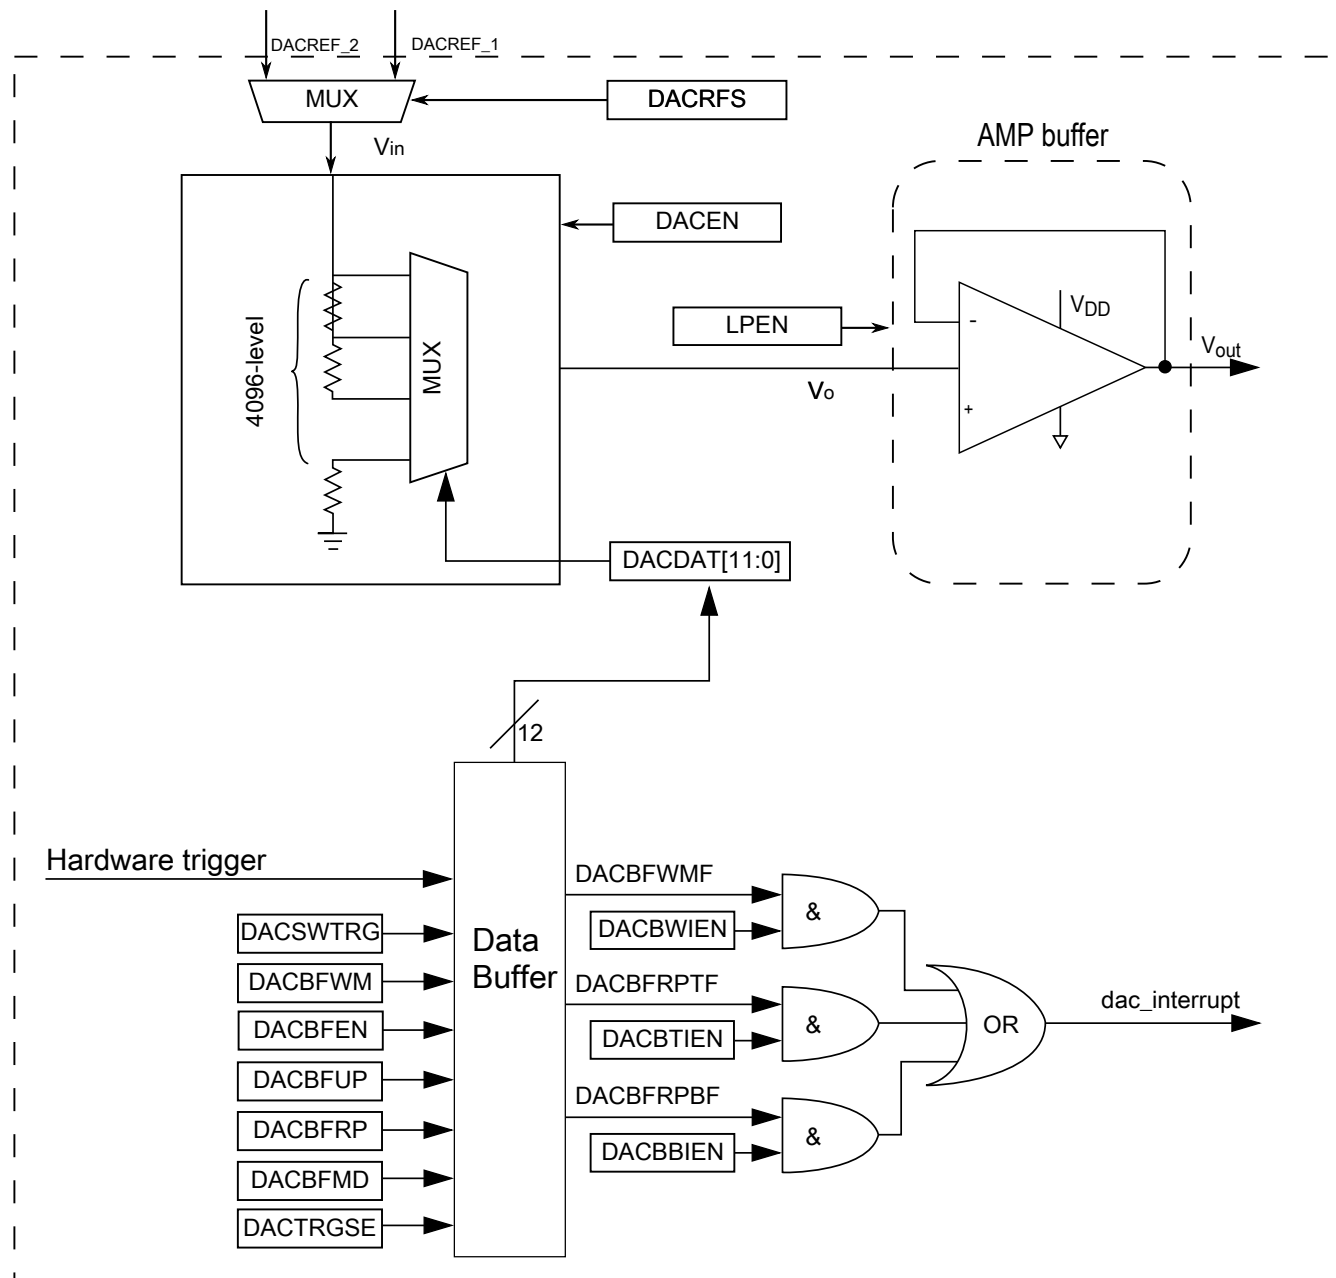

Figure 8-1. DAC block diagram

## 8.1.4 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

**DAC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

8.1.4.1 DAC Data Register (DACx\_DATn)

Address: Base address + 0h offset + (4d × i), where i=0d to 7d

DACx\_DATn field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–16 DATA1	DATA1  When the DAC buffer is not enabled, this field controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DAC\_DATn[DATA1])/4096$ When the DAC buffer is enabled, this field is mapped to the 16-word buffer.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DATA0	DATA0  When the DAC buffer is not enabled, this field controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DAC\_DATn[DATA0])/4096$ When the DAC buffer is enabled, this field is mapped to the 16-word buffer.

### 8.1.4.2 DAC Status and Control Register (DACx\_STATCTRL)

If DMA is enabled, the flags can be cleared automatically by DMA when the DMA request is done. Writing 0 to a field clears it whereas writing 1 has no effect. After reset, DACBFRPTF is set and can be cleared by software, if needed. The flags are set only when the data buffer status is changed.

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**DACx\_STATCTRL field descriptions**

Field	Description
31–28 DACBFRP	DAC Buffer Read Pointer Keeps the current value of the buffer read pointer.
27–24 DACBFUP	DAC Buffer Upper Limit Selects the upper limit of the DAC buffer. The buffer read pointer cannot exceed it.
23 DMAEN	DMA Enable Select

*Table continues on the next page...*

**DACx\_STATCTRL field descriptions (continued)**

Field	Description
	0 DMA is disabled. 1 DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.
22–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–19 DACBFWM	DAC Buffer Watermark Select  Controls when DACBFWMF is set. When the DAC buffer read pointer reaches the word defined by this field, which is 1–4 words away from the upper limit (DACBUP), DACBFWMF is set. This allows user configuration of the watermark interrupt.  00 1 word 01 2 words 10 3 words 11 4 words
18–17 DACBFMD	DAC Buffer Work Mode Select  00 Normal mode 01 Swing mode 10 One-Time Scan mode 11 Reserved
16 DACBFEN	DAC Buffer Enable  0 Buffer read pointer is disabled. The converted data is always the first word of the buffer. 1 Buffer read pointer is enabled. The converted data is the word that the read pointer points to. It means converted data can be from any word of the buffer.
15 DACEN	DAC Enable  Starts the Programmable Reference Generator operation.  0 The DAC system is disabled. 1 The DAC system is enabled.
14 DACRFS	DAC Reference Select  0 The DAC selects DACREF_1 as the reference voltage. 1 The DAC selects DACREF_2 as the reference voltage.
13 DACTRGSEL	DAC Trigger Select  0 The DAC hardware trigger is selected. 1 The DAC software trigger is selected.
12 DACSWTRG	DAC Software Trigger  Active high. This is a write-only field, which always reads 0. If DAC software trigger is selected and buffer is enabled, writing 1 to this field will advance the buffer read pointer once.  0 The DAC soft trigger is not valid. 1 The DAC soft trigger is valid.
11 LPEN	DAC Low Power Control

*Table continues on the next page...*

**DACx\_STATCTRL field descriptions (continued)**

Field	Description
	<b>NOTE:</b> See the 12-bit DAC electrical characteristics of the device data sheet for details on the impact of the modes below. 0 High-Power mode 1 Low-Power mode
10 DACBWIEN	DAC Buffer Watermark Interrupt Enable 0 The DAC buffer watermark interrupt is disabled. 1 The DAC buffer watermark interrupt is enabled.
9 DACBTIEN	DAC Buffer Read Pointer Top Flag Interrupt Enable 0 The DAC buffer read pointer top flag interrupt is disabled. 1 The DAC buffer read pointer top flag interrupt is enabled.
8 DACBBIEN	DAC Buffer Read Pointer Bottom Flag Interrupt Enable 0 The DAC buffer read pointer bottom flag interrupt is disabled. 1 The DAC buffer read pointer bottom flag interrupt is enabled.
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 DACBFWMF	DAC Buffer Watermark Flag 0 The DAC buffer read pointer has not reached the watermark level. 1 The DAC buffer read pointer has reached the watermark level.
1 DACBFRPTF	DAC Buffer Read Pointer Top Position Flag 0 The DAC buffer read pointer is not zero. 1 The DAC buffer read pointer is zero.
0 DACBFRPBF	DAC Buffer Read Pointer Bottom Position Flag 0 The DAC buffer read pointer is not equal to DACBFUP. 1 The DAC buffer read pointer is equal to DACBFUP.

**8.1.5 Functional description**

The 12-bit DAC module can select one of the two reference inputs—DACREF\_1 and DACREF\_2 as the DAC reference voltage,  $V_{in}$  by STATCTRL [DACRFS]. See the chip-specific DAC information to determine the source options for DACREF\_1 and DACREF\_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from  $V_{in}$  to  $V_{in}/4096$ , and the step is  $V_{in}/4096$ .

### 8.1.5.1 DAC data buffer operation

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in DAT0 to the analog output voltage.

When both the DAC and the buffer are enabled, the DAC converts the data in the data buffer to analog output voltage. The data buffer read pointer advances to the next word whenever a hardware or software trigger event occurs.

The data buffer can be configured to operate in Normal mode, Swing mode, One-Time Scan mode. When the buffer operation is switched from one mode to another, the read pointer does not change. The read pointer can be set to any value between 0 and STATCTRL[DACBFUP] by writing STATCTRL[DACBFRP].

#### 8.1.5.1.1 DAC data buffer interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer. STATCTRL[DACBFRPBF] is set when the DAC buffer read pointer reaches the DAC buffer upper limit, that is, STATCTRL[DACBFRP] = STATCTRL[DACBFUP]. STATCTRL[DACBFRPTF] is set when the DAC read pointer is equal to the start position, 0. Finally, STATCTRL[DACBFWMF] is set when the DAC buffer read pointer has reached the position defined by STATCTRL[DACBFWM]. STATCTRL[DACBFWM] can be used to generate an interrupt when the DAC buffer read pointer is between 1 to 4 words from STATCTRL[DACBFUP].

#### 8.1.5.1.2 Modes of DAC data buffer operation

The following table describes the different modes of data buffer operation for the DAC module.

**Table 8-1. Modes of DAC data buffer operation**

Modes	Description
Buffer Normal mode	This is the default mode. The buffer works as a circular buffer. The read pointer increases by one, every time the trigger occurs. When the read pointer reaches the upper limit, it goes to 0 directly in the next trigger event.
Buffer Swing mode	This mode is similar to the normal mode. However, when the read pointer reaches the upper limit, it does not go to 0. It will descend by 1 in the next trigger events until 0 is reached.
Buffer One-time Scan mode	The read pointer increases by 1 every time the trigger occurs. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it will increase to the upper address and stop there again.  <b>NOTE:</b> If the software set the read pointer to the upper limit, the read pointer will not advance in this mode.

### 8.1.5.2 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

### 8.1.5.3 Resets

During reset, the DAC is configured in the default mode and is disabled.

### 8.1.5.4 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

**Table 8-2. Modes of operation**

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	<p>If enabled, the DAC module continues to operate in Normal Stop mode and the output voltage will hold the value before stop.</p> <p>In low-power stop modes, the DAC is fully shut down.</p>

#### NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

## 8.2 Analog-to-Digital Converter (ADC)

### 8.2.1 Overview

The analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

### 8.2.1.1 Features

The features of the ADC are as follows:

- Configuration registers
  - 32-bit, word aligned, byte enabled registers. (byte and halfword access is not supported)
- Linear successive approximation algorithm with up to 12-bit resolution with 10/11 bit accuracy.
- Up to 10 ENOB (dedicated single ended channels)
- Up to 1MS/s sampling rate
- Up to 8 single-ended external analog inputs
- Single or continuous conversion (automatic return to idle after single conversion)
- Output Modes: (in right-justified unsigned format)
  - 12-bit
  - 10-bit
  - 8-bit
- Configurable sample time and conversion speed/power
- Conversion complete and hardware average complete flag and interrupt
- Input clock selectable from up to three sources
- Asynchronous clock source for lower noise operation with option to output the clock
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Operation in low power modes for lower noise operation
- Temperature sensor
- Hardware average function
- Self-calibration mode

### 8.2.1.2 ADC I/F block diagram

The following diagram represents the ADC I/F block.

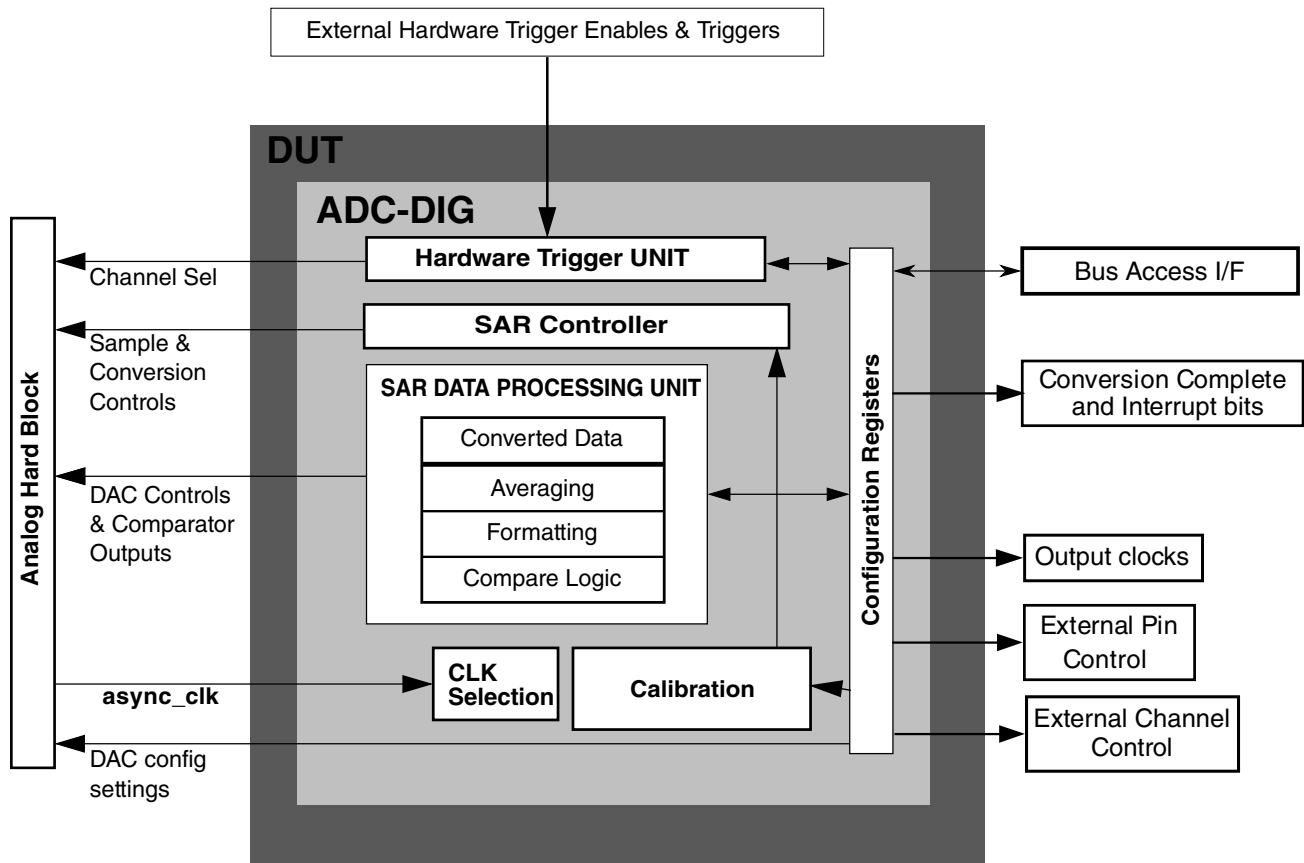

Figure 8-2. ADC I/F block diagram

### 8.2.1.3 ADC block diagram

The following figure shows a top-level block diagram of the ADC module.

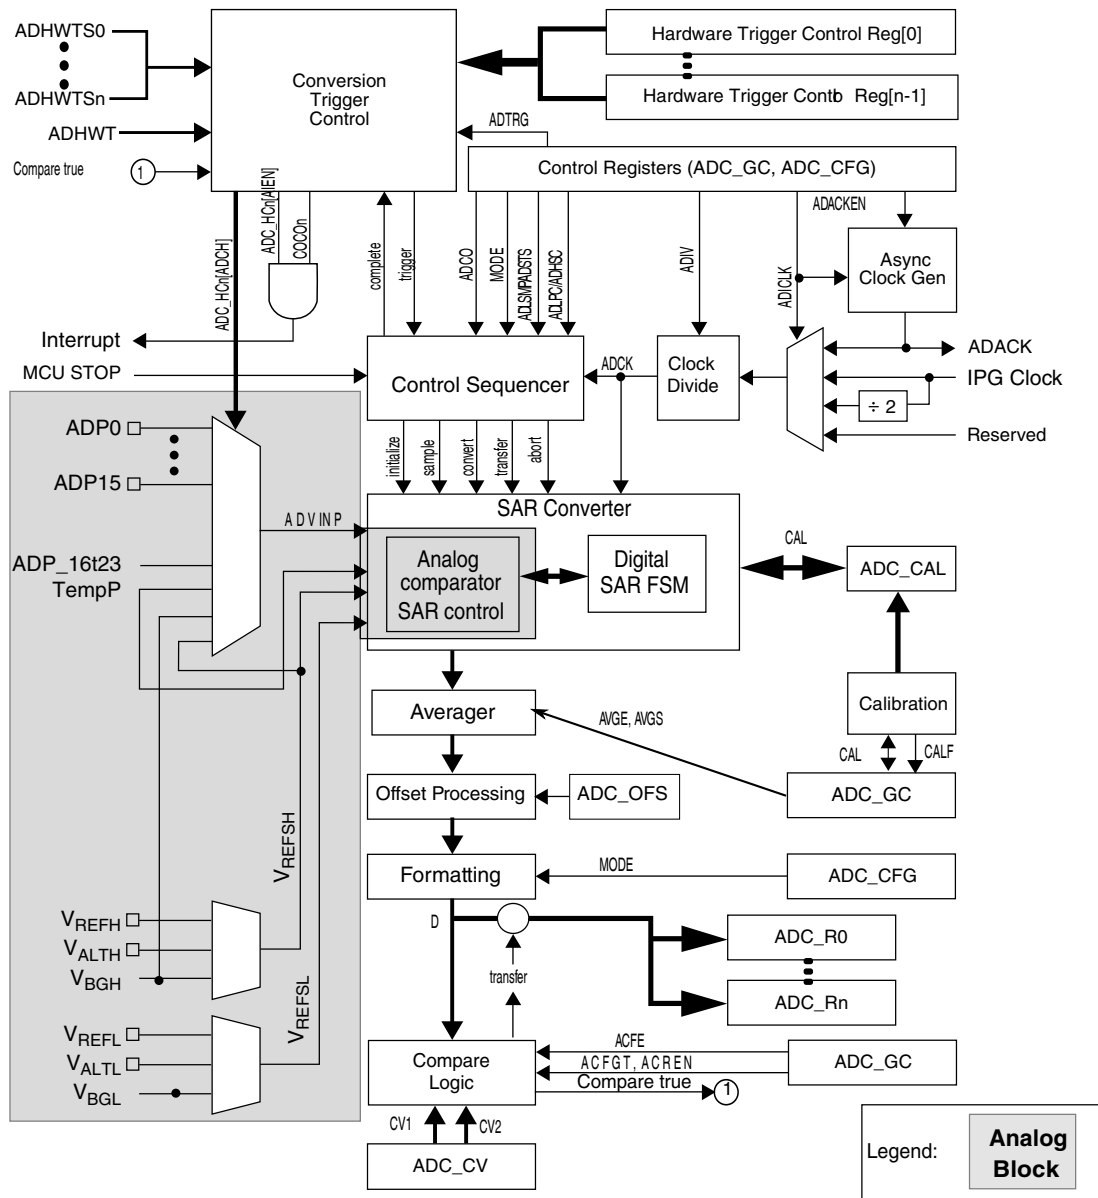

Figure 8-3. ADC block diagram

### 8.2.1.4 ADC module interface

The ADC is connected to many interfaces such as the clocks and reset, access bus, voltage references, interrupt controller, ADC pin control, and analog I/F as shown in the following figure.

Figure 8-4. ADC module interface

### 8.2.1.5 Modes of Operation

By default, the ADC is in disabled mode. In this state, no conversion or other actions occur. All of the ADC control registers are accessible in this state through an access bus interface. To enable the ADC, required configurations should be done by programming the ADC configuration registers.

## 8.2.2 External Signals

See the Chip Configuration section for channel assignments and I/O pins.

## 8.2.3 Functional Description

There are three possible states which ADC module can be in:

1. Disabled State
2. Idle state
3. Performing conversions

#### Disabled State:

The ADC module is disabled during reset or stop mode (if internal clock is not selected as source of clock).

#### Idle State:

The module is idle when a conversion has completed and another conversion has not been initiated. When idle and the asynchronous clock output enable is disabled (ADACKEN = 0), the module is in its lowest power state.

Conversion State:

The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications the ADC module must be calibrated using the on chip calibration function. Calibration is recommended to be done after any reset.

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the compare value registers. The compare function is enabled by setting ACFE (ADC Compare Function Enable) in the ADC general control register.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting AVGE in the ADC general control register.

8.2.3.1 Clock Select and Divide Control

The ADC digital module has two clock sources:

- IPG clock
- Internal clock (ADACK) is a dedicated clock used only by the ADC.

ADC digital block generates IPG clock/2 by internally dividing the IPG clock. The final clock is chosen from the following clocks.

- IPG clock
- IPG clock divided by 2
- ADACK

From the three clocks listed above, one is chosen depending on the configuration of ADICLK[1:0] bits of ADC\_CFG. This chosen clock is divided depending on the configuration of ADIV[1:0] bits of ADC\_CFG. The final generated clock is used as conversion clock for ADC.

ADICLK	Selected Clock Source
00	IPG clock
01	IPG clock divided by 2

Table continues on the next page...

ADICLK	Selected Clock Source
10	Reserved
11	Asynchronous clock (ADACK)

- The IPG clock. This is the default selection following reset.
- The IPG clock divided by two. For higher IPG clock rates, this allows a maximum divide by 16 of the IPG clock using the ADIV bits.
- The asynchronous clock (ADACK). This clock is generated from a clock source within the ADC module. Conversions are possible using ADACK as the input clock source while the MCU is in stop mode.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by the ADIV bits and can be divide-by 1, 2, 4, or 8.

### 8.2.3.2 Voltage Reference Selection

The ADC can be configured to use reference pairs as the reference voltages used for conversions ( $V_{REFSH}$  and  $V_{REFSL}$ ). Each pair contains a positive reference which must be between the minimum Ref Voltage High and  $V_{DDAD}$ , and a ground reference which must be at the same potential as  $V_{SSAD}$ . The pairs can be as follows:

- External ( $V_{REFH}$  and  $V_{REFL}$ )
- Alternate ( $V_{ALTH}$  and  $V_{ALTL}$ )
- Internal bandgap ( $V_{BGH}$  and  $V_{BGL}$ )

These voltage references are selected by configuring ADC\_CFG[REFSEL]. The alternate ( $V_{ALTH}$  and  $V_{ALTL}$ ) voltage reference pair may select additional external pins or internal sources depending on MCU configuration. For the chip-specific implementation details of this module, see the chip configuration information.

### 8.2.3.3 Conversion Control

Conversions are performed as determined by ADC\_CFG[MODE] field.

Conversions are initiated by a software trigger. In addition, the ADC can be configured for low power operation, long sample time, continuous conversion, hardware average, and automatic comparison of conversion results with predetermined values.

### 8.2.3.3.1 Initiating Conversions

A conversion is initiated:

- Following a write to ADC\_HC0 when a software triggered operation is selected (ADTRG=0).
- Following the transfer of the result to the data registers when continuous conversion is enabled (ADCO=1 in ADC\_GC register).

If continuous conversion is enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation (ADTRG=0), continuous conversions begin after ADC\_HC0 is written and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions is completed. In software triggered operation, conversions begin after ADC\_HC0 is written. If continuous conversions is also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

### 8.2.3.3.2 Completing Conversions

A conversion is completed when the result of the conversion is transferred into the data result registers. (provided the compare function & hardware averaging is disabled), this is indicated by the setting of COCON. If hardware averaging is enabled, COCON sets only, if the last of the selected number of conversions is complete. If the compare function is enabled, COCON sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then COCON sets only if the last of the selected number of conversions is complete and the compare condition is true. An interrupt is generated, if ADC\_HCn[AIEN] is high at the time that COCON is set and if DMAEN is set, DMA request is asserted, if COCON is set. Both the requests get deasserted when COCON is low, cleared, which happens when data is read.

In all modes a blocking mechanism prevents a new result from overwriting previous data in ADC\_Rn, if the previous data is in the process of being read. When blocking is active (OVWREN=0 in ADC\_CFG), the conversion result data transfer is blocked, COCON is not set, and the new result is lost. In all other cases of operation, when a conversion result data transfer is blocked, another conversion is initiated regardless of the state of ADCO (single or continuous conversions enabled).

### Note

If continuous conversions are enabled, the blocking mechanism could result in the loss of data occurring at specific timepoints. To avoid this issue, the data must be read in fewer cycles than an ADC conversion time, accounting for interrupt or software polling loop latency.

If single conversions are enabled, the blocking mechanism could result in several discarded conversions and excess power consumption. To avoid this issue, the data registers must not be read after initiating a single conversion until the conversion completes.

#### 8.2.3.3.3 Aborting Conversions

Any conversion in progress is aborted when:

- The MCU enters stop mode with ADACK not enabled.
- In software trigger mode, write to ADC\_HC0 register, while ADC\_HC0 is actively (already) controlling a conversion, aborts the current conversion.
- A write to any ADC register other than the ADC\_HC0 register occurs. This indicates a mode of operation change has occurred and the current conversion is therefore invalid.

### Note

When a conversion is aborted, the contents of the data result registers, ADCRn are not altered. The data result registers continue to hold the values, transferred after the completion of the last successful conversion. If the conversion is aborted by a reset or stop (not operated with internal ADACK), ADCRn (data result register) return to their reset states.

#### 8.2.3.3.4 Power Control

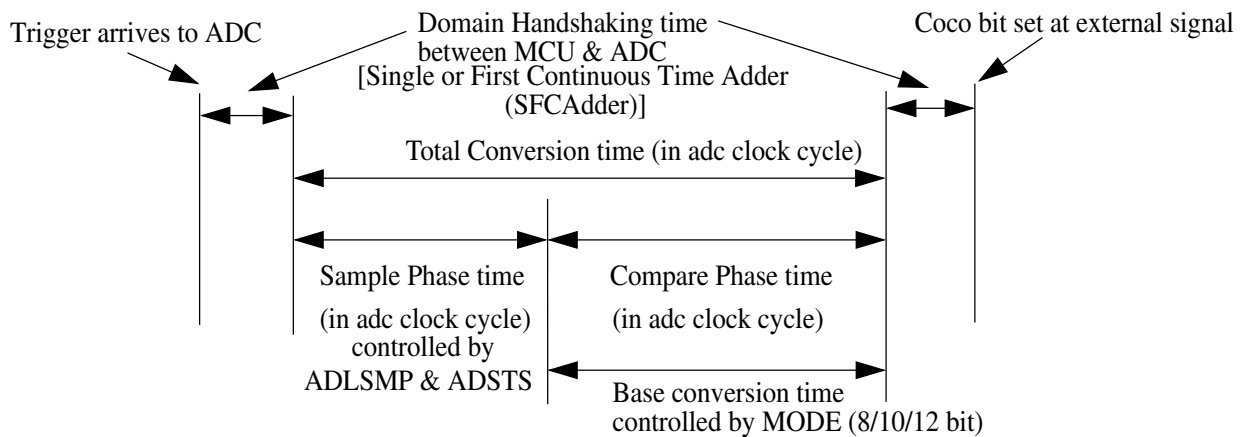

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source but the asynchronous clock output is disabled (ADACKEN=0), the ADACK clock generator will also remain in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled (ADACKEN=1), it will remain active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting ADLPC.

### 8.2.3.3.5 Sample Time and Total Conversion Time

The total conversion time depends upon the following:

- the sample phase time (as determined by ADLSMP and ADSTS bits in ADC\_CFG register),
- the compare phase time (determined by MODE bits)
- the frequency of the conversion clock ( $f_{ADCK}$ ).
- the MCU bus frequency (for Handshaking and selection of clock)

**Figure 8-5. ADC conversion time details**

After the module becomes active, sampling of the input begins. ADLSMP and ADSTS decide the sample time duration. When sampling is complete, the converter is isolated from the input channel and a successive approximation algorithm is performed to determine the digital value of the analog signal. The result of the conversion is transferred to ADC\_Rn upon completion of the conversion algorithm.

If the bus frequency is less than the  $f_{ADCK}$  frequency, precise sample time for continuous conversions cannot be guaranteed.

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by the ADICLK bits in ADC\_CFG register, and the divide ratio is specified by the ADIV bits.

The maximum total conversion time for all configurations is summarized in [Equation 1 on page 1019](#). Refer to [Table 8-3](#) through [Table 8-6](#) for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder})$$

**Equation 1****Table 8-3. Single or First Continuous Time Adder (SFCAdder)**

ADACKEN	ADICLK	Single or First Continuous Time Adder (SFCAdder)
x	0x, 10	3 ADCK cycles (before starting of conversion) + 1ADCK (after end of conversion) + 2 bus clock cycles
1	11	3 ADCK cycles (before starting of conversion) + 1 ADCK (after end of conversion) + 2 bus clock cycles
0	11	1.5μs + 3 ADCK cycles (before starting of conversion) + 1 ADCK (after end of conversion) + 2 bus clock cycles

**Table 8-4. Average Number Factor (AverageNum)**

AVGE	AVGS[1:0]	Average Number Factor (AverageNum)
0	xx	1
1	00	4
1	01	8
1	10	16
1	11	32

**Table 8-5. Base Conversion Time (BCT) (compare phase duration)**

Mode	Base Conversion Time (BCT) (compare phase duration)
8 bit	17 ADCK cycles
10 bit	21 ADCK cycles
12 bit	25 ADCK cycles

**Table 8-6. Long Sample Time**

ADLSMP	ADSTS	Long Sample Time Adder (LSTAdder)
0	00	3 ADCK cycles
0	01	5 ADCK cycles
0	10	7 ADCK cycles (default)
0	11	9 ADCK cycles

*Table continues on the next page...*

**Table 8-6. Long Sample Time (continued)**

ADLSMP	ADSTS	Long Sample Time Adder (LSTAdder)
1	00	13 ADCK cycles
1	01	17 ADCK cycles
1	10	21 ADCK cycles
1	11	25 ADCK cycles

**Note**

The ADCK frequency must be between  $f_{ADCK}$  minimum and  $f_{ADCK}$  maximum to meet ADC specifications.

**8.2.3.3.6 Conversion Time Examples**

The following examples uses [Equation 1 on page 1019](#) and the information provided in tables [Table 8-3](#) through [Table 8-6](#).

**8.2.3.3.6.1 Typical conversion time configuration**

A typical configuration for ADC conversion is: 10-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, ADLSMP=0, ADLSTS=10 and high speed conversion disabled. The conversion time for a single conversion is calculated by using [Equation 1 on page 1019](#) and the information provided in [Table 8-7](#) through [Table 8-9](#). The table below list the variables of [Equation 1 on page 1019](#).

**Table 8-7. Typical Conversion Time**

Variable	Time
SFCAdder	5 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	21 ADCK cycles
LSTAdder	7

The resulting conversion time is generated using the parameters listed in [Table 8-7](#). So for Bus clock equal to 40 Mhz and ADCK equal to 40 Mhz the resulting conversion time is 0.95 us.

### 8.2.3.3.6.2 Long conversion time configuration

A configuration for long ADC conversion is: 12-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-8 ratio selected, and a bus frequency of 40 MHz, long sample time enabled (ADLSMP=1, ADSTS=11) and configured for longest adder and high speed conversion disabled. Average enabled for 32 conversions (AVGE=1, AVGS=11). The conversion time for this conversion is calculated by using equation on [Sample Time and Total Conversion Time](#) and the information provided in [Table 8-3](#) through [Table 8-6](#). The table below lists the variables of equation.

**Table 8-8. Typical Conversion Time**

Variable	Time
SFCAdder	3 ADCK cycles + 5 bus clock cycles
AverageNum	32
BCT	25 ADCK cycles
LSTAdder	25 ADCK cycles

The resulting conversion time is generated using the parameters listed in [Table 8-8](#). So for Bus clock equal to 40 Mhz and ADCK equal to 5 Mhz the resulting conversion time is 10.0226 us (AverageNum). This results in a total conversion time of 320.725 us.

### 8.2.3.3.6.3 Short conversion time configuration

A configuration for short ADC conversion is: 8-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, long sample time disabled(ADLSMP=0, ADSTS=00) and high speed conversion enabled. The conversion time for this conversion is calculated by using the equation and the information provided in [Table 8-3](#) to [Table 8-6](#). The table below list the variables of equation.

**Table 8-9. Typical Conversion Time**

Variable	Time
SFCAdder	3 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	17 ADCK cycles
LSTAdder	3 ADCK cycles

The resulting conversion time is generated using the parameters listed in [Table 8-9](#). So for Bus clock equal to 40Mhz and ADCK equal to 40Mhz the resulting conversion time is 700 ns.

### 8.2.3.3.7 Hardware Average Function

The hardware average function can be enabled (AVGE=1) to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which select 4, 8, 16 or 32 conversions to be averaged. While the hardware average function is in progress the ADACT bit will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated once the selected number of conversions has been completed. When hardware averaging is selected the completion of a single conversion will not set the COCON bit.

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, ADC\_Rn, and the COCON bit is set. An ADC interrupt is generated upon the setting of COCON if the respective ADC interrupt is enabled (AIENn=1).

### 8.2.3.4 Automatic Compare Function

The compare function can be configured to check if the result is less than or greater-than-or-equal-to a single compare value, or if the result falls within or outside a range determined by two compare values. The compare mode is determined by ACFG, ACREN and the values in the compare value register (ADC\_CV). After the input is sampled and converted, the compare values (CV1 and CV2) are used as described in the table below. There are six compare modes as shown in the table below.

**Table 8-10. Compare Modes**

ACFGT	ACREN	CV1 relative to CV2	Function	Compare Mode Description
0	0	-	Less than threshold	Compare true if the result is less than the CV1 registers.
1	0	-	Greater than or equal to threshold	Compare true if the result is greater than or equal to CV1 registers.
0	1	Less than or equal	Outside range, not inclusive	Compare true if the result is less than CV1 <b>Or</b> the result is Greater than CV2
0	1	Greater than	Inside range, not inclusive	Compare true if the result is less than CV1 <b>And</b> the result is greater than CV2
1	1	Less Than or equal	Inside range, inclusive	Compare true if the result is greater than or equal to CV1 <b>And</b> the result is less than or equal to CV2
1	1	Greater than	Outside range, inclusive	Compare true if the result is greater than or equal to CV1 <b>Or</b> the result is less than or equal to CV2

With the ADC range enable bit set, `ADCREN = 1`, if compare value 1 (CV1 value) is less than or equal to the compare value 2 (CV2 value), setting `ACFGT` will select a trigger-if-inside-compare-range, inclusive-of-endpoints function. Clearing `ACFGT` will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than the CV2, setting `ACFGT` will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing `ACFGT` will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, `COCOn` is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, `COCOn` is not set and the conversion result data will not be transferred to the result register. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated upon the setting of `COCOn` if the respective ADC interrupt is enabled (`ADC_HCn[AIEN] = 1`).

### Note

The compare function can monitor the voltage on a channel while the MCU is in wait or stop3 mode. The ADC interrupt wakes the MCU when the compare condition is met.

### 8.2.3.5 Calibration Function

The ADC contains a self-calibration function that is required to achieve the specified accuracy. Calibration should be run or valid calibration values should be written after power up and system reset (as the calibration register will be reset on reset assertion) with specified settings before any conversion is initiated. The calibration function sets the calibration value at the end of running the full calibration sequence in `ADC_CAL` register. The user must configure the ADC correctly prior to starting the calibration process, and must allow the process to run the full calibration sequence by checking the status of `ADC_GC[CAL]` and `ADC_GS[CALF]` so that the generated calibration value can be loaded.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, averaging, and the high speed configuration according to the application's clock source availability and needs. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. The input channel, conversion mode, continuous function and compare function are all ignored during the calibration process.

To initiate calibration, the user sets the CAL bit and the calibration will automatically begin if the ADTRG bit = 0. If ADTRG = 1, the CAL bit will not get set and the calibration fail flag (CALF) will be set. While calibration is active, no ADC register can be written and no stop mode may be entered or the calibration routine will be aborted causing the CAL bit to clear and the CALF bit to set.

At the end of a calibration sequence the COCO[0] bit of the ADC\_HS register will be set. The ADC\_HCn[AIEN] bit can be used to allow an interrupt to occur at the end of a calibration sequence. If, at the end of calibration routine, the CALF bit is not set, the automatic calibration routine completed successfully.

To complete calibration, the user must follow the below procedure :

- Configure ADC\_CFG with actual operating values for maximum accuracy.
- Configure the ADC\_GC values along with CAL bit
- Check the status of CALF bit in ADC\_GS and the CAL bit in ADC\_GC
- When CAL bit becomes '0' then check the CALF status and COCO[0] bit status

When complete the user may reconfigure and use the ADC as desired.

A second calibration may also be performed if desired by clearing and again setting the CAL bit

Overall the calibration routine may take as many as 14000 ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen.

### 8.2.3.6 User Defined Offset Function

The ADC Offset Correction Register (ADC\_OFS) contains the user configured offset value. This register is 13 bit wide. The value in MSB (13th bit) is the operation bit, if this bit is '0' then the value in rest 12 bit is added with the converted result value to generate final result to be loaded into ADC\_Rn and if this bit is '1' then this field is subtracted from converted value to generate final Result (ADC\_Rn). If the Final result is above the maximum or below the minimum result value, it is forced to the appropriate limit for the current mode of operation. Forced to 0x0FFF if over and 0x0000 if lower for 12 bit mode.

The offset value has no effect during calibration on the final result.

The formatting of the ADC Offset Register is different from the Data Result Registers (ADC\_Rn) to preserve the resolution of the value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8b single-ended mode, the bits OFS[11:4] are subtracted from D[7:0] when bit OFS[12] (sign bit) is '1' ; indicates subtraction and bits OFS[4:0] are ignored. For 12b single-

ended mode, bits OFS[11:0] are directly subtracted from the conversion result data CDATA[11:0] when OFS[12] (sign bit) is '1'. The similar is the addition operation when OFS[12](sign bit) is 0.

ADC\_OFS is manually set according to user requirements once the self calibration sequence is done (CAL is cleared). The user have to write ADC\_OFS with desired value.

### NOTE

There is an effective limit to the values of Offset that can be set by the user. If the magnitude of the offset is too great the results of the conversions will cap off at the limits.

The offset function may be employed by the user to remove application offsets or DC bias values. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value.

For applications which may change the offset repeatedly during operation, it is recommended to store the initial offset value in flash so that it can be recovered and added to any user offset adjustment value and the sum stored in the ADC\_OFS registers.

### 8.2.3.7 Temperature Sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs. This channel can be selected through configuring the ADCH $n$  bits of any ADC\_HC $n$  register. Any trigger on this will give a temperature value converted for further processings.

See [Chip Configuration](#) for details on the actual channel number(s) and formula to calculate the temperature.

### 8.2.3.8 MCU Wait Mode Operation

Wait mode is a **lower power-consumption standby mode** from which **recovery is fast** because **the clock sources remain active**. If a conversion is in progress when the MCU enters wait mode, it continues until completion. Conversions can be initiated while the MCU is in wait mode if continuous conversions are enabled.

The bus clock, bus clock divided by two, and ADACK are available as conversion clock sources while in wait mode.

A conversion complete event sets the COCON and generates an ADC interrupt to wake the MCU from wait mode.

If the compare and hardware averaging functions are disabled, a conversion complete event sets the COCON and generates an ADC interrupt to wake the MCU from wait mode if the respective ADC interrupt is enabled (ADC\_HCN[AIEN]=1).

If the hardware averaging function is enabled the COCON will set (and generate an interrupt if enabled) when the selected number of conversions are complete.

If the compare function is enabled the COCON will set (and generate an interrupt if enabled) only if the compare conditions are met.

If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from wait mode.

### **8.2.3.9 MCU Stop Mode Operation**

Stop mode is a low power-consumption standby mode during which most or all clock sources on the MCU are disabled. Stop mode is entered when stop indication comes from the MCU.

#### **8.2.3.9.1 Stop Mode With ADACK Disabled**

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its idle state. The contents of the ADC registers, including ADC\_Rn are unaffected by stop mode. After exiting from stop mode, a software trigger is required to resume conversions.

#### **8.2.3.9.2 Stop Mode With ADACK Enabled**

If ADACK is selected as the conversion clock, the ADC continues operation during stop mode. For guaranteed ADC operation, the MCU's voltage regulator must remain active during stop mode.

If a conversion is in progress when the MCU enters stop mode, it continues until completion. Conversions can be initiated while the MCU is in stop mode if continuous conversions are enabled.

A conversion complete event sets the COCON and generates an ADC interrupt to wake the MCU from stop mode :

#### **Note**

The ADC module can wake the system from low-power stop and cause the MCU to begin consuming run-level currents without generating a system level interrupt. To prevent this

scenario, software should ensure the conversion result data transfer blocking mechanism (discussed in [Completing Conversions](#)) is cleared when entering stop and continuing ADC conversions.

## 8.2.4 Initialization Information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. User can configure the module for 8, 10, 12 bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options.

### 8.2.4.1 ADC Module Initialization Example

This section describes the initialization sequence along with pseudo-code.

#### 8.2.4.1.1 Initialization Sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is as follows:

- Calibrate the ADC by following the calibration instructions in [Calibration Function](#)
- Update the configuration register (ADC\_CFG) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
- Update General control register (ADC\_GC) to select whether conversions will be continuous or completed only once (ADCO) and to select whether to perform hardware averaging, etc.
- Update Trigger control register (ADC\_HCn) to select the conversion trigger and compare function options, if enabled.

#### 8.2.4.1.2 Pseudo-Code Example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

**ADC\_CFG**

## Analog-to-Digital Converter (ADC)

Bit 7	ADLPC	1	Configures for low power (lowers maximum clock speed).
Bit 6:5	ADIV	00	Sets the ADCK to the input clock $\div$ 1.
Bit 4	ADLSMP	1	Configures for long sample time.
Bit 3:2	MODE	10	Sets mode at 10-bit conversions.
Bit 1:0	ADICLK	00	Selects bus clock as input clock source.

## ADC\_GC

Bit 7	CAL	0	Flag indicates if a conversion is in progress.
Bit 6	ADCO	0	Software trigger selected.
Bit 5	AVGE	0	Compare function disabled.
Bit 4	ACFE	0	Compare function disabled.
Bit 3	ACFGT	0	Not used in this example.
Bit 2	ACREN	0	Not used in this example.
Bit 1	DMAEN	0	Not used in this example.
Bit 0	ADACKEN	0	Not used in this example.

## ADC\_HC0

Bit 7	AIEN	1	Conversion complete interrupt enabled.
Bit 4:0	ADCH	00001	Input channel 1 selected as ADC input channel.

## ADC\_R0

Holds results of conversion. Read high byte (ADCRHA) before low byte (ADCRLA) so that conversion data cannot be overwritten with data from the next conversion.

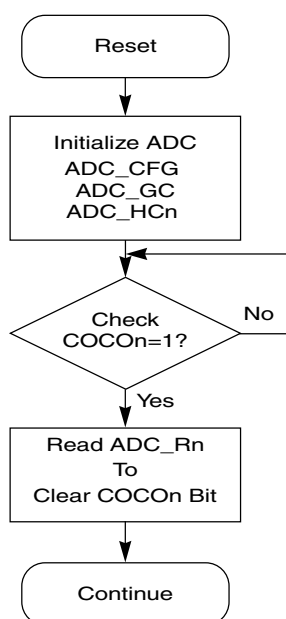

## ADC\_CV

Holds compare values when compare function enabled.

## ADC\_PCTL

AD1 pin I/O control disabled. All other AD pins remain general purpose I/O pins.

**Figure 8-6. Initialization Flowchart for Example**

## 8.2.5 Application Information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

### 8.2.5.1 Sources of Error

Several sources of error exist for A/D conversions. These are discussed in the following sections.

#### 8.2.5.1.1 Sampling Error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Given the maximum input resistance of approximately 7k $\Omega$  and input capacitance of approximately 1.3 pF, sampling to within 1/4LSB (at 12-bit resolution) can be achieved within the nominal sample window (6 cycles @ 40 MHz maximum ADCK frequency) provided the resistance of the external analog source ( $R_{AS}$ ) is kept below 4 k $\Omega$ .

Higher source resistances or higher-accuracy sampling is possible by setting ADLSMP and changing the ADSTS bits (to increase the sample window) or decreasing ADCK frequency to increase sample time.

### 8.2.5.1.2 Pin Leakage Error

Leakage on the I/O pins can cause conversion error if the external analog source resistance ( $R_{AS}$ ) is high. If this error cannot be tolerated by the application, keep  $R_{AS}$  lower than  $1 / (2^N * I_{LEAK})$  for less than 1/4LSB leakage error ( $N = 8$  in 8-bit, 10 in 10-bit or 12 in 12-bit mode).

### 8.2.5.1.3 Noise-Induced Errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1  $\mu$ F low-ESR capacitor from  $V_{REFH}$  to  $V_{REFL}$ .
- There is a 0.1  $\mu$ F low-ESR capacitor from to .
- If inductive isolation is used from the primary supply, an additional 1  $\mu$ F capacitor is placed from to .
- Operate the MCU in wait or stop mode immediately after initiating (software triggered conversions) the ADC conversion.
  - For software triggered conversions, immediately follow the write to ADCSC1 with a wait instruction or stop instruction.
  - For stop mode operation, select ADACK as the clock source. Operation in stop reduces  $V_{DD}$  noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive  $V_{DD}$  noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in wait or stop or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:

- Place a 0.01  $\mu$ F capacitor (CAS) on the selected input channel to  $V_{REFL}$  or  $V_{SS}$  (this improves noise issues, but affects the sample rate based on the external analog source resistance).

- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock (ADACK) and averaging. Noise that is synchronous to ADCK cannot be averaged out.

#### 8.2.5.1.4 Code Width and Quantization Error

##### Note

This will remain the same as long as the result is rounded for 8 and 10-bit modes. If the result is truncated in 8/10b modes then they will match 12b mode where the quantization error is -1 to 0.

The ADC quantizes the ideal straight-line transfer function into 4096 steps (in 12-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 8, 10 or 12), defined as 1LSB, is:

$$1\text{lsb} = (V_{\text{REFH}} - V_{\text{REFL}}) / 2^N$$

There is an inherent quantization error due to the digitization of the result. For 8-bit or 10-bit conversions the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be  $\pm 1/2$  lsb in 8- or 10-bit mode. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 lsb and the code width of the last (0xFF or 0x3FF) is 1.5 lsb.

For 12-bit conversions the code transitions only after the full code width is present, so the quantization error is -1 lsb to 0 lsb and the code width of each step is 1 lsb.

#### 8.2.5.1.5 Linearity Errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system should be aware of them because they affect overall accuracy. These errors are:

- Zero-scale error ( $E_{ZS}$ ) (sometimes called offset) — This error is defined as the difference between the actual code width of the first conversion and the ideal code width (1/2 lsb in 8-bit or 10-bit modes and 1 lsb in 12-bit mode). If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 lsb) is used.
- Full-scale error ( $E_{FS}$ ) — This error is defined as the difference between the actual code width of the last conversion and the ideal code width (1.5 lsb in 8-bit or 10-bit modes and 1LSB in 12-bit mode). If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1LSB) is used.
- Differential non-linearity (DNL) — This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL) — This error is defined as the highest-value the (absolute value of the) running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE) — This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

#### 8.2.5.1.6 Code Jitter, Non-Monotonicity, and Missing Codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes.

Code jitter is when, at certain points, a given input voltage converts to one of two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code (and vice-versa). However, even small amounts of system noise can cause the converter to be indeterminate (between two codes) for a range of input voltages around the transition voltage. This range is normally around  $\pm 1/2$  lsb in 8-bit or 10-bit mode, or around 2 lsb in 12-bit mode, and increases with noise.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally the techniques discussed in [Noise-Induced Errors](#) reduces this error.

Non-monotonicity is defined as when, except for code jitter, the converter converts to a lower code for a higher input voltage. Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

## 8.2.6 Memory map and register definition

The ADC-Digital contains 32-bit, word aligned, byte enables registers; byte or half word access are not supported. All configuration registers are accessible via 32-bit access bus Interface. Write access to reserved locations have no impact while read access to reserved locations always return 0.

### NOTE

No protection or indication mechanism is available (for example, 32-bit access starting with address offset value 0x01 or 0x02 or 0x03). The ADC does not check for correctness of the programmed values in the registers and the programmer must ensure that correct values are being written.

## 8.2.6.1 Control register (ADCx\_HC0)

ADC\_HC0 is used to control software triggers. Writing ADC\_HC0 while ADC\_HC0 is actively controlling a conversion aborts the current conversion. In software trigger mode (ADTRG=0), writes to ADC\_HC0 subsequently initiate a new conversion (if the ADCH bits are equal to a value other than all 1s).

11100-11110	Reserved.																
11111	Conversion Disabled.																

8.2.6.2 Status register (ADCx\_HS)

Bit 0 is used for software trigger modes of operation.

Address: Base address + 8h offset

ADCx\_HS field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 COCO0	Conversion Complete Flag  The COCOOn flag is a read-only bit that is set each time a conversion is completed when the compare function is disabled (ADC_GC[ACFE]=0) and the hardware average function is disabled (ADC_GC[AVGE]=0). When the compare function is enabled (ADC_GC[ACFE]=1), the COCOOn flag is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled (ADC_GC[AVGE]=1), the COCOOn flag is set upon completion of the selected number of conversions (determined by the ADC_CFG[AVGS] field). The COCO0 flag will also set at the completion of a Calibration and Test sequence. A COCOOn bit is cleared when the respective ADC_HCn is written or when the respective ADC_Rn is read.

### 8.2.6.3 Data result register (ADCx\_R0)

Contains the result of an ADC conversion of the channel selected by the respective channel control register (ADC\_HC0). Unused bits in the ADC\_Rn register are cleared in unsigned right justified modes. For example when configured for 10-bit single-ended mode, D[31:10] are cleared. The table below describes the behavior of the data result registers in the different modes of operation.

**Table 8-11. Data Result Register Description**

Conversion Mode	Data Result Register bits																Format
	D31	D30	...	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	
12b single-ended	0	0	0	0	D	D	D	D	D	D	D	D	D	D	D	D	unsigned right justified
10b single-ended	0	0	0	0	0	0	D	D	D	D	D	D	D	D	D	D	unsigned right justified
8b single-ended	0	0	0	0	0	0	0	0	D	D	D	D	D	D	D	D	unsigned right justified

Address: Base address + Ch offset

**ADCx\_CFG field descriptions**

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.
16 OVWREN	<p>Data Overwrite Enable</p> <p>Controls the overwriting of the next converted Data onto the existing (previous) unread data into the Data result register.</p> <p>1 Enable the overwriting. 0 Disable the overwriting. Existing Data in Data result register will not be overwritten by subsequent converted data.</p>
15–14 AVGS	<p>Hardware Average select</p> <p>Determines how many ADC conversions will be averaged to create the ADC average result. This functionality is activated when ADC_GC[AVGE] = 1.</p> <p>00 4 samples averaged 01 8 samples averaged 10 16 samples averaged 11 32 samples averaged</p>
13 ADTRG	<p>Conversion Trigger Select</p> <p>Only software trigger is supported. When software trigger is selected, a conversion is initiated following a write to ADC_HC0.</p> <p>0 Software trigger selected 1 Reserved</p>

*Table continues on the next page...*

## ADCx\_CFG field descriptions (continued)

Field	Description
12–11 REFSEL	<p>Voltage Reference Selection</p> <p>Selects the voltage reference source used for conversions. For the chip-specific implementation details of this module's instances, see the chip configuration information.</p> <p><b>NOTE:</b> VALTH and VBGH are connected to the same PMC_dig output (VALTH = VBGH).</p> <p>00 Selects VREFH/VREFL as reference voltage.  01 Selects VALTH/VALTL as reference voltage.  10 Selects VBGH/VBGL as reference voltage.  11 Reserved</p>
10 ADHSC	<p>High Speed Configuration</p> <p>This bit configures the ADC for high speed operation. The internal ADC clock is higher than normal.</p> <p>0 Normal conversion selected.  1 High speed conversion selected.</p>
9–8 ADSTS	<p>Defines the sample time duration. This has two modes, short and long. When long sample time is selected (ADLSMP=1) this works for long sample time otherwise this works for short sample. This allows higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required.</p> <p>00 Sample period (ADC clocks) = 2 if ADLSMP=0b  Sample period (ADC clocks) = 12 if ADLSMP=1b  01 Sample period (ADC clocks) = 4 if ADLSMP=0b  Sample period (ADC clocks) = 16 if ADLSMP=1b  10 Sample period (ADC clocks) = 6 if ADLSMP=0b  Sample period (ADC clocks) = 20 if ADLSMP=1b  11 Sample period (ADC clocks) = 8 if ADLSMP=0b  Sample period (ADC clocks) = 24 if ADLSMP=1b</p>
7 ADLPC	<p>Low-Power Configuration</p> <p>Puts the ADC hard block into low power mode and reduces the comparator enable period by controlling its timing in the SAR controller block towards the analog hard block.</p> <p>The signal indicating low power mode to the Analog block is asserted when this bit is set.</p> <p>0 ADC hard block not in low power mode.  1 ADC hard block in low power mode.</p>
6–5 ADIV	<p>Clock Divide Select</p> <p>Selects the divide ratio used by the ADC to generate the internal clock ADCK.</p> <p>00 Input clock  01 Input clock / 2  10 Input clock / 4  11 Input clock / 8</p>
4 ADLSMP	<p>Long Sample Time Configuration</p>

*Table continues on the next page...*

**ADCx\_CFG field descriptions (continued)**

Field	Description
	<p>Selects between different sample times based on the ADC_CFG[ADSTS] field. This bit adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. If high conversion rates are not required, longer sample times can also be used to lower overall power consumption when continuous conversions are enabled. When ADLSMP=1, the Long Sample Time mode is selected and the time is defined by ADSTS[1:0] of the ADC_CFG register.</p> <p>0 Short sample mode. 1 Long sample mode.</p>
3–2 MODE	<p>Conversion Mode Selection</p> <p>Used to set the ADC resolution mode.</p> <p>00 8-bit conversion 01 10-bit conversion 10 12-bit conversion 11 Reserved</p>
ADICLK	<p>Input Clock Select</p> <p>Selects the input clock source to generate the internal clock ADCK.</p> <p>00 IPG clock 01 IPG clock divided by 2 10 Reserved 11 Asynchronous clock (ADACK)</p>

**8.2.6.5 General control register (ADCx\_GC)**

Controls the calibration, continuous convert, hardware averaging functions, conversion active, compare function and voltage reference select of the ADC module.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ADCx\_GC field descriptions**

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
7 CAL	Calibration  CAL begins the calibration sequence when set. This bit stays set while the calibration is in progress and is cleared when the calibration sequence is complete. The ADC_GS[CALF] bit must be checked to determine the result of the calibration sequence. Once started, the calibration routine cannot be interrupted by writes to the ADC registers or the results will be invalid and the ADC_GS[CALF] bit will set. Setting the CAL bit will abort any current conversion.
6 ADCO	Continuous Conversion Enable  Enables continuous conversions.  0 One conversion or one set of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion. 1 Continuous conversions or sets of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion.
5 AVGE	Hardware average enable  Enables the hardware average function of the ADC.  0 Hardware average function disabled 1 Hardware average function enabled
4 ACFE	Compare Function Enable  Enables the compare function.  0 Compare function disabled 1 Compare function enabled
3 ACFGT	Compare Function Greater Than Enable  Configures the compare function to check the conversion result relative to the compare value register (ADC_CV) based upon the value of ACREN (bit 2 in ADC_GC register). The ACFE bit must be set for ACFGT to have any effect.  0 Configures "Less Than Threshold, Outside Range Not Inclusive and Inside Range Not Inclusive" functionality based on the values placed in the ADC_CV register. 1 Configures "Greater Than Or Equal To Threshold, Outside Range Inclusive and Inside Range Inclusive" functionality based on the values placed in the ADC_CV registers.
2 ACREN	Compare Function Range Enable  Configures the compare function to check the conversion result of the input being monitored is either between or outside the range formed by the compare values in register (ADC_CV) determined by the value of ACFGT. The ACFE bit must be set for ACFGT to have any effect.  0 Range function disabled. Only the compare value 1 of ADC_CV register (CV1) is compared. 1 Range function enabled. Both compare values of ADC_CV registers (CV1 and CV2) are compared.
1 DMAEN	DMA Enable  Enables the DMA logic.

*Table continues on the next page...*

**ADCx\_GC field descriptions (continued)**

Field	Description
	0 DMA disabled (default) 1 DMA enabled
0 ADACKEN	Asynchronous clock output enable  Enables the ADC's asynchronous clock source and the clock source output regardless of the conversion and input clock select (ADC_CFG[ADICLK]) settings of the ADC. Based on MCU configuration, the asynchronous clock may be used by other modules (see module introduction section). Setting this bit allows the clock to be used even while the ADC is idle or operating from a different clock source. Also, latency of initiating a single or first-continuous conversion with the asynchronous clock selected is reduced since the ADACK clock is already operational.  0 Asynchronous clock output disabled; Asynchronous clock only enabled if selected by ADICLK and a conversion is active. 1 Asynchronous clock and clock output enabled regardless of the state of the ADC

**8.2.6.6 General status register (ADCx\_GS)**

Indicates the status of the asynchronous wakeup interrupt, calibration failure and conversion active functions.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

R	0												AWKST		CALF	ADACT
W													w1c	w1c		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ADCx\_GS field descriptions**

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2 AWKST	Asynchronous wakeup interrupt status  Holds the status of asynchronous interrupt status that occurred during stop mode. This bit is set when ipg_stop is deasserted and ipg_clk has started. It is cleared by writing '1' to it. Clearing this bit also deasserts the Asynchronous interrupt to CPU.  1 Asynchronous wake up interrupt occurred in stop mode. 0 No asynchronous interrupt.
1 CALF	Calibration Failed Flag  Displays the result of the calibration sequence. The calibration sequence will fail if any ADC register is written, or any stop mode is entered before the calibration sequence completes. The CALF bit is cleared by writing a 1 to it.  0 Calibration completed normally. 1 Calibration failed. ADC accuracy specifications are not guaranteed.
0 ADACT	Conversion Active  Indicates that a conversion or hardware averaging is in progress. ADACT is set when a conversion is initiated and cleared when a conversion is completed or aborted.  0 Conversion not in progress. 1 Conversion in progress.

**8.2.6.7 Compare value register (ADCx\_CV)**

Contains compare values used to compare with the conversion result when the compare function is enabled (ADC\_GC[ACFE]=1). The compare values are right justified.

Therefore, the compare function only uses the compare value register bits that are related to the ADC mode of operation. (e.g. in 8 bit mode, CV1 = ADC\_CV[7:0] and CV2 = ADC\_CV[23:16], similarly in 10 bit mode, CV1 = ADC\_CV[9:0] and CV2 = ADC\_CV[25:16] etc.) The compare value 2 in this register is utilized only when the compare range function is enabled (ADC\_GC[ACREN]=1).

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ADCx\_CV field descriptions**

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–16 CV2	Compare Value 2  Contains a compare value used to compare with the conversion result when the compare function and compare range function are enabled (ADC_GC[ACFE]=1, ADC_GC[ACREN]=1).
15–12 Reserved	This read-only field is reserved and always has the value 0.
CV1	Compare Value 1  Contains a compare value used to compare with the conversion result when the compare function is enabled (ADC_GC[ACFE]=1).

**8.2.6.8 Offset correction value register (ADCx\_OFS)**

Contains the user-defined offset error correction value. This register is 13 bits wide. The value in the most significant bit (13th bit) is the operation bit. If this bit is ‘0’ then the value in the other 12 bits is added with the converted result value to generate final result to be loaded into ADC\_Rn; if this bit is ‘1’ then this field is subtracted from converted value to generate final result (ADC\_Rn).

Address: Base address + 24h offset

**ADCx\_OFS field descriptions**

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 SIGN	Sign bit  0 The offset value is added with the raw result 1 The offset value is subtracted from the raw converted value
OFS	Offset value  User configurable offset value.

### 8.2.6.9 Calibration value register (ADCx\_CAL)

Contains calibration information that is generated by the calibration function. This register contains a calibration value of four bits(CAL[3:0]); this is automatically set once the self calibration sequence is done (ADC\_SC[CAL] bit is cleared). If this register is written to by the user after calibration, the linearity error specifications may not be met.

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 8.3 Miscellaneous Control Module (MCM)

### 8.3.1 Introduction

The Miscellaneous Control Module (MCM) provides miscellaneous control functions and contains Cortex-M4 local memory descriptors.

#### 8.3.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Floating Point Exception monitor and interrupt control
- Local memory descriptors (ITCM, D0TCM, D1TCM, ICACHE, and DCACHE)

### 8.3.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

**MCM memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
E008_0008	Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)	16	R	00FFh	<a href="#">8.3.2.1/1050</a>
E008_000A	Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)	16	R	00FFh	<a href="#">8.3.2.2/1050</a>
E008_000C	Control Register (MCM_CR)	32	R/W	0000_0000h	<a href="#">8.3.2.3/1051</a>
E008_0010	Interrupt Status and Control Register (MCM_ISCR)	32	R	0002_0000h	<a href="#">8.3.2.4/1052</a>
E008_0020	Fault address register (MCM_FADR)	32	R	Undefined	<a href="#">8.3.2.5/1055</a>
E008_0024	Fault attributes register (MCM_FATR)	32	R	Undefined	<a href="#">8.3.2.6/1056</a>
E008_0028	Fault data register (MCM_FDR)	32	R	Undefined	<a href="#">8.3.2.7/1058</a>

8.3.2.1 Crossbar Switch (AXBS) Slave Configuration (MCM\_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device’s crossbar switch.

Address: E008\_0000h base + 8h offset = E008\_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ASC							
Write																
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

MCM\_PLASC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ASC	Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port.  0    A bus slave connection to AXBS input port <i>n</i> is absent 1    A bus slave connection to AXBS input port <i>n</i> is present

8.3.2.2 Crossbar Switch (AXBS) Master Configuration (MCM\_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008\_0000h base + Ah offset = E008\_000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reserved	This field is reserved.

**8.3.2.4 Interrupt Status and Control Register (MCM\_ISCR)**

The MCM\_ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, bus errors associated with the core's cache write buffer, and events associated with the debug ETB module. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

Address: E008\_0000h base + 10h offset = E008\_0010h

24 FIOCE	FPU invalid operation interrupt enable  0 Disable interrupt 1 Enable interrupt
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 CWBEE	Cache write buffer error enable  Enables the generation of an interrupt in response to a bus error termination reported on a system bus transfer initiated from the cache's write buffer.  0 Disable error interrupt 1 Enable error interrupt
19–16 Reserved	This field is reserved.
15 FIDC	FPU input denormal interrupt status  This read-only bit is a copy of the core's FPSCR[IDC] bit and signals input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit.  0 No interrupt 1 Interrupt occurred
14–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FIXC	FPU inexact interrupt status  This read-only bit is a copy of the core's FPSCR[IXC] bit and signals an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit.  0 No interrupt 1 Interrupt occurred
11 FUFC	FPU underflow interrupt status  This read-only bit is a copy of the core's FPSCR[UFC] bit and signals an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit.  0 No interrupt 1 Interrupt occurred
10 FOFC	FPU overflow interrupt status  This read-only bit is a copy of the core's FPSCR[OFC] bit and signals an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit.  0 No interrupt 1 Interrupt occurred
9 FDZC	FPU divide-by-zero interrupt status

*Table continues on the next page...*

**MCM\_ISCR field descriptions (continued)**

Field	Description
	<p>This read-only bit is a copy of the core's FPSCR[DZC] bit and signals a divide by zero has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[DZC] bit.</p> <p>0 No interrupt 1 Interrupt occurred</p>
8 FIOC	<p>FPU invalid operation interrupt status</p> <p>This read-only bit is a copy of the core's FPSCR[IOC] bit and signals an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit.</p> <p>0 No interrupt 1 Interrupt occurred</p>
7–5 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
4 CWBER	<p>Cache write buffer error status</p> <p>Signals a data transfer from the core's cache write buffer was terminated with a bus error. This bit only sets when the corresponding enable bit (CWBE) is set. The corresponding core fault address, attributes and write data are typically retrieved from the FADR, FATR, and FDR registers during the interrupt service routine before clearing the CWBER flag.</p> <p>0 No error 1 Error occurred</p>
3 DHREQ	<p>Debug Halt Request Indicator</p> <p>Indicates that a debug halt request is initiated due to a ETB counter expiration, ETBCC[2:0] = 3b111 &amp; ETBCV[10:0] = 11h0. This bit is cleared when the counter is disabled or when the ETB counter is reloaded.</p> <p>0 No debug halt request 1 Debug halt request initiated</p>
Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>

**8.3.2.5 Fault address register (MCM\_FADR)**

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM\_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM\_ISCR[CWBER] indicator cleared, the MCM\_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM\_ISCR[CWBER]. Attempted writes have no effect.

Miscellaneous Control Module (MCM)

Address: E008\_0000h base + 20h offset = E008\_0020h

- \* Notes:
- x = Undefined at reset.

MCM\_FADR field descriptions

Field	Description
ADDRESS	Fault address

8.3.2.6 Fault attributes register (MCM\_FATR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting attributes are captured in the MCM\_FATR register.

The bits in this register are set by hardware and signaled by the assertion of MCM\_ISCR[CWBER]. Attempted writes have no effect.

Address: E008\_0000h base + 24h offset = E008\_0024h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### MCM\_FATR field descriptions

Field	Description
31 BEOVR	<p>Bus error overrun</p> <p>Indicates if another cache write buffer bus error is detected before system software has retrieved all the error information from the original event, this overrun flag is set. The window of time is defined from the detection of the original cache write buffer error termination until the MCM_ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the CWBER bit.</p> <p>0 No bus error overrun 1 Bus error overrun occurred. The FADR and FDR registers and the other FATR bits are not updated to reflect this new bus error.</p>
30–12 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
11–8 BEMN	<p>Bus error master number</p> <p>Crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.</p>
7 BEWT	<p>Bus error write</p> <p>Indicates the type of system bus access when the error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, signaling a write operation.</p> <p>0 Read access 1 Write access</p>
6 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
5–4 BESZ	<p>Bus error size</p> <p>Indicates the size of the cache write buffer access when the error was detected.</p> <p>00 8-bit access 01 16-bit access</p>

Table continues on the next page...

**MCM\_FATR field descriptions (continued)**

Field	Description
	10 32-bit access 11 Reserved
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BEMD	Bus error privilege level  Indicates the privilege level of the cache write buffer access when the error was detected.  0 User mode 1 Supervisor/privileged mode
0 BEDA	Bus error access type  Indicates the type of cache write buffer access when the error was detected. This attribute is always a logical one signaling a data reference.  0 Instruction 1 Data

**8.3.2.7 Fault data register (MCM\_FDR)**

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM\_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM\_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes have no effect.

Address: E008\_0000h base + 28h offset = E008\_0028h

### 8.3.3 Functional description

This section describes the functional description of MCM module.

#### 8.3.3.1 Interrupts

The MCM's interrupt is generated if any of the following is true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC)
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC)
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC)
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC)
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC)
- FPU invalid operation interrupt is enabled (FDZCE) and an invalid occurs (FDZC)

##### 8.3.3.1.1 Determining source of the interrupt

To determine the exact source of the interrupt qualify the interrupt status flags with the corresponding interrupt enable bits.

1. From MCM\_ISCR[31:16] && MCM\_ISCR[15:0]
2. Search the result for asserted flags, which indicate the exact interrupt sources

## 8.4 Miscellaneous System Control Module (MSCM)

### 8.4.1 Overview

The Miscellaneous System Control Module (MSCM) contains Access Control and TrustZone Security hardware, CPU Configuration registers and Interrupt Router control.

## 8.4.2 Chip Configuration and Boot

The device configuration is defined by e-fuse bits, supported memory sizes and packing options. Collectively, these configuration bits define an RCON (reset configuration) value, input to the platform as a signal named num\_cores[1:0]. The supported processor configurations are detailed in the table below.

**Table 8-12. Processor Core Configurations**

num_cores[1:0]	Core Configuration
0	Cortex-A5 core only
1	Cortex-M4 core only
2	Dual core with Cortex-A5 as CP0 (boot core), Cortex-M4 as CP1
3	Dual core with Cortex-M4 as CP0 (boot core), Cortex-A5 as CP1

By default, both cores are intended to boot from a ROM based at system address 0 although the specifics of exception processing, including reset, differ between the processors. For the device, the exception vector table for the Cortex-A5 core is based at system address 0 while the first two words of the exception vector table for the Cortex-M4 are remapped (by the platform hardware) to system addresses 0x0001\_6000 and 0x0001\_6004; these two vectors correspond to the initial stack pointer value and the initial program counter respectively. The platform hardware remaps the first two non-debug code fetches after reset is negated from the Cortex-M4 core as follows:

- CodeBus address 0x0000\_0000 is translated to 0x0001\_6000 (initial stack pointer)
- CodeBus address 0x0000\_0004 is translated to 0x0001\_6004 (initial program counter)

By convention, the remapping of the CM4 reset vectors to these addresses implies the exception vector table for this core is based at system address 0x0001\_6000.

Once the cores have fetched the needed reset vector(s), it is expected they read core and system configuration information from a globally-accessible slave peripheral that properly converts the num\_cores[1:0] information into more appropriate values. More specifically, the cores access configuration information from a common set of peripheral addresses and the chip configuration logic properly evaluates based on the requesting processor and returns the appropriate value for the given processor including core identification including presence or absence of optional hardware capabilities, local memory sizes, logical processor number for multi-core configurations, bus master number, etc.

As an example, there is a single 32-bit read-only location for the core identification: a 32-bit read from this location returns a four character ASCII string: 0x43\_41\_35\_01 (“CA5”) or 0x43\_4D\_34\_01 (“CM4”) depending on the requesting master.

Given this approach, the processors can efficiently execute from a single Boot ROM image and pass control to the appropriate sections in the system startup code.

The programming model associated with the core configuration information is included as part of the Miscellaneous System Control Module (MSCM). It specifically includes multiple views of the processor configuration; one that is available generically to the cores and others that are available to any bus masters in the system.

### 8.4.3 MSCM Memory Map/Register Definition

#### 8.4.3.1 CPU Configuration Memory Map and Registers

The CPU configuration portion of the MSCM module provides a set of memory-mapped read-only addresses defining the processor setup. This portion of the MSCM programming model can only be accessed with privileged mode 32-bit read references; any other access type or size are terminated with an error. If the processor is logically not included in the chip configuration, reads of its configuration registers return zeroes.

The CPU Configuration registers are organized based on the logical processor number (not any type of physical port number) and partitioned into three equal sections:

- Offset addresses 0x000 - 0x01F define the generic processor "x" configuration. This region is only accessible to the processor cores; reads by non-core bus masters are treated as RAZ (read as zero) accesses.
- Offset addresses 0x020-0x03F define the configuration information for processor 0 (CP0). This region is accessible to any bus master.
- Offset addresses 0x040 - 0x05F define the configuration information for processor 1 (CP1). This region is accessible to any bus master. For uniprocessor chip configurations, reads of this section are treated as RAZ (read as zero).

Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

### 8.4.3.2 MSCM Interrupt Router Memory Map and Register Descriptions

The interrupt router portion of the MSCM module provides a set of memory-mapped registers defining the interrupt routing and directed processor interrupts. This portion of the MSCM programming model can only be accessed with privileged mode references from the processor cores or the debugger; any user mode reference is terminated with an error and all privileged accesses from non-core (and non-debug) masters are treated as RAZ/WI (read as zero, write ignored) references. Additionally, the access size must match the register size (including the reserved spaces) else an error is generated. On attempted read accesses that are error terminated, the returned read data is undefined; on attempted write accesses that are error terminated, the operation is aborted and the destination register unaffected.

the MSCM memory map is organized based on the logical processor number (not any type of physical number) and partitioned into two sections:

- Offset addresses 0x800 - 0x820 define the directed CPU interrupt requests
- Offset addresses 0x880 - 0x95E define the interrupt router control for the system

### 8.4.3.3 MSCM Access Control and TrustZone Security (ACTZS) Memory Map and Registers

The memory-mapped registers that supports the access control and TrustZone security functions are distributed across multiple modules. In particular, the CSU and all instances of the TZASC controllers are involved along with a portion of the MSCM module. The pertinent MSCM programming model can only be accessed with privileged mode 32-bit references; any other access type or size are terminated with an error.

The ACTZS configuration portion of the MSCM programming model map is partitioned into following two sections:

- Offset addresses 0xC00 - 0xC18 define basic system control and configuration for all the TZASC modules and the CSU.
- Offset addresses 0xD00 - 0xDDC contain captured access address and attribute information for CSL-detected violations. For the logic evaluating the CSLn security levels for all the slave peripheral modules, the errors are logically combined into one set of reporting registers for each PBRIDGE controller.

#### NOTE

Each TZASC module includes local registers within its programming model to record comparable information on TrustZone security violations.

Attempted writes to read-only registers are simply ignored (RO/WI). Privileged mode accesses of the reserved locations at offset addresses 0xC08 - 0xC0C and 0xC1C - 0xCFC are treated as RAZ/WI (read as zero, write ignored). Likewise, privileged mode accesses of the reserved locations at offset addresses 0xD04 + 16\*n (n = 0-13) and 0xDE0 - 0xFFC are treated as RAZ/WI (read as zero, write ignored). Attempted user mode accesses in the ACTZS section (offset addresses 0xC00 - 0xDFC) are terminated with an error as are any references with a size smaller than 32 bits.

8.4.3.4 Processor X Type Register (MSCM\_CPxTYPE)

The register provides a CPU-specific response indicating the personality of the core making the access. The 32 bit response includes 3 ASCII characters defining the CPU type (“CA5” or “CM4”) along with a byte defining the logical revision number. The logical revision number follows ARM’s rYpZ nomenclature.

Address: 4000\_1000h base + 0h offset = 4000\_1000h

- \* Notes:
- Personality field: See bit field description
  - rYpZ field: See bit field description

MSCM\_CPxTYPE field descriptions

Field	Description
31–8 Personality	Processor x Personality  This 24-bit read-only field defines the processor personality for CPx  if CPx = Cortex-A5, then Personality = 0x43_41_35 (“CA5”). if CPx = Cortex-M4, then Personality = 0x43_4D_34 (“CM4”).
rYpZ	Processor x Revision  This 8-bit read-only field defines the processor revision for CPx  if CPx = Cortex-A5, then rYpZ = 0x01 corresponding to the r0p1 core release. if CPx = Cortex-M4, then rYpZ = 0x01 corresponding to the r0p1 core release.

### 8.4.3.5 Processor X Number Register (MSCM\_CPxNUM)

The register provides a CPU-specific response indicating the logical processor number of the core making the access. In single processor configurations, the logical processor number is always zero; in dual core configurations, the boot (or primary) core is assigned number 0 while the secondary core is defined as number 1.

Address: 4000\_1000h base + 4h offset = 4000\_1004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0															CPN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*

\* Notes:

- CPN field: See bit field description

#### MSCM\_CPxNUM field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CPN	Processor x Number This zero-filled word defines the logical processor number for CPx If single core configuration, then CPN = 0 If dual core configuration and boot (primary) core, then CPN = 0 For secondary core, CPN = 1

### 8.4.3.6 Processor X Master Register (MSCM\_CPxMASTER)

The register provides a CPU-specific response indicating the physical bus master number the core making the access. The 32 bit response defines the physical master number for processor x.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

## Miscellaneous System Control Module (MSCM)

Address: 4000\_1000h base + 8h offset = 4000\_1008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

\* Notes:

- PPN field: See bit field description

### MSCM\_CPxMASTER field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PPN	Processor x Physical Port Number  This 5-bit read-only field defines the physical port number for CPx. The value is device specific. For the Cortex-A5 core in this device, PPN = 0x2 For the Cortex-M4 core in this device, PPN = 0x0

8.4.3.7 Processor X Count Register (MSCM\_CPxCOUNT)

The register provides a CPU-specific response indicating the total number of processor cores in the chip configuration. For this device, the count value is 0 or 1, depending on whether the configuration is a single (0) or dual (1) processor.

Address: 4000\_1000h base + Ch offset = 4000\_100Ch

- \* Notes:
- PCNT field: See bit field description

MSCM\_CPxCOUNT field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 PCNT	Processor Count This 1-bit read-only field defines the processor count for the chip configuration: If single core configuration, then PCNT = 0 If dual core configuration, then PCNT = 1

### 8.4.3.8 Processor X Configuration 0 Register (MSCM\_CPxCFG0)

The register provides a CPU-specific response detailing configuration information, in this case, information on the Level 1 caches (if present).

Address: 4000\_1000h base + 10h offset = 4000\_1010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**MSCM\_CP0NUM field descriptions**

Field	Description
31–1 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
0 CPN	<p>Processor x Number</p> <p>This zero-filled word defines the logical processor number for CPx</p> <p>If single core configuration, then CPN = 0</p> <p>If dual core configuration and boot (primary) core, then CPN = 0</p> <p>For secondary core, CPN = 1</p>

8.4.3.14 Processor 0 Master Register (MSCM\_CP0MASTER)

The register provides a CPU-specific response indicating the physical bus master number the core making the access. The 32 bit response defines the physical master number for processor x.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

Address: 4000\_1000h base + 28h offset = 4000\_1028h

- \* Notes:
- PPN field: See bit field description

MSCM\_CP0MASTER field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PPN	Processor x Physical Port Number  This 5-bit read-only field defines the physical port number for CPx. The value is device specific. For the Cortex-A5 core in this device, PPN = 0x2 For the Cortex-M4 core in this device, PPN = 0x0

8.4.3.15 Processor 0 Count Register (MSCM\_CP0COUNT)

The register provides a CPU-specific response indicating the total number of processor cores in the chip configuration. For this device, the count value is 0 or 1, depending on whether the configuration is a single (0) or dual (1) processor.

Address: 4000\_1000h base + 2Ch offset = 4000\_102Ch

- \* Notes:
- PCNT field: See bit field description

MSCM\_CP0COUNT field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 PCNT	Processor Count This 1-bit read-only field defines the processor count for the chip configuration: If single core configuration, then PCNT = 0 If dual core configuration, then PCNT = 1

### 8.4.3.16 Processor 0 Configuration 0 Register (MSCM\_CP0CFG)

The register provides a CPU-specific response detailing configuration information, in this case, information on the Level 1 caches (if present).

Address: 4000\_1000h base + 30h offset = 4000\_1030h

**8.4.3.28 Interrupt Router CP0 Interrupt Register (MSCM\_IRCP0IR)**

The MSCM\_IRCP0IR register provides an interrupt bit map where each bit defines the state of a unique CPU interrupt. CPU interrupts are asserted by the appropriate write to the MSCM\_IRCPGIR with the appropriate interrupt routing bit enabled see “Interrupt Router CPU Generate Interrupt Register”. A processor interrupt is cleared in an interrupt service routine by writing a “1” to the appropriate bit in the MSCM\_IRCP0IR register. Only the CA5, CM4 or debugger can clear its associated interrupt. Privileged accesses from non-core bus masters are treated as RAZ/WI and any attempted user mode reference is terminated with an error. Attempted accesses using a size different than a 32-bit word are also error terminated.

Address: 4000\_1000h base + 800h offset = 4000\_1800h

### 8.4.3.29 Interrupt Router CP1 Interrupt Register (MSCM\_IRCP1IR)

The MSCM\_IRCP1IR register provides an interrupt bit map where each bit defines the state of a unique CPU interrupt. CPU interrupts are asserted by the appropriate write to the MSCM\_IRCPGIR with the appropriate interrupt routing bit enabled; see “Interrupt Router CPU Generate Interrupt Register”. A processor interrupt is cleared in an interrupt service routine by writing a “1” to the appropriate bit in the MSCM\_IRCP1IR register. Only the CA5, CM4 or debugger can clear its associated interrupt. Privileged accesses from non-core bus masters are treated as RAZ/WI and any attempted user mode reference is terminated with an error. Attempted accesses using a size different than a 32-bit word are also error terminated.

This register’s functionality and format are equivalent to MSCM\_IRCP0IR except the directed interrupts are targeted at CP1.

Address: 4000\_1000h base + 804h offset = 4000\_1804h

### 8.4.3.30 Interrupt Router CPU Generate Interrupt Register (MSCM\_IRCPGIR)

The write-only MSCM\_IRCPGIR register provides the mechanism for processors to generate directed CPU interrupts. Processor writes to this register provide an indirect mechanism to assert the processor interrupts contained in the MSCM\_IRCPnIR registers. A directed CPU interrupt also requires that the appropriate routing enable is asserted. This register follows the format of the GIC's ICDSGIR (used for software generated interrupts). Privileged writes from non-core (and non-debug) bus masters are treated as WI and any attempted user mode or read reference is terminated with an error. Attempted accesses using a size different than a 32-bit word are also error terminated.

Address: 4000\_1000h base + 820h offset = 4000\_1820h

**8.4.3.31 Interrupt Router Shared Peripheral Routing Control Register n (MSCM\_IRSPRCn)**

The MSCM\_IRSPRCn register provides an array of halfword (16 bit) registers, where each register defines the routing control for the corresponding interrupt request. In this device, each interrupt request can be routed to neither (0), either (1, 2) or both (3) cores using the processor's logical number. If all the CPxEn bits are cleared, the interrupt request is disabled. Each routing control halfword can be locked by asserting the RO bit. Privileged accesses from non-core (and non-debug) bus masters are treated as RAZ/WI and any attempted user mode reference is terminated with an error. Attempted accesses using a size different than a 16-bit halfword are also error terminated.

Address: 4000\_1000h base + 880h offset + (2d × i), where i=0d to 111d

**MSCM\_IRSPRCn field descriptions**

Field	Description
15 RO	<p>Read-Only</p> <p>This register bit provides a mechanism to “lock” the routing of the corresponding interrupt request. Once asserted, attempted writes to the MSCM_IRSPRCn register are ignored until the next reset clears the flag.</p>

*Table continues on the next page...*

**MSCM\_IRSPRCn field descriptions (continued)**

Field	Description
	0 Writes to the MSCM_IRSPRCn are allowed 1 Writes to the MSCM_IRSPRCn are ignored
14–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 CP1En	Enable CP1 Interrupt  This register bit enables the routing of the corresponding interrupt request to CP1. This bit cannot be set in uniprocessor configurations.  0 Routing to CP1 for the corresponding interrupt request is disabled 1 Routing to CP1 for the corresponding interrupt request is enabled
0 CP0En	Enable CP0 Interrupt  This register bit enables the routing of the corresponding interrupt request to CP0.  0 Routing to CP0 for the corresponding interrupt request is disabled 1 Routing to CP0 for the corresponding interrupt request is enabled

**8.4.3.32 ACTZS TrustZone Enable Register (MSCM\_TZENR)**

The TrustZone Enable Register is a 32-bit register containing a bit map of enables for each TrustZone Address Space Controller in the device.

Given the AXI-TZASC functionality is complex and can add a cycle of latency to accesses being checked, this register provides the mechanism to completely bypass the module if it is disabled. The register also contains a global TZASC control signal indicating a secure boot process completed and certain registers within the TZASC modules are locked and cannot be altered.

In addition to the TZENR register bits, there is a single device fuse bit that provides a further level of qualification. This fuse signal is combined with the individual TZENi bits to form the fully qualified TZASC enable for each instance:

```
qualified_TZENi = ACTZS_TZENR[i] & tzenb_fuse
```

Where tzenb\_fuse serves as a global enable qualifier.

For the AHB-TZASC modules, the access checking is performed on-the-fly during the address phase bus cycle. If a given AHB-TZASC module is logically disabled, the internal logic is inhibited as if the action[reaction\_value] register field is cleared meaning neither bus error terminations nor security violation interrupts are generated.

All the programmable bits in the TZENR are “sticky”, that is, once set, they remain set until the next system reset clears all the bits.

**NOTE**

Software must idle the target address space before enabling or disabling a trust zone associated with that space. Otherwise this may cause logic errors on AXI transfers which are on the way at the time of the switching.

The TZENR also contains a lock bit (RO) that may be set to disable writes to the register, preserving the enabled/disabled state of the TZASC modules.

Address: 4000\_1000h base + C00h offset = 4000\_1C00h

**MSCM\_TZENR field descriptions**

Field	Description
31 RO	This bit provides a mechanism to “lock” the configuration state defined by ACTZS_TZENR. Once asserted, this bit remains set and attempted writes to the ACTZS_TZENR register are ignored until the next system reset clears the flag.  0 Writes to the ACTZS_TZENR are allowed 1 Writes to the ACTZS_TZENR are ignored
30–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 SBL	Secure Boot Lock  The state of this field is broadcast from MSCM to all the TZASC modules in the device. Once asserted, this bit remains set and it is used by the TZASC modules to lock certain register fields, preventing their contents from modification. Once locked, these special registers cannot be modified until a system reset clears this flag. See the TZASC documentation for details on the specific registers and fields locked by this bit.  0 TZASC’s special register contents are not locked. 1 TZASC’s special register contents are locked.
27–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 TZEN11	TrustZone Enable 11

**8.4.3.33 ACTZS TrustZone Interrupt Register (MSCM\_TZIR)**

The TrustZone Interrupt Register is a 32-bit read-only register containing a bit map of the interrupt requests from each TrustZone Address Space Controller in the device. This register is intended to provide a simple mechanism for an interrupt service routine to query the state of the TZASC interrupts with a single register read rather than polling all the individual modules.

Once the source of the TrustZone violation interrupt has been determined, the ISR can then query the responsible TZASC for additional details on the security violation.

Attempted privileged mode writes are ignored.

**8.4.3.34 ACTZS CSLn Interrupt Enable Register (MSCM\_CSlier)**

The CSLn Interrupt Enable Register is a 32-bit register containing a bit map of interrupt enables for CSLn logic reporting access check violations.

As the individual CSLn levels are evaluated for each bus transfer, access violations are error terminated and the resulting error status flags collected and posted in the ACTZS\_CSLIR. This register provides an optional enable to generate a CSLn alert interrupt which is subsequently routed into the CSU's alarm logic.

The CSLIER also contains a lock bit (RO) that may be set to disable writes to the register, preserving the enabled/disabled state of the CSLn interrupts.

Address: 4000\_1000h base + C10h offset = 4000\_1C10h

**8.4.3.35 ACTZS CSLn Interrupt Register (MSCM\_CSlier)**

The CSLn Interrupt Register is a 32-bit register containing a bit map of interrupts for CSLn logic reporting access check violations.

As the individual CSLn levels are evaluated for each bus transfer, access violations are error terminated and the resulting error status flags collected and posted in the ACTZS\_CSlier. This register is then combined with the ACTZS\_CSlier to optionally generate a CSLn alert interrupt which is subsequently routed into the CSU's alarm logic.

The ACTZS\_CSlier records all CSLn access violations regardless of the state of the interrupt enable (ACTZS\_CSlier). Accordingly, this register can be used by both interrupt service routines and/or bus error exception handlers to quickly determine the source of the CSLn access check violation. Each individual interrupt flag in this register is cleared by writing a "1" to it; this would typically be done after the captured fail address and attribute information is retrieved from the appropriate ACTZS\_CSF\*R register. Additionally, the clearing of an interrupt flag in this register also clears the corresponding bit in the ACTZS\_CSOVR register and rearms the logic for capturing the failed access information.

Address: 4000\_1000h base + C14h offset = 4000\_1C14h

1 INT1	CSLn Interrupt 1 This bit records each CSLn access violation alert interrupt. It is mapped to FlexBus. 0 FlexBus access check interrupt is negated. 1 FlexBus access check interrupt is asserted.
0 INT0	CSLn Interrupt 0 This bit records each CSLn access violation alert interrupt. It is mapped to Boot ROM. 0 Boot ROM access check interrupt is negated. 1 Boot ROM access check interrupt is asserted.

**8.4.3.36 ACTZS CSLn Interrupt Overrun Register (MSCM\_CSOVR)**

The CSLn Interrupt Overrun Register is a 32-bit read-only register containing a bit map of “overrun” interrupt conditions for the CSLn logic reporting access check violations.

The overrun condition is simply defined as the detection of another CSLn access check violation before the previous one has been full processed and cleared. Stated differently, if a CSLn access check violation is detected and the corresponding ACTZS\_CSLIR[i] bit still asserted, the ACTZS\_CSOVR[i] bit is set. Additionally, for the slave ACTZS ports using the AXI bus protocol, it is possible to detect simultaneous access violations on the read and write channels. For this condition, the CSLn Fail Status Registers (ACTZS\_CSFARn, ACTZS\_CSFCRn, ACTZS\_CSFIRn) capture the information associated with the write access and set the appropriate overrun indicator in the ACTZS\_CSOVR.

Each individual interrupt flags is cleared by writing a “1” to it and this is typically be done after the captured fail address and attribute information is retrieved from the appropriate ACTZS\_CSF\*R register. The clearing of an interrupt flag in the ACTZS\_CSLIR also clears the corresponding bit in the ACTZS\_CSOVR register and rearms the logic for capturing the fail access information.

Address: 4000\_1000h base + C18h offset = 4000\_1C18h

It is mapped to Boot ROM.  0 Boot ROM access check overrun has not been detected. 1 Boot ROM access check overrun has been detected.

### 8.4.3.37 ACTZS CSLn Fail Status Address (Low) Register (MSCM\_CSFAR<sub>n</sub>)

The CSFAR<sub>n</sub> is a 32-bit read-only register for capturing the low-order 32 bits of the address of the last captured access check violation detected by the CSLn logic. When the CSLn logic detects an access violation, the address and attributes associated with the memory reference are loaded into the CSFAR<sub>n</sub>, CSFCR<sub>n</sub> and CSFIR<sub>n</sub> registers, and the appropriate flag in the CSLn Interrupt Register (CSLIR) is asserted.

The device supports  $n = [0-13]$  and contains an array of ten 128-bit data structures and four reserved structures as defined in the following table.

Base Offset Address	Source
D00	Boot ROM
D10	FlexBus
D20	GPIO
D30	CM4-TCM backdoor port
D40	QuadSPI0
D50	Reserved
D60	Reserved
D70	Reserved
D80	Secure RAM
D90	QuadSPI1
DA0	RLE
DB0	Reserved
DC0	PBRIDGE0 = Logical Summation of CSR[12- 72]
DD0	PBRIDGE1 = Logical Summation of CSR[73-120]

The contents of the ACTZS\_CSFAR<sub>n</sub> is unaffected until the corresponding ACTZS\_CSLIR interrupt flag is cleared by writing a 1 to it, at which time, the capturing of fail information is rearmed.

Attempted privileged mode writes are ignored.

### NOTE

The next sequential word at offset address 0xD04 + 16\*n is reserved for systems where the address space is larger than 4 Gbytes. In the device, this read-only word is always hardwired to zero.

Address: 4000\_1000h base + D00h offset + (16d × i), where i=0d to 13d

Field	Description
FAD	CSLn Fail Address  This read-only field specifies the system address from the last captured CSLn access check violation.

### 8.4.3.38 ACTZS CSLn Fail Status Control Register (MSCM\_CSFCRn)

The CSFCRn is a 32-bit read-only register for capturing specific attribute bits of the last captured access check violation detected by the CSLn logic. When the CSLn logic detects an access violation, the address and attributes associated with the memory reference are loaded into the CSFARn, CSFCRn and CSFIRn registers, and the appropriate flag in the CSLn Interrupt Register (CSLIR) is asserted.

The device supports  $n = [0-13]$  and contains an array of ten 128-bit data structures and four reserved structures as defined in the following table.

Base Offset Address	Source
D08	Boot ROM
D18	FlexBus
D28	GPIO
D38	CM4-TCM backdoor port
D48	QuadSPI0
D58	Reserved
D68	Reserved
D78	Reserved
D88	Secure RAM
D98	QuadSPI1
DA8	RLE
DB8	Reserved
DC8	PBRIDGE0 = Logical Summation of CSR[12- 72]
DD8	PBRIDGE1 = Logical Summation of CSR[73-120]

The contents of the ACTZS\_CSFCRn is unaffected until the corresponding ACTZS\_CSLIR interrupt flag is cleared by writing a 1 to it, at which time, the capturing of fail information is rearmed.

Attempted privileged mode writes are ignored.

Address:  $4000\_1000h \text{ base} + D08h \text{ offset} + (16d \times i)$ , where  $i=0d$  to  $13d$

# Chapter 9

## ARM Platform and Debug

### 9.1 Peripheral Bridge (AIPS-Lite)

#### 9.1.1 Introduction

##### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of . (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

##### 9.1.1.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses

##### 9.1.1.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

Each peripheral is allocated one or more block(s) of the memory map. Two global external module enables are available for the remaining address space to allow for customization and expansion of addressed peripheral devices.

### **9.1.2 Memory map/register definition**

The AIPS module(s) on this device do(es) not contain any user-programmable registers.

### **9.1.3 Functional description**

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

#### **9.1.3.1 Access support**

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

## 9.2 Semaphores (SEMA4)

### 9.2.1 Introduction

The module provides the hardware support needed in multi-core systems for implementing semaphores and provide a simple mechanism to achieve "lock/unlock" operations via a single write access. This approach eliminates architecture-specific implementations like atomic (indivisible) read-modify-write instructions or reservation mechanisms. The result is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

#### 9.2.1.1 Multi-Core Programming 101: Software Gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism which is then used by system software to control access to shared data structures, shared hardware resources, etc. These "gating" mechanisms are used by the software to serialize (and synchronize) writes to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered "locking (or closing) a software gate." Once the gate has been locked, a properly-architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate, that is, other processes/processors are locked out. Many software implementations include a *spin-wait loop* within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, Processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, Processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly-implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a "gate" variable.

2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

"One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 471-472]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

"Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly "spin waiting" to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but that doesn't matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits, starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 472-473]

For multi-core SoCs developed in the Microcontroller Division, a hardware-enforced semaphore implementation as a platform IPS module is used for the following reasons:

- A smaller module size versus a platform reservation monitor for ARM Cortex A5 based designs and it does not introduce any timing-critical paths, for example, the AHB system bus address phase cycle like a reservation monitor
- Provides a more robust implementation with features not possible in a reservation-only approach
- Provides a more generic, architecture-neutral solution, applicable across *all* the processor families supported by the Microcontroller Division

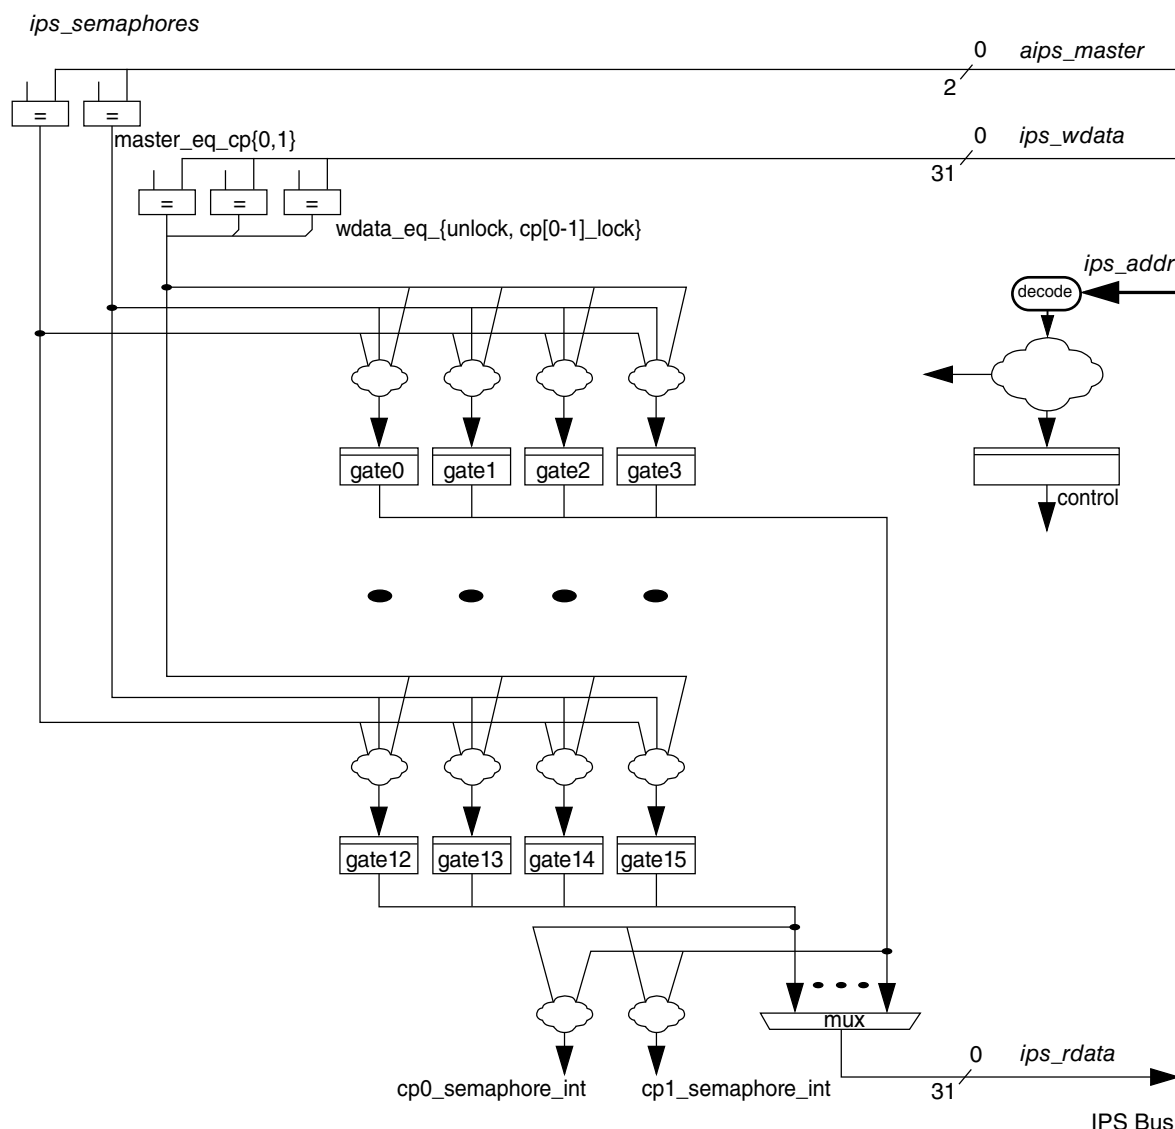

The sole drawback to a hardware-based semaphore module is the limited number of semaphores versus the "infinite" number that can be supported with ARM Cortex A5 based reservation instructions.

### 9.2.1.2 Overview

The IPS\_Semaphores module provides a platform IPS slave device which implements 16 hardware-enforced gates with the following features:

- Module definition supports 16 hardware-enforced gates in a dual-processor configuration, where cp0 is core processor 0 and cp1 is core processor 1
  - Hardware gates appear as a 16-entry byte-size array with read and write accesses
    - Processors lock gates by writing "processor\_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor
- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual semaphore gates or notification logic, as well as a clear\_all capability
- Programming model allocates memory space to support up to 8 processors and up to 64 gates

A simplified block diagram of the Semaphores module is shown in [Figure 9-1](#). In the diagram, the register blocks named gate0, gate1, ..., gate 15 include the finite state machines implementing the semaphore gates plus the interrupt notification logic.

**Figure 9-1. IPS\_Semaphores Block Diagram**

### 9.2.1.3 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a dual-processor configuration
  - Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
    - 3-state implementation

if gate = 0b00, then state = unlocked

if gate = 0b01, then state = locked by processor 0

- if gate = 0b10, then state = locked by processor 1
- Uses the bus master number as a reference attribute plus the specified data patterns to validate all write operations
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor
- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear\_all capability
- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses
  - Two outputs (one per processor) for interrupt notification of failed lock writes

#### 9.2.1.4 Modes of Operation

The Semaphores module does not support any special modes of operation. As a slave peripheral memory-mapped device located on the platform's IPS slave bus, it responds based strictly on the memory addresses of the connected bus. The IPS bus is used to access the Semaphores ' programming model.

### 9.2.2 External Signal Description

The Semaphores module does not include any external interfaces.

### 9.2.3 Memory map and register definition

The Semaphores module provides an IPS programming model mapped to an SPP-standard on-platform 16 KB space. The description here specifies a dual-core configuration with 16 semaphore gates. All the register names are prefixed with "Sema4" as an abbreviation for the full module name.

The programming model is referenced using 8-, 16- and 32-bit accesses. Reads can use any reference size, while writes are generally restricted to the size of the register. Exceptions to the write size restrictions are detailed in the individual register

descriptions. Attempted references using inappropriate access sizes, to undefined (reserved) addresses, or with a non-supported access type (for example, a write to a read-only register) generate an IPS error termination.

Finally, the programming model allocates space for a definition with up to 64 gates and up to 8 processor cores, even though this definition is considerably larger than any currently-planned module implementations. The number of gates and supported processor cores are independent; there is no relationship between these two system variables.

The 16 KB Semaphores programming model map is shown in the following table.

### NOTE

This module is big-endian. Therefore the byte addresses within a 32-bit word are reversed. Refer to the table below to find the correct address.

### NOTE

Some SWs are using Gate registers numbering from 0 to 15. In this case bit numbers in SEMA4\_CP<sub>x</sub> registers are {3, 2, 1, 0, 7, 6, 5, 4, 11, 10, 9, 8, 15, 14, 13, 12}

**9.2.3.1 Semaphores Gate 3 Register (SEMA4\_Gate03)**

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

For more details, see <a href="#">SEMA4_GATEn Operation</a> .  <b>NOTE:</b> The state of the gate reflects the last processor that locked it, which can be useful during system debug.  00 The gate is unlocked (free). 01 The gate has been locked by processor 0. 10 The gate has been locked by processor 1. 11 This state encoding is never used and therefore reserved. Attempted writes of 0x03 are treated as "no operation" and do not affect the gate state machine.

### 9.2.3.7 Semaphores Gate 5 Register (SEMA4\_Gate05)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

### 9.2.3.17 Semaphores Processor n IRQ Notification Enable (SEMA4\_CPnINE)

The application of a hardware semaphore module provides an opportunity for implementation of helpful system-level features. An example is an optional mechanism to generate a processor interrupt after a failed lock attempt. Recall traditional software gate functions execute a spin-wait loop in an effort to obtain and lock the referenced gate. With this module, the processor that fails in the lock attempt could continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function.

The optional notification interrupt function consists of two registers for each processor: an interrupt notification enable register (SEMA4\_CPnINE) and the interrupt request register (SEMA4\_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4\_CPnINE registers, unimplemented bits read as zeroes, and writes are ignored.

**9.2.3.18 Semaphores Processor n IRQ Notification (SEMA4\_CPnNTF)**

The Semaphores module optionally allows the processor that fails in the lock attempt to continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function rather than simply execute in a spin-wait loop.

The optional notification interrupt mechanism consists of two registers for each processor: an interrupt notification enable register (SEMA4\_CPnINE) and the read-only notification interrupt request register (SEMA4\_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4\_CPnNTF registers, unimplemented bits read as zeroes.

The notification interrupt is generated via a unique finite state machine, one per hardware gate. This machine operates in the following manner:

1. When an attempted lock fails, the FSM enters a first state where it waits until the gate is unlocked.
2. Once unlocked, the FSM enters a second state where it generates an interrupt request to the “failed lock” processor.
3. When the “failed lock” processor succeeds in locking the gate, the IRQ is automatically negated and the FSM returns to the idle state. However, if the other processor again locks the gate, the FSM returns to the first state, negates the interrupt request, and then waits for the gate to be unlocked (again).

The notification interrupt request is implemented in a 3-bit, 5-state machine, where two specific states are encoded and program-visible as SEMA4\_CP0NTF[GNn] and SEMA4\_CP1NTF[GNn].

### SEMA4\_CPnNTF field descriptions

Field	Description
0–15 GNn	Gate n Notification. This read-only field is a bitmap of the interrupt request notification from a failed attempt to lock gate n. For more details, see <a href="#">SEMA4_CPnNTF Operation</a> .

## 9.2.3.19 Semaphores (Secure) Reset Gate n (SEMA4\_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism which allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4\_RSTGT memory location. The most significant byte (SEMA4\_RSTGT[RSTGDP]) must be 0xE2; the least significant byte is a "don't\_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4\_RSTGT location. For this write, the upper byte (SEMA4\_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the lower byte (SEMA4\_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are cleared.
3. Reads of the SEMA4\_RSTGT location return information on the 2-bit state machine (SEMA4\_RSTGT[RSTGSM]) which implements this function, the bus master performing the reset (SEMA4\_RSTGT[RSTGMS]) and the gate number(s) last cleared (SEMA4\_RSTGT[RSTGTN]). Reads of the SEMA4\_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 4001\_D000h base + 102h offset = 4001\_D102h

The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip configuration chapter for this information.														
Write-Only	0-7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.														
8–15 RSTGTN	<p>Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write.</p> <p>If RSTGTN &lt; 64, then reset the single gate defined by RSTGTN, else reset all the gates. The corresponding secure IRQ notification state machine(s) are also reset.</p>															

### 9.2.3.20 Semaphores (Secure) Reset IRQ Notification (SEMA4\_RSTNTF)

As with the case of the secure reset function and the hardware gates, it is recognized that system operation may require a reset function to re-initialize the state of the IRQ notification logic without requiring a system-level reset.

To support this special notification reset requirement, the Semaphores module implements a "secure" reset mechanism which allows an IRQ notification (or all the notifications) to be initialized by following a specific dual-write access pattern. When successful, the specified IRQ notification state machine(s) are reset. Using a technique similar to that required for the servicing of a software watchdog timer, the secure reset mechanism requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the IRQ notification(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4\_RSTNTF memory location. The most significant byte (SEMA4\_RSTNTF[RSTNDP]) must be 0x47; the least significant byte is a "don't\_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4\_RSTNTF location. For this write, the upper byte (SEMA4\_RSTNTF[RSTNDP]) is the logical complement of the first data pattern (0xB8) and the lower byte (SEMA4\_RSTNTF[RSTNTN]) specifies the notification(s) to be reset. This field can specify a single notification be cleared, or that all notifications are cleared.
3. Reads of the SEMA4\_RSTNTF location return information on the 2-bit state machine (SEMA4\_RSTNTF[RSTNSM]) which implements this function, the bus master performing the reset (SEMA4\_RSTNTF[RSTNMS]) and the notification number(s) last cleared (SEMA4\_RSTNTF[RSTNTN]). Reads of the SEMA4\_RSTNTF register do not affect the secure reset finite state machine in any manner.

#### SEMA4\_RSTNTF field descriptions

Field	Description
0-7 RSTNSM_ RSTNMS_ RSTNDP	<b>NOTE:</b> This field contains subfields that vary depending on whether it is being read or written. Sub-fields indicated as having read access are valid only for read operations. Sub-fields indicated as having write access are valid only for write operations. Bit numbering in the descriptions begins with the most significant bit numbered 0. See the following table for details.

Table continues on the next page...

**SEMA4\_RSTNTF field descriptions (continued)**

Field	Description		
	<b>Access</b>	<b>Sub-Field</b>	<b>Description</b>
	Read-Only	0-1 Reserved	Reserved. Always reads 0.
		2-3 RSTNSM	Reset Notification Finite State Machine. Reads of the SEMA4_RSTNTF register return the encoded state machine value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified notification reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. Note the RSTNSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. 11 This state encoding is never used and therefore reserved..
		4 Reserved	Reserved. Always reads 0.
		5-7 RSTNMS	Reset Notification Bus Master. This 3-bit read-only field records the logical number of the bus master performing the notification reset function. The reset function requires that the two consecutive writes to this register be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip configuration chapter for this information.
	Write-Only	0-7 RSTNDP	Reset Notification Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the notification reset mechanism. For the first write, RSTNDP = 0x47 while the second write requires RSTNDP = 0xb8.
8–15 RSTNTN	Reset Notification Number. This 8-bit field specifies the specific IRQ notification state machine to be reset. This field is updated by the second write.  If RSTNTN < 64, then reset the single IRQ notification machine defined by RSTNTN, else reset all the notifications.		

## 9.2.4 Functional Description

In this section, the functional operation of the Semaphores module, specifically the state machines of the SEMA4\_GATE<sub>n</sub> and SEMA4\_CP<sub>n</sub>NTF registers are detailed.

### 9.2.4.1 SEMA4\_GATE<sub>n</sub> Operation

Recall each of the SEMA4\_GATE<sub>n</sub> registers implements a 2-bit, 3-state machine. The state transitions for each gate are shown in the following figure.

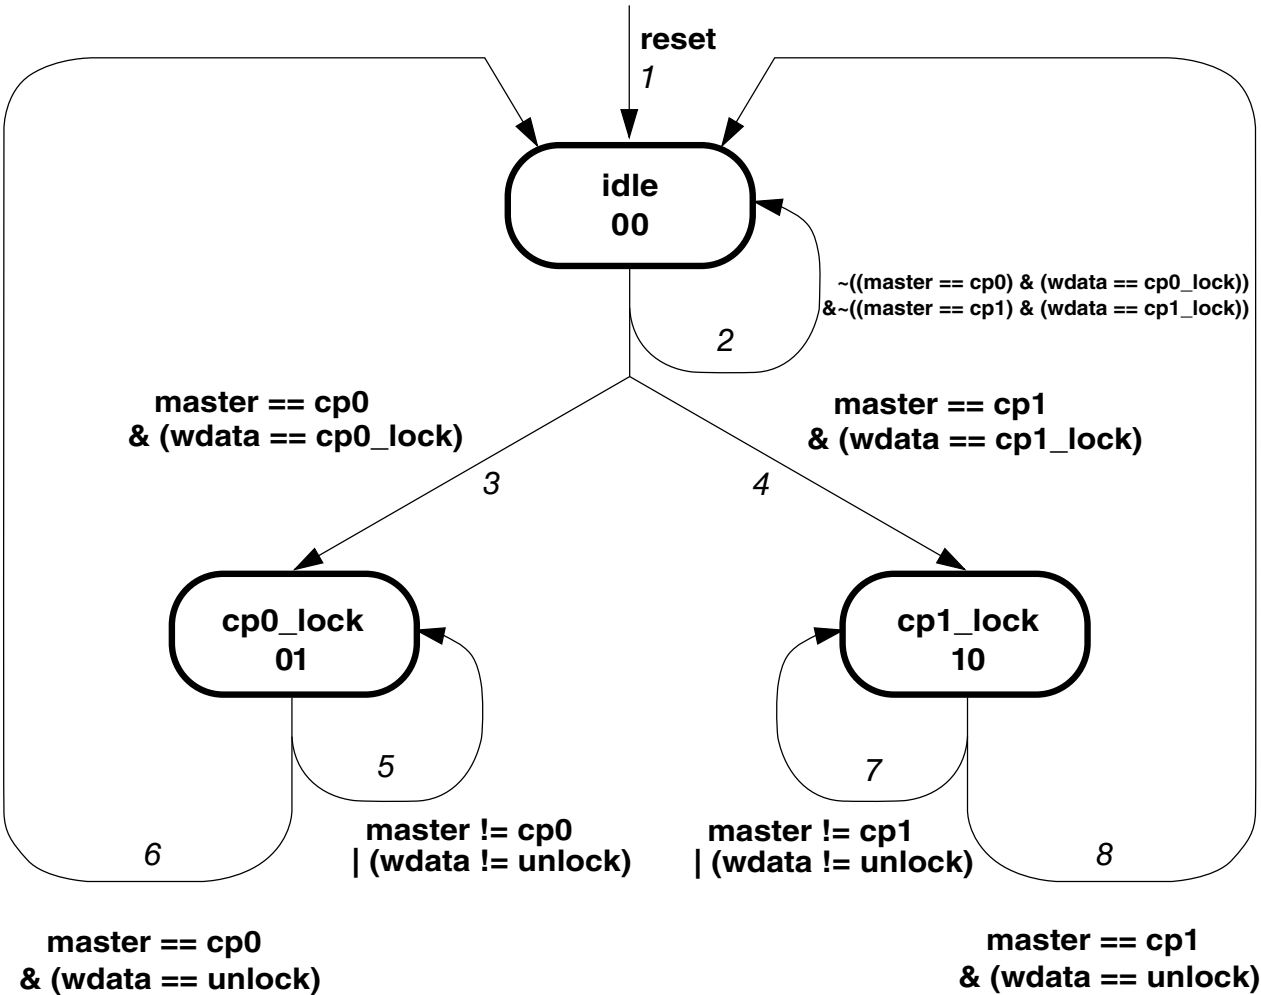

Figure 9-2. SEMA4\_GATEn State Machine

The bus master number is used to identify core processor 0 (cp0) or core processor 1 (cp1). The Standard (or Reduced) Product Platform passes the AHB bus master number (`hmaster[2:0]`) through the AIPS (or AIPS-Lite) controller and drives an `aips_master[2:0]` output to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4\_GATEn are defined in the following table.

Table 9-1. SEMA4\_GATEn State Transitions

Current State	Next State	Transition	Description
—	idle	1	Any reset, whether a system reset or an individual gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.

Table continues on the next page...

**Table 9-1. SEMA4\_GATEn State Transitions  
(continued)**

Current State	Next State	Transition	Description
idle	cp1_lock	4	When a write of the "cp1_lock" value is initiated by processor 1, the gate transitions into the cp1_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cp1_lock	cp1_lock	7	Once in this state, the gate remains here if any attempted write is not from cp1 with the unlock data value.
cp1_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cp1 with the unlock data value occurs.

#### 9.2.4.2 SEMA4\_CPnNTF Operation

The failed lock write notification interrupt request is implemented in a 3-bit, 5-state machine which records failed lock attempts and transitions based on gate locking and unlocking. Two specific states are encoded and program-visible as SEMA4\_CP0NTF[GNn] and SEMA4\_CP1NTF[GNn]. See the following figure.

**Figure 9-3. IRQ Notification State Machine**

The state transitions of the IRQ notification function are defined in the following. Specific states of this machine are program-visible as the SEMA4\_CPnNTF registers. In particular, two states are program-visible:

```

if state = wait4_cp0_lock (0b110) // generate cp0_semaphore_int if properly enabled
then SEMA4_CP0NTF[GNn] = 1; else SEMA4_CP0NTF[GNn] = 0
if state = wait4_cp1_lock (0b101) // generate cp1_semaphore_int if properly enabled
then SEMA4_CP1NTF[GNn] = 1; else SEMA4_CP1NTF[GNn] = 0
  
```

**Table 9-2. IRQ Notification State Transitions**

Current State	Next State	Transition	Description
—	idle	1	Any reset, including a system reset or an individual notification or secure gate reset, unconditionally forces the machine into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor to an already-locked gate occurs, the machine remains in the idle state.
idle	wait4_cp1_unlock	3	When a write of the "cp0_lock" data value is initiated by processor 0 but the gate is already locked by cp1, the machine transitions into this state, where it waits for cp1 to unlock the gate.
idle	wait4_cp0_unlock	4	When a write of the "cp1_lock" data value is initiated by processor 1 but the gate is already locked by cp0, the machine transitions into this state, where it waits for cp0 to unlock the gate.
wait4_cp1_unlock	wait4_cp1_unlock	5	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp1_unlock	wait4_cp0_lock	6	From this state, the machine transitions into the next state, waiting for cp0 to lock the gate, once it has been unlocked.
wait4_cp0_unlock	wait4_cp0_unlock	7	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp0_unlock	wait4_cp1_lock	8	From this state, the machine transitions into the next state, waiting for cp1 to lock the gate, once it has been unlocked.
wait4_cp0_lock	wait4_cp0_lock	9	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 0 or the gate is again locked by processor 1.
wait4_cp0_lock	wait4_cp1_unlock	10	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 1. With this transition, the notification interrupt request is negated.
wait4_cp0_lock	idle	11	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	wait4_cp1_lock	12	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 1 or the gate is again locked by processor 0.
wait4_cp1_lock	wait4_cp0_unlock	13	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	idle	14	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 1. With this transition, the notification interrupt request is negated.

The Semaphores module generates two interrupt request output signals, one per processor, combining the SEMA4\_CPnINE and SEMA4\_CPnNTF registers, where the boolean equations are:

```

cp0_semaphore_int
=   sema4_cp0ine[ine0]    &   sema4_cp0ntf[gn0]
  |   sema4_cp0ine[ine1]    &   sema4_cp0ntf[gn1]
  |   sema4_cp0ine[ine2]    &   sema4_cp0ntf[gn2]
  |   ...
  |   sema4_cp0ine[ine15]   &   sema4_cp0ntf[gn15]
cp1_semaphore_int
=   sema4_cp1ine[ine0]    &   sema4_cp1ntf[gn0]
  |   sema4_cp1ine[ine1]    &   sema4_cp1ntf[gn1]
  |   sema4_cp1ine[ine2]    &   sema4_cp1ntf[gn2]
  |   ...
  |   sema4_cp1ine[ine15]   &   sema4_cp1ntf[gn15]

```

## 9.2.5 Initialization Information

The reset state of the IPS\_Semaphores module allows it to begin operation without the need for any further initialization. All the internal state machines are cleared by any reset event, allowing the module to immediately begin operation.

## 9.2.6 Application Information

In an operational multi-core system, most interactions involving the Semaphores module involves reads and writes to the SEMA4\_GATE<sub>n</sub> registers for implementation of the hardware-enforced software gate functions. Typical code segments for gate functions perform the following operations:

- To lock (close) a gate
  - The processor performs a byte write of "logical\_processor\_number + 1" to gate[i]
  - The processor reads back gate[i] and checks for a value of "logical\_processor\_number + 1"

If the compare indicates the expected value, then the gate is locked; proceed with the protected code segment. If the compare does not indicate the expected value, the lock operation failed; repeat the process beginning with byte write to gate[i] in spin-wait loop, or proceed with another execution path and wait for failed lock interrupt notification.

A simple C-language example of a `gateLock` function is shown in the following figure. This function follows the Hennessy/Patterson example described in [Multi-Core Programming 101: Software Gates](#).

```

#define UNLOCK    0
#define CP0_LOCK  1
#define CP2_LOCK  2

void gateLock (n)
int  n;                /* gate number to lock */
{
    int i;
    int current_value;
    int locked_value;

    i = processor_number(); /* obtain logical CPU number */

    if (i == 0)
        locked_value = CP0_LOCK;
    else
        locked_value = CP1_LOCK;

    /* read the current value of the gate and wait until the state == UNLOCK */
    do {
        current_value = gate[n];
    } while (current_value != UNLOCK);

    /* the current value of the gate == UNLOCK. attempt to lock the gate for this
       processor. spin-wait in this loop until gate ownership is obtained */
    do {
        gate[n] = locked_value; /* write gate with processor_number + 1 */
        current_value = gate[n]; /* read gate to verify ownership was obtained */
    } while (current_value != locked_value);
}

```

**Figure 9-4. Sample gateLock Function**

- To unlock (open) a gate
  - After completing the protected code segment, the locking processor performs a byte write of zeroes to gate[i], opening (unlocking) the gate

A few comments on the logical CPU number are appropriate. In this example, a reference to `processor_number()` is used to retrieve this hardware configuration value. Typically, the logical processor numbers are defined by a hardwired input vector to the individual cores. The exact method for accessing the logical processor number varies by architecture. For PowerPC cores, there is a processor ID register (PIR) which is SPR 286 and contains this value. A single instruction can be used to move the contents of the PIR into a general-purpose register: `mf spr rx,286` where `rx` is the destination GPRn. Other architectures may support a specific instruction to move the contents of the logical processor number into a general-purpose register, e.g., `rdcpn rx` for a "read CPU number" instruction.

If the optional failed lock IRQ notification mechanisms are used, then accesses to the related registers (SEMA4\_CPnINE, SEMA4\_CPnNTF) are required. Note that there is no required negation of the failed lock write notification interrupt as the request is automatically negated by the Semaphores module once the gate has been successfully locked by the "failing" processor.

Finally, in the event a system state requires a software-controlled reset of a gate or IRQ notification register(s), accesses to the secure reset control registers (SEMA4\_RSTGT, SEMA4\_RSTNTF) are required. For these situations, it is recommended that the appropriate IRQ notification enable(s) (SEMA4\_CPnINE) bits be disabled *before* initiating the secure reset 2-write sequence to avoid any race conditions involving spurious notification interrupt requests.

## 9.3 On-Chip Memory Controller (OCMEM)

### 9.3.1 Overview

The device includes an on-chip ROM (OCROM) controller supporting an 8 MB address space plus three on-chip RAM (OCRAM) memory controllers also supporting an 8 MB address space allocated for this storage type.

The OCRAM address space is logically partitioned into two equal 4 MB spaces: one defined for system RAM (sys) and the other for graphics RAM (gfx). The 1.5 MB of RAM is spread across three controllers to provide an appropriate amount of data bandwidth to this critical system memory. Additionally, the capabilities associated with these memories vary, based on the required functionality. See the table below for details.

**Table 9-3. On-Chip Map Region Details**

Start Address	End Address	Size [Kbytes]	OCMEM Description	Features
On-chip ROM				
0x0000_0000	0x007F_FFFF	8192	OCROM(3)	Boot Memory
On-chip RAM				
0x3F00_0000	0x3F03_FFFF	256	OCRAM0_sys	ECC protected
0x3F04_0000	0x3F07_FFFF	256	OCRAM1_sys	ECC protected
0x3F08_0000	0x3F3F_FFFF	3584	Reserved for future use	-
0x3F40_0000	0x3F47_FFFF	512	OCRAM2_gfx	Pixel Converter
0x3F48_0000	0x3F4F_FFFF	512	Configurable OCRAM2 gfxRAM or Data Array for L2 Cache	Pixel Converter
0x3F50_0000	0x3F7F_FFFF	3072	Reserved for future use	-

### 9.3.2 Functional Description

The functional description of OCMEM is described below.

### 9.3.2.1 OCRAM Error Correcting Code (ECC)

To support market requirements related to improved functional and transient fault detection capabilities, this device includes ECC support on the system memory portion of the on-chip RAM. This implementation follows the traditional memory ECC design as the check logic is localized to the OCRAM\_sys memory controllers.

The implemented ECC is a single error correction, double error detection (SECDDED) code using a Hsiao minimum odd weight column definition. The ECC is calculated based on a 64-bit data width. Additionally, the error codes are generated based on more than just the data associated with the storage location in order to protect additional information associated with an access. Specifically, the address corresponding to the access location is combined with the data in the OCRAM\_sys controllers to generate error protection codes which cover certain types of addressing errors which may occur in the memory controller or memory array(s). The 8-bit ECC implementation in the OCRAM\_sys memory controllers cover the 64 data bits plus the upper 29 bits of the access address. Details on the H matrix which defines the relationship between the 29-bit address and the 64-bit data fields to produce the 8 checkbits are detailed in [ECC Checkbit / Syndrome Coding](#).

#### NOTE

Only single bit errors in the data or checkbit fields can be corrected (on-the-fly); single bit errors pointing to the address field and all detected multi-bit errors are treated as uncorrectable ECC events.

#### NOTE

The terminology uncorrectable or non-correctable are used interchangeably.

The OCRAM\_sys ECC function can be summarized in the following steps. Consider reads and writes separately.

For data writes received by the OCRAM\_sys memory controller:

- If enabled, the ECC logic generates the 8-bit checkbit field based on the 29-bit address + 64-bit data
- The 64 data bits + 8 checkbits are stored in the memory

For data reads processed by the OCRAM\_sys memory controller:

- The memory reads the addressed location returning 64 data bits + 8 checkbits

- If enabled, the ECC logic forms an 8-bit syndrome which is the XOR of the 8 checkbits read from memory and the (re)calculated checkbits formed by passing the 64 data bits (plus the address field checkbits) through the H-matrix logic. An all-zero syndrome indicates an error-free memory read, else a memory corruption event has occurred.
- The ECC logic decodes the syndrome to determine if the event is a 1-bit data error that can be corrected on the fly, or some type of uncorrectable (aka non-correctable) ECC event. If the data or checkbits contains a 1-bit error, it is corrected and returned to the requesting bus master; The device optionally includes the ability to generate an ECC alert interrupt signaling a correctable 1-bit data error occurred. For uncorrectable ECC events, the bus transfer is terminated with an error response, and a separate ECC alert interrupt can be generated. Additionally, the Miscellaneous System Control Module (MSCM) module contains hardware to record the specifics of the uncorrectable ECC event. The Section XREF HERE for details.

Recall the ECC is organized based on a 64-bit data field. Accordingly, the OCRAM\_sys memory controllers automatically performs the required read-modify-write sequence needed to generate the correct 8 checkbits when a memory write of less than 64 bits is performed. Consider an 8-bit byte write; for this operation, the OCRAM\_sys controller reads the 64-bit data location containing the byte to be updated, performs the standard data read ECC evaluation (correcting any single-bit errors) and then merges the new data byte into the 64-bit read data, calculates the new checkbits and writes the entire 64 data bits and 8 checkbits back into the memory. If the read portion of this sequence detects an uncorrectable ECC event, it is immediately signaled, the data write error terminated and the memory update aborted.

The ECC read-modify-write adds two cycles of latency on a less-than-64 bit write: one cycle is needed for the read and a second cycle to perform the ECC operations associated with the read syndrome generation and possible on-the fly correction. The new data is merged with the read data in the “normal” write setup cycle. Given this 2 cycle latency addition for ECC read-modify-writes, for maximum system performance, writes less than 64 bits should be minimized and/or operated in a decoupled (aka “imprecise”) manner to lessen their impact.

### NOTE

Standard ECC operation requires that the entire memory be written during system startup to “initialize” correct checkbit values for all locations before read operations can be checked. To assist in this process, the device implements two independent control flags for each OCRAM\_sys controller: one that enables checkbit generation on writes and another to enable

checking on read operations. The memory initialization writes can be performed directly by a processor or an appropriately configured DMA channel.

#### 9.3.2.1.1 ECC Checkbit / Syndrome Coding

In the device, ECC scheme implements a single-error correction, double-error detection code using the so-called Hsiao minimum odd-weight column criteria. The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting specification of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all zeroes columns.
2. Every column is distinct
3. Every column contains an odd number of ones, and hence is “odd weight”.

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. The resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within 64-bit (8-byte) data field).

The basic H-matrix for this (101, 93) code (93 is the total number of “data” bits (64 data + 29 address), 101 is the total number of data and address bits plus 8 checkbits) is shown in the figure below, where the shaded cells indicate the corresponding data or address bit is XOR’ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR’ed) together to the final value driven on the checkbit[7:0] outputs.

Checkbits [7:0]	Data Bit <sup>1</sup>

<sup>1</sup> Bit numbering follows the standard ARM-AMBA little endian convention with bit 0 as LSB: D[7:0] corresponds to byte at address 0, and D[63:56] corresponds to byte at address 7.

Figure 9-5. ECC H-Matrix Definition

The codeblock below shows an alternative representation of the ECC encode process, written as a C language function:

```

    encodeEcc (addr, data64)
    unsigned int      addr;                /* 32-bit byte address */
    unsigned long long data64;             /* 64-bit data */

{
    unsigned int      addr_ecc;             /* 8 bits of ecc for address */
    unsigned int      ecc;                 /* 8 bits of ecc codeword */

    /* the following equations calculates the 8-bit wide ecc codeword by examining
    each addr or data bit and xor'ing the appropriate H-matrix value if the bit = 1 */

    addr_ecc
    = (((addr >> 31) & 1) ? 0x1f : 0x0)    /* addr[31] */
    ^ (((addr >> 30) & 1) ? 0xf4 : 0x0)    /* addr[30] */
    ^ (((addr >> 29) & 1) ? 0x3b : 0x0)    /* addr[29] */
    ^ (((addr >> 28) & 1) ? 0xe3 : 0x0)    /* addr[28] */
    ^ (((addr >> 27) & 1) ? 0x5d : 0x0)    /* addr[27] */
    ^ (((addr >> 26) & 1) ? 0xda : 0x0)    /* addr[26] */
    ^ (((addr >> 25) & 1) ? 0x6e : 0x0)    /* addr[25] */
    ^ (((addr >> 24) & 1) ? 0xb5 : 0x0)    /* addr[24] */

    ^ (((addr >> 23) & 1) ? 0x8f : 0x0)    /* addr[23] */
    ^ (((addr >> 22) & 1) ? 0xd6 : 0x0)    /* addr[22] */
    ^ (((addr >> 21) & 1) ? 0x79 : 0x0)    /* addr[21] */
    ^ (((addr >> 20) & 1) ? 0xba : 0x0)    /* addr[20] */
    ^ (((addr >> 19) & 1) ? 0x9b : 0x0)    /* addr[19] */
    ^ (((addr >> 18) & 1) ? 0xe5 : 0x0)    /* addr[18] */
    ^ (((addr >> 17) & 1) ? 0x57 : 0x0)    /* addr[17] */
    ^ (((addr >> 16) & 1) ? 0xec : 0x0)    /* addr[16] */

    ^ (((addr >> 15) & 1) ? 0xc7 : 0x0)    /* addr[15] */
    ^ (((addr >> 14) & 1) ? 0xae : 0x0)    /* addr[14] */
    ^ (((addr >> 13) & 1) ? 0x67 : 0x0)    /* addr[13] */
    ^ (((addr >> 12) & 1) ? 0x9d : 0x0)    /* addr[12] */

ecc = ecc ^ addr_ecc;    /* combine data and addr ecc values */
return(ecc);
}

```

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value. If the syndrome value matches one

of the H-matrix values associated with the address bits, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

### 9.3.2.1.2 ECC and System Performance Implications

The logic used for the generation of checkbits on writes, calculation of the syndrome and on-the-fly single bit correction on reads is fundamentally integrated into the OCRM memory controller's microarchitecture. As a result, the enabling of ECC does not add any machine cycles to RAM reads and 64-bit writes.

As previously discussed, writes for sizes less than 64 bits require an additional 2 cycles of processing to perform the required read-modify-write to calculate the checkbits needed by the 64-bit ECC algorithm. Additionally, the enabling of the ECC check function requires that the appropriate memory has been completely written to place initialized data in all locations.

### 9.3.2.2 OCRM\_gfx Pixel Conversion

The performance of graphic algorithms on a SIMD extension like ARM NEON depends pretty much on the capability to efficiently load and store pixels in the appropriate format. The color components have to be placed in the components of the SIMD register to allow efficient processing.

For byte-aligned pixel format like ARGB8888 this can be easily achieved with the VLD and VST instructions of ARM NEON. While this pixel format offers the full color resolution it requires a significant amount of memory (32 bits per pixel). For single chip solutions without external memory this makes it difficult or even impossible to support larger displays.

One potential solution for this problem is to limit the color depth and spend only 16 bits per pixel for some or all frame buffers / layers. While this halves the amount of memory required for the frame buffers or layers it is not well suited to be handled with ARM NEON as it requires significant pre-/post-processing to get the pixel components adjusted into the vector components of the SIMD registers.

While implementing the pixel packing and unpacking is a pretty performance intensive task on ARM NEON this is something that can be very easily implemented in a small hardware block located in the memory controller of the on-chip SRAM pool. The purpose of the Pixel Converter is to do the required conversions in a rather simple hardware block.

Accordingly, the Faraday memory controllers include a programmable ability to perform specific pixel conversions based on alternate address spaces mapped to the physical OGRAM\_gfx memory. Specifically, the pixel converter hardware reformats memory-resident 16 bit graphics pixel data into 32 bit processor words for the Cortex-A5's NEON SIMD execution.

Graphics algorithms often require simultaneous support for three remapped regions as it is common to have images in two different formats blended together to create a third (output) image. Additionally, the core views the pixel data as “expanded” 32 bit words which is double the size of the actual packed 16 bit pixel data in the OGRAM\_gfx.

Given the physical OGRAM\_gfx space is defined as 4 MB, then the alternate pixel converter view needs 3 regions \* (2 \* 4 MB/region) = 24 MB as a minimum size. Rounding up, the Faraday memory map allocates 32 MB to this alternate pixel view into the OGRAM\_gfx. This alternate pixel view is located in the system address space defined as 0x7E00\_0000 - 0x7FFF\_FFFF.

#### 9.3.2.2.1 OGRAM\_gfx Pixel Converter Functional Description

The three alternate OGRAM\_gfx address spaces are dedicated to specific 16-bit pixel formats. The device architecture supports 3 formats, generically represented as {A}RGB{w}xyz where w defines the number of optional alpha bits, x is the number of red bits, y is the number of green bits and z is the number of blue bits:

- RGB565
- ARGB1555
- ARGB4444

Next, consider the actual data manipulations performed to convert these three 16-bit pixel formats into the 32-bit ARGB8888 format needed by the CA5's NEON SIMD engine. The required conversions are presented both graphically and in C code.

##### 9.3.2.2.1.1 RGB565

In general, the pixel expansion process involves copying the {x,y,z} bits of the color component into the 8-bit ARGB8888 format left justified and then padding the remaining low-order bits with the appropriate number of most significant bits. The figure below shows the RGB565 conversion into ARGB8888. Throughout this section, let rx {x = 0, 1, 2, 3, 4} define the bits of the red color component, gy {y = 0, 1, 2, 3, 4, 5} be the bits of the green color component and bz {z = 0, 1, 2, 3, 4} the bits of the blue color component.

**Figure 9-6. RGB565 to ARGB8888 Conversion**

For this conversion, all 8 bits of the alpha byte are set in the ARGB8888 format (0xFF).

### 9.3.2.2.1.2 ARGB1555

Using the same notation, the ARGB1555 conversion into ARGB8888 is shown in below

**Figure 9-7. ARGB1555 to ARGB8888 Conversion**

For this conversion, 1 bit alpha value is slewed across the upper byte of the ARGB8888 format.

### 9.3.2.2.1.3 ARGB4444

Using the same notation, the ARGB4444 conversion into ARGB8888 is shown in below

**Figure 9-8. ARGB4444 to ARGB8888 Conversion**

### 9.3.2.2.1.4 ARGB8888 Conversions to 16-bit Pixel Data

The preceding sections provided details on the bit remapping when converting from the supported 16-bit pixel formats into the 32-bit ARGB8888 format. These conversions are performed on alternate address space reads of the OGRAM\_gfx memory.

When performing a write of 32-bit ARGB8888 pixel data, the conversion process supports two modes of operation, uniquely selectable for each alternate pixel address space. The store modes are truncation or round/clip.

Truncation simply places the most significant bits for each color component into the available positions in the 16-bit target format.

**Figure 9-9. ARGB8888 to ARGB4444 Conversion**

For the truncation operation for this destination format, the low-order 4 bits of each color component, namely a[4-7], r[4-7], g[4-7] and b[4-7] are simply discarded when creating the 16-bit ARGB4444 format.

If the round/clip mode is enabled, the pixel converter first performs two's complement rounding (always round up) by adding a "1" to the bit immediately to the right of the rounding point. The rounding bit position is determined by the number of available bits in the given color component of the 16-bit data format; after the addition, the low-order bits to the right of the rounding point are discarded. Specifically, the rounding "1" factor is defined in a C language expression as  $1 \ll (8 - \text{bitwidth} - 1)$  where bitwidth is the size of the color component in the 16-bit pixel data.

After the rounding addition is performed, the result is checked for a carry out. If a carry out is signaled, the data has "overflowed" and the final color component is forced to all ones (the clipped value).

A complete definition of the round/clip functionality, is expressed in the following C code function.

```

/* Pixel Conversion C Code: Round/Clip Function */
unsigned char roundclip (unsigned char intensity, int bitwidth)
{
    unsigned int val = intensity;
    val += 1U << (8-bitwidth-1);    /* rounding step */
    if (val & 0x100)                /* check for a cout */
        val = 0xff;                /* set to clipped value*/

    return (val & 0xff);
}

```

Where intensity is the source data byte extracted from the ARGB8888 format, and bitwidth is the number of bits available in the destination field of the 16-bit pixel data. From the resulting value only the bitwidth MSBs are used, that is, a truncation step is applied after round/clip arithmetic is calculated.

### 9.3.2.3 Pixel Conversion and System Performance Implications

Like the ECC implementation, the pixel converter logic is fundamentally integrated into the OCRMAM memory controller microarchitecture. As a result, the accesses via the pixel converters do not add any machine cycles to 32- and 64-bit RAM reads and writes. The conversion on writes is integrated into the first stage (address/write data setup) of the OCRMAM's data pipeline and read conversions are handled in the third stage (read data return).

## 9.3.3 OCMEM Memory Map/Register Definition

OCMEM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4000_1400	On-Chip Memory Descriptor Register (OCMEM_OCMDR0)	32	R/W	8A06_2000h	<a href="#">9.3.3.1/1178</a>
4000_1404	On-Chip Memory Descriptor Register (OCMEM_OCMDR1)	32	R/W	8A06_2000h	<a href="#">9.3.3.1/1178</a>

9.3.3.1 On-Chip Memory Descriptor Register (OCMEM\_OCMDRn)

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information on the attached memories as well as configurable controls (where appropriate).

A privileged 32-bit read from the CA5, the CM4 or the debugger returns the appropriate processor information. Reads from any other bus master return all zeroes. Privileged writes from the CA5, the CM4 or the debugger to writeable registers update the appropriate fields, while privileged writes from other bus masters are ignored. Attempted user mode accesses or any access with a size different than 32 bits are terminated with an error.

NOTE

The size of the OCRM2\_gfx memory (OCMDR2) depends on the presence of the Cortex-A5’s 512 KB Level 2 Cache {0xC if the L2 is disabled, 0xB if the L2 is enabled).

Address: 4000\_1000h base + 400h offset + (4d × i), where i=0d to 3d

### OCMEM\_OCMDRn field descriptions

Field	Description
31 V	OCMEM Valid bit. This read-only field defines the validity (presence) of the on-chip memory 0 OCMEMn is not present. 1 OCMEMn is present.
30–29 -	This field is reserved. Reserved
28 OCMSZH	OCMEM Size “Hole”. For on-chip memories that are not fully populated, that is, include a memory “hole” in the upper 25% of the address range, this bit is used. 0 OCMEMn is a power-of-2 capacity. 1 OCMEMn is not a power-of-2, with a capacity is 0.75 * OCMSZ.
27–24 OCMSZ	OCMEM Size. This 4-bit read-only field provides an encoded value of the on-chip memory size. The capacity of the memory is expressed as Size [bytes] = 2(8+SZ) where SZ is non-zero; a SZ = 0 indicates the memory is not present.  0000 no OCMEMn 0001 4KB OCMEMn 0010 8KB OCMEMn 0011 16KB OCMEMn 0100 32KB OCMEMn : 1111 8192KB OCMEMn
23–20 -	This field is reserved. Reserved
19–17 OCMW	OCMEM datapath Width. This 3-bit read-only field defines the width of the on-chip memory:  000-001 Reserved 010 OCMEMn 32-bits wide 011 OCMEMn 64-bits wide 100-111 Reserved

Table continues on the next page...

**OCMEM\_OCMDR<sub>n</sub> field descriptions (continued)**

Field	Description
16 RO	Read-Only. This register bit provides a mechanism to “lock” the configuration state defined by OCMDR <sub>n</sub> [11:0]. Once asserted, attempted writes to the OCMDR <sub>n</sub> [11:0] register are ignored until the next reset clears the flag.  0 writes to the OCMDR <sub>n</sub> [11:0] are allowed 1 writes to the OCMDR <sub>n</sub> [11:0] are ignored
15–14 OCMT	OCMEM Type. This 2-bit read-only field defines the type of the on-chip memory:  00 OCMEM <sub>n</sub> is a system RAM. 01 OCMEM <sub>n</sub> is a graphics RAM. 10 Reserved 11 OCMEM <sub>n</sub> is a ROM.
13 OCMTZ	OCMEM Trust Zone Protection. This 1-bit read-only field identifies a memory protected by a Trust Zone address space controller.  0 OCMEM <sub>n</sub> is not protected by a Trust Zone address space controller. 1 OCMEM <sub>n</sub> is protected by a Trust Zone address space controller.
12 OCMPU	OCMEM Memory Protection Unit. This 1-bit read-only field identifies a memory protected by a Memory Protection Unit.  0 OCMEM <sub>n</sub> is not protected by a Memory Protection Unit. 1 OCMEM <sub>n</sub> is protected by a Memory Protection Unit.
11–8 OCMC2	OCMEM Control Field 2. This 4-bit field (if used) defines the configuration of the on-chip memory. The field’s functionality is dependent on the OCMT value.  If OCMT = 00 (system RAM), this field is unused.  If OCMT = 01 (graphics RAM), this field configures alternate view 2 (ARGB4444) for the pixel converter with the following bit definitions:  OCMC2[11] = AVENB. This is the alternate view enable. <ul style="list-style-type: none"> <li>if AVENB = 0, then the alternate view is disabled.</li> <li>if AVENB = 1, then the alternate view is enabled.</li> </ul> An attempted reference using the alternate view address to a disabled space, that is, OCMC2[AVENB] = 0, is error terminated. <ul style="list-style-type: none"> <li>OCMC2[10] = AVE1W. This is the alternate view one wait state enable. This function is not supported on the device as its memory is zero wait state.</li> <li>OCMC2[9] = AVERN. This is the enable for round/clip functionality on writes. <ul style="list-style-type: none"> <li>if AVERN = 0, then the round/clip on writes is disabled (truncation is used)</li> <li>if AVERN = 1, then the round/clip on writes is enabled</li> </ul> </li> <li>OCMC2[8] = Reserved.</li> </ul> If OCMT = 10, this field is unused. If OCMT = 11 (boot ROM), this field is unused.
7–4 OCMC1	OCMEM Control Field 1. This 4-bit field (if used) defines the configuration of the on-chip memory. The field’s functionality is dependent on the OCMT value.  If OCMT = 00 (system RAM), this field is unused.  If OCMT = 01 (graphics RAM), this field configures alternate view 2 (ARGB1555) for the pixel converter with the following bit definitions:  OCMC1[7] = AVENB. This is the alternate view enable.

### 9.3.3.2 On-Chip Memory ECC Control Register (OCMEM\_OCMECR)

For designs including error-correcting code (ECC) implementations to improve the quality and reliability of memories, there are a number of program-visible registers for the sole purpose of reporting and logging of memory failures. These registers include:

- On-Chip Memory ECC Configuration Register (OCMECR)
- On-Chip Memory ECC Interrupt Register (OCMEIR)
- On-Chip Memory ECC Error Generation Register (OCMEGR)
- On-Chip Memory ECC Fault Address Register (OCMFAR)
- On-Chip Memory ECC Fault Attributes Register (OCMFTR)
- On-Chip Memory ECC Fault Read Data Register (OCMFDR)

The details on the ECC registers are provided in the subsequent sections.

For all the ECC registers, privileged 32-bit reads from the CA5, the CM4 or the debugger return the appropriate processor information. Reads from any other bus master return all zeroes (RAZ). Privileged writes from the CA5, the CM4 or the debugger to writeable registers update the appropriate fields, while privileged writes from other bus masters are ignored (WI). Attempted user mode accesses or any access with a size different than 32 bits are terminated with an error.

The On-Chip Memory ECC Control Register is an 32-bit control register for specifying which types of memory errors are reported. In systems with ECC, the occurrence of a non-correctable error causes the current access to be terminated with an error condition. In many cases, this error termination is reported directly by the initiating bus master. However, there are certain situations where the occurrence of this type of non-correctable error is not reported by the master. Examples include speculative instruction fetches which are discarded due to a change-of-flow operation, and buffered operand writes. The ECC reporting logic provides an optional error interrupt mechanism to signal all non-correctable memory errors. Single bit memory corrections are performed on-the-fly, returning the corrected read data to the requesting bus master. For these single bit corrections, another configuration bit allows reporting of these events.

Address: 4000\_1000h base + 420h offset = 4000\_1420h

### OCMEM\_OCMECR field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 ER1BR	<p>Enable RAM ECC 1 Bit Reporting. The occurrence of a single-bit on-chip RAM ECC correction generates an “ECC correctable” alert interrupt as signaled by the assertion of one or more bits in the OCMEIR[15:8] field. The address, attributes and data are captured in the OCM{FAR, FTR, FDR} registers.</p> <p>0 Reporting of single-bit on-chip RAM corrections is disabled 1 Reporting of single-bit on-chip RAM corrections is enabled</p>
7–1 -	This field is reserved. Reserved.
0 ERNCR	<p>Enable RAM ECC Noncorrectable Reporting. The occurrence of any non-correctable RAM ECC event generates an “ECC noncorrectable” alert interrupt as signaled by the assertion of one or more bits in the OCMEIR[7:0] field. The address, attributes and data are also captured in the OCM{EAR, ETR, EDR} registers.</p> <p>0 Reporting of noncorrectable on-chip RAM corrections is disabled 1 Reporting of noncorrectable on-chip RAM corrections is enabled</p>

### 9.3.3.3 On-Chip Memory ECC Interrupt Register (OCMEM\_OCMEIR)

The On-Chip Memory ECC Interrupt Register is a 32-bit control register for signaling which types of properly-enabled ECC events have occurred. The OCMEIR includes two bit maps to record the occurrence of individual ECC events, both 1-bit correctable and multi-bit noncorrectable events. The generation of the two ECC interrupt requests are defined by the boolean equations:

```

ECCNC_IRQ // noncorrectable ECC event alert
= OCMECR[0] // error qualifier from OCMECR
& (OCMEIR[0] // noncorrectable from OCMDR0
| OCMEIR[1] // noncorrectable from OCMDR1
| OCMEIR[2] // noncorrectable from OCMDR2
| OCMEIR[3] // noncorrectable from OCMDR3
| OCMEIR[4] // noncorrectable from OCMDR4
| OCMEIR[5] // noncorrectable from OCMDR5
| OCMEIR[6] // noncorrectable from OCMDR6
| OCMEIR[7]) // noncorrectable from OCMDR7
ECC1B_IRQ // 1-bit correctable ECC event alert
= OCMECR[8] // error qualifier from OCMECR
& (OCMEIR[8] // 1-bit correction from OCMDR0
| OCMEIR[9] // 1-bit correction from OCMDR1
| OCMEIR[10] // 1-bit correction from OCMDR2
| OCMEIR[11] // 1-bit correction from OCMDR3
| OCMEIR[12] // 1-bit correction from OCMDR4
| OCMEIR[13] // 1-bit correction from OCMDR5
| OCMEIR[14] // 1-bit correction from OCMDR6
| OCMEIR[15]) // 1-bit correction from OCMDR7

```

where ECCNC\_IRQ is named ECC0 and ECC1B\_IRQ is ECC1

Only the system RAM controllers (OCMDR0 and OCMDR1) source ECC events. Accordingly, OCMEIR[15:10, 7:2] are always logical zeroes. The corresponding ECC enables in OCMECR must be asserted to allow the OCMEIR indicators to be set when an ECC event occurs, that is, OCMECR[8] qualifies OCMEIR[15:8] and OCMECR[0] qualifies OCMEIR[7:0].

In rare cases, it may be possible to have more than one ECC event recorded in the OCMEIR (as signaled by multiple bits asserted) with only the address, attributes and read data from the first event recorded in the OCMF\* (fault) registers.

It is the responsibility of the ECC alert interrupt service routine to properly associate the contents of the OCMEIR and the OCMF\* registers.

Address: 4000\_1000h base + 428h offset = 4000\_1428h

### OCMEM\_OCMEIR field descriptions

Field	Description
31 V	Valid. The assertion of this flag signals the ECC Error Location field is valid. The address, attributes and read data are also captured in the OCM{FAR, FTR, FDR} registers. When any set bit in the E1Bn or ENCn field as specified by the EELOC field is cleared by a “write 1” operation, the V bit is also cleared.  0 Contents of the OCMF* registers are invalid. 1 Contents of the OCMF* registers are valid, captured from the OCMEM controller defined by EELOC.
30–28 -	This field is reserved. Reserved
27–24 EELOC	ECC Error Location. The occurrence of a properly-enabled RAM ECC event that is captured in the OCMF* registers is signaled by the assertion of the V bit plus the source on-chip memory controller captured in this field. The only supported EELOC values are {0, 1, 8, 9}:  0000 A noncorrectable ECC event from OCRAM0_sys has been captured 0001 A noncorrectable ECC event from OCRAM1_sys has been captured 1000 A 1-bit correctable ECC event from OCRAM0_sys has been captured 1001 A 1-bit correctable ECC event from OCRAM1_sys has been captured
23–16 -	This field is reserved. Reserved.
15–8 E1Bn	ECC 1-bit Error n, where n = 0, 1, ..., 7. The assertion of any of these bits signals a properly-enabled ECC 1-bit error has been detected. If the V bit and EELOC field matches the specific bit number n, then the faulting address, attributes and read data are available in the OCMF* registers.  These bits are the source interrupt requests for ECC 1-bit error alerts. The interrupt source request is cleared by writing a “1” from the appropriate service routine. This operation also clears the V bit. When the interrupt source being cleared matches the on-chip memory controller defined by EELOC, the OCMF* registers are re-armed.
ENCn	ECC Noncorrectable Error n, where n = 0, 1, ..., 7. The assertion of any of these bits signals a properly-enabled noncorrectable ECC error has been detected. If the V bit and EELOC field matches the specific bit number n, then the faulting address, attributes and read data are available in the OCMF* registers.  These bits are the source interrupt requests for ECC noncorrectable error alerts. The interrupt source request is cleared by writing a “1” from the appropriate service routine. This operation also clears the V bit. When the interrupt source being cleared matches the on-chip memory controller defined by EELOC, the OCMF* registers are re-armed.

### 9.3.3.4 On-Chip Memory ECC Error Generation Register (OCMEM\_OCMEGR)

The On-Chip Memory ECC Error Generation Register is a 32-bit control register used to force the generation of single- and double-bit data inversions in the memories with ECC, most notably the system RAM. This capability is provided for two purposes:

- It provides a software-controlled mechanism for “injecting” errors into the on-chip memories during data writes to verify the integrity of the ECC logic.
- It provides a mechanism to allow testing of the software service routines associated with memory error logging.

For these on-chip memories, the intent is to generate errors during data write cycles, such that subsequent reads of the corrupted address locations generate ECC events, either single-bit corrections or double-bit noncorrectable errors that are terminated with an error response.

The only allowable values for the 4 control bit enables {FR11BI, FRC1BI, FRCNCI, FR1NCI} are {0,0,0,0}, {1,0,0,0}, {0,1,0,0}, {0,0,1,0} and {0,0,0,1}. All other values result in undefined behavior.

Address: 4000\_1000h base + 42Ch offset = 4000\_142Ch

## OCMEM\_OCMEGR field descriptions (continued)

Field	Description
	0 No 2-bit data inversion in the selected on-chip RAM is generated 1 One 2-bit data inversion in the selected on-chip RAM is generated
15–8 ERR1BIT	<p>Error Bit Position 1. The vector defines the bit position which is complemented to create the data inversion on the write operation. For the creation of 2-bit data inversions, the bit specified by this field plus the ERR2BIT bit of the ECC code are inverted.</p> <p>The on-chip RAM controller follows a vector bit ordering scheme where LSB=0. Errors in the ECC checkbits can be generated by setting this field to a value greater than the data width. The following association between the ERR1BIT field and the 64-bit corrupted memory bit is defined:</p> <pre> if ERR1BIT = 0, then write_data[0] is inverted     if ERR1BIT = 1, then write_data[1] is inverted     ...     if ERR1BIT = 63, then write_data[63] is inverted     if ERR1BIT = 64, then write_chkbit[0] is inverted     if ERR1BIT = 65, then write_chkbit[1] is inverted     ...     if ERR1BIT = 71, then write_chkbit[7] is inverted           </pre> <p>For ERR1BIT values greater than 71, no bit position is inverted.</p>
ERR2BIT	<p>Error Bit Position 2. The vector defines the second bit position which is complemented to create a 2-bit data inversion on the write operation. For the creation of 2-bit data inversions, the bit specified by this field plus the ERR1BIT bit of the ECC code are inverted. The bits specified by ERR1BIT and ERR2BIT must be different, else the behavior is undefined.</p> <p>The on-chip RAM controller follows a vector bit ordering scheme where LSB=0. Errors in the ECC checkbits can be generated by setting this field to a value greater than the data width. The following association between the ERR2BIT field and the 64-bit corrupted memory bit is defined:</p> <pre> if ERR2BIT = 0, then write_data[0] is inverted     if ERR2BIT = 1, then write_data[1] is inverted     ...     if ERR2BIT = 63, then write_data[63] is inverted     if ERR2BIT = 64, then write_chkbit[0] is inverted     if ERR2BIT = 65, then write_chkbit[1] is inverted     ...     if ERR2BIT = 71, then write_chkbit[7] is inverted           </pre> <p>For ERR2BIT values greater than 71, no bit position is inverted.</p>

9.3.3.5 On-Chip Memory ECC Fault Address Register (OCMEM\_OCMFAR)

The OCMFAR is a 32-bit read-only register for capturing the address of the last, properly-enabled ECC event in the on-chip memory. Depending on the state of the On-Chip Memory ECC Control Register, an ECC event in the on-chip memory causes the address, attributes and read data associated with the access to be loaded into the OCMFAR, OCMFTR and OCMFDR registers, and the appropriate flag in the On-Chip Memory ECC Interrupt Register to be asserted. Attempted privilege mode writes are ignored.

Address: 4000\_1000h base + 430h offset = 4000\_1430h

OCMEM\_OCMFAR field descriptions

Field	Description
EFADD	On-Chip Memory ECC Fault Address. This read-only field specifies the system address from the last captured ECC event.

### 9.3.3.6 On-Chip Memory ECC Fault Attribute Register (OCMEM\_OCMFTR)

The OCMFTR is a 32-bit read-only register for capturing the attributes of the last, properly-enabled ECC event in the on-chip memory. Depending on the state of the On-Chip Memory ECC Control Register, an ECC event in the on-chip memory causes the address, attributes and read data associated with the access to be loaded into the OCMFAR, OCMFTR and OCMFDR registers, and the appropriate flag in the On-Chip Memory ECC Interrupt Register to be asserted. Attempted privilege mode writes are ignored.

Address: 4000\_1000h base + 434h offset = 4000\_1434h

#### OCMEM\_OCMFTR field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 EFSYN	On-Chip Memory ECC Fault Syndrome. This read-only field specifies the checkbit syndrome from the last captured ECC event.
15–8 EFMST	On-Chip Memory ECC Fault Master Number. This read-only field specifies the bus master responsible for initiating the last captured ECC event.
7 EFW	On-Chip Memory ECC Fault Write. This read-only field specifies the last captured ECC event was a write bus cycle.  Since the ECC check only occurs on read operations, if the EFW bit is asserted, the captured ECC event was associated with the read-modify-write needed to generate the required check bits. This type of read-modify-write sequence only occurs on writes of less than 64 bits; for 64-bit writes, the destination check bits are calculated directly from the write data without the need for any read-modify-write sequence.
6–4 EFSIZ	On-Chip Memory ECC Fault Master Size. This read-only field specifies the access size of the last captured ECC event. The size encodings are:  000 8-bit access 001 16-bit access 010 32-bit access

Table continues on the next page...

## OCMEM\_OCMFTR field descriptions (continued)

Field	Description
	011 64-bit access 1xx Reserved
EFPRT	On-Chip Memory ECC Fault Protection. This read-only field specifies the protection field of the last captured ECC event. The protection encodings are: <ul style="list-style-type: none"> <li>EFPRT[3]: Cacheable 0 = Non-cacheable, 1 = Cacheable</li> <li>EFPRT[2]: Bufferable 0 = Non-bufferable, 1 = Bufferable</li> <li>EFPRT[1]: Mode 0 = User mode, 1 = Supervisor mode</li> <li>EFPRT[0]: Type 0 = I-Fetch, 1 = Data</li> </ul>

## 9.3.3.7 On-Chip Memory ECC Fault Data Register (OCMEM\_OCMFDR)

The OCMFDR is a 64-bit read-only register for capturing the read data of the last, properly-enabled ECC event in the on-chip memory. Depending on the state of the On-Chip Memory ECC Control Register, an ECC event in the on-chip memory causes the address, attributes and read data associated with the access to be loaded into the OCMFAR, OCMFTR and OCMFDR registers, and the appropriate flag in the On-Chip Memory ECC Interrupt Register to be asserted. The read data is captured after it has been processed by the ECC logic, that is, in the case of a correctable single-bit ECC event, the read data is the corrected value. The contents of OCMFTR[EFSYN] can be used to locate the original faulted data bit. Attempted privilege mode writes are ignored.

Address: 4000\_1000h base + 438h offset = 4000\_1438h

## OCMEM\_OCMFDR field descriptions

Field	Description
63–32 EFDH	On-Chip Memory ECC Fault Data High. This read-only field specifies the upper 32-bit read data word (data[63:32]) from the last captured ECC event.
EFDL	On-Chip Memory ECC Fault Data Low. This read-only field specifies the lower 32-bit read data word (data[31:0]) from the last captured ECC event.

## 9.4 Local Memory Controller (LMEM)

### 9.4.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Local Memory Controller provides the ARM®Cortex-M4™ processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces.

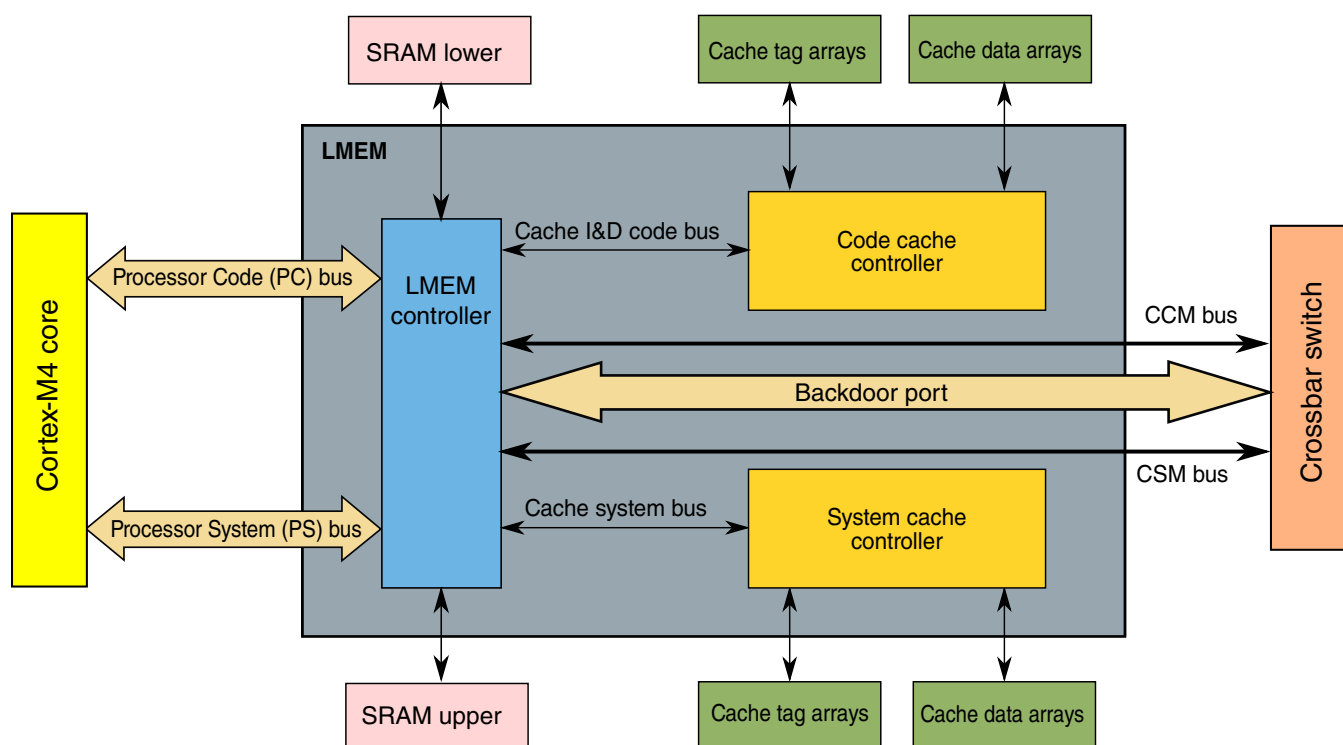

#### 9.4.1.1 Block Diagram

The Cortex-M4 processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000\_0000 through 0x1FFF\_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000\_0000 through 0xFFFF\_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled memories for the PC and PS buses. The memories include RAMs and caches. These local memories provide zero wait state access to RAM and cacheable address spaces.

The local memory controller includes four memory controllers and their attached memories:

- SRAM lower (SRAM\_L) controller via the PC bus
- SRAM upper (SRAM\_U) controller via the PS bus
- Cache memory controller via the PC bus
- Cache memory controller via the PS bus

**Figure 9-10. Local memory controller block diagram**

### NOTE

The SRAM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources. The address spaces are device-specific and are specified in the device's Chip Configuration chapter.

The CM4 core address space is decoded as follows:

**Table 9-4. Address Space Decode**

Address Range	Core/Slave Bus <sup>1</sup>	Slave Target, XBAR Port	Cache Mode at reset
0x0000_0000 → 0x07FF_FFFF	PC/CCM	Boot Rom (S0A)	cacheable write-through
0x0800_0000 → 0x0FFF_FFFF	PC/CCM	DDR code alias (S8)	cacheable write-through
0x1000_0000 → 0x17FF_FFFF	PC/CCM	QuadSPI0 alias (S2)	cacheable write-through
0x1800_0000 → 0x1EFF_FFFF	PC/CCM	FlexBus code alias (S0B)	cacheable write-through
0x1F00_0000 → 0x1F7F_FFFF	PC/CCM	OCRAM code alias (S3/S4/S5)	cacheable write-through
0x1F80_0000 → 0x1FFF_FFFF	PC/---	CM4_TCML Frontdoor	non-cacheable
0x2000_0000 → 0x2FFF_FFFF	PS/CSM	QuadSPI0 (S2)	cacheable write-back

*Table continues on the next page...*

**Table 9-4. Address Space Decode (continued)**

Address Range	Core/Slave Bus <sup>1</sup>	Slave Target, XBAR Port	Cache Mode at reset
0x3000_0000 → 0x3EFF_FFFF	PS/CSM	FlexBus (S0B)	cacheable write-back
0x3F00_0000 → 0x3F7F_FFFF	PS/CSM	OCRAM (S3/S4/S5)	cacheable write-back
0x3F80_0000 → 0x3FFF_FFFF	PS/---	CM4_TCMU Frontdoor	non-cacheable
0x4000_0000 → 0x4006_FFFF	PS/CSM	IPS0 Peripherals (S0C)	non-cacheable
0x4007_0000 → 0x4007_FFFF	PS/CSM	Secure RAM (S6)	non-cacheable
0x4008_0000 → 0x400F_EFFF	PS/CSM	IPS1 Peripherals (S1C)	non-cacheable
0x400F_0000 → 0x400F_FFFF	PS/CSM	RGPIO (S1A)	non-cacheable
0x4010_0000 → 0x4FFF_FFFF	PS/CSM	NOT USED	–
0x5000_0000 → 0x5FFF_FFFF	PS/CSM	QuadSPI1 (S7A)	cacheable
0x6000_0000 → 0x77FF_FFFF	PS/CSM	NOT USED	–
0x7800_0000 → 0x79FF_FFFF	PS/CSM	RLE (S7B)	cacheable write-through
0x7A00_0000 → 0x7BFF_FFFF	PS/CSM	QS1 RxBuf (S7A)	cacheable write-through
0x7C00_0000 → 0x7DFF_FFFF	PS/CSM	QS0 RxBuf (S2)	cacheable write-through
0x7E00_0000 → 0x7FFF_FFFF	PS/CSM	altGFXRAM (S5)	cacheable write-through
0x8000_0000 → 0xDFFF_FFFF	PS/CSM	DDR (S8)	cacheable write-back
0xE000_0000 → 0xE00F_FFFF	1	CM4 PPB	–

1. All references are routed to the core's Private Peripheral Bus (PPB) and never appear on the PS/CSM buses.

### 9.4.1.2 Cache features

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- **Spatial locality** — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- **Temporal locality** — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports three modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
  - A read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
  - A write-through read hit to a valid cache location returns data from the cache with no output bus access.
  - A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).
  - A write-through write hit updates the cache hit line with the write data and writes to the output bus.
2. Write-back — access to address spaces with this cache mode are cacheable.
  - A write-back read miss on the input bus will cause a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and marked as valid and not modified.
  - A write-back read hit to a valid cache location will return data from the cache with no output bus access.
  - A write-back write miss will do a "read-to-write" (allocate on write miss policy for write-back mode spaces). A line read on the output bus of a 32 byte aligned memory address containing the desired write address is performed. This miss data is loaded into the cache and marked as valid and modified; and the write data will then update the appropriate cache data locations.
  - A write-back write hit updates the cache hit line with the write data plus marks the line as modified.
3. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

## 9.4.2 Memory Map and Registers

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

**LMEM memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
E008_2000	Cache control register (LMEM_PCCCR)	32	R/W	0000_0000h	<a href="#">9.4.2.1/1196</a>

## LMEM\_PCCCR field descriptions

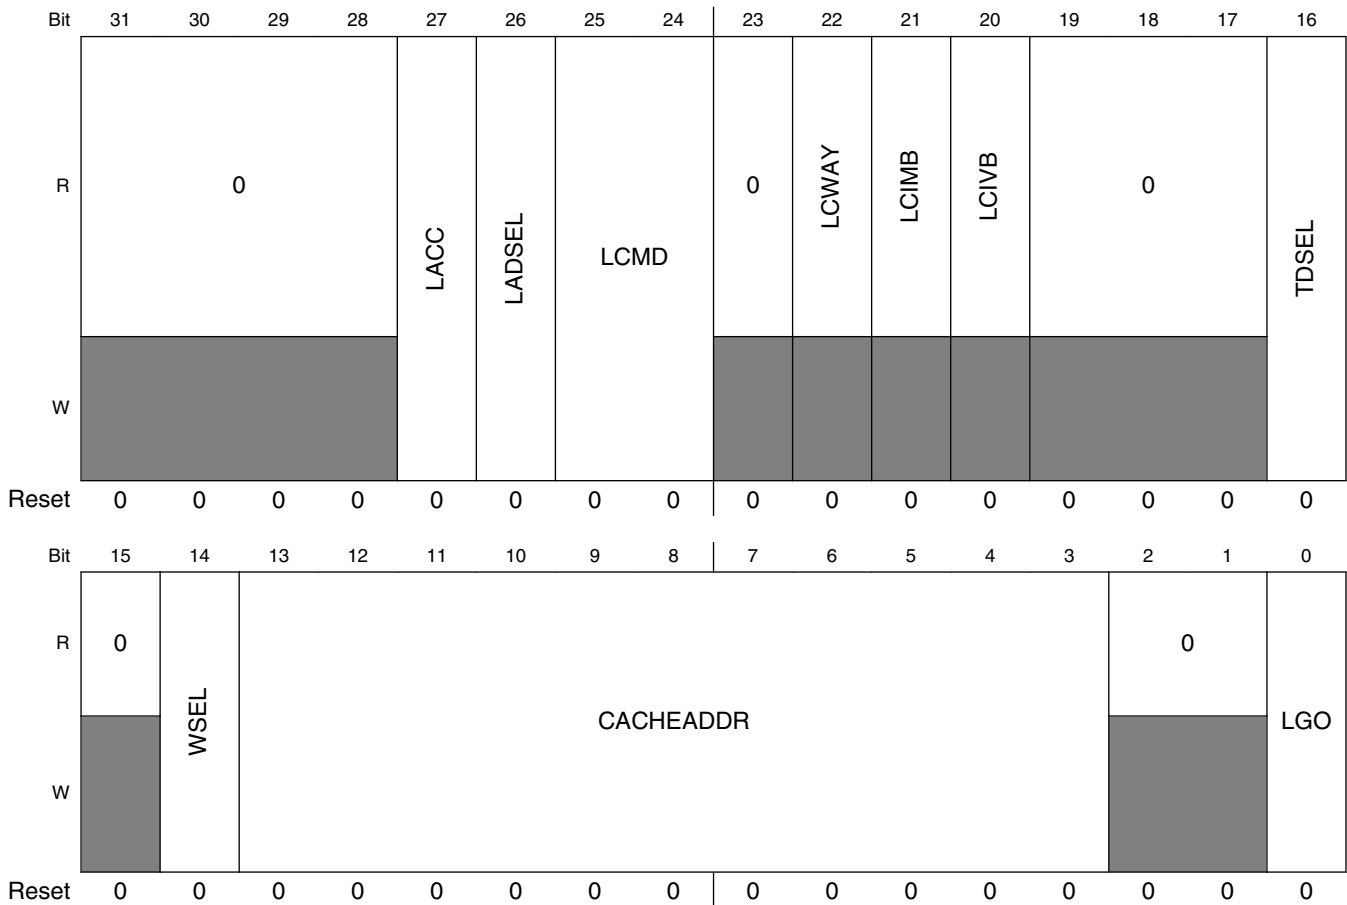

Field	Description
31 GO	<p>Initiate Cache Command</p> <p>Setting this bit initiates the cache command indicated by bits 27-24. Reading this bit indicates if a command is active</p> <p><b>NOTE:</b> This bit stays set until the command completes. Writing zero has no effect.</p> <p>0 Write: no effect. Read: no cache command active. 1 Write: initiate command indicated by bits 27-24. Read: cache command active.</p>
30–28 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
27 PUSHW1	<p>Push Way 1</p> <p>0 No operation 1 When setting the GO bit, push all modified lines in way 1</p>
26 INVW1	<p>Invalidate Way 1</p> <p><b>NOTE:</b> If the PUSHW1 and INVW1 bits are set, then after setting the GO bit, push all modified lines in way 1 and invalidate all lines in way 1 (clear way 1).</p> <p>0 No operation 1 When setting the GO bit, invalidate all lines in way 1</p>
25 PUSHW0	<p>Push Way 0</p> <p>0 No operation 1 When setting the GO bit, push all modified lines in way 0</p>
24 INVW0	<p>Invalidate Way 0</p> <p><b>NOTE:</b> If the PUSHW0 and INVW0 bits are set, then after setting the GO bit, push all modified lines in way 0 and invalidate all lines in way 0 (clear way 0).</p> <p>0 No operation 1 When setting the GO bit, invalidate all lines in way 0.</p>
23–4 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
3 PCCR3	Forces no allocation on cache misses (must also have PCCR2 asserted)
2 PCCR2	Forces all cacheable spaces to write through
1 ENWRBUF	<p>Enable Write Buffer</p> <p>0 Write buffer disabled 1 Write buffer enabled</p>
0 ENCACHE	<p>Cache enable</p> <p>0 Cache disabled 1 Cache enabled</p>

9.4.2.2 Cache line control register (LMEM\_PCCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008\_2000h base + 4h offset = E008\_2004h

LMEM\_PCCLCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL].

Table continues on the next page...

**LMEM\_PCCLCR field descriptions (continued)**

Field	Description
	When using the physical address, both ways are searched and the command is performed only if a hit. 0 Cache address 1 Physical address
25–24 LCMD	Line Command 00 Search and read or write 01 Invalidate 10 Push 11 Clear
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LCWAY	Line Command Way Indicates the way used by the line command. Only applies if valid bit LCIVB = 1.
21 LCIMB	Line Command Initial Modified Bit If command used cache address and way, then this bit shows the initial state of the modified bit If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero.
20 LCIVB	Line Command Initial Valid Bit If command used cache address and way, then this bit shows the initial state of the valid bit If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.
19–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TDSEL	Tag/Data Select Selects tag or data for search and read or write commands. 0 Data 1 Tag
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WSEL	Way select Selects the way for line commands. 0 Way 0 1 Way 1
13–3 CACHEADDR	Cache address CLCR[12:5] bits are used to access the tag arrays CLCR[12:3] bits are used to access the data arrays
2–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## LMEM\_PCCLCR field descriptions (continued)

Field	Description
0 LGO	<p>Initiate Cache Line Command</p> <p>Setting this bit initiates the cache line command indicated by bits 27-24. 1 ENWRBUF	Enable Write Buffer  0 Write buffer disabled 1 Write buffer enabled
0 ENCACHE	Cache enable  0 Cache disabled 1 Cache enabled

**9.4.2.6 Cache line control register (LMEM\_PSCLCR)**

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008\_2000h base + 804h offset = E008\_2804h

## Local Memory Controller (LMEM)

**LMEM\_PSCLCR field descriptions**

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL]. When using the physical address, both ways are searched and the command is performed only if a hit. 0 Cache address 1 Physical address
25–24 LCMD	Line Command 00 Search and read or write 01 Invalidate 10 Push 11 Clear
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LCWAY	Line Command Way Indicates the way used by the line command. Only applies if valid bit LCIVB = 1.
21 LCIMB	Line Command Initial Modified Bit If command used cache address and way, then this bit shows the initial state of the modified bit If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero.
20 LCIVB	Line Command Initial Valid Bit If command used cache address and way, then this bit shows the initial state of the valid bit If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.

Table continues on the next page...

**LMEM\_PSCLCR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
19–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TDSEL	Tag/Data Select Selects tag or data for search and read or write commands.  0 Data 1 Tag
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WSEL	Way select Selects the way for line commands.  0 Way 0 1 Way 1
13–3 CACHEADDR	Cache address CLCR[12:5] bits are used to access the tag arrays CLCR[12:3] bits are used to access the data arrays
2–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command  Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active  <b>NOTE:</b> This bit stays set until the command completes. Writing zero has no effect.  <b>NOTE:</b> This bit is shared with CSAR[LGO]  0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits 27-24. Read: line command active.

9.4.2.7 Cache search address register (LMEM\_PSCSAR)

The CSAR register is used to define the explicit cache address or the physical address for line-sized commands specified in the CLCR[LADSEL] bit.

Address: E008\_2000h base + 808h offset = E008\_2808h

LMEM\_PSCSAR field descriptions

Field	Description
31–3 PHYADDR	Physical Address  PHYADDR represents bits [31:3] of the system address.  CSAR[31:13] bits are used for tag compare CSAR[12:5] bits are used to access the tag arrays CSAR[12:3] bits are used to access the data arrays
2–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command  Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active  <b>NOTE:</b> This bit stays set until the command completes. Writing zero has no effect.  <b>NOTE:</b> This bit is shared with CLCR[LGO]  0   Write: no effect. Read: no line command active. 1   Write: initiate line command indicated by bits CLCR[27:24]. Read: line command active.

### 9.4.2.8 Cache read/write value register (LMEM\_PSCCVR)

The CCVR register is used to source write data or return read data for the commands specified in the CLCR register.

Address: E008\_2000h base + 80Ch offset = E008\_280Ch

## 9.4.3 Functional Description

### 9.4.3.1 LMEM Function

The Local Memory Controller receives the following requests:

- Core master bus requests on the Processor Code (PC) bus,
- Core master bus requests on the Processor Space (PS) bus, and
- SRAM controller requests from all other bus masters on the backdoor port.

The Local Memory Controller address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all SRAM controller and cacheable accesses.

The programming model for the Code and System Caches is accessed via the core's Private Peripheral Bus (PPB).

### 9.4.3.1.1 Processor Code accesses

Processor Code accesses are routed to the SRAM\_L if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

### 9.4.3.1.2 Processor System accesses

Processor Space accesses are routed to the SRAM\_U if they are mapped to that space. All other PS accesses are routed to the PS Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master1 port.

### 9.4.3.1.3 Backdoor port accesses

All LMEM backdoor port accesses are for the SRAM controller. These accesses go to the SRAM\_L or the SRAM\_U depending on their specific address.

## 9.4.3.2 SRAM Function

### 9.4.3.2.1 SRAM Configuration

The figure below shows how the SRAM controller is configured.

**Figure 9-11. SRAM Configuration**

#### 9.4.3.2.2 SRAM Arrays

The on-chip SRAM is split into two logical arrays, SRAM\_L and SRAM\_U.

From equal-sized memories, valid address ranges for SRAM\_L and SRAM\_U are then defined as:

- $\text{SRAM\_L} = 0x1F80\_0000 - (0x1F80\_0000 + \text{SRAM\_size}/2)$
- $\text{SRAM\_U} = 0x3F80\_0000 - (0x3F80\_0000 + \text{SRAM\_size}/2)$

#### 9.4.3.2.3 SRAM Accesses

The SRAM is split into two logical arrays that are 64-bits wide:

- **SRAM\_L** — Accessible by the code bus of the Cortex-M4 core and by the backdoor port.
- **SRAM\_U** — Accessible by the system bus of the Cortex-M4 core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

Figure 9-12 illustrates the SRAM accesses within the device.

**Figure 9-12. SRAM access diagram**

The following simultaneous accesses can be made to different logical halves of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

#### **NOTE**

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM\_{L,U} arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

### **9.4.3.3 Cache Function**

The caches on this device are structured as follows. Both caches have a 2-way set-associative cache structure with a total size of 16 KBytes. The caches have 32-bit address, 64-bit data paths and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For these these 16-KByte caches, each cache TAG function uses two 256 x 21-bit RAM arrays and the cache DATA function uses two 1024 x 64-bit RAM arrays. The cache TAG entries store 19 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight bytes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CACHE - 16 KByte size = (256 sets) x (32-byte lines) x (2-way set associative)

**TAG:**

- address[31:13] used in tag for compare (hit) logic
- address[12:5] used to select 1 of 256 sets
- address[4:0] not used

**DATA**

- address[31:13] not used
- address[12:5] used to select one of 256 sets
- address[4:3] used to select one of four 64-bit words within a set
- address[2:0] used to select the byte within the 64-bit word

**9.4.3.4 Cache Control**

The Code and System Caches are disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the caches, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

**9.4.3.4.1 Cache set commands**

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the CCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, CCR[ENCACHE].

A cache set command is initiated by setting the CCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in [Table 9-5](#). Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.
- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

**Table 9-5. Cache Set Commands**

CCR[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1; clear all way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting CCR to 0x8500\_0003 will invalidate the cache and enable the cache and write buffer.

#### 9.4.3.4.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by bits [12:5] of the physical address. If they hit, the commands perform their action on the hit way.

Cache line commands are specified using the upper bits in the CLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (CCR[ENCACHE]). Using a cache address, the command can be completely specified using the CLCR register. Using a physical address, the command must also use the CSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (CLCR[LGO] or CSAR[LGO]). This bit also acts as a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The CLCR[27:24] bits select the line command as follows:

**Table 9-6. Cache Line Commands**

CLCR[27:24]			Command
LACC	LADSEL	LCMD	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	xx	Reserved, NOP

#### 9.4.3.4.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the CLCR.

- Place the command in CLCR[27:24],
- Set the way (CLCR[WSEL]) and tag/data (CLCR[TDSEL]) controls as needed,
- Place the cache address in CLCR[CACHEADDR], and
- Set the line command go bit (CLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 3 to step through data or at bit 5 to step through lines), and
- Set the line command go bit (CLCR[LGO]).

#### 9.4.3.4.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the CLCR.
  - Place the command in CLCR[27:24]
  - Set the tag/data (CLCR[TDSEL]) control
- Place the physical address in CSAR[PHYADDR] and set the line command go bit (CSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 3 to step through data or at bit 5 to step through lines), and
- Set the line command go bit (CSAR[LGO]).

The line command go bit is shared between the CLCR and CSAR registers, so that the above steps can be completed in a single write to the CSAR register.

#### 9.4.3.4.2.3 Line command results

At completion of a line command, the CLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit cleared if the command misses. In general, if the valid indicator (CLCR[LCIVB]) is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

**Table 9-7. Line command results**

CLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
0	0	0	Way 0 line was invalid	No hit
0	0	1	Way 0 valid, not modified	Way 0 valid, not modified
0	1	0	Way 0 line was invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line was invalid	No hit
1	0	1	Way 1 valid, not modified	Way 1 valid, not modified
1	1	0	Way 1 line was invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

At completion of a line command other than a write, the CCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the CCVR holds the write data.

## 9.5 System Bus Interconnect

### 9.5.1 Overview

The CoreLink Network Interconnect (NIC301) is a second generation highly configurable IP component that enables the creation of a complete high performance, optimized AMBA-compliant network infrastructure. It is based around a high-performance AXI crossbar switch known as the AXI bus matrix.

Recall the AMBA-AXI protocol is ARM's Advanced eXensible Interface, the third generation AMBA interface definition. It is targeted for high performance, high frequency system designs and is suitable for high bandwidth, low latency data transfers. The key features of the AXI protocol include:

- Burst-based, split transaction bus
- Separate address/control and data phases
- Ability to issue multiple outstanding addresses
- Out-of-order transaction completion
- Five independent channels
  - Read address
  - Write address
  - Read data
  - Write data
  - Write response
- Each channel uses 2-way handshake mechanism (VALID, READY control signals)

The possible configurations for the CoreLink Network Interconnect can range from a single bridge component, for example an AHB to AXI protocol bridge, to a complex infrastructure that consists of up to 128 masters and 64 slaves of a combination of different AMBA protocols.

As the device includes a large number of bus master and slave devices implementing both AXI and AHB bus protocols with 32- or 64-bit datapath widths and operating at multiple synchronous frequencies, the NIC301 is an ideal system bus “fabric” and provides the needed hardware interconnect matrix for the device.

A CoreLink Network Interconnect configuration can consist of multiple switches with many topology options. Figure 9-13 shows a top-level block diagram of the CoreLink Network Interconnect that contains:

- Multiple switches
- Multiple AMBA Slave Interface Blocks (ASIBs)
- Multiple AMBA Master Interface Blocks (AMIBs)

Note in the context of the NIC301, a *system bus master* connects to an *AMBA Slave Interface* (ASIB) and a *bus slave* connects to an *AMBA Master Interface Block* (AMIB).

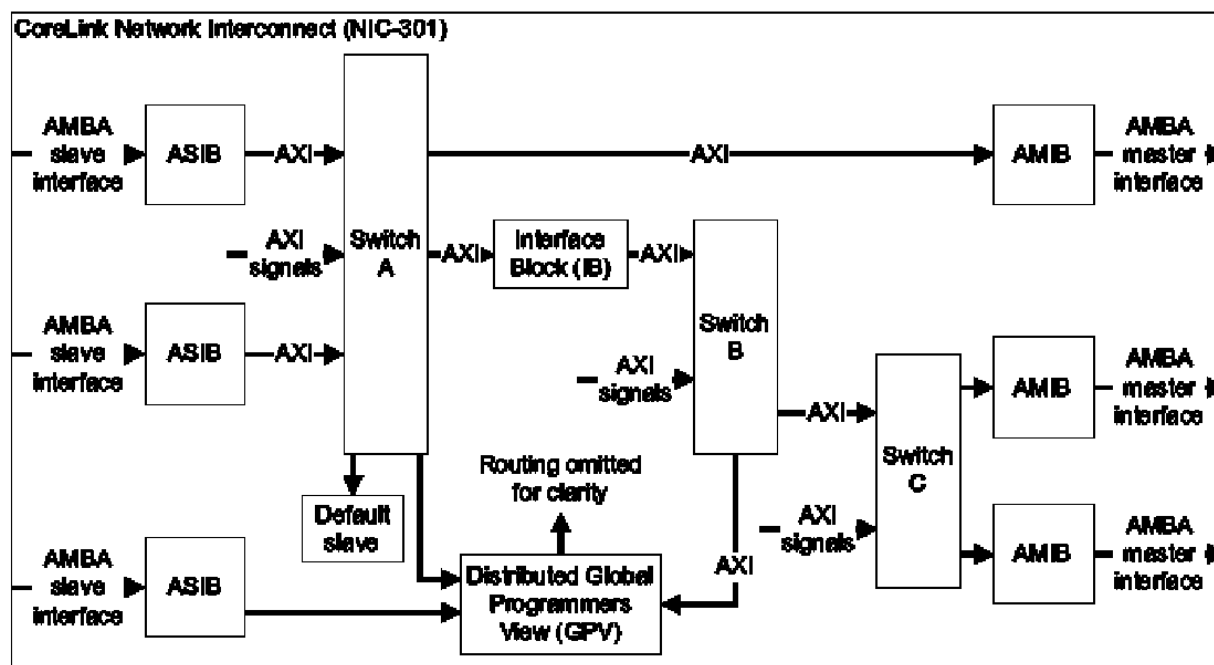

Figure 9-13. NIC301 Block Diagram

The table below provides an overview of the characteristics of the bus masters and slaves.

Table 9-8. Bus Master and Slave Interface Characteristics

Module	Type	interface Protocol	Interface Ports	Datapath Width	Operating Speed
Cortex-A5	Master	AXI	1	64b	High-speed Core
Cortex-M4	Master	AHB-Lite	2	64b	Low-speed Core = Platform
DMA2x	Master	AHB-Lite	2 <sup>1</sup>	64b	Platform

Table continues on the next page...

**Table 9-8. Bus Master and Slave Interface Characteristics (continued)**

Module	Type	Interface Protocol	Interface Ports	Datapath Width	Operating Speed
DCU	Master	AXI	2 <sup>1</sup>	64b	Platform
USB OTG	Master	AHB-Lite	2 <sup>1</sup>	32b	Platform/2
Open VG	Master	AXI	1	64b	Platform
ENET	Master	AHB-Lite	2 <sup>2</sup>	32b	Platform/2
VIU3	Master	AHB-Lite	1	64b	Platform
eSDHC	Master	AHB-Lite	2 <sup>1</sup>	32b	Platform
NFC	Master	AHB-Lite	1	32b	Platform
CAAM	Master	AXI	1	32b	Platform
Debug Access Port (DAP)	Master	AHB-Lite	1	32b	Platform
ROM	Slave	AHB-Lite	1	64b	Platform
FlexBus	Slave	AHB-Lite	1	32b	Platform
QuadSPI, RLE	Slave	AHB-Lite	2 <sup>1</sup>	64b	Platform
OCRAM	Slave	AXI	3 <sup>1</sup>	64b	Platform
CM4_TCM	Slave	AHB-Lite	1	64b	Platform
SDRAMC (DDR)	Slave	AXI	2	64b	Platform
SecureRAM	Slave	AXI	1	32b	Platform
PBRIDGE (Peripheral Bridges)	Slave	AHB-Lite	2	64b	Platform

1. For these master and slaves, the multiple interface ports are due to multiple instances of the given module, for example, there are two DCU modules and two DMA2x modules. etc.
2. One of the ENET master ports (ENET1) is statically muxed with the master port from the MLB50 module which supports the MediaLB protocol for transfers on the MOST@data network. From the perspective of the NIC301 switch, the combined ENET1/MLB50 port appears as a single bus master.

## 9.5.2 Features

The CoreLink Network Interconnect NIC301 is a highly configurable infrastructure component that includes the following features:

- 1-128 AXI or AHB-Lite slave interfaces for bus master connections
- 1-64 master interfaces that can be AXI, AHB-Lite, APB2, or APB3 for bus slave connections
- Single-cycle arbitration Full pipelining to prevent master stalls
- Programmable control for FIFO transaction release
- Multiple switch networks
- AXI or AHB-Lite masters and slaves
  - Address width of 32-64 bits
  - Data width of 32, 64, 128, or 256 bits

- Non-contiguous APB slave address map for a single master interface
- Independent widths of user-defined sideband signals for each channel
- Global Programmers View (GPV) for the entire infrastructure, configurable for customizing the memory mapped visibility
- Highly flexible timing closure options

A very important attribute of the entire system bus fabric supported by the NIC301 and its split transaction protocol is the ***optimization for multi-master data bandwidth*** (versus data transfer latencies). *The device architecture implements a high performance microprocessor architecture where system performance is maximized by making effective use of the processor local memories (L1 and L2 caches, tightly coupled memories) and 32-byte cache line size 4-beat burst data transfers on the system bus fabric.* In environments and application spaces where these runtime characteristics are *not met*, data latency concerns can degrade system performance substantially.

### 9.5.3 NIC301 Physical Structure and Programming Model

#### 9.5.3.1 NIC301 Physical Structure

The port assignments and NodeNumbers are of interest in the this section's discussion on the physical structure of the NIC301. The NodeNumbers are associated with the NIC301's Global Programmers View of the control and configuration registers. See [Table 9-9](#)

**Table 9-9. NIC301 Port Assignments and NodeNumbers**

Module	Type	PortNumber	NodeNumber
Cortex-M4 Code	Master	m0	66
Cortex-M4 System	Master	m1	67
Cortex-A5	Master	m2	68
DMA2x0	Master	m3	69
DMA2x1	Master	m4	70
DCU0	Master	m5	71
USB OTG0	Master	m6	72
Open VG	Master	m7	73
ENET0	Master	m8	74
ENET1 / MLB50	Master	m9(a,b)	75
VIU3	Master	m10	76
USB OTG1	Master	m11	77
DCU1	Master	m12	78

Table continues on the next page...

**Table 9-9. NIC301 Port Assignments and NodeNumbers (continued)**

Module	Type	PortNumber	NodeNumber
eSDHC0	Master	m13	79
eSDHC1	Master	m14	80
NFC	Master	m15	81
CAAM	Master	m16	82
Debug Access Port (DAP)	Master	m17	83
ROM	Slave	s0	2
FlexBus	Slave	s0	2
PBRIDGE0	Slave	s0	2
CM4_TCMx	Slave	s1	3
PBRIDGE1	Slave	s1	3
QuadSPI0	Slave	s2	4
OCRAM0_sys	Slave	s3	5
OCRAM1_sys	Slave	s4	6
OCRAM2_gfx	Slave	s5	7
SecureRAM	Slave	s6	8
QuadSPI1	Slave	s7	9
RLE	Slave	s7	9
SDRAMC (AXI0)	Slave	s8	10
SDRAMC (AXI1)	Slave	s9	11

**NOTE**

Masters that can access S8 (DDR0):

- M0, M1 (CM4)
- M5 (DCU0)
- M6 (USB)
- M10 (VIU2)
- M3, M8, M13, M15, M17 (DMA0, ENET0, eSDHC0, NFC, DBG)

**NOTE**

Masters that can access S9 (DDR1) are:

- M2 (CA5)
- M7 (Open VG)
- M12 (DCU1)
- M4, M9a, M9b, M11, M14, M16 (DMA1, ENET1, MLB, USB, eSDHC2, CAAM)

**NOTE**

There are a few restrictions on the masters that can access S6 port. The following masters cannot access S6 (SecureRAM):

- M5 (DCU0)
- M7 (Open VG)
- M10 (VIU2)
- M12 (DCU1)

Note the multiple shared NIC301 port connections (s0, s1, s7) to slave modules. For these shared slave connections, the device dual core platform includes “port splitters” to route the data transfers to the appropriate target module.

The internal structure of the device NIC301 implementation is shown in the figure below. For this complex system bus fabric, the structure balances the masters and slaves based on the expected data traffic and by grouping modules with similar bus protocols. The structure includes 3 master switch concentrators feeding, along with 6 masters with direct connections, into the main bus switch (switch3). Additionally, there is a 1-to-4 bus splitter on the slave side of the main switch. The resulting structure represents a trade-off balancing bus switch size, MHz timing and system bandwidth considerations.

Figure 9-14. NIC301 Physical Block Diagram

### 9.5.3.2 NIC301 Programming Model

The individual AMBA master and slave interface blocks contained in the NIC301 each support a number of configuration registers for defining the operation of the bus switch. This section provides details on the memory map associated with the NIC301's GPV address space; details on the operation of specific control fields within these GPV registers can be found in the appropriate ARM documentation. The device implementation only allows privilege mode references; attempted references in user mode are error terminated.

As previously noted, the NIC301 is a very highly configurable IP component. To support the wide range of possible NIC301 configurations, the GPV is defined by the maximum configuration, and occupies a 1 Mbyte address space consisting of 256 4 Kbyte address spaces. Specifically, this 1 Mbyte address space consists of the following concatenation of register blocks:

- Address control register block
- Peripheral ID register block
- 64 master interface (AMIB) register blocks
- 128 slave interface (ASIB) register blocks
- 62 internal interface (IB) register blocks

The replicated register blocks are *very sparsely populated*, both in terms of address locations used as well as the total number of defined register bits. As examples, the AMIB register block only includes 14 register bits per 4 Kbyte space; the ASIB includes 21 registers bit per 4 Kbyte space and the IB 12 register bits per 4 Kbyte space. The internal interface (IB) register blocks are *not used in the device*, but are partially supported in the architectural definition of the GPV address compression scheme.

The device uses an address compression technique to reduce the NIC301 GPV address space from 1 MB down to 32 Kbytes, which is then mapped to 8 consecutive 4 Kbyte “slots” managed by the PBRIDGE0 bus controller. This space is located at addresses 0x4000\_8000 - 0x4000\_FFFF in the device memory map.

To support the required 32:1 address space compression, the GPV’s 20-bit 1 Mbyte address must be reduced to a 15-bit 32 Kbyte address for the PBRIDGE. For the GPV, the register base offset address is calculated as  $4096 * \text{NodeNumber}$ ; in general, the PBRIDGE register offset address is defined as  $256 * \text{NodeNumber}$  with special handling of ADDR[7] providing the final bit of address compression. See [Table 9-10](#) for the association between the GPV and PBRIDGE register address offsets. Recall the NodeNumbers were defined in [Table 9-9](#)

**Table 9-10. NIC301 GPV → PBRIDGE Base Address Offset Compression**

GPV Register Block	GPV Base Offset	PBRIDGE Base Offset	NodeNumber	GPV Address Offset	PBRIDGE Address Offset
Address Control	0x0_0000	0x0000	0	$4096 * \text{NodeNumber}$	$256 * \text{NodeNumber}$
Peripheral ID	0x0_1000	0x0100	1	$4096 * \text{NodeNumber}$	$256 * \text{NodeNumber}$
Master (AMIB) Interface [0-31]	0x0_2000 - 0x2_1000	0x0200 - 0x2100	2-33	$4096 * \text{NodeNumber}$	$256 * \text{NodeNumber}$
Master (AMIB) Interface [32-63]	0x2_2000 - 0.x4_1000	Not supported	34-65	$4096 * \text{NodeNumber}$	Not supported
Slave (ASIB) Interface [0-63]	0x4_2000 - 0x8_1000	0x2200 - 0x6100	66-129	$4096 * \text{NodeNumber}$	$256 * (\text{NodeNumber} - 32)$
Slave (ASIB) Interface [64-127]	0x8_2000 - 0xC_1000	Not supported	130-193	$4096 * \text{NodeNumber}$	Not Supported
Internal (IB) Interface [0-29]	0xC_2000 - 0xD_F000	0x6200 - 0x7F00	194 - 223	$4096 * \text{NodeNumber}$	$256 * (\text{NodeNumber} - 96)$
Internal (IB) Interface [30-61]	0xE_0000 - 0xF_F000	Not supported	224-255	$4096 * \text{NodeNumber}$	Not Supported

The final details associated with the GPV address space compression involves the behavior of ADDR[7]. For register offsets < 0x80, the GPV and PBRIDGE addresses are identical. Fortunately, the number of register offsets not meeting this condition are small in number. See [Table 9-11](#) for the details on the required compression between GPV\_ADDR[11:0] and PBRIDGE\_ADDR[7:0].

**Table 9-11. NIC301 GPV and PBRIDGE Register Offset Addresses**

GPV Register Block	GPV_ADDR [11:0]	PBRIDGE_ADDR [7:0]	Register
All	< 0x080	< 0x80	Any register with these offsets
Address Control	0x080	0x80	security30
	0x084	0x84	security31 (Max GPV address = 0x084)
Peripheral ID	0xFD0	0xD0	Peripheral ID4
	0xFD4	0xD4	Peripheral ID5
	0xFD8	0xD8	Peripheral ID6
	0xFDC	0xDC	Peripheral ID7
	0xFE0	0xE0	Peripheral ID0
	0xFE4	0xE4	Peripheral ID1
	0xFE8	0xE8	Peripheral ID2
	0xFEC	0xEC	Peripheral ID3
	0xFF0	0xF0	Component ID0
	0xFF4	0xF4	Component ID1
	0xFF8	0xF8	Component ID2
	0xFFC	0xFC	Component ID3
Master (AMIB) Interface [0-31]	0x108	0x88	fn_mod
Slave (ASIB) Interface [0-63]	0x100	0x80	read_qos
	0x104	0x84	write_qos
	0x108	0x88	fn_mod
Internal (IB) Interface [0-29]	0x108	0x88	fn_mod

Combining all the information detailed in [Table 9-10](#) and [Table 9-11](#), the complete definition of the device memory map for the NIC301 GPV registers is presented in [Table 9-12](#).

**Table 9-12. NIC301 GPV Registers and PBRIDGE Access Addresses**

GPV Register Block	GPV_ADDR [11:0]	Device ADDR	Register

### 9.5.3.3 NIC301 Bus Arbitration

The NIC301 switch implements a two level arbitration mechanism that is partially programmable.

There is a 4-bit *Quality of Service (QoS)* priority that can be assigned (both a default value at reset plus a software programmed value) to each master port. Within the NIC301, the arbitration logic uses the QoS values for a first level fixed priority scheme; the higher the QoS value, the higher the master's priority. For multiple requesting masters with the same QoS value, a second level least-recently-used (also known as a least-recently-granted) scheme is applied.

The NIC301 Technical Reference Manual states “At any arbitration node, a fixed priority exists for transactions with a different QoS. The highest value has the highest priority. If there are coincident transactions at an arbitration node with the same QoS that require arbitration, then the Network uses a Least Recently Used (LRU) algorithm.”

Given these arbitration capabilities, the device dual-core platforms defines a default set of QoS values that represents a “recommended system configuration”. The default QoS values for the NIC301's bus masters are shown in the table below.

**Table 9-13. NIC301 Default QoS Arbitration Priorities**

System Bus Master	Port Number	Default QoS
Cortex-M4 Core	m0	1
Cortex-M4 System	m1	2
Cortex-A5	m2	0
DMA2x0	m3	4
DMA2x1	m4	4
DCU0	m5	14
USB OTG0	m6	11
Open VG	m7	12
ENET0	m8	10
ENET1 / MLB50	m9{a,b}	10
VIU3	m10	13
USB OTG1	m11	11
DCU1	m12	14
eSDHC0	m13	9
eSDHC1	m14	9
NFC	m15	3
CAAM	m16	5
Debug Access Port (DAP)	m17	15

## 9.6 AHB-TrustZone Address Space Controller (AHBTZASC)

### 9.6.1 Overview

The AHB-TZASC provides functionality equivalent to the (AXI) TZASC module. There are four instances of the basic AHB-TZASC functionality, each supporting 8 memory “region descriptors” with a programming model exactly equivalent to the (AXI) TZASC’s capabilities.

### 9.6.2 AHB-TZASC Programming Model Differences vs. (AXI) TZASC

The (AXI) TZASC module supports the notion of read and write speculative accesses. This support reflects, to some degree, to the basic nature and timing requirements of the AXI protocol. At reset, both read and write speculations are enabled and the transaction address and attributes are forwarded to the slave destination before the validity of the access has been evaluated.

The TZASC allows AXI data transfers only if the access check allows the reference; if the access check detects a violation, the data transfer is inhibited and the access is redefined as a Denied AXI transaction. The address speculation is programmable and can be disabled by asserting the appropriate bits in the speculation\_control register. There are system performance implications: if address speculation is disabled, then the TZASC module adds one clock cycle of latency to perform the access check before the address is forwarded to the slave destination.

By contrast, the AHB-TZASC does not support, nor need any form of address speculation. Instead, the module is able to perform the required access check on-the-fly without adding any cycle of latency. If the access check indicates a violation, the AHB-TZASC module is still able to inhibit the reference to the slave.

Accordingly, there are 3 register bits in the TZASC programming model that are specifically related to the address speculation and not implemented in the AHB-TZASC module. As highlighted in Figure 64-1, these include:

1. Register bit = lockdown\_select[2]
  - This register bits provides a lock function for speculation\_control register, making its content read-only. Since the AHB-TZASC module does not need nor support speculation, this bit is not required and therefore not implemented. This bit is RAZ/WI.
2. Register bits = speculation\_control[1:0]

- These register bits control the read and write address speculation. Again, since the AHB-TZASC module does not need nor support speculation, these bits are not required and not implemented. These bits are RAO/WI (read as one, write ignored). This signals that speculation is disabled, but as discussed previously, there are no added cycles of latency.

In addition to these programming model differences, the AHB-TZASC does not implement the integration test registers (itop, itip, iterg) nor the component configuration registers (periph\_id\_[4:0], component\_id[3:0]).

### 9.6.3 AHB-TZASC Memory Map/Register Definition

This section provides an overview summary of the AHB-TZASC's programming model. See the (AXI) TZASC documentation for the specific register details. In particular, see the ARM document, “CoreLink™ TrustZone Address Space Controller TZC-380 Technical Reference Manual, (Rev r0p1 or newer)”, available at <http://infocenter.arm.com>.

Each instance of the AHB-TZASC is allocated a 1 KB address space, so that all 4 instances can be supported in a single 4 KB slave peripheral slot (on-platform slot 16, based at address 0x4001\_0000) of the PBRIDGE0 controller.

**Table 9-14. AHB-TZASC Programming Model Memory Map**

System Base Address Range	AHB-TZASC Programming Model Description

Field	Description
REGION_ATTRIBUTES	Region Attributes

## 9.7 Watchdog Timer (WDOG)

### 9.7.1 Overview

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG asserts the internal system reset signal, `wdog_rst_b` to the System Reset Controller (SRC).

There is also a provision for WDOG signal assertion by timeout counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter timeout is programmable. There is a power down counter which is enabled out of any reset (POR, Warm/Cold). This counter has a fixed timeout period of 16 seconds, upon which it asserts the WDOG signal.

Flow diagrams for the timeout counter, power down counter and interrupt operations are shown in [Flow Diagrams](#).

**Figure 9-15. WDOG Diagram**

### 9.7.1.1 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG\_RESET\_B\_DEB reset signal .
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout
- The duration between interrupt and timeout events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- Power down counter with fixed timeout period of 16 seconds, which if not disabled after reset will assert WDOG\_B signal low

- Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

## 9.7.2 External signals

**Table 9-15. Off-chip block signals**

Signal	I/O	Description	Reset State <sup>1</sup>	Pull-Up/ Down <sup>1</sup>
WDOG_b	O	This signal will power down the chip. See <a href="#">WDOG_B generation</a> .	1	-
wdog_rst_b	O	This signal is a reset source for the chip. See <a href="#">Watchdog reset generation</a> .	1	-

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

## 9.7.3 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG uses the low frequency reference clock for its counter and control operations. The peripheral bus clock is used for register read/write operations.

The low frequency reference clock is a free-running clock and can't be gated. The peripheral bus clock can't be gated and is selectively switched ON whenever read/write operations takes place.

## 9.7.4 Watchdog mechanism and system integration

The modules are disabled by default (after reset). WDOG1 will be configured during boot while WDOG2 is dedicated for secure world purposes and will be activated by TZ software if required. The TZ watchdog (TZ watchdog) module protects against TZ starvation by providing a method of escaping normal mode and forcing a switch to the TZ mode. TZ starvation is a situation where the normal OS prevents switching to the TZ mode. Such a situation is undesirable as it can compromise the system's security.

Once the TZ WDOG module is activated, it must be serviced by TZ on a periodic basis. If servicing does not take place, the timer times out. Upon a timeout, the TZ WDOG asserts a TZ-mapped interrupt that forces switching to the TZ mode. If it is still not serviced, the TZ WDOG asserts a security violation signal to the CSU. The TZ WDOG module cannot be programmed or de-activated by normal mode software.

The WDOG modules operate as follows:

- If servicing does not take place, the timer times out and the `wdog_rst_b` signal is activated (low)
- Interrupt can be generated before the counter actually times out
- The `wdog_rst_b` signal can be activated by software
- There is a power-down counter which gets enabled out of any reset. This counter has a fixed timeout period of 16 seconds upon which it will assert the `ipp_wdog_b` signal.

See [Watchdog Connectivity](#) for more details.

## 9.7.5 Functional description

This section provides a complete functional description of the block.

### 9.7.5.1 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the [Watchdog Control Register \(WDOG\\_WCR\)](#). The WDOG must be enabled by setting the WDE bit of [Watchdog Control Register \(WDOG\\_WCR\)](#) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and the WDOG outputs a system reset signal, `wdog_rst` and asserts `WDOG_B` (WDT bit should be set in [Watchdog Control Register \(WDOG\\_WCR\)](#)).

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of `WDOG_WCR`) if a service routine (see [Servicing WDOG to reload the counter](#)) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the [Watchdog Service Register](#)

(WDOG\_WSR), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the [Watchdog Control Register \(WDOG\\_WCR\)](#) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in [Flow Diagrams](#).

### NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

#### 9.7.5.1.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter the proper service sequence begins by writing 0x\_5555 followed by 0x\_AAAA to the [Watchdog Service Register \(WDOG\\_WSR\)](#). Any number of instructions can be executed between the two writes. If the WDOG\_WSR is not loaded with 0x\_5555 prior to writing 0x\_AAAA to the WDOG\_WSR, the counter is not reloaded. If any value other than 0x\_AAAA is written to the WDOG\_WSR after 0x\_5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of [Watchdog Control Register \(WDOG\\_WCR\)](#). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.

#### 9.7.5.2 Interrupt event

Prior to timeout, the WDOG can generate an interrupt which can be considered a warning that timeout will occur shortly.

The duration between interrupt event and timeout event can be controlled by writing to the WICT field of [Watchdog Interrupt Control Register \(WDOG\\_WICR\)](#). It can vary between 0 and 127.5 seconds. If the WDOG is serviced ([Servicing WDOG to reload the counter](#)) before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of [Watchdog Control Register \(WDOG\\_WCR\)](#) and the interrupt will not be triggered.

#### 9.7.5.3 Power-down counter event

The power-down counter inside WDOG will be enabled out of reset. This counter has a fixed timeout value of 16 seconds, after which it will drive the WDOG\_B signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of [Watchdog Miscellaneous Control Register \(WDOG\\_WMCR\)](#) within 16 seconds of reset deassertion. Once disabled, this counter can't be enabled again until the next system reset occurs. This feature is intended to prevent the hanging up of cores after reset, as WDOG is not enabled out of reset.

## 9.7.5.4 Low power modes

### 9.7.5.4.1 STOP and DOZE mode

If the WDOG timer disable bit for low power STOP and DOZE mode (WDZST) bit in the [Watchdog Control Register \(WDOG\\_WCR\)](#), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP or DOZE mode. Upon exiting low power STOP or DOZE mode, the WDOG operation returns to what it was prior to entering the STOP or DOZE mode.

### 9.7.5.4.2 WAIT mode

If the WDOG timer disable bit for low power WAIT mode (WDW) bit in the [Watchdog Control Register \(WDOG\\_WCR\)](#), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power WAIT enable (WDW) bit is set, the WDOG timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

#### NOTE

The WDOG timer won't be able to detect events that happen for periods shorter than one low frequency reference clock cycle. For example, in repeated WAIT mode entry or exit, if the RUN mode time is less than one low frequency reference clock cycle and if the WDW bit is set, the WDOG timer may never time out, even though the system is in RUN mode for a finite duration; WDOG may not see a low frequency reference clock edge during its wake time.

## 9.7.5.5 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the [Watchdog Control Register \(WDOG\\_WCR\)](#), the WDOG timer operation is suspended in debug mode. If the

WDBG bit is set and the debug mode is entered, WDOG timer operation is suspended after two low frequency reference clocks. Similarly, WDOG timer operation continues after two low frequency reference clocks of debug mode exit. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of [Watchdog Control Register \(WDOG\\_WCR\)](#) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

### NOTE

If the WDE bit of [Watchdog Control Register \(WDOG\\_WCR\)](#) is set/cleared while in debug mode, it remains set/cleared even after exiting debug mode.

## 9.7.5.6 Operations

### 9.7.5.6.1 Watchdog reset generation

The WDOG generated reset signal  $\overline{\text{wdog\_rst}}$  is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the [Watchdog Control Register \(WDOG\\_WCR\)](#).
- WDOG timeout. See [Timeout event](#).

The  $\overline{\text{wdog\_rst}}$  will be asserted for one clock cycle of low frequency reference clock for both a timeout condition and a software write occurrence. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between.

[Figure 9-17](#) shows the timing diagram of this signal due to a timeout condition.

### 9.7.5.6.2 WDOG\_B generation

The WDOG asserts WDOG\_B in the following scenarios:

- Software write to WDA bit of [Watchdog Control Register \(WDOG\\_WCR\)](#). WDOG\_B signal remains asserted as long as the WDA bit is "0".
- WDOG timeout condition, WDT bit of [Watchdog Control Register \(WDOG\\_WCR\)](#) must be set for this scenario. A description of the timeout condition can be found in the [Timeout event](#). WDOG\_B signal remains asserted until a power-on reset (POR) occurs. It gets cleared after the POR occurs (not due to any other system reset). [Figure 9-18](#) shows the timing diagram of WDOG\_B due to timeout condition.
- WDOG power-down counter timeout, PDE bit of [Watchdog Miscellaneous Control Register \(WDOG\\_WMCR\)](#) should not be cleared for this scenario. A description of

## Watchdog Timer (WDOG)

this counter can be found in the [Power-down counter event](#). WDOG\_B signal remains asserted for one clock cycle of low frequency reference clock.

Figure 9-16 shows the scenarios under which WDOG\_B gets asserted.

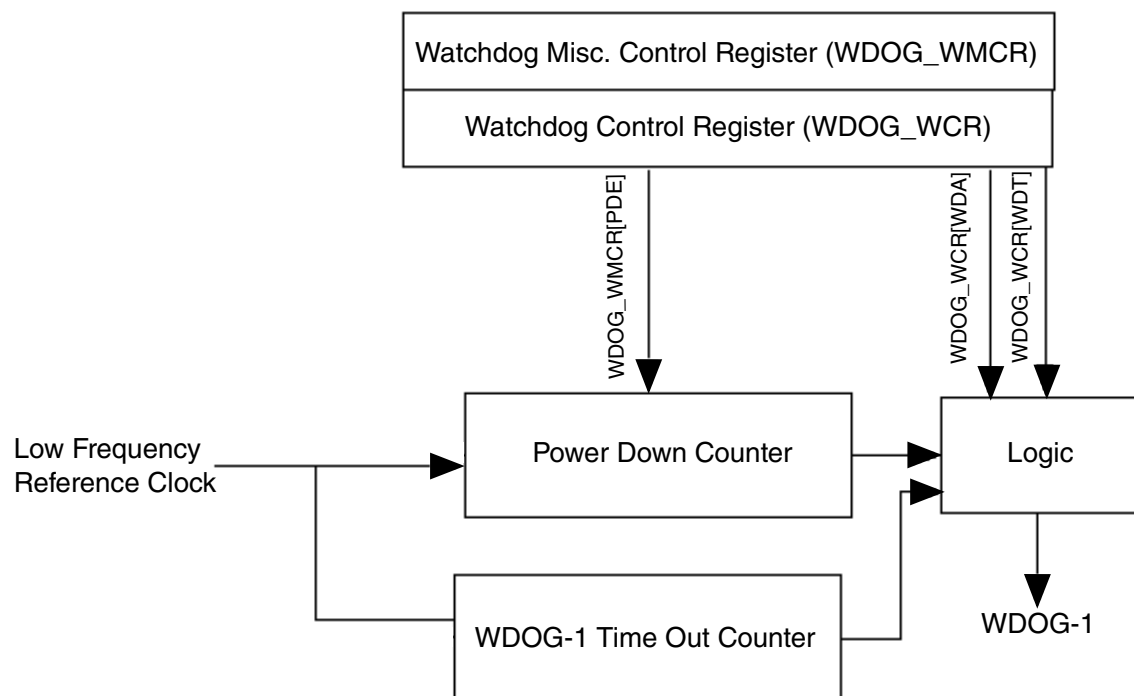

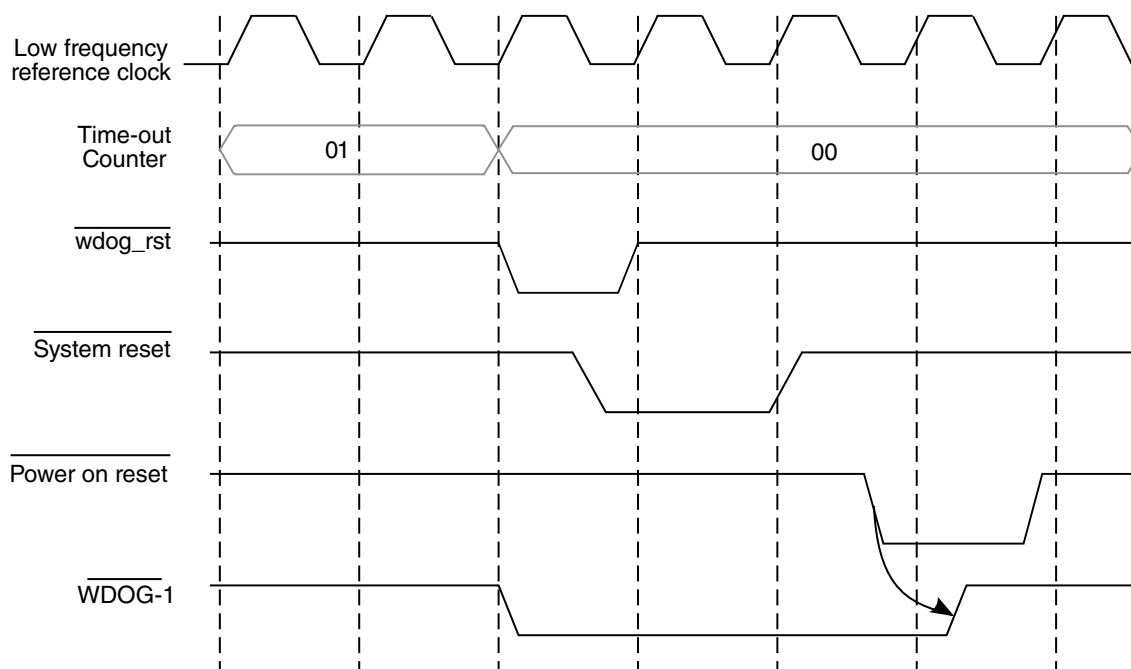

Figure 9-16. WDOG\_B generation

**Figure 9-17. WDOG timeout condition/WDT bit is not set**

**Figure 9-18. WDOG timeout condition/WDT bit is set**

### 9.7.5.7 Reset

The block is reset by a system reset and the WDOG counter will be disabled. The power-down counter is enabled and starts counting.

### 9.7.5.8 Interrupt

The WDOG has the feature of Interrupt generation before timeout.

The interrupt will be generated only if the WIE bit in [Watchdog Interrupt Control Register \(WDOG\\_WICR\)](#) is set. The exact time at which the interrupt should occur (prior to timeout) depends on the value of WICT field of [Watchdog Interrupt Control Register \(WDOG\\_WICR\)](#). For example, if the WICT field has a value 0x04, then the interrupt will be generated two seconds prior to timeout. Once the interrupt is triggered the WTIS bit in [Watchdog Interrupt Control Register \(WDOG\\_WICR\)](#) will be set. The software needs to clear this bit to deassert the interrupt. If the WDOG is serviced before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of [Watchdog Control Register \(WDOG\\_WCR\)](#) and interrupt would not be triggered.

### 9.7.5.9 Flow Diagrams

A flow diagram of WDOG operation is shown below.

**Figure 9-19. Power-Down Counter Flow Diagram**

Figure 9-20. Interrupt Generation Flow Diagram

### 9.7.6 Initialization

The following sequence should be performed for WDOG initialization.

- PDE bit of [Watchdog Miscellaneous Control Register \(WDOG\\_WMCR\)](#) should be cleared to disable the power down counter.

- WT field of [Watchdog Control Register \(WDOG\\_WCR\)](#) should be programmed for sufficient timeout value.
- WDOG should be enabled by setting WDE bit of [Watchdog Control Register \(WDOG\\_WCR\)](#) so that the timeout counter loads the WT field value of [Watchdog Control Register \(WDOG\\_WCR\)](#) and starts counting.

### 9.7.7 WDOG Memory Map/Register Definition

The WDOG Memory Map/Register Definition can be found here.

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed, the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

**WDOG memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Watchdog Control Register (WDOG_WCR)	16	R/W	0030h	<a href="#">9.7.7.1/1249</a>
2	Watchdog Service Register (WDOG_WSR)	16	R/W	0000h	<a href="#">9.7.7.2/1251</a>
4	Watchdog Reset Status Register (WDOG_WRSR)	16	R	0000h	<a href="#">9.7.7.3/1252</a>
6	Watchdog Interrupt Control Register (WDOG_WICR)	16	R/W	0004h	<a href="#">9.7.7.4/1253</a>
8	Watchdog Miscellaneous Control Register (WDOG_WMCR)	16	R/W	0001h	<a href="#">9.7.7.5/1254</a>

#### 9.7.7.1 Watchdog Control Register (WDOG\_WCR)

The Watchdog Control Register (WDOG\_WCR) controls the WDOG operation.

- WDZST, WDBG and WDW are write-once only bits. Once the software does a write access to these bits, they will be locked and cannot be reprogrammed until the next system reset assertion.

## Watchdog Timer (WDOG)

- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next POR. This bit does not get reset/cleared due to any system reset.

Address: 0h base + 0h offset = 0h

Bit	15	14	13	12	11	10	9	8
Read	WT							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	WDW	SRE	WDA	SRS	WDT	WDE	WDBG	WDZST
Write								
Reset	0	0	1	1	0	0	0	0

### WDOG\_WCR field descriptions

Field	Description
15–8 WT	<p>Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter.</p> <p><b>NOTE:</b> The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG is enabled or after the service routine has been performed. For more information see <a href="#">Timeout event</a>.</p> <p>0x00 - 0.5 Seconds (Default).  0x01 - 1.0 Seconds.  0x02 - 1.5 Seconds.  0x03 - 2.0 Seconds.  0xff - 128 Seconds.</p>
7 WDW	<p>Watchdog Disable for Wait. This bit determines the operation of WDOG during Low Power WAIT mode. This is a write once only bit.</p> <p>0 Continue WDOG timer operation (Default).  1 Suspend WDOG timer operation.</p>
6 SRE	<p>Software Reset Extension</p> <p>It was found that under some rare conditions the software reset could fail. By setting this bit an alternate reset circuit is enabled that guaranties proper software reset functionality. It is recommended to set this bit. This bit will be reset with power-on reset.</p> <p>0 using original way to generate software reset (default)  1 using alternate way to generate software reset (recommended)</p>
5 WDA	<p>WDOG_B assertion. Controls the software assertion of the WDOG_B signal.</p> <p>0 Assert WDOG_B output.  1 No effect on system (Default).</p>
4 SRS	<p>Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal <code>wdog_rst</code>. This bit automatically resets to "1" after it has been asserted to "0".</p>

Table continues on the next page...

**WDOG\_WCR field descriptions (continued)**

Field	Description
	<p><b>NOTE:</b> This bit does not generate the software reset to the block.</p> <p>0 Assert system reset signal. 1 No effect on the system (Default).</p>
3 WDT	<p>WDOG_B Time-out assertion. Determines if the WDOG_B gets asserted upon a Watchdog Time-out Event. This is a write-one once only bit.</p> <p><b>NOTE:</b> There is no effect on <math>\overline{\text{wdog\_rst}}</math> (WDOG Reset) upon writing on this bit. WDOG_B gets asserted along with <math>\overline{\text{wdog\_rst}}</math> if this bit is set.</p> <p>0 No effect on WDOG_B (Default). 1 Assert WDOG_B upon a Watchdog Time-out event.</p>
2 WDE	<p>Watchdog Enable. Enables or disables the WDOG block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set.</p> <p><b>NOTE:</b> This bit can be set/reset in debug mode (exception).</p> <p>0 Disable the Watchdog (Default). 1 Enable the Watchdog.</p>
1 WDBG	<p>Watchdog DEBUG Enable. Determines the operation of the WDOG during DEBUG mode. This bit is write once only.</p> <p>0 Continue WDOG timer operation (Default). 1 Suspend the watchdog timer.</p>
0 WDZST	<p>Watchdog Low Power. Determines the operation of the WDOG during low-power modes. This bit is write once-only.</p> <p><b>NOTE:</b> The WDOG can continue/suspend the timer operation in the low-power modes (STOP and DOZE mode).</p> <p>0 Continue timer operation (Default). 1 Suspend the watchdog timer.</p>

**9.7.7.2 Watchdog Service Register (WDOG\_WSR)**

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the timeout condition.

**NOTE**

Executing the service sequence will reload the WDOG timeout counter.

Address: 0h base + 2h offset = 2h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WSR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## WDOG\_WSR field descriptions

Field	Description
WSR	<p>Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows:</p> <p>0x5555 Write to the Watchdog Service Register (WDOG_WSR).</p> <p>0xAAAA Write to the Watchdog Service Register (WDOG_WSR).</p>

## 9.7.7.3 Watchdog Reset Status Register (WDOG\_WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error .

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

Address: 0h base + 4h offset = 4h

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	0			POR	0		TOUT	SFTW
Write								
Reset	0	0	0	0	0	0	0	0

## WDOG\_WRSR field descriptions

Field	Description
15–5 Reserved	This read-only field is reserved and always has the value 0.
4 POR	<p>Power On Reset. Indicates whether the reset is the result of a power on reset.</p> <p>0 Reset is not the result of a power on reset.</p> <p>1 Reset is the result of a power on reset.</p>
3–2 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

### WDOG\_WRSR field descriptions (continued)

Field	Description
1 TOUT	Timeout. Indicates whether the reset is the result of a WDOG timeout. 0 Reset is not the result of a WDOG timeout. 1 Reset is the result of a WDOG timeout.
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

### 9.7.7.4 Watchdog Interrupt Control Register (WDOG\_WICR)

The WDOG\_WICR controls the WDOG interrupt generation.

Address: 0h base + 6h offset = 6h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WIE	WTIS	0						WICT							
Write		w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

### WDOG\_WICR field descriptions

Field	Description
15 WIE	Watchdog Timer Interrupt enable bit. Reset value is 0. <b>NOTE:</b> This bit is a write once only bit. Once the software does a write access to this bit, it will get locked and cannot be reprogrammed until the next system reset assertion 0 Disable Interrupt (Default). 1 Enable Interrupt.
14 WTIS	Watchdog Timer Interrupt Status bit will reflect the timer interrupt status, whether interrupt has occurred or not. Once the interrupt has been triggered software must clear this bit by writing 1 to it. 0 No interrupt has occurred (Default). 1 Interrupt has occurred
13–8 Reserved	This read-only field is reserved and always has the value 0.
WICT	Watchdog Interrupt Count Time-out (WICT) field determines, how long before the counter time-out must the interrupt occur. The reset value is 0x04 implies interrupt will occur 2 seconds before time-out. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds. <b>NOTE:</b> This field is write once only. Once the software does a write access to this field, it will get locked and cannot be reprogrammed until the next system reset assertion. 0x00 WICT[7:0] = Time duration between interrupt and time-out is 0 seconds. 0x01 WICT[7:0] = Time duration between interrupt and time-out is 0.5 seconds. 0x04 WICT[7:0] = Time duration between interrupt and time-out is 2 seconds (Default). 0xff WICT[7:0] = Time duration between interrupt and time-out is 127.5 seconds.

9.7.7.5 Watchdog Miscellaneous Control Register (WDOG\_WMCR)

WDOG\_WMCR Controls the Power Down counter operation.

Address: 0h base + 8h offset = 8h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0															PDE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

WDOG\_WMCR field descriptions

Field	Description
15–1 Reserved	This read-only field is reserved and always has the value 0.
0 PDE	<p>Power Down Enable bit. Reset value of this bit is 1, which means the power down counter inside the WDOG is enabled after reset. The software must write 0 to this bit to disable the counter within 16 seconds of reset de-assertion. Once disabled this counter cannot be enabled again. See <a href="#">Power-down counter event</a> for operation of this counter.</p> <p><b>NOTE:</b> This bit is write-one once only bit. Once software sets this bit it cannot be reset until the next system reset.</p> <p>0 Power Down Counter of WDOG is disabled. 1 Power Down Counter of WDOG is enabled (Default).</p>

9.8 External Watchdog Monitor (EWM)

9.8.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the RESET

pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent  $\overline{\text{EWM\_out}}$  signal that when asserted resets or places an external circuit into a safe mode. The  $\overline{\text{EWM\_out}}$  signal is asserted upon the EWM counter time-out. An optional external input  $\text{EWM\_in}$  is provided to allow additional control of the assertion of  $\overline{\text{EWM\_out}}$  signal.

### 9.8.1.1 Features

Features of EWM module include:

- Independent LPO\_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO\_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of  $\overline{\text{EWM\_out}}$ .
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 63 (*EWM\_refresh\_time*) peripheral bus clock cycles.
- One output port,  $\overline{\text{EWM\_out}}$ , when asserted is used to reset or place the external circuit into safe mode.
- One Input port,  $\text{EWM\_in}$ , allows an external circuit to control the assertion of the  $\overline{\text{EWM\_out}}$  signal.

### 9.8.1.2 Modes of Operation

This section describes the module's operating modes.

### 9.8.1.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 63 (*EWM\_refresh\_time*) peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

### 9.8.1.2.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

### 9.8.1.2.3 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

### 9.8.1.3 Block Diagram

This figure shows the EWM block diagram.

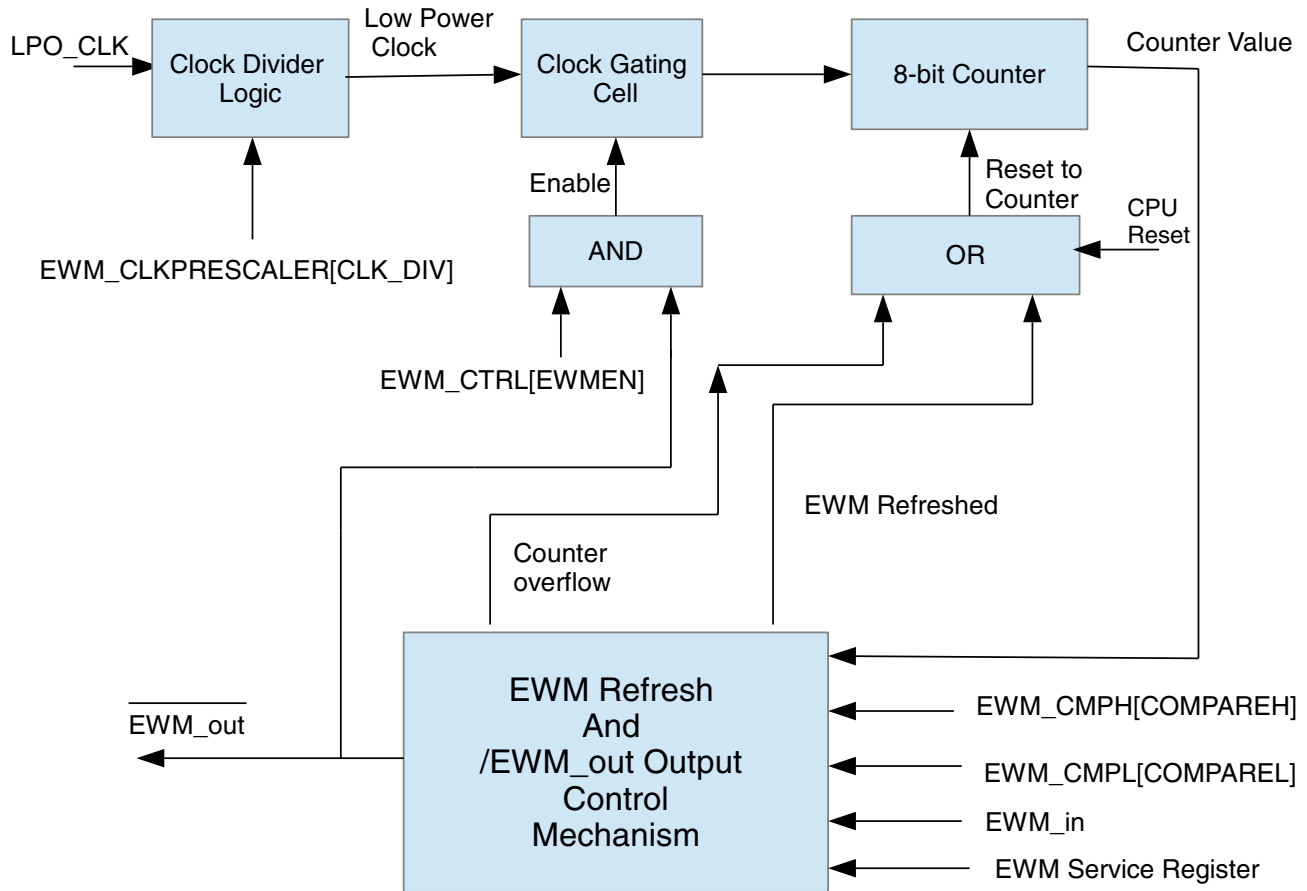

Figure 9-21. EWM Block Diagram

### 9.8.2 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

Table 9-16. EWM Signal Descriptions

Signal	Description	I/O
EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low.	I
$\overline{\text{EWM\_out}}$	EWM reset out signal	O
lpo_clk[3:0]	Low power clock sources for running counter All four lpo_clk clocks are SOSC clocks.	I

### 9.8.3 Memory Map/Register Definition

This section contains the module memory map and registers.

#### EWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4006_5000	Control Register (EWM_CTRL)	8	R/W	00h	<a href="#">9.8.3.1/1258</a>
4006_5001	Service Register (EWM_SERV)	8	W (always reads 0)	00h	<a href="#">9.8.3.2/1259</a>
4006_5002	Compare Low Register (EWM_CMPL)	8	R/W	00h	<a href="#">9.8.3.3/1259</a>
4006_5003	Compare High Register (EWM_CMPH)	8	R/W	FFh	<a href="#">9.8.3.4/1260</a>
4006_5004	Clock Control Register (EWM_CLKCTRL)	8	R/W	00h	<a href="#">9.8.3.5/1260</a>
4006_5005	Clock Prescaler Register (EWM_CLKPRESCALER)	8	R/W	00h	<a href="#">9.8.3.6/1261</a>

#### 9.8.3.1 Control Register (EWM\_CTRL)

The CTRL register is cleared by any reset.

##### NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

Address: 4006\_5000h base + 0h offset = 4006\_5000h

Bit	7	6	5	4	3	2	1	0
Read	0				INTEN	INEN	ASSIN	EWMEN
Write								
Reset	0	0	0	0	0	0	0	0

#### EWM\_CTRL field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 INTEN	Interrupt Enable.  This bit when set and $\overline{\text{EWM\_out}}$ is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.

Table continues on the next page...

**EWM\_CTRL field descriptions (continued)**

Field	Description
2 INEN	Input Enable.  This bit when set, enables the EWM_in port.
1 ASSIN	EWM_in's Assertion State Select.  Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one.
0 EWMEN	EWM enable.  This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_out signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit.

**9.8.3.2 Service Register (EWM\_SERV)**

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

Address: 4006\_5000h base + 1h offset = 4006\_5001h

Bit	7	6	5	4	3	2	1	0
Read	0							
Write	SERVICE							
Reset	0	0	0	0	0	0	0	0

**EWM\_SERV field descriptions**

Field	Description
SERVICE	The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true. <ul style="list-style-type: none"> <li>The first or second data byte is not written correctly.</li> <li>The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called <i>EWM_refresh_time</i>.</li> </ul>

**9.8.3.3 Compare Low Register (EWM\_CMPL)**

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

## External Watchdog Monitor (EWM)

Address: 4006\_5000h base + 2h offset = 4006\_5002h

Bit	7	6	5	4	3	2	1	0
Read	COMPAREL							
Write								
Reset	0	0	0	0	0	0	0	0

### EWM\_CMPL field descriptions

Field	Description
COMPAREL	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required.

## 9.8.3.4 Compare High Register (EWM\_CMPH)

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

### NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

### NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

Address: 4006\_5000h base + 3h offset = 4006\_5003h

Bit	7	6	5	4	3	2	1	0
Read	COMPAREH							
Write								
Reset	1	1	1	1	1	1	1	1

### EWM\_CMPH field descriptions

Field	Description
COMPAREH	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required.

## 9.8.3.5 Clock Control Register (EWM\_CLKCTRL)

This CLKCTRL register is reset to 0x00 after a CPU reset.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

**NOTE**

User should select the required low power clock before enabling the EWM.

Address: 4006\_5000h base + 4h offset = 4006\_5004h

Bit	7	6	5	4	3	2	1	0
Read	0						CLKSEL	
Write								
Reset	0	0	0	0	0	0	0	0

**EWM\_CLKCTRL field descriptions**

Field	Description
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CLKSEL	EWM has 4 possible low power clock sources for running EWM counter. One of the clock source can be selected by writing into this field. <ul style="list-style-type: none"> <li>00 - lpo_clk[0] will be selected for running EWM counter.</li> <li>01 - lpo_clk[1] will be selected for running EWM counter.</li> <li>10 - lpo_clk[2] will be selected for running EWM counter.</li> <li>11 - lpo_clk[3] will be selected for running EWM counter.</li> </ul>

**9.8.3.6 Clock Prescaler Register (EWM\_CLKPRESCALER)**

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

**NOTE**

Write the required prescaler value before enabling the EWM.

**NOTE**

The implementation of this register is chip-specific. See the Chip Configuration details.

Address: 4006\_5000h base + 5h offset = 4006\_5005h

Bit	7	6	5	4	3	2	1	0
Read	CLK_DIV							
Write								
Reset	0	0	0	0	0	0	0	0

**EWM\_CLKPRESCALER field descriptions**

Field	Description
CLK_DIV	Selected low power clock source for running the EWM counter can be prescaled as below. <ul style="list-style-type: none"> <li>Prescaled clock frequency = low power clock source frequency / ( 1 + CLK_DIV )</li> </ul>

## 9.8.4 Functional Description

The following sections describe functional details of the EWM module.

### NOTE

When the BUS\_CLK is lost, then EWM module doesn't generate the EWM\_out signal and no refresh operation is possible

### 9.8.4.1 The EWM\_out Signal

The EWM\_out is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM\_out could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM\_out signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM\_out signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM\_in pin is enabled and EWM\_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM\_out pin)

The EWM\_out is asserted after any reset by the virtue of the external pull-down mechanism on the EWM\_out signal. Then, to deassert the EWM\_out signal, set EWMEN bit in the CTRL register to enable the EWM.

If the  $\overline{\text{EWM\_out}}$  signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the  $\overline{\text{EWM\_out}}$  signal only after the EWM is enabled by the EW MEN bit in the CTRL register.

### Note

$\overline{\text{EWM\_out}}$  pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

#### 9.8.4.2 The EWM\_in Signal

The EWM\_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the  $\overline{\text{EWM\_out}}$  signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the  $\overline{\text{EWM\_out}}$  signal that controls the gating circuit.

The EWM\_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EW MEN] bit) and enabling EWM\_in functionality (setting the CTRL[INEN] bit), the EWM\_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the  $\overline{\text{EWM\_out}}$  stays in the deasserted state; otherwise, the  $\overline{\text{EWM\_out}}$  output signal is asserted.

### Note

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM\_in pin is deasserted.

#### 9.8.4.3 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

### 9.8.4.4 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1),  $\overline{\text{EWM\_out}}$  is asserted.

### 9.8.4.5 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

**Table 9-17. EWM Refresh Mechanisms**

Condition	Mechanism
An EWM refresh action completes when: $\text{CMPL} < \text{Counter} < \text{CMPH}$ .	The software behaves as expected and the EWM counter is reset to zero. The $\overline{\text{EWM\_out}}$ output signal remains in the deasserted state if, during the EWM refresh action, the $\overline{\text{EWM\_in}}$ input has been in deasserted state..
An EWM refresh action completes when $\text{Counter} < \text{CMPL}$	The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the $\overline{\text{EWM\_out}}$ output signal is asserted irrespective of the input $\overline{\text{EWM\_in}}$ .
Counter value reaches CMPH prior to completion of EWM refresh action.	Software has not refreshed the EWM. The EWM counter is reset to zero and the $\overline{\text{EWM\_out}}$ output signal is asserted irrespective of the input $\overline{\text{EWM\_in}}$ .

### 9.8.4.6 EWM Interrupt

When  $\overline{\text{EWM\_out}}$  is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect  $\overline{\text{EWM\_out}}$ . The  $\overline{\text{EWM\_out}}$  signal can be deasserted only by forcing a system reset.

### 9.8.4.7 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

### 9.8.4.8 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK\_DIV]. This divided clock is used to run the EWM counter.

#### NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

## 9.9 Watchdog Configuration (WCON)

### 9.9.1 Watchdog Scheme

The following three Watchdogs are included in this device:

- a) General Purpose WDOG (WDOG-A5) - Monitors A5
- b) General Purpose WDOG (WDOG-M4) - Monitors CM4
- c) TrustZone Watchdog (WDOG - SNVS) - Part of TrustZone and monitors Secure world

#### NOTE

Above does not include another WDOG that is part of A5 core complex (CA5-internal) that runs on core clock.

WDOG\_SNVS is another instance of the general purpose WDOG mainly intended for secure platforms and with the WDOG reset being controlled by CSU. Since WDOG\_SNVS monitors secure word, TZ-WDOG does not have any significance for non-secure parts.

**Table 9-18. WDOG Configuration**

Configuration	Security	WDOG-SNVS	WDOG-A5	WDOG-M4	Comments
A5 only configuration	Enabled	Functional	Functional	Disabled	
A5 only configuration	Disabled	Disabled	Functional	Disabled	
M4 only Configuration	Enabled	Enabled	Disabled	Functional	

*Table continues on the next page...*

**Table 9-18. WDOG Configuration (continued)**

Configuration	Security	WDOG-SNVS	WDOG-A5	WDOG-M4	Comments
M4 only Configuration	Disabled	Disabled	Disabled	Functional	
Dual Core(A5 Primary)	Enabled	Functional	Functional	Functional	
Dual Core (A5 Primary)	Disabled	Disabled	Functional	Functional	
Dual Core (M4 Primary)	Enabled	INVALID Configuration			Security cannot be enabled with M4 as primary core
Dual Core (M4 Primary)	Disabled	Disabled	Functional	Functional	Security Switch should automatically disable or ignore WDOG_SNVS

**NOTE**

1. TZ-WDOG is only relevant for secure parts as this part of Trust Zone.

All WDOGs are disabled by default (after the reset). WDOG-A5, WDOG-M4 will be configured during the boot while WDOG-SNVS is dedicated for secure world purposes and will be activated by TZ Software if required.

- If servicing does not take place, the timer times out and WDOG reset signal activated
- Interrupt can be generated before the counter actually times out
- wdog\_rst\_b signal can be activated by Software
- There is a power down counter which gets enabled out of any reset. This counter has a fixed time out period of 16 seconds upon which it will assert the ipp\_wdog\_b signal

## 9.9.2 Watchdog Connectivity

The following Figure shows the way different WDOG on this device needs to be connected to GIC, NVIC, SRC , CSU and the pins.

**Figure 9-22. WDOG Connectivity**

Any WDOG that times out (except WDOG\_SNVS) must generate a reset to Reset controller(SRC). This is applicable for both conditions a) where A5 is primary and M4 is secondary b) where M4 is Primary and A5 is secondary.

### NOTE

This device does not support a system recovery where A5 only domain or M4 only domain is reset. Either WDOG-A5 or WDOG-M4 generated reset should eventually RESET the system.

Reset generated by the WDOG\_SNVS is moderated by CSU.

WDOG\_b output to the pins could be optionally used by external power management IC to turn off/control the power to the chip.

## 9.9.3 WDOG clocking options

WDOG-A5 WDOG-M4 & WDOG-SNVS should supply following clock options

- a) 128K IRC
- b) 32K Crystal

c) Bus clock (Divided)

Default option MUST be 128 IRC.

The low frequency clock selection is not user configurable. When the 32 KHz Xtal clock is available, it will be used as clock source. Otherwise, the SIRC clock will automatically be used (128 KHz/4).

### **9.9.4 WDOG Debug requirement**

1. The CM4 watchdog(WDOG-M4) should freeze if the CM4 enters debug halt mode.
2. The CA5 watchdog(WDOG-A5) should freeze if the CA5 enters debug halt mode.

The above requirements are on top of what is already supported by the IP.

## **9.10 Wakeup Unit (WKPU)**

### **9.10.1 Introduction**

#### **NOTE**

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The WKPU supports 16 external sources that can generate interrupts or wakeup events and 1 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from 5 other wakeup sources to supply a single wakeup to the system. The block diagram of the WKPU and its interfaces to other system components is shown below.

#### **NOTE**

The signal widths in the following diagram might not depict this device's particular configuration. See the Chip-specific WKPU information for more information.

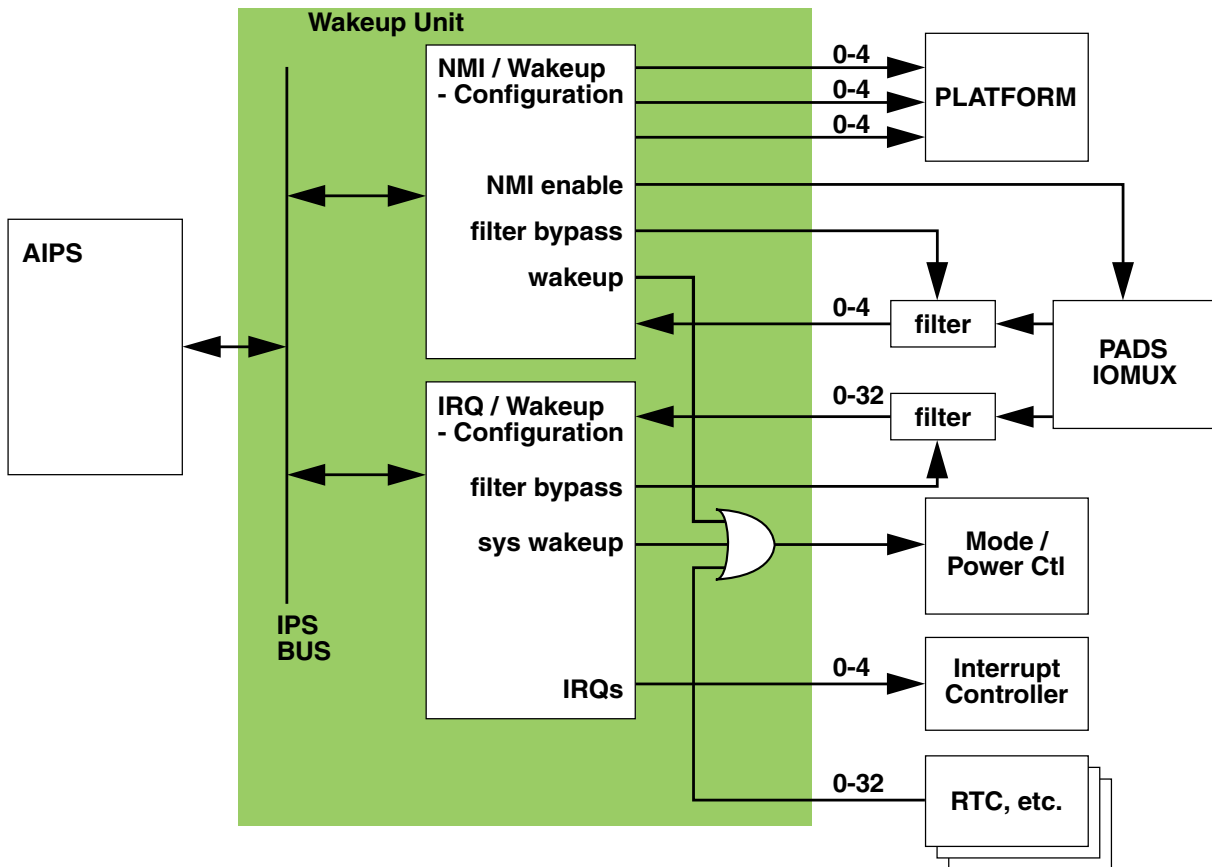

Figure 9-23. WKPU and connected system components

### 9.10.2 Features

The WKPU supports these features:

- Non-maskable Interrupt support with:
  - One external NMI source
  - One analog glitch filter
- Independent interrupt destination for each core:
  - Non-maskable interrupt
- Active edge selection control for events to each core
- Configurable system wakeup triggering from NMI source(s)
- External wakeup/interrupt support with:
  - One system interrupt vector for interrupt sources

- 16 analog glitch filters
- Independent interrupt mask
- Edge detection
- Configurable system wakeup triggering from all interrupt sources
- Configurable pullup
- On-chip wakeup support:
  - Five wakeup sources
  - Wakeup status mapped to same register as external wakeup/interrupt status

### 9.10.3 External signal description

The WKPU has 16 signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

### 9.10.4 WKPU memory map and register definition

This section provides a detailed description of all registers accessible in the WKPU module.

#### NOTE

Reserved registers will read as 0, writes will have no effect. Transfer error will be generated when trying to access completely reserved register space. The field length in external pad control registers depends on the number of WKPU channels implemented in a chip.

#### WKPU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4006_A000	NMI Status Flag Register (WKPU_NSR)	32	w1c	0000_0000h	<a href="#">9.10.4.1/1271</a>
4006_A008	NMI Configuration Register (WKPU_NCR)	32	R/W	<a href="#">See section</a>	<a href="#">9.10.4.2/1272</a>

*Table continues on the next page...*

**WKPU memory map (continued)**

R	0				0				0				0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### WKPU\_NSR field descriptions

Field	Description
31 NIF0	NMI Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an interrupt request.  0 No event has occurred on the pad 1 An event as defined by NREE0 and NFEE0 has occurred
30 NOVF0	NMI Overrun Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVFO causes an interrupt request.  0 No overrun has occurred on NMI input 0 1 An overrun has occurred on NMI input 0
29–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 9.10.4.2 NMI Configuration Register (WKPU\_NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

**NOTE**

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing a 0 to both NREE[n] and NFEE[n] disables the NMI functionality completely (i.e., no system wakeup or interrupt will be generated on any pad activity).

Access: User read/write

Address: 4006\_A000h base + 8h offset = 4006\_A008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

\* Notes:

- See the chip-specific WKPU information for the reset value of this register.

**WKPU\_NCR field descriptions**

Field	Description
31 NLOCK0	NMI Configuration Lock Register 0. Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset or STANDBY0 mode exit . Writing a 0 has no effect.
30–29 NDSS0	NMI Destination Source Select 0. This value is reset on STANDBY0 mode entry. 00 Non-maskable interrupt 01 Reserved 10 Reserved 11 Reserved
28 NWRE0	NMI Wakeup Request Enable 0 <b>NOTE:</b> If wakeup requests are disabled, the corresponding NDSS field must be set to 11 to disable wakeups from an NMI, critical interrupt, or machine check. 0 System wakeup requests from the corresponding NIF0 bit are disabled. 1 A set NIF0 bit or set NOVFO bit causes a system wakeup request.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 NREE0	NMI Rising-edge Events Enable 0.

Table continues on the next page...

**WKPU\_NCR field descriptions (continued)**

Field	Description
	0 Rising-edge event is disabled 1 Rising-edge event is enabled
25 NFEE0	NMI Falling-edge Events Enable 0.  0 Falling-edge event is disabled 1 Falling-edge event is enabled
24 NFE0	NMI Filter Enable 0. Enable analog glitch filter on the NMI pad input.  0 Filter is disabled 1 Filter is enabled
Reserved	This field is reserved. Always write 0 to this field.

**9.10.4.3 Wakeup/Interrupt Status Flag Register (WKPU\_WISR)**

This register holds the wakeup/interrupt flags.

**NOTE**

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/ wakeups do not have corresponding bits.

Access: User read/write

Address: 4006\_A000h base + 14h offset = 4006\_A014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																	EIF															
W																	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**WKPU\_WISR field descriptions**

Field	Description
EIF	External Wakeup/Interrupt Status Flag x. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER[x]), EIF[x] causes an interrupt request.  0 No event has occurred on the pad 1 An event as defined by WIREER and WIFEER has occurred

### 9.10.4.4 Interrupt Request Enable Register (WKPU\_IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

#### NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Address: 4006\_A000h base + 18h offset = 4006\_A018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### WKPU\_IRER field descriptions

Field	Description
EIRE	External Interrupt Request Enable x. 0 Interrupt requests from the corresponding EIF[x] bit are disabled 1 A set EIF[x] bit causes an interrupt request

### 9.10.4.5 Wakeup Request Enable Register (WKPU\_WRER)

This register is used to enable the system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

#### NOTE

This register is accessible only by 32-bit read/write operations.

If a pin is disabled through this register, the corresponding bits in the WIFEER and WIREER registers must be written to 0 to ensure that the pin does not respond to any change.

Access: User read/write

Address: 4006\_A000h base + 1Ch offset = 4006\_A01Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**WKPU\_WIREER field descriptions**

Field	Description
IREE	External Interrupt Rising-edge Events Enable x.  0 Rising-edge event is disabled 1 Rising-edge event is enabled

**9.10.4.7 Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU\_WIFEER)**

This register is used to enable falling-edge triggered events on the corresponding wakeup/interrupt pads.

**NOTE**

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Address: 4006\_A000h base + 2Ch offset = 4006\_A02Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### WKPU\_WIFEER field descriptions

Field	Description
IFEEEx	External Interrupt Falling-edge Events Enable x.  1 Falling-edge event is enabled 0 Falling-edge event is disabled

### 9.10.4.8 Wakeup/Interrupt Filter Enable Register (WKPU\_WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

#### NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Address: 4006\_A000h base + 30h offset = 4006\_A030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### WKPU\_WIFER field descriptions

Field	Description
IFE	External Interrupt Filter Enable x. Enable analog glitch filter on the external interrupt pad input.  0 Filter is disabled 1 Filter is enabled

### 9.10.4.9 Wakeup/Interrupt Pullup Enable Register (WKPU\_WIPUER)

This register is used to enable a pullup on the corresponding interrupt pads to pull an unconnected wakeup/interrupt input to a high voltage level (See the Chip-specific WKPU information for the exact level of voltage) .

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Address: 4006\_A000h base + 34h offset = 4006\_A034h

WKPU\_WIPUER field descriptions

Field	Description
IPUE	External Interrupt Pullup Enable x.  0 Pullup is disabled 1 Pullup is enabled

9.10.5 Functional description

This section provides a functional description of the WKPU.

9.10.5.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, though it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

Figure 9-24. NMI pad diagram

### 9.10.5.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see [NMI Configuration Register \(WKPU\\_NCR\)](#)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

#### Note

After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI. Please see chip specific section for details on NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See [NMI Configuration Register \(WKPU\\_NCR\)](#) for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see [NMI Status Flag Register \(WKPU\\_NSR\)](#)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (i.e. has not yet been cleared).

### **Note**

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

During an NMI ISR, on wakeup of the SoC from an NMI, any writes to ECC-protected memory must have the correct ECC.

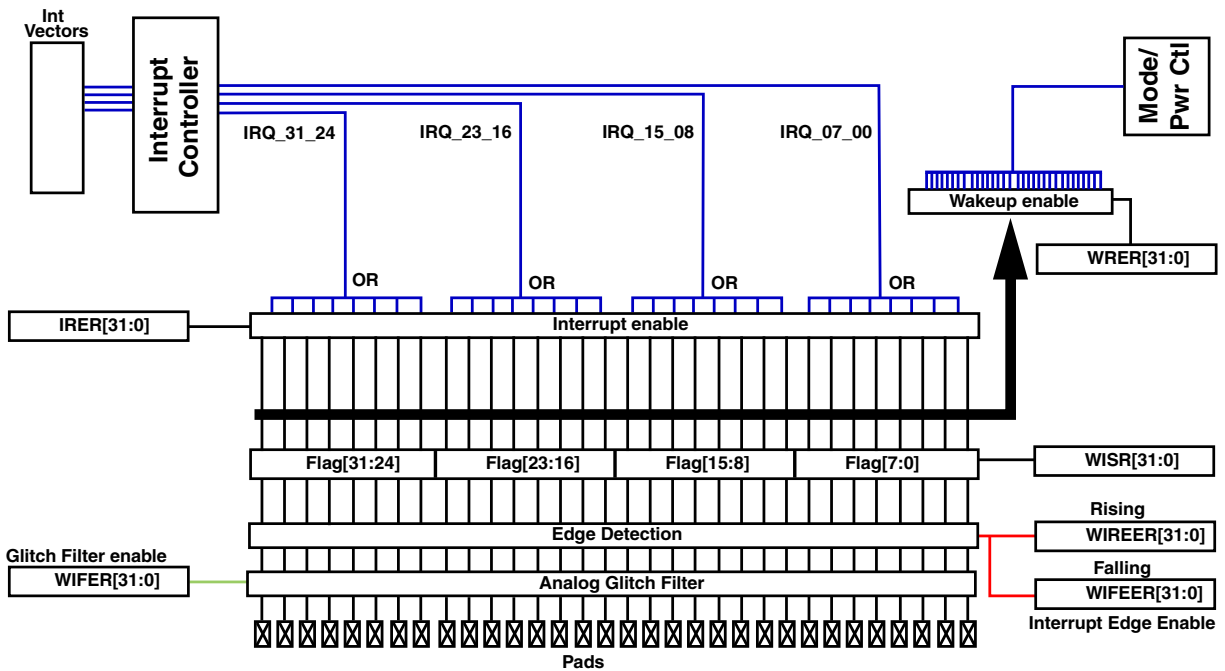

## **9.10.5.2 External wakeups/interrupts**

The WKPU supports 1 interrupt vector(s) to the interrupt controller of the SoC. Each interrupt vector can support up to the number of external interrupt sources from the device pads with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt sources is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

Refer to the following figure for an overview of the external interrupt implementation for the example of four interrupt vectors with eight external interrupt sources each.

### **NOTE**

The figure below shows a generic representation of the WKPU. See the chip-specific WKPU information for details on how this device's configuration might differ from this figure.

**Figure 9-25. External interrupt pad diagram**

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the SoC.

External interrupt lines have a digital glitch filters applied to them.

#### 9.10.5.2.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register ([Interrupt Request Enable Register \(WKPU\\_IRER\)](#)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active.

#### Note

Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (i.e. no system wakeup or interrupt will be generated on any activity on that pad)!

The active IRQ edge is controlled by the users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag which is held in the flag register (WISR). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

### **9.10.5.3 On-chip wakeups**

The WKPU supports 5 on-chip wakeup sources. It combines the on-chip wakeups with the external ones to generate a single wakeup to the system.

#### **9.10.5.3.1 On-chip wakeup management**

In order to allow software to determine the wakeup source at one location, on-chip wakeups are reported along with external wakeups in the WISR register (see [Wakeup/Interrupt Status Flag Register \(WKPU\\_WISR\)](#) for details). Enabling and clearing of these wakeups are done via the on-chip wakeup source's own registers, along with WKPU\_IRER and WISR register set and clearance respectively.

### **9.10.6 Initialization Information**

This section discusses initialization for the following features:

- [Glitch Filter and Pad Configuration](#)
- [Non-Maskable Interrupts](#)
- [Reset Request](#)

#### **9.10.6.1 Glitch Filter and Pad Configuration**

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NREE, NFEE, RREE, and RFEE, bits in the same register write.

### 9.10.6.2 Non-Maskable Interrupts

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. Mask interrupts by clearing NSR[NIF $n$ ] and NSR[NOVF $n$ ].
2. Clear NCR[NFEE $n$ ] and NCR[NREE $n$ ], preferably by writing 0 to all bits in the register.
3. Configure the analog glitch filter using NCR[NFE0].
4. Configure the appropriate SIUL2\_MSCR register for the desired NMI interrupt pin(s) as follows:
  - a. Clear the OBE bits to disable output.
  - b. Set the IBE bit to enable the pin's input buffer.
  - c. If the internal weak pull-up/pull-down is used, configure the appropriate PUE and PUS bits.

#### NOTE

NMI interrupt pins should never be configured as outputs, i.e., MSCR[OBE] bits should not be zero, when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

5. Write appropriate bit values to the NCR register to configure:
  - NMI source (NDSS $n$ ).
  - Wakeup request (NWRE $n$ ).
  - Glitch filter (NFE0)
  - Rising/falling edge events enable (NFEE $n$  and NREE $n$ ).
  - NMI configuration lock (NLOCK $n$ ).

### 9.10.6.3 Reset Request

When an NMI reset request pin is first enabled, it is possible to get a false reset request. To prevent a false reset request during pin reset request initialization, the user must do the following:

1. Mask reset requests by clearing NSR[RIF] and NSR[ROVF].
2. Clear NCR[RFEE] and NCR[RREE], preferably by writing 0 to all bits in this register.
3. Configure the analog glitch filter, as desired, using NCR[NFE0].
4. Configure the appropriate SIUL2\_MSCR register for the NMI interrupt pin(s) as follows:
  - a. Clear the ODC bits to disable output.
  - b. Set the IBE bit to enable the pin's input buffer.
  - c. If the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits.

### NOTE

NMI reset request pins should never be configured as outputs (i.e., MSCR[ODC] bits are not zeros) when external reset request inputs are desired since false reset requests could be detected (e.g., from a GPIO configuration).

5. Write appropriate bit values to the NCR register to configure:
  - Reset destination source (RDSS).
  - Reset wakeup request (RWRE).
  - Glitch filter (NFE0)
  - Rising/falling edge events enable (RFEE and RREE).
  - Reset configuration lock (RLOCK).

## 9.11 System Debug

### 9.11.1 Overview

This document describes the hardware and software debug and application development features and resources of this device.

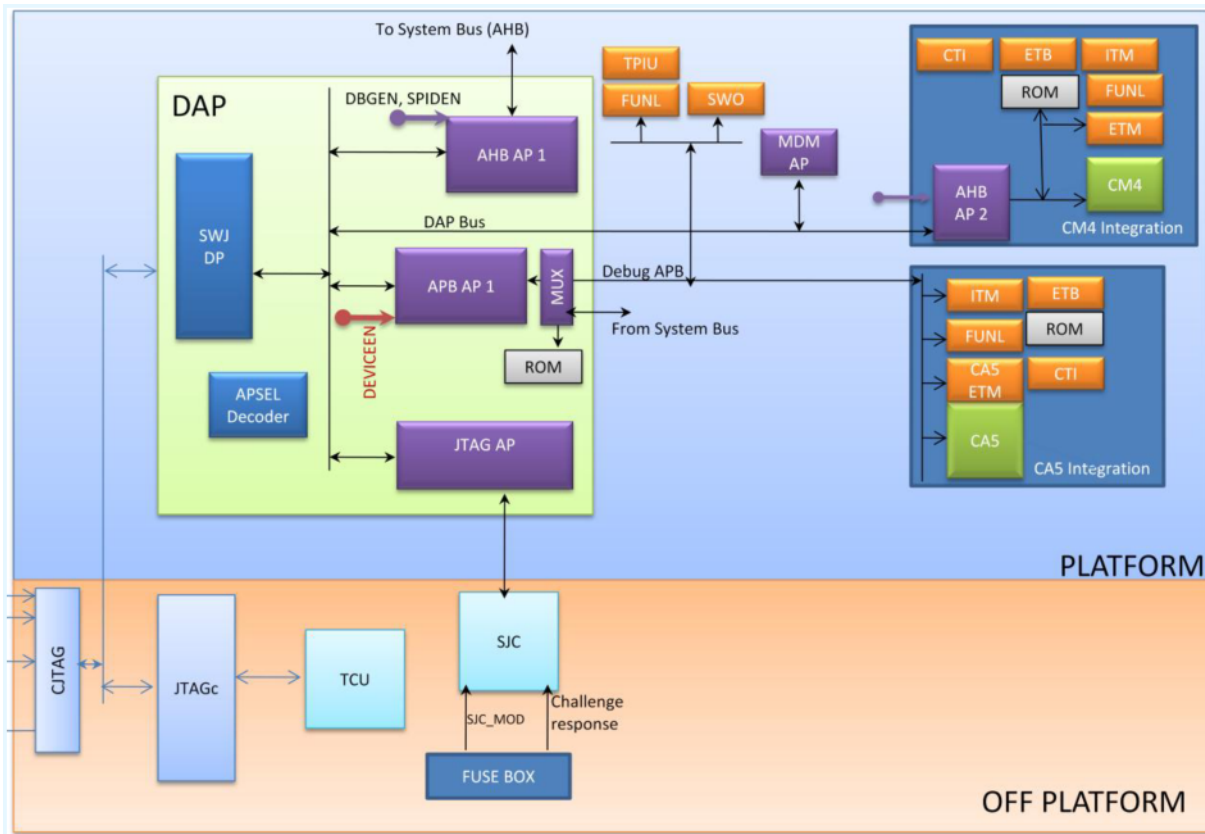

The device debug and trace is based on ARM CoreSight architecture supplemented with the Secured JTAG controller (SJC) to allow security features.

1. Supports IEEE 1149.1 JTAG, IEEE 1149.7 JTAG, and ARM Serial Wire Debug (SWD) interface.
2. A range of security levels from NO JTAG to fully Open based on eFuse configuration for both debug and Test.
3. Support for Secured and non secured invasive/ non invasive debug to allow further granularity in debug accesses.
4. Support for field return parts to open access for debug and test to allow failure analysis.
5. Cross Trigger supported between the two cores as recommended by ARM.
6. Following debug capabilities are supported:
  - a. Access to core and memory mapped resource examination and modification.
  - b. Support for monitor mode and halt mode.
  - c. Breakpoint/ Watchpoint control.
7. System profiling and performance monitoring.
8. CoreSight Embedded Trace Macrocell (ETM) and Instrumentation Trace Macrocell (ITM) to generate traces from the Cortex A5 and Cortex M4 cores.
9. Support ARM Real Time trace Interfaces: Trace Port Interface Unit (TPIU) and Serial Wire Output (SWO).
10. For TPIU trace port the maximum trace packets extraction bandwidth is limited by the pads and is equal to 160MByte/s (80Mhz x 16-bit).
11. For SWO the maximum frequency of operation is targeted for 24Mhz.

### 9.11.2 System Level Debug Architecture

This section discusses the overall debug and trace architecture from system perspective. The figure below gives the overall block diagram and design topology of the debug architecture.

**Figure 9-26. Debug Architecture Block Diagram**

All ARM specific debug logic – Debug Access Port (DAP) and trace modules are integrated in the platform. The term platform is just a design partition consisting of cores integration, interconnect, debug, DMA, OCRAM controllers and a few other blocks.

The access to core and memory mapped resources is based on DAP. The access is controlled by security level configuration and authentication using the (Secure JTAG Controller) SJC block. SJC is accessible through the JTAG Access Port (JTAG AP) of DAP.

If the device is in fab or is a field return (both conditions set by way of eFuse configuration) all accesses to core/ memory mapped resources are fully available else these accesses are subject to authentication using SJC.

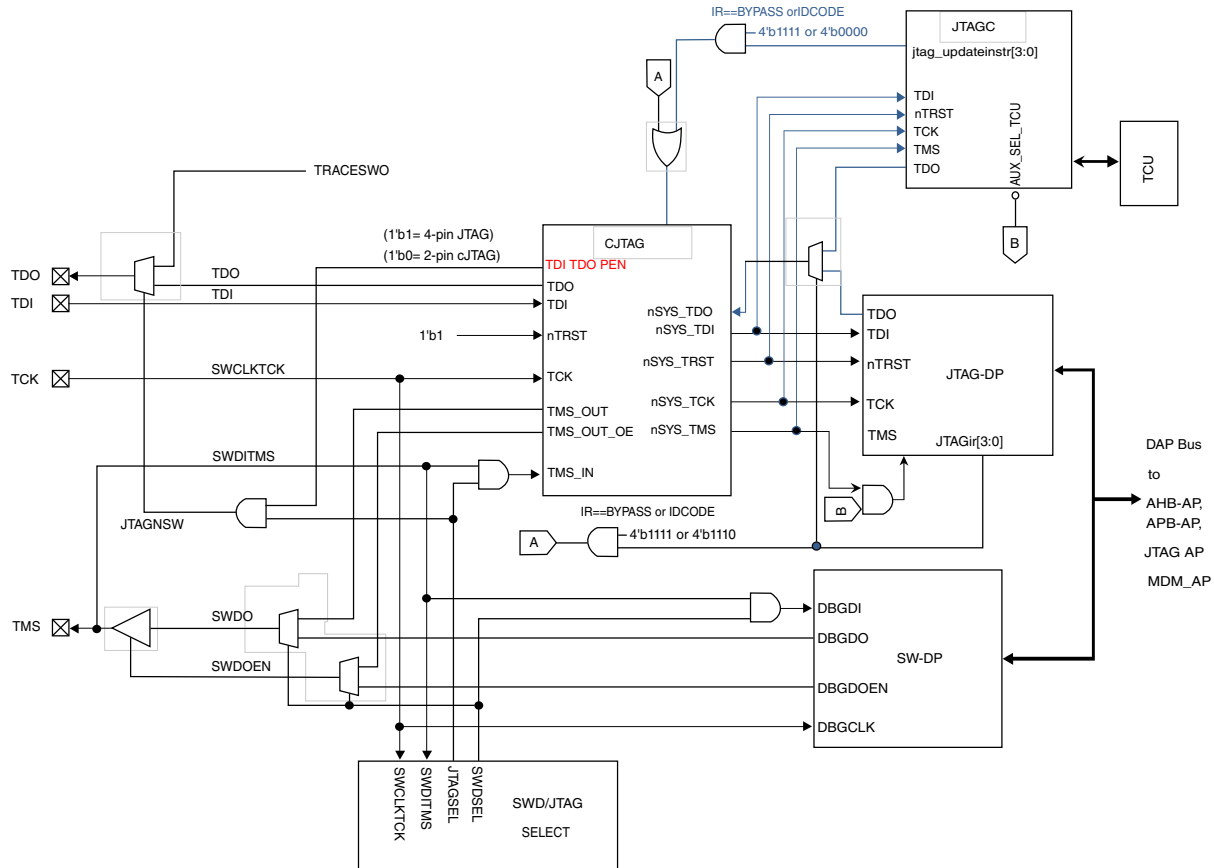

The TCU is fully accessible in fab and for field return; else it is completely blocked for security reasons.

The JTAGc is *always* available to allow boundary scan.

The debug IDCODE in case of JTAG DP is 0x4BA00477 and in case of SW DP it is 0x3BA02477.

### 9.11.3 Test and Debug Access Port Connectivity

The figure below gives a detailed TAP connectivity diagram.

**Figure 9-27. Detailed TAP connectivity diagram**

In [Figure 9-27](#) the *SWD/JTAG SELECT*, *SW-DP* and *JTAG-DP* are part of ARM DAP.

Please note the following points from [Figure 9-27](#) :

1. The Debug port comes out of reset in a standard 4 wire JTAG mode only. It is switched into SWD or cJTAG mode by change sequences described in [JTAG-to-SWD change sequence](#) and [JTAG-to-cJTAG change sequence](#). Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions. Once switched to C-JTAG or SWD, switching back to 4-Wire JTAG is not possible.
2. The JTAG pads are connected to cJTAG as the primary interface. Besides the TMS is also observed by the SWD/ JTAG switcher logic of the DAP (*SWDITMS* input in *SWD/JTAG SELECT* block).

3. The JTAG DP and JTAGC are connected to cJTAG in an *overlay scheme*; both have an IR length of *four*.
4. The TCU is an auxiliary TAP on the JTAGC.
5. If TCU is selected (*AUX\_SEL\_TCU goes HIGH*), the TMS input for the JTAG-DP is driven LOW (Refer to connector "B" in the diagram). Thus giving exclusive access to the auxiliary TAP (this allows auxiliary TAP to have an IR length greater than four).
6. If the DAP switches from JTAG to SWD (when SWD/ JTAG SELECT receives the switching sequence), the TMSIN for cJTAG is driven low (as JTAGSEL goes LOW) and the TMS pad is used for SWD data inout.

## 9.11.4 JTAG to SWD cJTAG switching sequence

### 9.11.4.1 JTAG-to-SWD change sequence

- Send more than 50 TCK cycles with TMS(SWDIO) =1
- Send the 16-bit sequence on TMS(SWDIO) = 0111\_1001\_1110\_0111 (MSB transmitted first)
- Send more than 50 TCK cycles with TMS (SWDIO) =1.

This is shown in the [Figure 9-28](#).

Figure 9-28. JTAG-to-SWD switching sequence

### 9.11.4.2 JTAG-to-cJTAG change sequence

- Reset the debug port.
- Set the control level to 2 via the zero-bit scans.
- Execute the Store Format (STFMT) command (00011) to set the scan format register to 1149.7 scan format.

### 9.11.4.3 System JTAG Controller (JTAGC)

The system JTAG controller (JTAGC) is connected in parallel with ARM TAP controller (JTAG DP of ARM DAP). The IR length is 4-bits. The JTAGC IR codes overlay the ARM DAP controller IR codes. JTAGC uses *twelve* instructions and the DAP uses rest *four*. The outputs of the TAPs (TDO) are muxed based on the IR Code which is selected. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP.

The [Table 9-19](#) gives the IR codes for the system JTAG controller. For the instructions used by ARM DAP TAP refer to [Table 9-20](#).

**Table 9-19. JTAG instructions for system JTAG controller (JTAGc)**

Code	JTAGC IR
4'b0000	IDCODE
4'b0001	CENSOR_CTRL
4'b0010	SAMPLE-PRELOAD
4'b0011	SAMPLE
4'b0100	EXTEST
4'b0101	HI-Z
4'b0110	TEST_CTRL
4'b0111	TEST_LEAKAGE
4'b1000	<i>Not used by JTAGC (used by DAP)</i>
4'b1001	AUX ACCESS 1 (TCU selection)
4'b1010	<i>Not used by JTAGC (used by DAP)</i>
4'b1011	<i>Not used by JTAGC (used by DAP)</i>
4'b1100	Reserved
4'b1101	CLAMP
4'b1110	<i>Not used by JTAGC (used by DAP)</i>
4'b1111	BYPASS

The Test Control Unit (TCU) is an auxiliary TAP on the JTAGc. It is selected by the instruction "AUX ACCESS 1". When TCU is selected the DAP JTAG DP is disconnected (TMS input to JTAG DP goes low), giving TCU exclusive access of the JTAG port. DFT Specification for details related to TCU.

### 9.11.4.4 Debug Access Port (DAP) TAP

DAP is a standard ARM component. The DAP provides multiple master driving ports, all accessible and controlled through a single external interface port to provide system-wide debug.

As discussed earlier the DAP IR overlay with the system JTAG controller IR. The DAP Instruction Registers is listed in [Table 9-20](#).

DAP uses five Instructions but since BYPASS is identical with JTAGC it has been dropped out.

**Table 9-20. ARM DAP IR Codes**

Code	DAP IR
4'b1000	ABORT
4'b1010	DPACC
4'b1011	APACC
4'b1110	IDCODE

The DAP offers AHB and APB master interfaces to access system buses. It also exports the internal DAP bus to allow to extend the access ports as per the system requirement. It offers JTAG AP to allow adding auxiliary TAPs. The device uses JTAG AP to connect the Secure JTAG controller (SJC) block as an auxiliary TAP. For more information on DAP TAP refer to ARM Debug Interface v5 Architecture specification

The AHB AP provides the debugger access to all memory and registers in the system. System access is independent of the processor status. AHB-AP does not do back to back transactions on the bus, so all transactions are non sequential.

The APB AP is used to access the CoreSight components for the CA5 and also the shared debug components of the system trace like TPIU, SWO.

The exported DAP bus is used to host AHB AP access port (integrated as part CM4 integration) and the Miscellaneous Debug module Access Port (MDM AP).

The MDM AP hosts system level JTAG status and control registers (refer to [Debug Status and Control Registers](#)) which can be used for cross triggering, synchronized debug, low power and other misc control/ status.

The selection of different access ports in the DAP is done based on the APSEL value set in the SELECT register of SWJ-DP. APSEL is 31:24 bit field of the DAP SELECT register.

The APSEL will be decoded as given in [Table 9-21](#).

**Table 9-21. APSEL decode**

APSEL (SELECT[31:24])	Selection	Identification Register (IDR) value
8'h00	AHB-AP to System Bus (NIC-301)	0x4477_0001
8'h01	APB-AP to "Shared" debug IP and CA5 debug IP	0x2477_0002
8'h02	JTAG-AP to SJC	0x1476_0010
8'h03	AHB-AP to CM4	0x2477_0011
8'h04	Miscellaneous Debug module AP (MDM-AP)	0x001C_0000
8'h05- 8'hff	Reserved (Default AP response)	-

#### 9.11.4.4.1 ROM Table

The ROM table is used to hold the information about the debug components.

There are three ROM tables.

1. The CM4 ROM table resides on the AHB AP2 and has entries for CM4 debug components.
2. The DAP ROM table resides on the APB AP. It has entries for the common trace components, MDM AP and the last entry points to the CA5 ROM table. The DAP ROM table last entry has a "valid" bit (bit-0 in the ROM table entry). When this bit is "0", the last entry returns 0x00000000. When this bit is "1" the last entry returns the pointer to CA5 ROM table.
3. The CA5 ROM Table resides on APB AP. This has entries for CA5 debug components.

**Table 9-22. ROM Table Entries bit assignment**

Bits	Name	Description
[31:12]	Address offset	Base address of the component, relative to the ROM address. Negative values are permitted using two's complement. ComponentAddress = ROMAddress + (AddressOffset SHL 12).
[11:2]	-	Reserved SBZ.
[1]	Format	1 = 32-bit format. In the DAP Debug ROM this is set to 1. 0 = 8-bit format.
[0]	Entry present	Set HIGH to indicate an entry is present.

The device supports three core configurations:

1. Both CA5 and CM4 are present: All ROM tables are accessible and "valid" bit is set.

2. CM4 only: CM4 and DAP ROM tables are accessible. DAP ROM table "valid" bit is cleared and hence CA5 ROM table is not accessible.
3. CA5 Only: DAP ROM table is accessible and the "valid" bit is set, so CA5 ROM table is accessible. In this case the CM4 ROM table is not accessible.

Note for Implementation: In case of "CA5 only" the clock for the CM4 should be gated and the DBGEN/ SPIDEN for the AHB AP2 in CM4 integration should be held LOW.

## 9.11.5 Debug Port Pin Descriptions

The debug port pins default after reset to their JTAG functionality and can be later reassigned to their alternate functionalities. In cJTAG and SWD modes TDI can be configured to alternate GPIO functions. Refer to [Table 9-23](#) for pin assignments in different modes.

**Table 9-23. Debug Port Pins**

Pin Name	JTAG Debug Port		cJTAG Debug Port		SWD Debug Port		Internal Pullup/Down
	Type	Description	Type	Description	Type	Description	
TMS/SWDIO	I/O	JTAG Test mode selection	I/O	cJTAG Data	I/O	Serial Wire Data	Pull-up
TCK/SWCLK	I	JTAG Test clock	I	cJTAG Clock	I	Serial wire clock	Pull-down
TDI	I	JTAG Test Data input	-	-	-	-	Pull-up
TDO/TRACESWO	O	JTAG Test Data output	O	Trace output over a single pin	O	Trace output over a single pin	NC

### 9.11.6 Secure JTAG Controller (SJC)

SJC is accessed through the JTAG AP of the DAP. The SJC has a 5-bit Instruction Register which is described in [Table 9-24](#).

**Table 9-24. System JTAG Controller Instruction Registers**

Code	SJC IR
5'b00000 - 5'b00011	Reserved
5'b00100	Enable Extra misc registers
5'b00101 - 5'b01011	Reserved
5'b01100	Security Output Challenge
5'b01101	Security input response
5'b01110 – 5'b11110	Reserved
5'b11111	BYPASS

The Extra misc registers IR allows accessing the extra miscellaneous registers. These include the register to understand the status of the authentication in case of challenge/response. There can be other uses of these registers which the SOC can define.

The Security Output Challenge and Security Input Response IRs allows the debugger to read the security challenge and feed the response for authentication in case the Challenge-Response based authentication is in place. For details of the SJC block refer to [System JTAG Controller \(SJC\)](#) chapter.

The various security level configurations are discussed in section [Secured JTAG](#).

#### 9.11.6.1 Challenge Response Access Sequence

When JTAG\_SMODE is 2'b01 (Secure JTAG mode is enabled), Fuse SJC\_CHALL[63:0] and SJC\_RESP[53:0] would have programmed. Now following steps need to follow to pass the challenge response.

1. Program SPIDEN and SPNIDEN in SRC\_SECR\_DOUT register through Software (if secured traces are required: this is possible only for authenticated software running in secured world).
2. PowerUp DAP
3. Select Port 0 for SJC in JTAG-AP PORT SELECT registers.

4. Reset SJC TAP by writing into JTAG-AP CSW register. Set TRST\_OUT = 1. Also set TMS High for 5 clocks in BWFIPO 1 register change the bank select. After some random delay, release TRST\_OUT.
5. Move SJC TAP to IDLE state.
6. Shift in the Challenge Instruction.
7. Read out the challenge Value.
8. Shift IR RESPONSE Instruction.
9. Shift DR Response 56 bit value.
10. READ MDM AP STATUS Register if Debug Enable bit is Set and Secure Debug bit is set

If the First attempt with Incorrect Challenge Response results into failure, subsequent attempts of correct Challenge Response will still be discarded. Only POR reset will let Debugger start the attempts from beginning.

### 9.11.7 Debug Status and Control Registers

The debugger has access to the status and control elements, implemented as registers in MDM-AP on the DAP bus as shown in [Figure 9-26](#). These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also provide a means for the debugger to get updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

It is important to note that these DAP control and status registers are not memory mapped within the system memory map and are only accessible via the Debug Access Port (DAP) using JTAG, cJTAG, or SWD. The MDM-AP is accessible as Debug Access Port 4 (refer to [Table 9-21](#)). The MDM-AP registers are listed in [Table 9-25](#).

**Table 9-25. MDM-AP Register Summary**

Address	Register	Description
0x0400_0000	Status	MDM AP Status Register (Refer <a href="#">Table 9-27</a> )
0x0400_0004	Control	MDM AP Control Register (Refer <a href="#">Table 9-26</a> )
0x0400_00FC	ID	Read only Identification register that always reads as 0x001C_0000

### 9.11.7.1 Miscellaneous Debug Module (MDM) AP Control Register

The debugger can write to MDM-AP control register only if the DBGGEN is SET ie the debugger security authentication has been cleared. In case the debugger makes an access while DBGGEN=0, the access will be simply ignored and no error will be reported.

**Table 9-26. MDM AP Control Register Assignments**

Bit	Name	Description
0-1	Reserved	Not used
2	CM4 Debug Request	Drives "EDBGREQ" input for CM4. When the core goes into debug state it acknowledges with "HALTED" output signal.  If the core is in STOP mode this bit is used to wake-up the core and transition to halted state.
3	System reset request (SYSRESETREQ)	Set to force the system reset. The system remains in reset till this bit remains asserted.  When this bit is reset the entire system comes out of reset.
4	Reserved	unused
5	Standby mode debug request (STANDBYDBGREQ)	Set to configure the system to be held in reset after the next recovery from standby modes (LPSTOP1/2/3).  This bit is sampled by the SRC as "HOLD reset latch" just before the GPC moves the part in any of the LPSTOP modes and remains latched in always ON domain during the standby phase. On exit from standby mode SRC holds the CM4 and CA5 in reset at the end of system reset sequencing until hold reset release is asserted.  The STANDBYDDBREQ is cleared due to POR reset generated as part of LPSTOP recovery.
6	Standby mode debug acknowledge (STANDBYDBGACK)	Set to release the cores being held in reset following a standby recovery due to SRC "HOLD reset latch". This bit drives directly the SRC to control this feature.  Besides this bit also clears the "standby mode exit" status bit.  The debugger re-initializes all debug IP and then asserts this control bit to allow the SRC to release the cores from reset and allow CPU operation to begin.  The STANDBYDBGACK bit is cleared by JTAG or clears automatically due to POR reset generated as part of standby recovery.
7	Reserved	Unused
8	Timestamp disable	Freeze Time stamp during HALT mode.  0: The timestamp counter continues to count when the core is halted.  1: The timestamp counter freezes when either of the cores is halted. This allows to avoid generation of generation of timestamp overflow messages when the core is halted.
9	Inhibit Sleep	This bit is monitored by the power controller. If set the device will not move into power gated mode. Thus debugger can make safe accesses without risk of losing communication due to debug logic going into power down.
10-17	Reserved	Unused
18	CA5 Debug Request	Drives "EDBGREQ" input for CA5. When the core goes into debug state it acknowledges with "HALTED" output signal. If the core is in STOP mode this bit is used to wake-up the core and transition to halted state.
19-23	Reserved	unused

*Table continues on the next page...*

**Table 9-26. MDM AP Control Register Assignments (continued)**

Bit	Name	Description
24	CTI trigger input	Connects to CTI trigger input
25	CTI trigger output ack Reserved	Acknowledgement for the CTI trigger out received on bit-22 of the MDM-AP status register.
26-29	Reserved	unused
30	CM4 debug restart	CM4 debug restart input to CM4 core.
31	CA5 debug restart	CA5 debug restart input to CA5 core.

### 9.11.7.2 Miscellaneous Debug Module (MDM) AP Status Register

**Table 9-27. MDM-AP Status Register Assignments**

Bit	Name	Description
0-1	Reserved	Not used
2	System reset	Indicates the system reset state 1: system not in reset 0: system is in reset
3	debug access enable	Indicates if the debugger can access to AHB and APB AP. This bit reflects the status of DBGEN (which is same as NIDEN).
4	debug secured access enable	Indicates if the debugger can make secured accesses to the debug logic and can trace out secured traces. This bit reflects the status of SPIDEN/ SPNIDEN. SPIDEN and SPNIDEN are same and are controlled by configurable bit by secured software.
5-9	Reserved	Not used
10	Standby mode exit	This bit indicates an exit from standby mode has occurred. The debugger had lost communication while the system is in standby mode (including access to this register). Once communication is reestablished, this bit indicates that the system had been standby mode. Since the debug modules lose their state during standby mode, they need to be reconfigured.  This bit is implemented in SoC glue logic and is set during the standby mode recovery sequence. The standby Mode Exit bit is held until the debugger has had a chance to recognize that a standby mode was exited and is cleared by a write of 1 to the STANDBYDBGACK bit[6] in MDM AP Control register.
11-15	Reserved	Not used
16	CM4 Halted	CM4 has entered debug halt mode
17	CM4 SLEEPDEEP	CM4 asserted SLEEPDEEP
18	CM4 SLEEPING	CM4 asserted SLEEPING
19	CA5 halted	CA5 has entered debug halt mode
20	CA5 STANDBYWFI	
21	CA5 STANDBYWFE	
22	CTI trigger out	Cross Trigger Interface Trigger out asserted.
23-29	Reserved	unused

*Table continues on the next page...*

**Table 9-27. MDM-AP Status Register Assignments (continued)**

Bit	Name	Description
30	CM4 debug restarted	Debug restarted output status from CM4.
31	CA5 debug restarted	Debug restarted output status from CA5.

Note for Implementation: The MDM-AP control register is accessible only after debug authentication. The MDM-AP status register is always accessible.

### 9.11.8 Debug Resets

The debug system receives the following sources of reset:

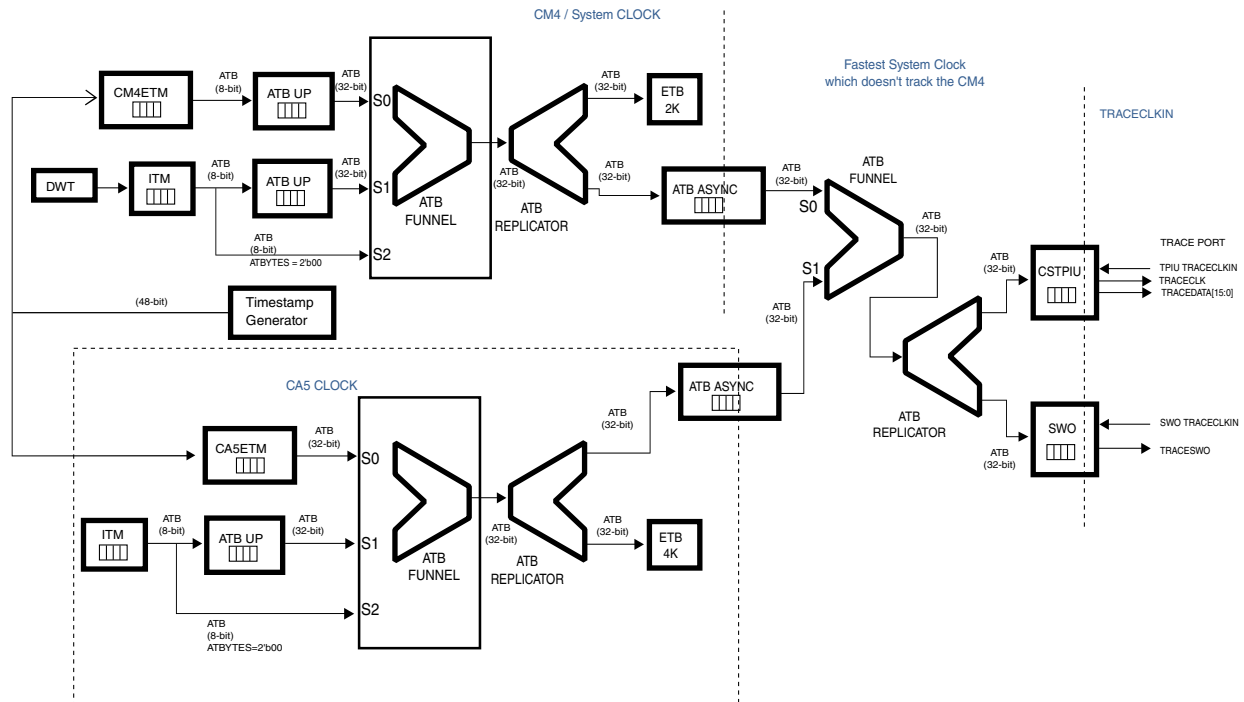

- Debug reset (CDBGIRSTREQ bit within the SWJ-DP CTRL/STAT register) in the TCLK domain that allows the debugger to *reset the debug logic*. This includes ATRESETn for cm4\_atbasync, csfunnel, csreplicator, csswo, cstpiu, CSATBUPSIZER\_etm, CSATBUPSIZER\_itm, CSREPLICATOR, CSETB, ca5\_itm\_upsizer) AND PRESETDBGn for csfunnel, csswo, cstpiu, DAP APs, faraday\_dbg\_trace\_ctrl, CSTFUNNEL, CSETB, CSCTI, ca5\_itm, ca5\_funnel, ca5\_etb.
- System POR reset.

Conversely the debug system is capable of generating system reset using the following mechanism:

- A system reset in the MDM-AP control register which allows the debugger to hold the *system* in reset.

### 9.11.9 Trace Architecture

The figure below shows the trace architecture for the device.

**Figure 9-29. Trace Bus Connectivity diagram**

The following Trace Paths are supported:

- Trace paths on a Cortex-M4 only device:

CM4 ATB path to TPIU enabled, CA5 ATB path to disabled to ensure that the CA5 ATB isn't requesting a transaction

- Trace paths on a Cortex-A5 only device:

CM4 ATB path to TPIU disabled, CA5 ATB path to enabled to ensure that the CM4 ATB isn't requesting a transaction.

- Trace paths on a dual-core device:

a) CM4 ETM/ITM to ETB and CA5 ETM/ITM to ETB. The TPIU is disabled; both trace path disable bits can be left enabled (or disabled).

b) CM4 ETM/ITM to TPIU and CA5 ETM/ITM to TPIU. Both trace paths (CM4 ATB Path and CA5 ATB path) enabled.

c) CM4 ETM/ITM to ETB and CA5 ETM/ITM to TPIU. The trace path from the CM4 to TPIU must be disabled.(CM4 ATB path to TPIU disabled, CA5 ATB path to enabled)

d) CM4 ETM/ITM to TPIU and CA5 ETM/ITM to ETB. The trace path from the CA5 to TPIU must be disabled. (CM4 ATB path to TPIU enabled, CA5 ATB path to disabled)

In case SWO is enabled as the output port, the possible trace paths are

- a) CA5 ITM -> CA5 ATB FUNNELS2 -> CA5 ATB REPL -> ATB ASYNC -> shared ATB funnel -> shared ATB RELP -> SWO (in this path only LSByte of the ATB data bus is used)
- b) CM4 ITM -> CM4 ATB FUNNELS2 -> CM4 ATB REPL -> ATB ASYNC -> shared ATB funnel -> shared ATB RELP -> SWO (in this path only LSByte of the ATB data bus is used)
- c) We can have traces from both CA5 and CM4 ITMs active and these merged by shared ATB funnel and traced out to SWO.
- d) One of path a) or b) active while the other core traces logged to the corresponding ETB.

### Note

There are *four* clock domains in the trace connectivity. The trace components associated with the CM4 and CA5 work in respective core clock domains. These are separated from the common trace components at the system level through ATB Async interfaces. This allows us to clock the common components at a fixed high frequency clock (limited by the pad frequency) thereby offering highest possible output bandwidth for draining out the traces, independent of the core frequencies. The TRACECLKIN is driven internally from a mux select from different sources and feeds both TPIU and SWO.

The Platform Trace Control (Pltf-TCTL) module controls the trace flow: The register is at the offset 0x4009\_3000 with the following fields:

- Ctrl[0] = CM4 to TPIU Disable
- Ctrl[1] = CA5 to TPIU Disable
- Ctrl[2] = CM4ITM to SWO Enable
- Ctrl[3] = CM5ITM to SWO Enable

#### 9.11.9.1 Data Watchpoint and Trace (DWT)

DWT is part of *Cortex M4 trace connectivity only*. The DWT is a unit that performs the following debug functionality:

- It contains four comparators that you can configure as a hardware watchpoint, an ETM trigger, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT\_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT\_COMP1, can also be used as a data comparator.
- The DWT contains counters for:
  - Clock cycles (CYCCNT)
  - Folded instructions
  - Load store unit (LSU) operations
  - Sleep cycles
  - CPI (all instruction cycles except for the first cycle)
  - Interrupt overhead

### 9.11.9.2 Flash Patch and Breakpoints (FPB) (CM4 only)

The FPB implements hardware breakpoints and patches code and data from code space to system space. This is applicable to *CM4 core only*.

The FPB unit contains two literal comparators for matching against literal loads from Code space, and remapping to a corresponding area in System space.

The FBP also contains six instruction comparators for matching against instruction fetches from Code space, and remapping to a corresponding area in System space. Alternatively, the six instruction comparators can individually configure the comparators to return a Breakpoint Instruction (BKPT) to the processor core on a match, so providing hardware breakpoint capability.

### 9.11.9.3 Instrumentation Trace Macrocell (ITM)

The ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are three sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output.

The three sources in decreasing order of priority are:

1. Software trace -- Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace -- The DWT generates these packets, and the ITM emits them (not supported by CA5 ITM)
3. Time stamping -- Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bit clock rate of the Serial Wire Viewer (SWV) output clocks the counter.

#### 9.11.9.4 Embedded Trace Macrocell (ETM)

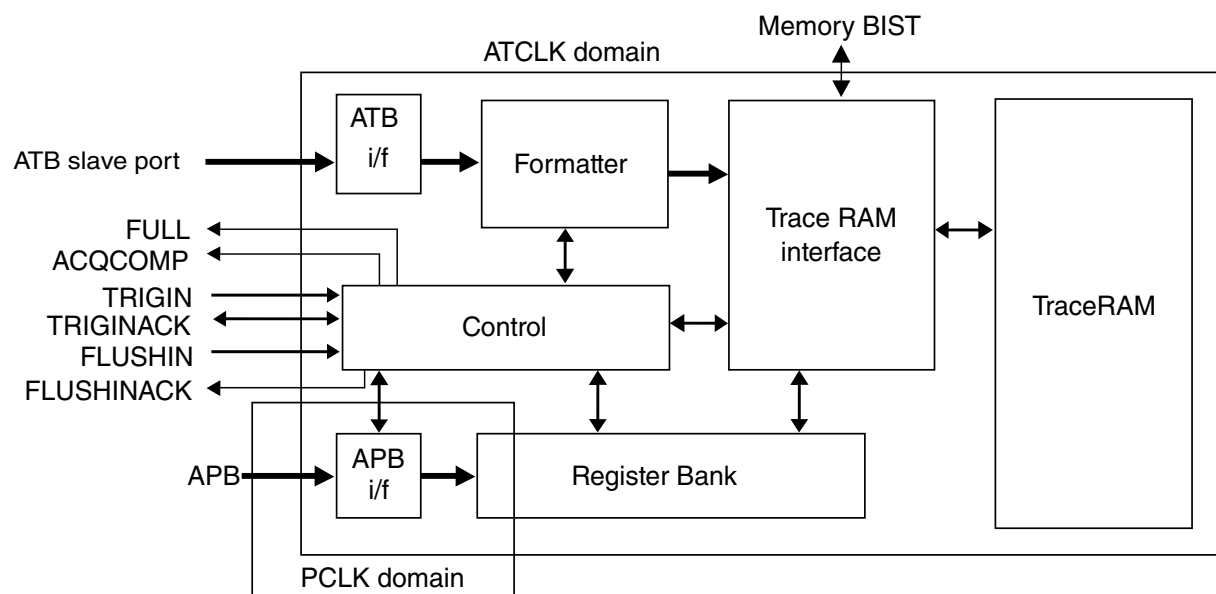

The ETM v3.5 is supported. The Cortex-M4 Embedded Trace Macrocell (ETM-M4) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M4 supports only instruction trace. You can use it either with the Cortex-M4 Trace Port Interface Unit (M4-TPIU), or with the CoreSight ETB.

The main features of an ETM are:

- tracing of 16-bit and 32-bit Thumb instructions
- four EmbeddedICE watchpoint inputs
- a Trace Start/Stop block with EmbeddedICE inputs
- one reduced function counter
- two external inputs
- a 24-byte FIFO queue (cortex M4).
- global timestamping

#### 9.11.9.5 CoreSight Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from any CoreSight-compliant component trace source with an ATB master port, such as a trace source or a trace funnel. It is included in this device to remove dependencies from the trace pin pad speed, and enable low cost trace solutions. The device has two ETBs – one each for CM4 and CA5 traces. The ETB for collecting CM4 traces is 2KB while the one to collect CA5 traces is 4KB.

**Figure 9-30. ETB Block Diagram**

The ETB contains the following blocks:

- **Formatter** -- Inserts source ID signals into the data packet stream so that trace data can be re-associated with its trace source after the data is read back out of the ETB.
- **Control** -- Control registers for trace capture and flushing.
- **APB interface** -- Read, write, and data pointers provide access to ETB registers. In addition, the APB interface supports wait states through the use of a PREADYDBG signal output by the ETB. The APB interface is synchronous to the ATB domain.
- **Register bank** -- Contains the management, control, and status registers for triggers, flushing behavior, and external control.
- **Trace RAM interface** -- Controls reads and writes to the Trace RAM..

#### 9.11.9.6 Trace Port Interface Unit (TPIU)

TPIU acts as a bridge between the on chip trace data from ETM and ITM, with separate IDs to a data stream encapsulating IDs where required to provide external visibility of the packet stream to a Trace Port analyzer. The device offers a synchronous trace port consisting of 16-bit TRACEDATA, TRACECTL and TRACECLK.

### 9.11.9.7 Serial Wire Output

The CoreSight SWO is a trace data drain that acts as a bridge between the on-chip trace data to a data stream that is captured by a *Trace Port Analyzer* (TPA). The device also offers an asynchronous Serial Wire out (TRACESWO) interface. The SWO can work at a maximum frequency of 24Mhz.

### 9.11.9.8 Performance Monitoring Unit (for CA5 Only)

Each core in the Cortex-A5 MPCore processor contains a PMU which provides two counters to gather statistics on the operation of the core and memory system. Each counter can count any of the events available in the Cortex-A5 MPCore processor. It also provides a single 32-bit cycle counter with support for scaling and filtering on the processor mode and security state. See the *ARM Architecture Reference Manual, ARMv7-A* and *ARM Architecture Reference Manual Performance Monitors v2 Supplement* for more information about performance monitoring.

### 9.11.9.9 Embedded Cross Trigger

Embedded Cross Trigger (ECT) is used for multi core run control and trace cross triggering for example synchronous stop start for all cores or trigger program trace on a trigger event from another core or IP.

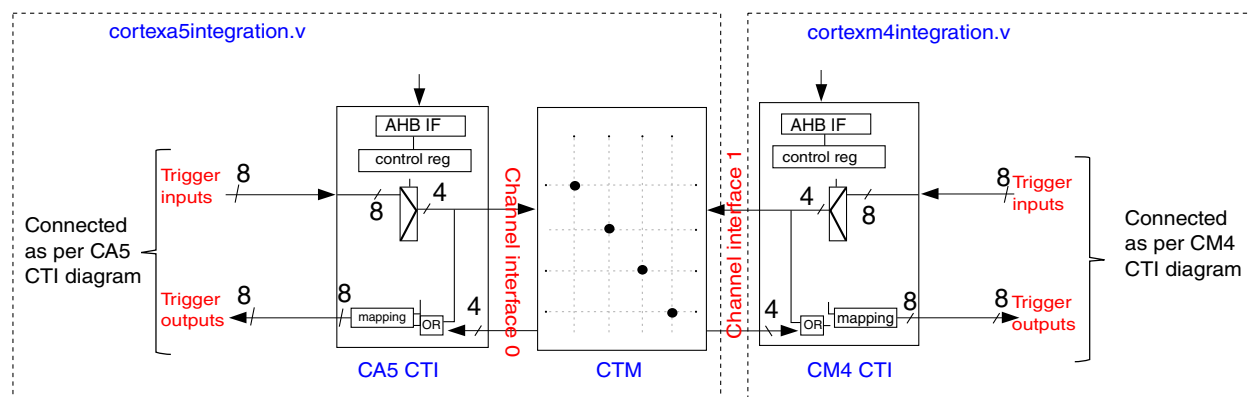

ECT is made up of Cross Trigger Interfaces (CTI) and Cross Trigger Matrix (CTM).

Cross Trigger Interface (CTI) provided by ARM:

- 8 trigger inputs, 8 trigger outputs, basic signal conditioning
- Programmable channel routing (mapping trigger inputs to channels and channels to trigger output).
- Limited to 4 channels

Cross Trigger Matrix (CTM) provided by ARM:

- Provides channel routing when more than 2 CTIs are used.
- Limited to 4 channels

Note: Channel Interface 2 and 3 are unused.

## 9.11.9.9.1 CM4 CTI Triggers

CM4 CTI Trigger Inputs:

**Table 9-28. CM4 CTI Trigger inputs**

Trigger Bit	Source Signal	Source Device
[7]	ETMTRIGOUT	ETM
[6]	ETMTRIGGER[2]	DWT
[5]	ETMTRIGGER[1]	DWT
[4]	ETMTRIGGER[0]	DWT
[3]	ACQCOMP	ETB
[2]	FULL	ETB
[1]	MDMAP CTITRIGIN (MDM-AP Control[24])	MDM-AP
[0]	DBGACK	Core

CM4 CTI Trigger Outputs:

**Table 9-29. CM4 CTI Trigger outputs**

Trigger Bit	Source Signal	Source Device
[7]	DBGRESTART (This bit is ORed with the CM4 debug restart bit from MDM-AP control register before connected as input to the core)	core
[6]	MDMAP CTITRIGOUT (MDM-AP status[22]) The ack is driven by MDM AP trigout ack(MDM-AP Control[25].	MDM-AP
[5]	ETMEXTIN[1]	ETM

Table continues on the next page...

**Table 9-29. CM4 CTI Trigger outputs (continued)**

Trigger Bit	Source Signal	Source Device
[4]	ETMEXTIN[0]	ETM
[3]	NVIC IntID[5]	NVIC
[2]	Not used	-
[1]	INTISR[x]	NVIC
[0]	EDBGRQ	Core

### 9.11.9.9.2 CA5 CTI Triggers

CA5 CTI Trigger Inputs:

**Table 9-30. CA5 Trigger Inputs**

Trigger Bit	Source Signal	Source Device
[7]	Not used (tied to 1'b0)	-
[6]	TRIGGER	ETM
[5]	COMMRX = ctiasicctl0_o[5] ? etb_acqcomp : commrx[0]	Core
[4]	COMMTX = ctiasicctl0_o[4] ? etb_full : commtx[0]	Core
[3]	EXTOUT[1]	ETM
[2]	EXTOUT[0]	ETM
[1]	PMUIRQ[n]	Core
[0]	DBGTRIGGER[n]	Core

For CA5 CTI trigin[5:4] the select used for mux control "ctiasicctl[5:4]" is the "ASICCTL[5:4]" provided by the CTI.

CA5 CTI Trigger Outputs:

**Table 9-31. CA5 Trigger Outputs**

Trigger Bit	Source Signal	Source Device
[7]	DBGRESTRAT  (This bit is ORed with the CA5 debug restart bit from MDM-AP control register before connected as input to the core)	Core
[6]	GIC IntID[37]	Core
[5]	Not used	-
[4]	EXTIN[3]	ETM
[3]	EXTIN[2]	ETM
[2]	EXTIN[1]	ETM

*Table continues on the next page...*

**Table 9-31. CA5 Trigger Outputs (continued)**

Trigger Bit	Source Signal	Source Device
[1]	EXTIN[0]	ETM
[0]	EDBGRQ[n]	Core

### 9.11.10 Low Power Debug

The device supports two types of low power modes:

1. Module clock gating (STOP mode): If the debug power up request, CxxxPWRUPREQ is high and the system *attempts to enter STOP mode*, the DAP clock and the FCLK continue to run to support core register access and trace. In this case the debug module will have access to core registers but not modules which are clock gated.

If the device *is in STOP mode*, the debugger can assert the EDBGREQ by writing to the MDM-AP control bits (CM4 Debug Request and CA5 Debug Request). This will wakeup the core and it will move to halted state.

2. Power gated mode (LPSTOP1/2/3): When the device goes into power gated mode the device debug logic is also powered off. The debugger cannot gather any debug data for the duration of low power mode.

If the device is expected to enter into the power gated mode and the debugger wants to restore debug on recovery, the debugger sets bit[5] of MDM-AP control register (STANDBYDBGREQ).

The debugger continues to try to reestablish connection to the debug port while the device is in power gated mode. Once the device exits power gated mode, this status is available in MDM-AP status register- bit[10], "Standby mode exit". The debugger can read the status after it regains JTAG access to be sure that power gated mode was exited and not just any other reset.

The debugger is now able to reconfigure the desired debug state. Once done, it sets the Standby mode debug acknowledge (STANDBYDBGACK) – bit[6] in MDM-AP control register to let SRC to de-assert the core reset.

3. Inhibit Sleep: This is another way in which the debugger can handle the system standby modes. The inhibit Sleep is set using the configuration of MDM-AP control register. The debugger can set this bit, check if it is set (if yes the system has not gone into standby while the bit was being set) and then carry on with the debug accesses. Since inhibit sleep bit is set the system cannot move into standby and the debugger can continue with the accesses without risk of losing communication. Once

the debugger is done it can reset the bit and allow the standby transitions (in case the system so desire). The same is repeated every time the debugger wants to make debug accesses.

In case the system goes into standby while the inhibit Sleep was reset and the debugger now wants to make debug accesses, it initiates a write to SET inhibit Sleep and on read back does not get the expected response. Thus it knows that the system is in standby. The debugger can continue this until the device comes out of standby.

### 9.11.11 Secured JTAG

The SJC block offers a range of security levels. The SJC blocks the access to debug based on eFuse configuration and authentication. This is summarized in the table below:

S. No.	Name	Fuse used	Comments	Security Level	Flexibility to change the security level	Field Return
1	No Debug	JTAG_SMODE[1:0]	Closed for debug but allows basic JTAG features like IDCODE, BSR ...	High	No change possible	The field return is supported using Fuse bit "FIELD_RETURN"  This fuse is blown based on an authenticated image. The part which is received as field return is not returned to the customer.  The field return part offers complete access to TCU and debug just like the in fab part.
2	Secured JTAG	JTAG_SMODE[1:0]	Authentication based on challenge-Response (C-R)	Medium	Can switch to no debug	
3	JTAG enabled	JTAG_SMODE[1:0]	Open	No security	Can switch to secured JTAG or No Debug	Full support possible for field return.

#### 9.11.11.1 Additional Authentication Interface

Authentication interface aims to restrict access to debug and trace functionality. This is done by controlling the ARM debug authentication signals. For more details please refer to CoreSight v1.0 Architecture Specification. These are listed below:

## Configuration sequence

Control Signal name	Description	Controlled by
DBGEN	Invasive Debug Enable	SJC based on security authentication
NIDEN	Non invasive Debug Enable	SJC based on security authentication
SPIDEN	Secure invasive debug enable	control bit In SRC (can be SET by only s/w running in secure world)
SPNIDEN	Secure non-invasive debug enable	control bit In SRC (can be SET by only s/w running in secure world)

While in FAB or for field return all the controls are enabled to allow open access.

The SJC controls the DBGEN and NIDEN based on the security authentication and perceived security incident related to power up. This allows debugger access to non secure coresight components and allows non secure traces to be traced out.

In case debug in the secure world is required the SPIDEN and SPNIDEN needs to be set. This is feasible only by s/w running in the secure world.

## 9.11.12 Configuration sequence

### 9.11.12.1 Halt mode

This section explains how the different debugger types can make accesses to the debug logic.

1. In case of 2 wire CJTAG debugger send the sequence over TMS and TCK to switch CJTAG in 2 wires (refer to [JTAG-to-cJTAG change sequence](#) )

Else

In case of ARM SWD debugger send the sequence to switch the DAP from JTAG to SWD (refer to [JTAG-to-SWD change sequence](#))

Else

Continue with the IEEE 1149.1 4-wire interface.

2. Access ARM DAP Instruction registers.
3. Access "SJC" through JTAG AP.
4. Clear security authentication.
5. Continue with debug access.

### 9.11.12.2 Monitor mode

This is an application initiated mode where in debugger is not connected. In this mode the application writes to a bit in the CCM which allows to override CDBGPWRUPREQ and hence un gate the dap clock. In case of monitor mode only the CA5 debug IPs can be configured and used. We cannot use it for CM4 debug.

## 9.12 System JTAG Controller (SJC)

### 9.12.1 Introduction

Secure JTAG Controller (SJC) provides the security authentication for debug access to the chip. It is accessible through the JTAG Access Port (AP) of the ARM DAP.

This figure shows SJC connections to external contacts and other blocks.

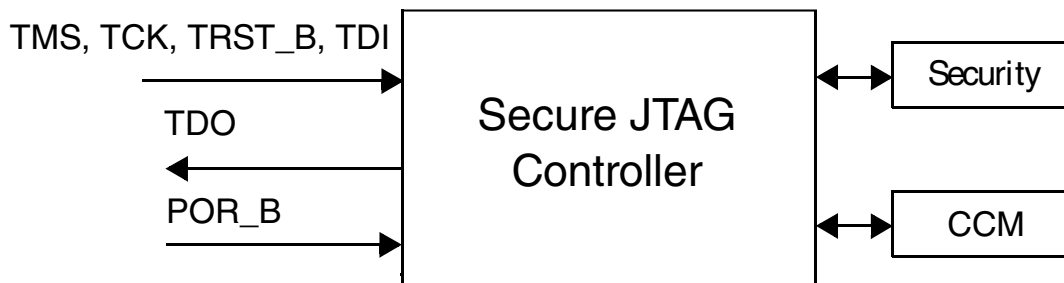

Figure 9-31. SJC connections

### 9.12.2 External signal description

#### 9.12.2.1 External signal overview

SJC provides test and debug control with a minimum number of contacts.

This table describes the SJC external connections along with the signal properties.

Table 9-32. SJC signal properties

Name/Port	Function
POR_B	POR reset input.
TCK	Test Clock (TCK). This is used to synchronize the test logic.

Table continues on the next page...

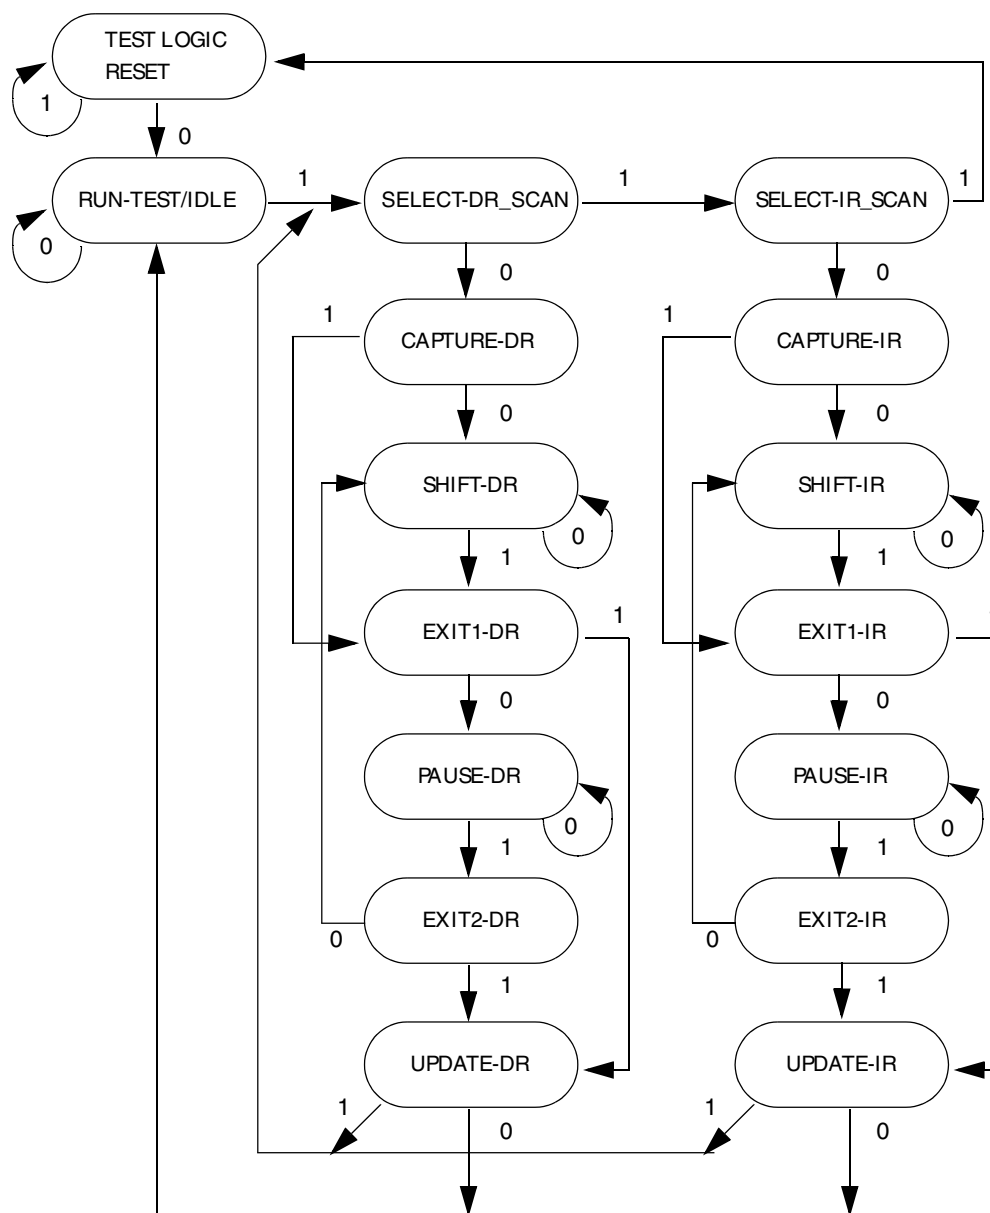

**Table 9-32. SJC signal properties (continued)**

Name/Port	Function
TDI	Test Data Input (TDI). Serial test instruction and data are received through the test data input (TDI) pin. TDI is sampled on the rising edge of TCK.
TDO	Test Data Output (TDO). The serial output for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TMS	Test Mode Select (TMS). This is used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK.

### 9.12.2.2 TAP controller

The TAP controller is responsible for interpreting the sequence of logical values on the TMS signal. It is a synchronous state machine that controls the operation of the JTAG logic. For a description of the TAP controller states, refer to the appropriate IEEE 1149.1 document.

The state machine is shown in this figure. The value shown adjacent to each arc represents the value of the TMS signal sampled on the rising edge of TCK signal.

**Figure 9-32. TAP controller state machine**

State changes occurs on the rising edge of TCK. TMS and TDI change on the falling edge of TCK. TDO also changes on the falling edge of TCK following entry into the Shift\_DR or Shift\_IR states.

This figure shows the SJC signal timings.

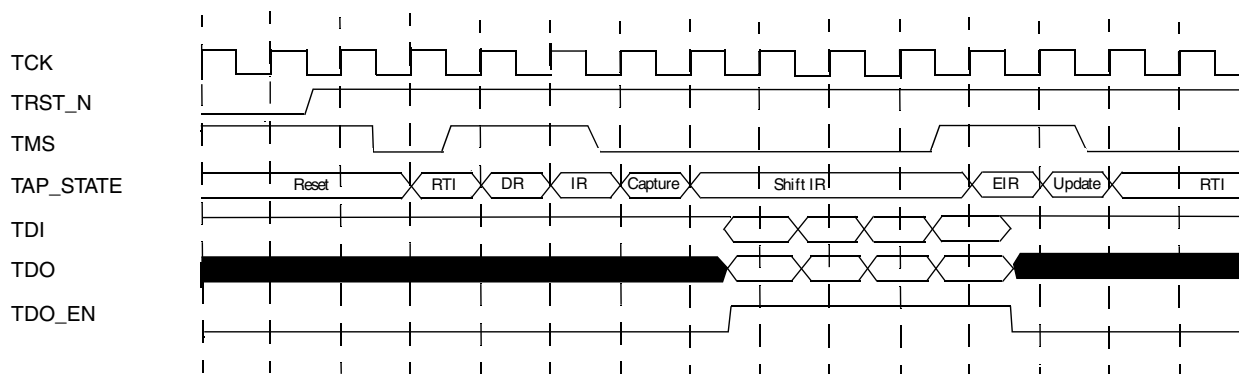

Figure 9-33. SJC signals timing diagram

### 9.12.2.3 Accessing ExtraDebug register

Accessed through the Select-DR-Scan path, the ExtraDebug shift register consists of 38 bits (maximum) including a 32-bit data field (max length, see the ExtraDebug register description), a 5 bit address field and read/write bit.

The write occurs when the JTAG TAP controller enters the Update-DR state. On a read, the data field is ignored (the user should shift only 5 times to enter Read=1 and the address), the read takes place on the next path through DR at the Capture-DR state, and the data is shifted-out during the Shift-DR state.

On the second path for a read access, simultaneous write access is not supported. Command converter software shifts in zeros so the TAP decodes a write to the CSR (read-only register) which does not have any effect.

The number of shift depends on the width of the accessed register as explained in the following diagrams. First a write access (one path through Select-DR-Scan):

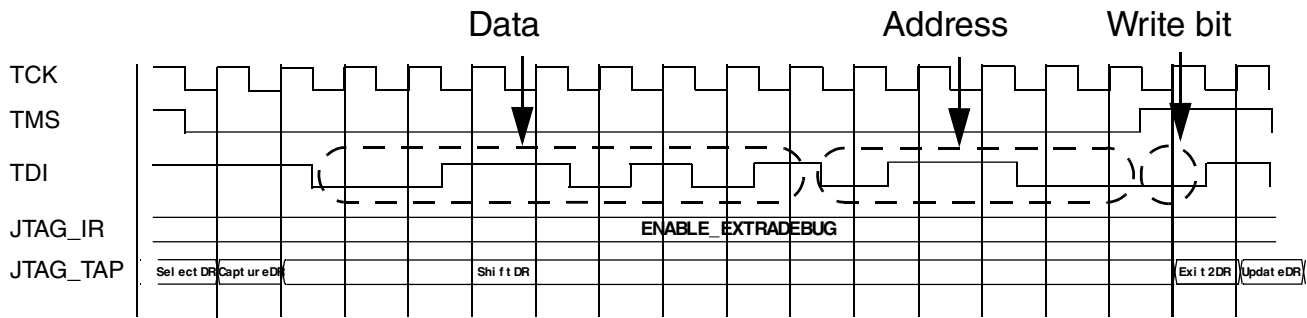

Figure 9-34. TDI/TDO on write access

Then a read access (requires two paths through JTAG DR Scan path):

*First path**Second path***Figure 9-35. TDI/TDO on read access**

For example, write value 1010\_1100b to Debug Control Register (address = 00110b).

**Figure 9-36. Example: Write access to DCR**

The SJC registers have different levels of security (refer to [JTAG Security Modes](#)):

- Secured—accessible only in Mode 2 (correct response entered), Mode 3 and Mode 4.
- Unsecured—accessible in all modes

### 9.12.3 JTAG Instruction Register (SJIR)

The JTAG Instruction register is 5 bits wide.

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	Reserved
0	0	0	0	1	Reserved
0	0	0	1	0	Reserved
0	0	0	1	1	Reserved
0	0	1	0	0	Enable Extra misc registers
0	0	1	0	1	Reserved
0	0	1	1	0	Reserved
0	0	1	1	1	Reserved
0	1	0	0	0	Reserved
0	1	0	0	1	Reserved
0	1	0	1	0	Reserved
0	1	0	1	1	Reserved
0	1	1	0	0	Security Output Challenge
0	1	1	0	1	Security input response
01110–01111					Reserved
1	1	1	1	1	BYPASS

The instruction register is reset to 00000b in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01b in the least significant bits as required by the standard; the most significant bits are loaded with the values 00b, leading to a capture value of 00001b.

### 9.12.3.1 BYPASS instruction

This instruction selects the single bit bypass register and the system logic controls the I/O pins. This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register.

When the bypass register is selected, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register is always a logic zero.

For more details on the function and use of BYPASS, refer to the appropriate IEEE 1149.1 document.

### 9.12.3.2 ENABLE\_ExtraDebug instruction

This instruction connects the TDI and TDO pins directly to the ExtraDebug registers, the SJC TAP controller remaining connected to TDI and TMS.

The ExtraDebug shift register consists of 38 bits (maximum) including a 32-bits data field (maximum length, see [Accessing ExtraDebug register](#)), a 5 bits address field and read/write bit. On a register read, the data field does not need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

### 9.12.4 Security

The SJC provides means to block any malicious JTAG access. The JTAG security modes are as follows:

- Mode 1: No Debug—maximum security. All security sensitive JTAG features are permanently blocked.
- Mode 2: Secure JTAG—high security. JTAG use is regulated by secret key based authentication mechanism.
- Mode 3: JTAG Enabled—low security. JTAG always enabled.

The JTAG security modes are configured using fuses, which can be burned after packaging by applying electrical signals. Fuse burning is an irreversible process. Once a fuse is burned it is not possible to change the fuse back to the un-burned state.

#### 9.12.4.1 JTAG Security Modes

##### 9.12.4.1.1 Mode 1: no debug—maximum security

No debug security mode provides the highest security level.

In this mode:

- All security sensitive JTAG features are permanently blocked
- Boundary scan still allowed
- MBIST, all modes except for debug modes which enable controlled memory contents output
- BIST of peripherals

These features do not reduce the security level, and they allow important tests and board connectivity checks.

#### **9.12.4.1.2 Mode 2: secure JTAG–high security**

The secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is checked. Only authorized debug devices (that is, devices having the right response) can access the JTAG. Unauthorized JTAG access attempts are denied.

##### **9.12.4.1.2.1 Challenge/response mechanism**

When SJC is in system JTAG mode, the authentication process is as follows:

1. Shift the output challenge instruction to the IR
2. Pass through Capture-DR state and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift the enter response instruction to the IR. By performing Shift-DR, operations enter response code value through TDI. As Update-DR state is entered, response code is compared with the correct one.

In fixed challenge-response pair mode, each chip has its individual challenge/response pair which is determined at manufacturing time. The SJC compares the user's response to the expected response.

**Figure 9-37. Mode #2 - Secure JTAG with fixed challenge/response pair**

#### 9.12.4.1.3 Mode 3: JTAG enabled—low security

In the JTAG enabled security mode, all JTAG features are enabled.

#### 9.12.4.2 Software enabled JTAG

To increase the flexibility of SJC, an option to enable the JTAG using software is available in secure JTAG mode. By writing a 1 to the HAB\_JDE (HAB JTAG DEBUG ENABLE) bit in the eFuse controller module (), the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit.

Additionally, a corresponding LOCK bit is available (in the eFuse control module) to ensure that only trusted software is able to set the HAB\_JDE bit. When the LOCK bit is set, no future change of HAB\_JDE is possible, until the next POR (power-on-reset) cycle.

The platform initialization software should set the LOCK bit before transferring control to the application code.

The software JTAG enable allows JTAG enabling without activating the challenge/response mechanism (which requires JTAG access tool enhancement or special hardware). The JTAG software enable does not allow debug in case of boot or memory fault as it requires reset before entering debug.

This feature can be permanently blocked by burning the dedicated fuse.

#### **NOTE**

The software enabled JTAG feature reduces the overall security level of the system as it relies on software protections. If this feature is not required, it is strongly recommended to burn the JTAG\_HEO fuse to disable this feature.

### **9.12.5 Programmable registers**

This section lists additional registers to the standard accessible JTAG registers (per IEEE1149.1 standard). The following registers are accessed using the ExtraDebug mechanism, controlled by the ENABLE\_ExtraDebug IR instruction.

#### **NOTE**

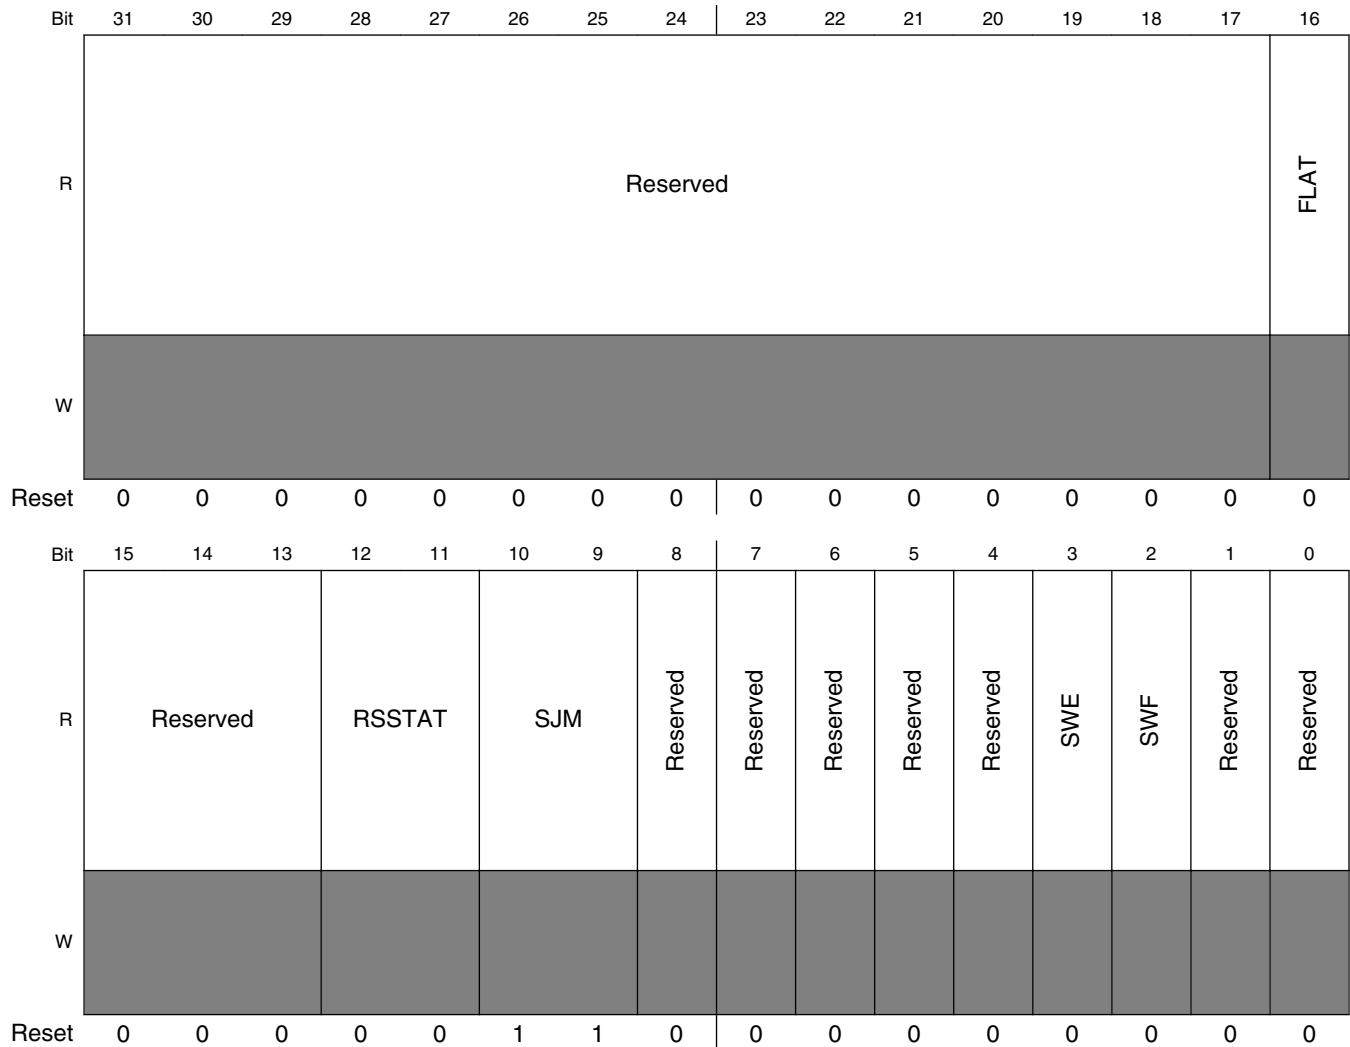

SJC registers are only accessible by JTAG interface and are not memory mapped to processor address space.

#### **SJC memory map**

<b>Absolute address (hex)</b>	<b>Register name</b>	<b>Width (in bits)</b>	<b>Access</b>	<b>Reset value</b>	<b>Section/ page</b>
5	Security Status Register (SJC_SSR)	32	R	0000_0600h	<a href="#">9.12.5.1/1321</a>

### 9.12.5.1 Security Status Register (SJC\_SSR)

Address: 0h base + 5h offset = 5h

**SJC\_SSR field descriptions**

Field	Description
31–17 Reserved	This field is reserved.
16 FLAT	Fuse latch 0 Fuses are not yet latched 1 Fuses have been latched
15–13 Reserved	This field is reserved.
12–11 RSSTAT	Response status 00 Response not entered

*Table continues on the next page...*

### SJC\_SSR field descriptions (continued)

Field	Description
	01 Response entered but not verified 10 Response entered and is incorrect 11 Response is correct
10–9 SJM	SJC mode. Secure JTAG mode, as set by external fuses. These bits do not include the setting of the BSF fuse.  00 No debug (Mode 1) 01 Secure JTAG (Mode 2) 10 Reserved 11 JTAG enabled (Mode 3)
8 Reserved	This field is reserved.
7 Reserved	This field is reserved.

## External Memory and Mass Storage

### 10.1 LPDDR2/DDR3 SDRAM Memory Controller (DDRMC)

#### 10.1.1 Introduction

The memory controller supports high performance applications for 16-bit or 8-bit DDR3, or LPDDR2 SDRAM memories.

The features of this Memory Controller (MC) include:

- Supports interfacing to LPDDR2 and DDR3 memory types.
- Fully pipelined command, read and write data interfaces to the memory controller.
- Advanced bank look-ahead features for high memory throughput.
- Front-end interface to 2 standard AXI ports.
- A programmable register interface to control memory parameters and protocols including auto pre-charge.
- Full initialization of memory on memory controller reset.
- ECC functionality with single bit and double bit error reporting and automatic correction of single bit error events. 10 bit memory interface required for ECC (8 bit user data + 2 bits ECC). Programmable removal of ECC storage.
- Programmable memory datapath size of full memory data (16 bit) width or half memory data (8 bit) width.
