- Clock frequencies from 100 MHz to 400 MHz supported.

## 10.1.2 Block diagram

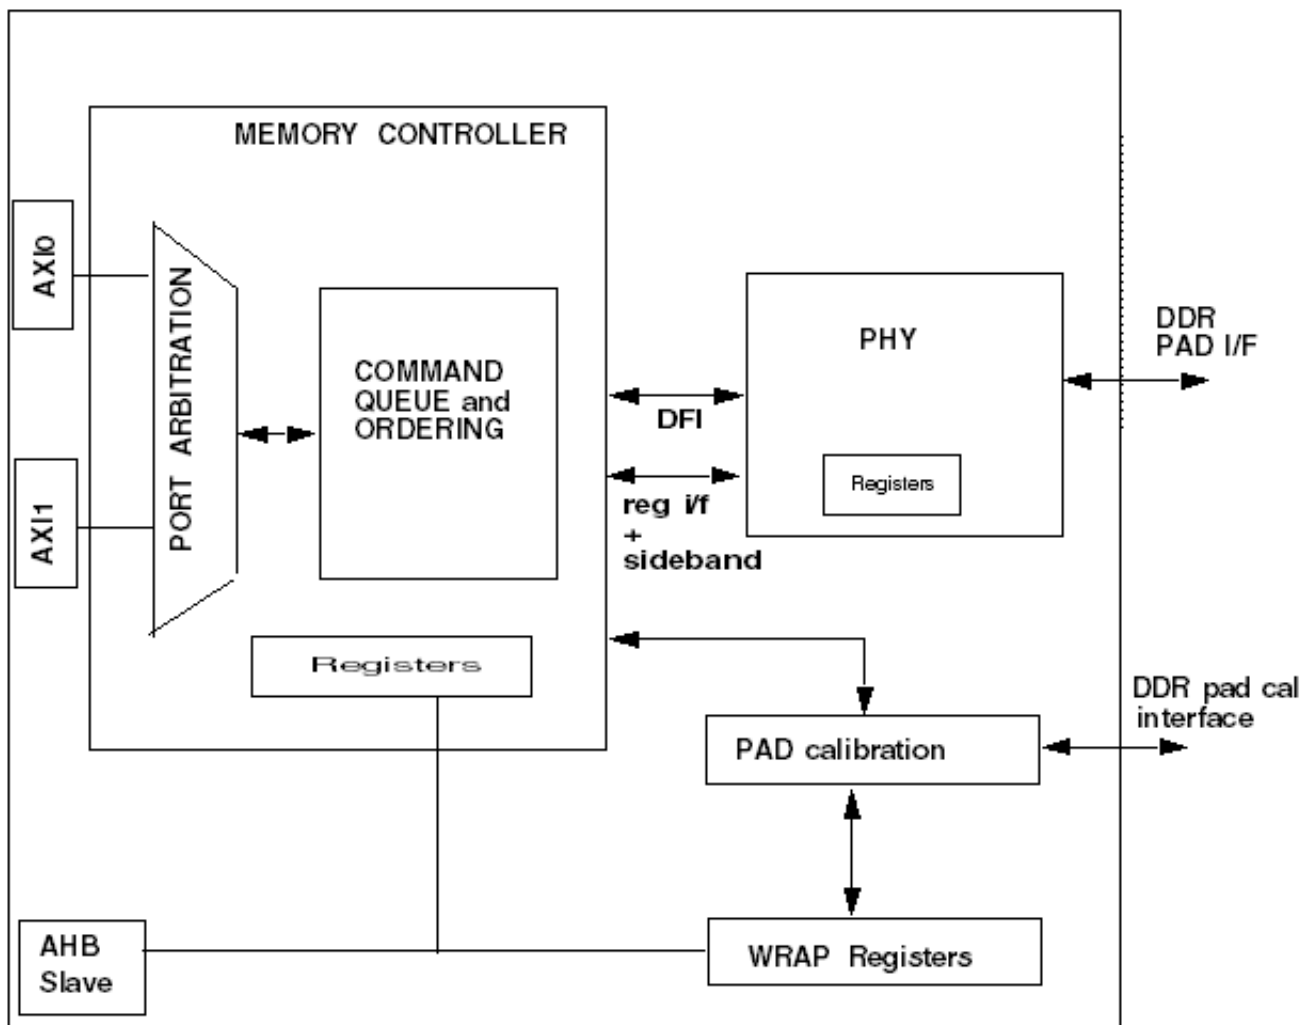

Figure 10-1. DDRMC Block Diagram

## 10.1.3 Modes of Operation

The following operating modes are available:

- LPDDR2
- DDR3

### 10.1.3.1 Low Power Modes

For details see [Low Power Operation](#).

### 10.1.4 Signal Description

The following table lists the memory controller's external memory interface signals.

**Table 10-1. Signal Properties**

Name	Function	I/O	Reset
DDR_A[10:0] DDR_A[14:0]	Selects the column when $\overline{\text{DDR\_CAS}}$ is asserted Selects the row when $\overline{\text{DDR\_RAS}}$ is asserted.	O	0000
DDR_BA[2:0]	Selects 1 of 8 SDRAM Banks when $\overline{\text{DDR\_RAS}}$ is asserted (precharge or active) or when $\overline{\text{DDR\_CAS}}$ is asserted (read or write).  000 - Bank1 001 - Bank2 ----- 111 - Bank8	O	0
$\overline{\text{DDR\_CAS}}$	Column address select	O	1
DDR_CKE	Clock enable. Asserts when the clock is valid	O	0
DDR_CLK $\overline{\text{DDR\_CLK}}$	Differential clock	O	0 1
$\overline{\text{DDR\_CS}}$	Chip select	O	1
DDR_DQ[15:0]	Write or read data from the SDRAM. DDR_DQ[7:0] + ECC lines [9:8] when ECC is used.	I/O	—
DDR_DM	Data mask: 00 No mask 01 Low byte mask enable 10 High byte mask enable 11 Low and high byte mask enable	O	11
DDR_DQS[1:0]	Differential data strobe <b>Note:</b> Pull down is active in LPDDR2 mode only.	I/O	—
DDR_ODT	On-die-termination	O	0
$\overline{\text{DDR\_RAS}}$	Row address select	O	1
$\overline{\text{DDR\_WE}}$	Write enable	O	1
DDR_VREF	Voltage supply reference	—	—
DDR_RESET	Reset signal	O	—

### 10.1.4.1 Detailed Signal Descriptions

The following table describes the external signals in more detail with timing to DDR\_CLK and how the signals interact with each other.

**Table 10-2. Detailed Signal Descriptions**

Signal	I/O	Description
DDR_A[15:0]	O	Provides the row address for ACTIVE commands, and the column address and AUTO PRECHARGE bit for READ/WRITE commands, to select one location out of the memory array in the respective bank. A10 is sampled during a precharge command to determine whether the PRECHARGE applies to one bank (A10 LOW) or all banks (A10 HIGH). If only one bank is to be precharged, the bank is selected by BA0, BA1 and BA2. The address outputs also provide the op-code during a MODE REGISTER SET command. BA0, BA1 and BA2 define which mode register is loaded during the MODE REGISTER SET (MRS or EMRS's)
		<b>State Meaning</b> Please see <a href="#">Table 10-4</a> for the LPDDR2 SDRAM commands.
		<b>Timing</b> Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_BA[2:0]	O	BA0, BA1 and BA2 define which 1 of 8 banks an ACTIVE, READ, WRITE, or PRECHARGE command is being applied to.
		<b>Timing</b> Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_CAS	O	Command input. Along with $\overline{\text{DDR\_CS}}$ , $\overline{\text{DDR\_RAS}}$ , and $\overline{\text{DDR\_WE}}$ defines the current command.
		<b>State Meaning</b> Please see <a href="#">Table 10-3</a> for the DDR3 SDRAM commands.
		<b>Timing</b> Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_CKE	O	CKE must be maintained high throughout READ and WRITE accesses. Input buffers, excluding DDR_CLK, $\overline{\text{DDR\_CLK}}$ , and DDR_CKE, are disabled during POWER DOWN or SELF REFRESH.
		<b>State Meaning</b> Asserted— Activates internal clock signals and device input buffers and output drivers. Negated—Deactivates internal clock signals and device input buffers and output drivers.
		<b>Timing</b> Assertion — Asynchronous for SELF-REFRESH exit and for output disable Negation— Occurs synchronously with DDR_CLK
DDR_CLK $\overline{\text{DDR\_CLK}}$	O	DDR_CLK and $\overline{\text{DDR\_CLK}}$ are differential clock outputs. All address and control output signals are sent on the crossing of the positive edge of DDR_CLK and the negative edge of $\overline{\text{DDR\_CLK}}$ . Output data is referenced to the crossing of DDR_CLK and $\overline{\text{DDR\_CLK}}$ (both directions of crossing).
		<b>Timing</b> Command signals are synchronously with the rising edge of this clock. The data signals can change on both the rising and falling edge of the clock.
DDR_CS	O	DDR_CS provides for external chip selection on systems with multiple chips. DDR_CS is considered part of the command code.
		<b>State Meaning</b> Asserted— Commands for the selected chip will occur Negated—All commands are masked.
		<b>Timing</b> Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_DQ[15:0]	I/O	Data bus. DDR_DQ[15:0] or DDR_DQ[7:0]+ECC[9:8].
		<b>Timing</b> Assertion/Negation— Occurs on both crossing of DDR_CLK and $\overline{\text{DDR\_CLK}}$ on write command. Synchronous with DDR_DQS input on read command.
DDR_DM[1:0]	O	Output mask signal for write data. During Reads, $\overline{\text{DDR\_DM}}$ may be driven high, low, or floating.
		<b>State Meaning</b> Asserted— Data is written to SDRAM Negation— Data is masked

Table continues on the next page...

**Table 10-2. Detailed Signal Descriptions (continued)**

Signal	I/O	Description	
DDR_DQS[1:0]	I/O	<b>Timing</b>	Assertion/Negation— Occurs on both crossing of DDR_CLK and $\overline{\text{DDR\_CLK}}$ .
		<b>State Meaning</b>	Edge-aligned with read data, centered in write data. Used to capture data.
		<b>Timing</b>	Assertion/Negation—Occurs on both crossing of DDR_CLK and $\overline{\text{DDR\_CLK}}$ on write command. Asynchronous with DDR_CLK and $\overline{\text{DDR\_CLK}}$ on read command.
DDR_ODT	O		DDR_ODT enables termination resistance internal to the DDR2 SDRAM.
		<b>State Meaning</b>	Assertion— Enable termination resistance Negation— Disable termination resistance Please see <a href="#">Table 10-3</a> for DDR3 SDRAM commands.
		<b>Timing</b>	Assertion/Negation— Occurs synchronously with DDR_CLK
$\overline{\text{DDR\_RAS}}$	O		Command input. Along with $\overline{\text{DDR\_CS}}$ , $\overline{\text{DDR\_CAS}}$ , and $\overline{\text{DDR\_WE}}$ defines the current command.
		<b>State Meaning</b>	Please see <a href="#">Table 10-3</a> for DDR3 SDRAM commands.
		<b>Timing</b>	Assertion/Negation— Occurs synchronously with DDR_CLK.
DDR_WE	O		Command input. Along with $\overline{\text{DDR\_CS}}$ , $\overline{\text{DDR\_CAS}}$ , and $\overline{\text{DDR\_RAS}}$ defines the current command.
		<b>State Meaning</b>	Please see <a href="#">Table 10-3</a> for DDR3 SDRAM commands.
		<b>Timing</b>	Assertion/Negation— Occurs synchronously with DDR_CLK. Refer device datasheet for the PU/PD details.
DDR_VREF	—		SDRAM reference voltage. Reference voltage for differential I/O pad cells should be half the voltage of the memory used in the system. For example, 1.5 V DDR3 results in an DDR_VREF of 0.75 V and 1.2 V LPDDR2 results in an DDR_VREF of 0.6 V. See the device's datasheet for the voltages and tolerances for the various memory modes.
$\overline{\text{DDR\_RESET}}$	O		DDR3 memory reset signal.
		<b>State Meaning</b>	Assertion: Memory is in Reset Negation: Memory is in normal operating mode
		<b>Timing</b>	ASSERTS asynchronously and de-assertion is synchronour to DDR_CLK per JEDEC timings

Function	Abbreviation	CKE		CS#	RAS#	CAS#	WE #	BA0 - BA2	A13 - A15	A12 - BC#	A10 -AP	A0-A9, A11	Notes
		Previous Cycle	Current Cycle										
ZQ Calibration Short	ZQCS	H	H	L	H	H	L	X	X	X	L	X	

**Note**

1. CKE is HIGH for all commands shown except SELF REFRESH.
2. BA0--BA1 select either the Base or the Extended Mode Register (BA0 = 0, BA1 = 0 selects Mode Register; BA0 = 1, BA1 = 0 selects Extended Mode Register; other combinations of BA0--BA1 are reserved; A0--A13 provide the op--code to be written to the selected Mode Register.
3. BA0--BA1 provide bank address and A0--A13 provide row address.
4. BA0--BA1 provide bank address; A0--Ai provide column address; A10 HIGH enables the auto precharge feature (non-persistent), A10 LOW disables the auto precharge feature.
5. A10 LOW: BA0--BA1 determine which bank is precharged. A10 HIGH: all banks are precharged and BA0--BA1 are "Don't Care."
6. This command is AUTO REFRESH if CKE is HIGH; SELF REFRESH if CKE is LOW.
7. Internal refresh counter controls row addressing; all inputs and I/Os are "Don't Care" except for CKE.
8. Applies only to read bursts with autoprecharge disabled; this command is undefined (and should not be used) for read bursts with autoprecharge enabled, and for write bursts.
9. DESELECT and NOP are functionally interchangeable.
10. Used to mask write data, provided coincident with the corresponding data.

11. Operation or timing that is not specified is illegal and after such an event, in order to guarantee proper operation, the DRAM must be powered down and then restarted through the specified initialization sequence before normal operation can continue.
12. VREF must be maintained during Self Refresh operation.

				X										

**Note**

1. All LPDDR2 commands are defined by states of CS\_n, CA0, CA1, CA2, CA3, and CKE at the rising edge of the clock. CA refers to command/address slice.
2. For LPDDR2 SDRAM, Bank addresses BA0, BA1, BA2 (BA) determine which bank is to be operated upon.
3. AP is significant only to SDRAM.
4. AP "high" during a READ or WRITE command indicates that an auto-precharge will occur to the bank associated with the READ or WRITE command.
5. "X" means "H or L (but a defined logic level)"
6. Self refresh exit and Deep Power Down exit are asynchronous.
7. VREF must be between 0 and VDDQ during Self Refresh and Deep Power Down operation.

8. CA<sub>xr</sub> refers to command/address bit "x" on the rising edge of clock.
9. CA<sub>xf</sub> refers to command/address bit "x" on the falling edge of clock.
10. CS<sub>n</sub> and CKE are sampled at the rising edge of clock.
11. Per Bank Refresh is only allowed in devices with 8 banks.
12. The least-significant column address C0 is not transmitted on the CA bus, and is implied to be zero.

### 10.1.5 Memory map and register description

#### NOTE

Register read or write for any register in the DDR controller requires the DDRMC clock to be configured from CCM\_CCSR [DDRC\_CLK\_SEL] in addition to enabling the clock from the clock gating register: CCM\_CCGR6[CG110].

**DDRMC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

**10.1.5.1 Control Register 0 (DDRMC\_CR00)**

Address: 400A\_E000h base + 0h offset = 400A\_E000h

## DDRMC\_CR00 field descriptions

Field	Description
31–16 VERSION	Holds the controller version number.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 DRAM_CLASS	Defines the mode of operation of the controller. Only the following settings are applicable. <ul style="list-style-type: none"> <li>• <b>0101</b> - LPDDR2 (supports burst lengths of 4 or 8)</li> <li>• <b>0110</b> - DDR3 (supports burst length of 8 only)</li> <li>• All other settings are reserved.</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 START	Initiate command processing in the controller.  Prior to setting this parameter to 'b1, the Memory Controller will not issue any commands to the DRAM devices or respond to any signal activity except for reading and writing register parameters and accepting traffic that the processor core may send to the Memory Controller internal queues. Once this parameter is set to 'b1, the Memory Controller will respond to inputs from the ASIC and begin to process memory access commands.  <b>NOTE:</b> Until the MC initialization complete bit is set to 'b1 in INT_STAT (DDRMC_CR80 bit [8]), the Memory Controller will not accept commands into the Memory Controller command queue. Resetting this parameter to 'b0 will not shut off traffic. <ul style="list-style-type: none"> <li>• <b>0</b> - Memory Controller is not in active mode.</li> <li>• <b>1</b> - Initiate active mode for the Memory Controller.</li> </ul>

## 10.1.5.2 Control Register 1 (DDRMCR01)

Address: 400A\_E000h base + 4h offset = 400A\_E004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0														MAX_CS_REG	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				MAX_COL_REG				0				MAX_ROW_REG			
W																
Reset	0	0	0	0	1	0	1	1	0	0	0	1	0	0	0	0

## DDRMCR01 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 MAX_CS_REG	This parameter defines the maximum number of DDR chip selects implemented within this SoC.

Table continues on the next page...

### DDRMC\_CR01 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>• <b>10</b> - One Chip Select</li> <li>• This is a read-only field</li> </ul>
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 MAX_COL_REG	<p>This parameter defines the maximum width of memory column addresses implemented within this SOC.</p> <ul style="list-style-type: none"> <li>• The default value is 11, which corresponds to DDR_A[11,9:0] pins when DDR_CAS_B is active.</li> <li>• This is a read only field.</li> </ul> <p><b>NOTE:</b> COL_DIFF (DDRMCR73 bit [18:16]) contains the field that defines the number of address columns used on the memory device selected with the user's system.</p>
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
MAX_ROW_REG	<p>This parameter defines the maximum width of the memory row addresses implemented within this SoC. The default is 16, which corresponds to DDR_A[15:0] pins when DDR_RAS_B is active. This is a read-only field.</p> <p><b>NOTE:</b> ROW_DIFF (DDRMCR73 bit [9:8]) contains the field that defines the number of address rows used on the memory device selected within the user's system.</p>

### 10.1.5.3 Control Register 2 (DDRMCR02)

Address: 400A\_E000h base + 8h offset = 400A\_E008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								TINIT																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### DDRMCR02 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TINIT	<p>This parameter defines the DRAM initialization time, in cycles. This refers to the time required for the clocks to be started and stabilized before the clock enable signal becomes active.</p> <ul style="list-style-type: none"> <li>• Loading a value of 0x0 will create the maximum delay count.</li> </ul> <p><b>For DDR3:</b></p> <p>The JEDEC spec defines this as: "Clocks (CK, CK#) need to be started and stabilized for at least 10 ns or 5 tCK (which is larger) before CKE goes active."</p> <ul style="list-style-type: none"> <li>• For DDR3 &amp; 400MHz clock designs, set the counter value = 0x5.</li> </ul> <p><b>For LPDDR2:</b></p> <p>This counter value correlates to the JEDEC "t<sub>INIT1</sub>" time value.</p> <p>The JEDEC spec defines this as: "CKE must remain low for at least t<sub>INIT1</sub> = 100 ns, after which it may be asserted high."</p> <ul style="list-style-type: none"> <li>• For LPDDR2 &amp; 400MHz clock designs, set the counter value = 0x28</li> </ul>

### 10.1.5.4 Control Register 3 (DDRMC\_CR03)

Address: 400A\_E000h base + Ch offset = 400A\_E00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								TINIT3																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### DDRMC\_CR03 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TINIT3	<p>LPDDR2 <math>t_{INIT3}</math> value in cycles.</p> <p><b>For DDR3:</b> This parameter is not used.</p> <p><b>For LPDDR2:</b> This counter value defines the number of cycles required from the CKE assertion to the memory reset. This parameter should be programmed to the <math>t_{INIT3}</math> value from the memory specification.</p> <ul style="list-style-type: none"> <li>Loading a value of 0x0 will create the maximum delay count.</li> </ul> <p>The JEDEC spec defines this as: <math>t_{INIT3} = 200 \mu\text{sec}</math>.</p> <ul style="list-style-type: none"> <li>For LPDDR2 &amp; 400MHz clock designs, set the counter value = 0x13880</li> <li>The user should verify the <math>t_{INIT3}</math> time value from their memory datasheet.</li> </ul>

### 10.1.5.5 Control Register 4 (DDRMC\_CR04)

Address: 400A\_E000h base + 10h offset = 400A\_E010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								TINIT4																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### DDRMC\_CR04 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TINIT4	<p>LPDDR2 <math>t_{INIT4}</math> value in cycles.</p> <p><b>For DDR3:</b> This parameter is not used.</p>

Table continues on the next page...

### DDRMC\_CR04 field descriptions (continued)

Field	Description
	<p><b>For LPDDR2:</b></p> <p>This counter value defines the number of cycles required from a memory reset to a MRR command. This parameter should be programmed to the <math>t_{INIT4}</math> value from the memory specification.</p> <ul style="list-style-type: none"> <li>Loading a value of 0x0 will create the maximum delay count.</li> </ul> <p>The JEDEC spec defines this as: <math>t_{INIT4} = 1 \mu\text{sec}</math>.</p> <ul style="list-style-type: none"> <li>For LPDDR2 &amp; 400MHz clock designs, set the counter value = 0x190</li> <li>The user should verify the <math>t_{INIT4}</math> time value from their memory datasheet.</li> </ul>

### 10.1.5.6 Control Register 5 (DDRMC\_CR05)

Address: 400A\_E000h base + 14h offset = 400A\_E014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### DDRMC\_CR13 field descriptions

Field	Description
31–24 TRC	<p>Defines the DRAM period between active commands for the same bank, in memory clocks.</p> <p><b>For DDR3 &amp; LPDDR2:</b></p> <p>The JEDEC spec defines this as: "<i>ACTIVE to ACTIVE command period - <math>t_{RC}</math></i>".</p> <ul style="list-style-type: none"> <li>This parameter is defined within the memory device datasheet.</li> </ul>
23–16 TRRD	<p>Defines the DRAM activate to activate delay to different bank groups, in memory clocks.</p> <p><b>For DDR3:</b></p> <p>The JEDEC spec defines this as: "<i>ACTIVE to ACTIVE command period delay - <math>t_{RRD}</math></i>".</p> <p><b>For LPDDR2:</b></p> <p>The JEDEC spec defines this as: "<i>The minimum time interval between Activate commands to different banks - <math>t_{RRD}</math></i>".</p> <ul style="list-style-type: none"> <li>This parameter is defined within the memory device datasheet.</li> </ul>
15–13 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
12–8 TCCD	<p>Defines the minimum delay between CAS commands, in memory clocks. This value is loaded into a counter when a memory burst is issued and a new command may be issued when the counter reaches 0.</p> <p><b>For DDR3:</b></p> <p>The JEDEC spec defines this as: "<i>CAS# to CAS# command delay - <math>t_{CCD}</math></i>".</p> <p><b>For LPDDR2:</b></p> <p>The JEDEC spec defines this as: "<i>The minimum CAS to CAS delay is defined by - <math>t_{CCD}</math></i>".</p> <ul style="list-style-type: none"> <li>The <math>t_{CCD}</math> parameter is defined within the memory device datasheet.</li> <li>Loading a value of 0x0 will create the maximum delay count.</li> </ul>
7–3 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
TBST_INT_INTERVAL	<p>DRAM burst interrupt interval value in cycles.</p> <p><b>For DDR3:</b></p> <p>The JEDEC spec defines this as: "<i>Burst reads or writes cannot be terminated or interrupted</i>"</p>

Table continues on the next page...

### DDRM\_Cr13 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>Set <b>tbst_int_interval</b> value to 0x0.</li> <li>A value of 0x0 will create the maximum delay count and inhibit any command interruptions.</li> </ul> <p><b>For LPDDR2:</b></p> <ul style="list-style-type: none"> <li>The JEDEC spec defines this as: <ul style="list-style-type: none"> <li>"For LPDDR2-S4 (and LPDDR2-N) devices, a new burst access must not interrupt the previous 4-bit burst operation in case of BL = 4 setting. In case of BL = 8 and BL = 16 settings, Reads may be interrupted by Reads and Writes may be interrupted by Writes, provided that this occurs on even clock cycles after the Read or Write command and <math>t_{CCD}</math> is met."</li> <li>"For LPDDR2-S2 devices, Reads may interrupt Reads and Writes may interrupt Writes, provided that <math>t_{CCD}</math> is met."</li> </ul> </li> <li>The <b>tbst_int_interval</b> value is loaded into the counter when a memory burst command is issued.</li> <li>The counter is automatically reloaded with the <b>tbst_int_interval</b> value when it hits 0 and the burst memory command is not completed.</li> <li>The <math>t_{CCD}</math> counter and the <b>tbst_int_interval</b> counter decrement in parallel at the start of the memory burst command.</li> <li>When the <math>t_{CCD}</math> counter has elapsed, then the <b>tbst_int_interval</b> counter will control the delay.</li> <li>Although the next command can be sent when <math>t_{CCD}</math> has elapsed; the command execution will be delayed until the <b>tbst_int_interval</b> counter value equals 0x0.</li> <li>Loading a <b>tbst_int_interval</b> value of 0x0 will create the maximum delay count.</li> <li>For example with a LPDDR2 memory, consider a system where the memory burst length = 8, <math>t_{CCD}</math> = 2. <ul style="list-style-type: none"> <li>At memory clock 0, a burst memory command was issued</li> <li>Another burst memory command can be issued on memory clock 2 or later (based on <math>t_{CCD}</math>)</li> <li>Then the command execution will interrupt the current memory burst based on the <b>tbst_int_interval</b> programmed value: <ul style="list-style-type: none"> <li><b>tbst_int_interval</b> = 0x3, can interrupt on beats 3 and 6.</li> <li><b>tbst_int_interval</b> = 0x4, can interrupt on beat 4.</li> <li><b>tbst_int_interval</b> = 0x2, can interrupt on beats 2, 4 and 6.</li> <li>where a <i>beat</i> equals 1/2 a clock cycle.</li> </ul> </li> </ul> </li> </ul>

### 10.1.5.15 Control Register 14 (DDRM\_Cr14)

Address: 400A\_E000h base + 38h offset = 400A\_E038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0										0						0

#### DDRMC\_CR16 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 TMRD	Defines the minimum number of memory clocks required between two mode register write commands. This is the time required to complete the write operation to the mode register. There are two parameters that control the timing after a mode register write: TMOD (DDRMC_CR17 bit [7:0]) and the TMRD. This parameter TMRD is typically the shorter of the two timing delays. <ul style="list-style-type: none"> <li>The memory controller will wait this delay TMRD after a mode register command before sending the next mode register command.</li> <li>The memory controller does not need to wait for the longer TMOD (DDRMC_CR17 bit [7:0]) timer to expire since termination is not used for mode register commands.</li> </ul> <p><b>For DDR3:</b></p> <p>The JEDEC spec defines this as: "<i>the Mode Register Set command cycle time - <math>t_{MRD}</math></i>".</p> <ul style="list-style-type: none"> <li>The <math>t_{MRD}</math> parameter is defined within the memory device datasheet.</li> </ul> <p><b>For LPDDR2:</b></p> <p>The JEDEC spec defines this as: "<i>the MRW command period is defined by <math>t_{MRW}</math></i>".</p> <ul style="list-style-type: none"> <li>The <math>t_{MRW}</math> parameter is defined within the memory device datasheet.</li> </ul>
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 TRTP	Defines the DRAM $t_{RTP}$ (read to precharge time) parameter, in cycles. <p><b>For DDR3 &amp; LPDDR2:</b></p> <p>The JEDEC spec defines this as: "<i>the Internal READ Command to PRECHARGE Command delay - <math>t_{RTP}</math></i>".</p> <ul style="list-style-type: none"> <li>The <math>t_{RTP}</math> parameter is defined within the memory device datasheet.</li> </ul>
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 10.1.5.18 Control Register 17 (DDRMC\_CR17)

Address: 400A\_E000h base + 44h offset = 400A\_E044h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								TRAS_MAX																TMOD							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## DDRMC\_CR17 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–8 TRAS_MAX	<p>Defines the DRAM maximum row active time, in memory clocks.</p> <ul style="list-style-type: none"> <li>In practical use, the Memory Controller will use the value in this parameter with adjustments made for write recovery time, memory burst length and any internal delays if required.</li> </ul> <p><b>For DDR3 &amp; LPDDR2:</b></p> <p>The JEDEC spec defines this as: "<i>Row Active Time - <math>t_{RAS}</math></i>".</p> <ul style="list-style-type: none"> <li>Use the values defined in the MAX column for <math>t_{RAS}</math>.</li> <li>The <math>t_{RAS}</math> parameter is defined within the memory device datasheet.</li> </ul>
TMOD	<p>Defines the number of memory clocks of delay needed after a mode register write to any non-mode register write command. It is determined by the number of memory clocks of wait time required after an MRS command until ODT is re-enabled.</p> <ul style="list-style-type: none"> <li>There are two parameters that control the timing after a mode register write: TMOD and TMRD (<b>DDRMCR16 bit [28:24]</b>).</li> <li>This parameter (TMOD) is typically the longer timing delay (defined by the memory specification) and controls the spacing of a mode register command to any other memory command.</li> <li>The Memory Controller will wait this delay after a mode register command before sending any other command to memory since the controller has no way of knowing whether or not termination (ODT) will be used.</li> </ul> <p><b>For DDR3:</b></p> <p>The JEDEC spec defines this as: "<i>the Mode Register Set command update delay - <math>t_{MOD}</math></i>".</p> <ul style="list-style-type: none"> <li>The <math>t_{MOD}</math> parameter is defined within the memory device datasheet.</li> </ul> <p><b>For LPDDR2:</b></p> <p>The JEDEC spec does not separate the delay into 2 parameters as with DDR3 because ODT is not implemented in LPDDR2.</p> <ul style="list-style-type: none"> <li>This field should be set to <math>t_{MRW}</math>.</li> <li>The <math>t_{MRW}</math> parameter is defined within the memory device datasheet.</li> </ul>

## 10.1.5.19 Control Register 18 (DDRMCR18)

Address: 400A\_E000h base + 48h offset = 400A\_E048h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### DDRMC\_CR33 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 CKE_DELAY	This parameter adds additional memory clocks to delay the updates to the CKE_STAT status bits ( <b>DDRMC_CR124 bit [17:16]</b> ). This allows the status register changes to reflect the actual timing of the CKE pin assertion (at the device pad). <ul style="list-style-type: none"> <li>Default value of 0x0 results in a 2 clock delay.</li> <li>This parameter does not effect memory performance.</li> <li>This device requires less than 2 clock cycles. Set this parameter to 0x0</li> </ul>
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EN_QK_SREF	When this bit is set to 'b1, the memory initialization sequence may be interrupted and the memory may enter self-refresh mode. This is used to place the memories into self-refresh mode when a power loss is detected during the initialization process. Setting this parameter does not initiate a self-refresh entry during initialization. However, if a self-refresh entry is requested during initialization, it will only occur if this parameter is also set to 'b1. <ul style="list-style-type: none"> <li>This parameter should be set to 'b1 to allow entering self-refresh.</li> <li>0 - Continue memory initialization.</li> <li>1 - Interrupt memory initialization and enter self-refresh mode.</li> </ul>
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SREF_EX_NOREF	When a self-refresh exit command is executed, an automatic refresh is requested. By setting this bit, the automatic refresh request is inhibited. <ul style="list-style-type: none"> <li>This parameter should be set to 'b0 to allow automatic refresh</li> </ul>

Table continues on the next page...

### DDRMC\_CR33 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>• <b>0</b> - Allow automatic refresh.</li> <li>• <b>1</b> - Inhibit automatic refresh.</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 PWUP_SREF_ EX	<p>Allows the controller to exit low power state by executing a self-refresh exit instead of the full memory initialization.</p> <ul style="list-style-type: none"> <li>• This parameter provides a means to skip full initialization when the DRAM memories are in a known self-refresh state.</li> <li>• This parameter should be set to 'b0 to force full memory initialization</li> </ul> <ul style="list-style-type: none"> <li>• <b>0</b> - Disable (must exit low power with full memory initialization)</li> <li>• <b>1</b> - Enable exiting low power by executing a self-refresh exit command</li> </ul>

## DDRMC\_CR71 field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–8 ZQRESET	Specifies the duration of wait time, in memory clocks, required for the memories to complete a ZQRESET command.  <b>For DDR3:</b> This parameter does not apply to DDR3.  <b>For LPDDR2:</b> The JEDEC spec defines this as: " <i>Calibration Reset Time - <math>t_{ZQRESET}</math></i> ". <ul style="list-style-type: none"> <li>The <math>t_{ZQRESET}</math> parameter is defined within the memory device datasheet.</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 ZQ_IN_PROG	Indicates that a ZQ command is currently in progress. <ul style="list-style-type: none"> <li>If a ZQ command is requested while this parameter is set to 'b1, the new ZQ request will be ignored.</li> <li>This parameter is read-only.</li> </ul> <ul style="list-style-type: none"> <li><b>0</b> - Not in progress</li> <li><b>1</b> - ZQ command in progress</li> </ul>

## 10.1.5.73 Control Register 72 (DDRMC\_CR72)

Address: 400A\_E000h base + 120h offset = 400A\_E120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### DDRMC\_CR73 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 APREBIT	Defines the Address Pin of the auto precharge bit in the DRAM address in decimal encoding. <p><b>For DDR3:</b> The JEDEC spec defines this as: "Auto-precharge: A10 is sampled during Read/Write commands to determine whether Autoprecharge should be performed to the accessed bank after the Read/Write operation."</p> <ul style="list-style-type: none"> <li>• Set this field to 0xA for proper operation.</li> </ul> <p><b>For LPDDR2:</b> The JEDEC spec defines the Auto Pre-Charge (AP) bit as CA0f (The falling clock edge of the CA0 bit).</p>

Table continues on the next page...

## DDRMC\_CR73 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>For this implementation, set to 0xA to set CA0f as the AP bit.</li> </ul> <p><b>NOTE:</b> This parameter will be cleared to 0x0 on reset, but will change to the default value on the first controller clock edge after reset.</p>
23–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 COL_DIFF	Defines the difference between the maximum column width available (11 as shown in MAX_COL_REG (DDRMC_CR01 bit [11:8])) and the actual number of column pins being used by the DRAM device. <ul style="list-style-type: none"> <li>The user address is automatically shifted so that the user address space is mapped contiguously into the memory map based on the value of this parameter.</li> <li>The user should set this value from their memory datasheet.</li> </ul>
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 ROW_DIFF	Defines the difference between the maximum number of address pins configured (16 as shown in MAX_ROW_REG (DDRMC_CR01 bit [5:0])) and the actual number of address pins being used by the DRAM device. <ul style="list-style-type: none"> <li>The user address is automatically shifted so that the user address space is mapped contiguously into the memory map based on the value of this parameter.</li> <li>The user should set this value from their memory datasheet.</li> </ul>
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
BANK_DIFF	Defines the difference between the maximum number of banks configured (3) and the actual number of banks being used. <ul style="list-style-type: none"> <li><b>00</b> - All bank bits are being used (8 banks)</li> <li><b>01</b> - Only 2 bank bits are being used (4 banks)</li> <li><b>10</b> - Only 1 bank bit is being used (2 banks)</li> <li><b>11</b> - Reserved</li> </ul>

## 10.1.5.75 Control Register 74 (DDRMC\_CR74)

Address: 400A\_E000h base + 128h offset = 400A\_E128h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							BANKSPLT_EN	0							ADDR_CMP_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMD_AGE_CNT								AGE_CNT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### DDRMC\_CR74 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 BANKSPLT_EN	Allows the memory controller to service lower priority access requests to memory, when a higher priority request requires a row change within a single bank. <ul style="list-style-type: none"> <li>• This feature may increase performance by allowing the memory controller to execute a READ/ WRITE command to another bank during the overhead time required to wait for multiple READ/ WRITE commands within the same bank.</li> <li>• Disable this feature when strict adherence to memory access priority assignments is desired.</li> </ul> <ul style="list-style-type: none"> <li>• <b>0</b> - Disable</li> <li>• <b>1</b> - Enable</li> </ul>
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ADDR_CMP_EN	Forces the memory controller to service READ/WRITE commands to the same memory address in the order received, regardless of priority. <ul style="list-style-type: none"> <li>• If this feature is disabled, a WRITE command to an address space may get executed before an earlier READ command if the WRITE command is received with a higher priority (or vice versa).</li> </ul> <ul style="list-style-type: none"> <li>• <b>0</b> - Disable</li> <li>• <b>1</b> - Enable</li> </ul>
15–8 CMD_AGE_CNT	The Command Age Counter holds the initial counter value assigned to each command in the command queue. <ul style="list-style-type: none"> <li>• As a command waits in the queue, the Command Age Counter will decrement down by one each time the Master Age Counter reaches 0 and resets.</li> <li>• When the Command Age Counter reaches 0, the priority level of the command is reduced by 1 (priority is increased).</li> <li>• Upon reaching 0, the Command Age Counter is then reset back to its initial counter value, and begins the cycle again.</li> <li>• When the command is serviced, the counter is removed.</li> </ul> <p>This parameter is only applicable when priority, PRI_EN (DDRMC_CR75 bit [8]), is enabled as a placement factor.</p>
AGE_CNT	The Master Aging-Rate Counter holds the initial counter value assigned to the command queue. <ul style="list-style-type: none"> <li>• As commands wait in the queue, the Master Aging-Rate Counter will decrement down by one for each clock cycle.</li> <li>• When the Master Aging-Rate Counter reaches 0, a signal is sent to each Command Age Counter in the Command queue to decrement by 1.</li> <li>• The Master Aging-Rate Counter is then reset back to its initial counter value, and begins the cycle again.</li> </ul> <p>The Master Aging-Rate Counter is continuously running.</p> <p>This parameter is only applicable when priority, PRI_EN (DDRMC_CR75 bit [8]), is enabled as a placement factor.</p>

### 10.1.5.76 Control Register 75 (DDRMC\_CR75)

Address: 400A\_E000h base + 12Ch offset = 400A\_E12Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							RW_ PG_ EN	0							RW_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0							PRI_EN	0							PLEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_CR75 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RW_PG_EN	Enables page grouping within a READ/WRITE group to reorder commands in the command queue. <ul style="list-style-type: none"> <li>Allows the command queue to reorder new commands in the command queue next to similar READ or WRITE commands that access the same memory page.</li> <li>This feature may only be used if RW_EN is enabled.</li> </ul> <ul style="list-style-type: none"> <li><b>0</b> - Disable</li> <li><b>1</b> - Enable</li> </ul>
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 RW_EN	Enables READ/WRITE grouping to reorder commands in the command queue. <ul style="list-style-type: none"> <li>Allows the command queue to reorder new commands in the command queue next to similar READ or WRITE commands.</li> <li>This may increase the efficiency of the Memory Controller by reducing overhead time required to execute different command types.</li> <li>This placement logic will be used only if it does not violate higher priority placement logic: <ul style="list-style-type: none"> <li>AXI Priority assignment</li> <li>Source ID</li> <li>Address Collision</li> </ul> </li> </ul> <ul style="list-style-type: none"> <li><b>0</b> - Disable</li> <li><b>1</b> - Enable</li> </ul>
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PRI_EN	Enables priority to be used to reorder commands in the command queue. <ul style="list-style-type: none"> <li>Priority is determined by the source (requesting module) of the memory command request and the command issued. <ul style="list-style-type: none"> <li>Values are set in registers <b>DDRMC_CR117</b> and <b>DDRMC_CR118</b>.</li> </ul> </li> </ul>

Table continues on the next page...

### DDRMC\_CR75 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>• <b>0</b> - Disable</li> <li>• <b>1</b> - Enable</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 PLEN	Enables using the placement logic to fill the command queue. <ul style="list-style-type: none"> <li>• <b>0</b> - Disable placement logic. The command queue is a straight FIFO.</li> <li>• <b>1</b> - Enable placement logic.               <ul style="list-style-type: none"> <li>• The command queue will be filled according to the placement logic as enable by the RW_PG_EN, RW_EN, and PRI_EN parameters.</li> </ul> </li> </ul>

### 10.1.5.77 Control Register 76 (DDRMC\_CR76)

Address: 400A\_E000h base + 130h offset = 400A\_E130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0					NQENT_ACTDIS			0					D_RW_G_BKCN		
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0							W2R_SPLT_EN	0							CS_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### DDRMC\_CR76 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 NQENT_ACTDIS	Specifies the number of entries of the command queue in which ACT requests are allowed. <ul style="list-style-type: none"> <li>• This feature allows a command in the queue to issue an ACT before it is executed.</li> <li>• The queue depth selection should be used to prevent situations in which an ACT is issued for a command in the queue, and before that command can be executed, a new command is placed ahead of it which accesses the same bank but a different row. This would require a PRE-ACT sequence that may have been avoided if the first ACT was never issued.</li> <li>• Deeper queue depth settings increase the probability that additional PRE-ACT sequences may occur.</li> <li>• For this 8-deep command queue, the entries are numbered 0-7, where entry 0 is the command next to execute.</li> </ul>

Table continues on the next page...

## DDRMC\_CR76 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>• <b>'b000</b> - ACT allowed from entries 0-7 (<i>full 8-deep queue</i>)</li> <li>• <b>'b001</b> - ACT allowed from entries 0-6</li> <li>• <b>'b010</b> - ACT allowed from entries 0-5</li> <li>• <b>'b011</b> - ACT allowed from entries 0-4</li> <li>• <b>'b100</b> - ACT allowed from entries 0-3</li> <li>• <b>'b101</b> - ACT allowed from entries 0-2</li> <li>• <b>'b110</b> - ACT allowed from entries 0-1</li> <li>• <b>'b111</b> - ACT allowed from entry 0 (<i>next command to execute</i>)</li> </ul> <ul style="list-style-type: none"> <li>• This feature is normally set to 'b011 for general operation.</li> </ul>
23–18 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
17–16 D_RW_G_BKCN	<p>Enables reordering of command placement within the command queue based on READ or WRITE groups within the same bank.</p> <ul style="list-style-type: none"> <li>• <b>'b00</b> - No new command placement restrictions for bank conflicts.</li> <li>• <b>'b01</b> - Prohibits placement of a new command immediately before or immediately after the command with a bank conflict in the command queue.</li> <li>• <b>'b10</b> - Reserved</li> <li>• <b>'b11</b> - Prohibits placement of a new command within two queue positions before or two queue positions after a command with a bank conflict in the command queue.</li> </ul> <ul style="list-style-type: none"> <li>• "Bank conflict" is defined as commands that affect the same memory bank but different rows, which then requires additional overhead time.</li> <li>• PLEN (DDRMC_CR75 Bit [0]) must be enabled to allow bank conflict command reordering.</li> </ul>
15–9 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
8 W2R_SPLT_EN	<p>Enables write-to-read turnaround time optimization when reordering commands in the command queue. The placement logic will attempt to insert the new command into the command queue to separate two commands of different types where the write is going to execute before the read.</p> <ul style="list-style-type: none"> <li>• <b>0</b> - Disable</li> <li>• <b>1</b> - Enabled</li> </ul>
7–1 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
0 CS_EN	<p>Enables rank grouping within a READ or WRITE group as a condition when reordering commands within the command queue.</p> <ul style="list-style-type: none"> <li>• Ranking is based on chips select numbers. CS0 = Rank0 and CS1 = Rank1</li> </ul> <ul style="list-style-type: none"> <li>• <b>0</b> - Disable (This device only supports one chip select)</li> <li>• <b>1</b> - Reserved</li> </ul>

### 10.1.5.78 Control Register 77 (DDRMC\_CR77)

Address: 400A\_E000h base + 134h offset = 400A\_E134h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0						CS_MAP		0						IN_DRAM_CMD

#### DDRMC\_CR77 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 CS_MAP	This parameter defines which Chip Selects are active. <ul style="list-style-type: none"> <li>This device only implements CS0</li> <li>'b00 - Reserved, disabling CS0 will prevent proper memory operations.</li> <li>'b01 - CS0 is the active memory chip select.</li> <li>'b1x - Reserved, CS1 is not implemented.</li> </ul> This parameter should always be set to 'b01.
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 IN_DRAM_CMD	Inhibits certain types of commands from being executed from the command queue. <ul style="list-style-type: none"> <li>Even when this parameter is programmed to a non-zero value, commands may still be accepted into the Controller and the Controller core command queue, but they will not be executed.</li> </ul> <p><b>For DDR3:</b></p> <ul style="list-style-type: none"> <li>This field is not supported.</li> <li>Set to 'b00.</li> </ul> <p><b>For LPDDR2:</b></p> <ul style="list-style-type: none"> <li>'b00 - Enable any command in the command queue to execute.</li> <li>'b01 - Inhibit read/write traffic and associated bank commands in the command queue from being executed.</li> </ul>

Table continues on the next page...

## DDRMC\_CR77 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>• <b>'b10</b> - Inhibit MRR and peripheral MRR commands in the command queue from being executed.</li> <li>• <b>'b11</b> - Inhibit MRR commands and read/write commands in the command queue from being executed.</li> </ul>
15–9 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
8 DI_RD_ INTLEAVE	<p>Disables READ command reordering in the command queue from the same port with different Source ID.</p> <ul style="list-style-type: none"> <li>• Read data may still be returned out of order regardless of the value of this parameter.</li> <li>• Two read commands from different AXI Source IDs on a port may be automatically reordered in the Memory Controller core to execute out-of-order.</li> </ul> <ul style="list-style-type: none"> <li>• <b>0</b> - Allow READ command (from the same port) reordering in the command queue</li> <li>• <b>1</b> - Disable READ command reordering of READ commands from the same port</li> </ul> <p>This feature is normally set to 'b1.</p>
7–1 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
0 SWAP_EN	<p>Enables command execution interruption and swapping for a higher priority command.</p> <ul style="list-style-type: none"> <li>• If the selected command queue entry is of a higher priority (not the same priority), from a different ID, and it does not have an address or Source ID conflict with the current command being executed, then the original command will be interrupted.</li> <li>• If the command is to be interrupted, it will be halted after completing the current burst, stored and placed at the top of the command queue, and the new command will begin executing.</li> <li>• As long as the command queue is not full, new commands may continue to be inserted into the command queue based on the placement rules, even at the top of the queue ahead of the interrupted command.</li> <li>• The selection logic will determine the command to execute next.</li> <li>• Whenever the interrupted command is resumed, it will start from the point at which it was interrupted.</li> <li>• INODR_ACT (DDRMC_CR79) will determine if one command or 4 commands are evaluated for priority levels.</li> <li>• Priority 0 commands will never be interrupted, so the user should set any commands that should not be interrupted to priority 0.</li> </ul> <ul style="list-style-type: none"> <li>• <b>0</b> - Disable swapping</li> <li>• <b>1</b> - Enable swapping</li> </ul> <p>This feature is normally set to 'b1.</p>

### 10.1.5.79 Control Register 78 (DDRMC\_CR78)

Address: 400A\_E000h base + 138h offset = 400A\_E138h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0					Q_FULLNESS			0							LPDDR2_S4
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0							REDUC	0				BUR_ON_FLY_BIT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DDRMC\_CR78 field descriptions**

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 Q_FULLNESS	Defines the number of commands waiting in the command queue that will be used to determine if the command queue is full. <ul style="list-style-type: none"> <li>If this counter value is reached, a <i>Queue Almost Full</i> signal is sent to the Memory Controller Arbiter and the Arbiter will not attempt to place anymore commands into the command queue.</li> <li>The Arbiter will resume command placement when the number of commands in the command queue falls below this value.</li> </ul> <p>This parameter value is normally set to 'b111, to allow maximum command queue depth.</p>
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 LPDDR2_S4	Indicates the type of LPDDR2 memory being used. <p><b>For DDR3:</b></p> <ul style="list-style-type: none"> <li>This feature is not supported.</li> <li>Maintain the reset value for this field, - 'b0.</li> </ul> <p><b>For LPDDR2:</b></p> <p>The user must set this bit for LPDDR2-S4 memory.</p> <ul style="list-style-type: none"> <li><b>0</b> - LPDDR2-S2 memory device</li> <li><b>1</b> - LPDDR2-S4 memory device</li> </ul>
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 REDUC	Reduces the size of the DDR Data Bus.

*Table continues on the next page...*

**DDRMC\_CR78 field descriptions (continued)**

Field	Description
	<ul style="list-style-type: none"> <li>This parameter should not be changed after the START (DDRMC_CR00 bit [0]) parameter has been set to 'b1.</li> <li>0 - 16-bit data bus (default)</li> <li>1 - 8-bit data bus</li> </ul>
7–4 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
BUR_ON_FLY_ BIT	<p>Defines the specific bit of the DRAM address that enables Burst-On-Fly behavior.</p> <p><b>For DDR3:</b></p> <ul style="list-style-type: none"> <li>This field is not supported.</li> <li>Set to 'b1100 for accurate system operations.</li> <li>All other settings are reserved.</li> </ul> <p><b>For LPDDR2:</b></p> <ul style="list-style-type: none"> <li>This field is not supported.</li> <li>Set to 0x0 (Reset default)</li> </ul>

### 10.1.5.80 Control Register 79 (DDRMC\_CR79)

**DDRMC\_CR79 field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CTLUPD_AREF	When enabled, the Memory Controller will send a signal to the PHY to update the DLLs and reset the FIFOs after a refresh operation. <ul style="list-style-type: none"> <li>• <b>0</b> - Disable</li> <li>• <b>1</b> - Enable Automatic Update signal to PHY</li> </ul>
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## DDRMC\_CR79 field descriptions (continued)

Field	Description
16 CTLUPD_REQ	Manually triggers a controller-initiated PHY update request. This field will force the PHY to update the DLL delay values, and reset the FIFOs. This field can be used by SW to immediately change the DLL delays rather than to wait for the next Self-Refresh period. <ul style="list-style-type: none"> <li>This parameter is write-only and will always read back as 0x0.</li> <li>For Proper operation, the user must issue at least one read or write command to memory after reset prior to setting this parameter.</li> <li>The PHY will execute this command, but will not respond back to the MC with any acknowledgments.</li> <li><b>0</b> - No action</li> <li><b>1</b> - Force PHY to update all DLLs.</li> </ul>
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 CTLBUSY	Status indicator that the controller is actively processing a command from any port. <ul style="list-style-type: none"> <li>This information is also passed to the AXI bus via a HW connection internal to the processor.</li> <li>This parameter is read-only.</li> <li><b>0</b> = Memory Controller is not busy.</li> <li><b>1</b> = Memory Controller is busy.</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 INODR_ACT	Forces the Memory Controller to processes commands in the order in which they are placed in the command queue. <ul style="list-style-type: none"> <li>Once a command has been placed in the command queue, Internal Memory Controller Selection Logic will be used to determine how to pull commands from the queue for execution.</li> <li>The selection logic may be disabled by setting this bit to 'b1. <ul style="list-style-type: none"> <li>Commands will then be executed in the order that they are placed in the command queue without modification.</li> </ul> </li> <li>If this parameter is cleared to 'b0, the selection logic will be utilized. <ul style="list-style-type: none"> <li>Internal Memory Controller Selection Logic will scan the top 4 entries of the command queue to determine which command to execute.</li> <li>Commands are considered for execution based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing and conflicts.</li> </ul> </li> <li><b>0</b> - Enable use of internal Memory Controller Selection Logic.</li> <li><b>1</b> - Disable use of internal Memory Controller Selection Logic.</li> </ul> <p>This field should be set to 'b0 for normal operations.</p>

## 10.1.5.81 Control Register 80 (DDRMC\_CR80)

Address: 400A\_E000h base + 140h offset = 400A\_E140h

W2W_SMCSL	<p>Additional delay to insert between two writes to the same chip select. Any value including 0x0 supported.</p> <p>Defines the number of additional controller clocks of delay to insert between two write commands to the same chip select. This parameter may be programmed to any value including 0x0.</p>

10.1.5.94 Control Register 93 (DDRMC\_CR93)

Address: 400A\_E000h base + 174h offset = 400A\_E174h

DDRMC\_CR93 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 SWLVL_START	User request to initiate software leveling selected in the SW_LVL_MODE bits. Set to 1 to trigger.  Initiates the software leveling operation defined in the SW_LVL_MODE bits. This parameter is write-only and will always read back as 0x0. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 'b0110)  0 No Action 1 Initiate software leveling operation
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SWLVL_LOAD	User request to load delays and execute software leveling. Set to to trigger.

Table continues on the next page...

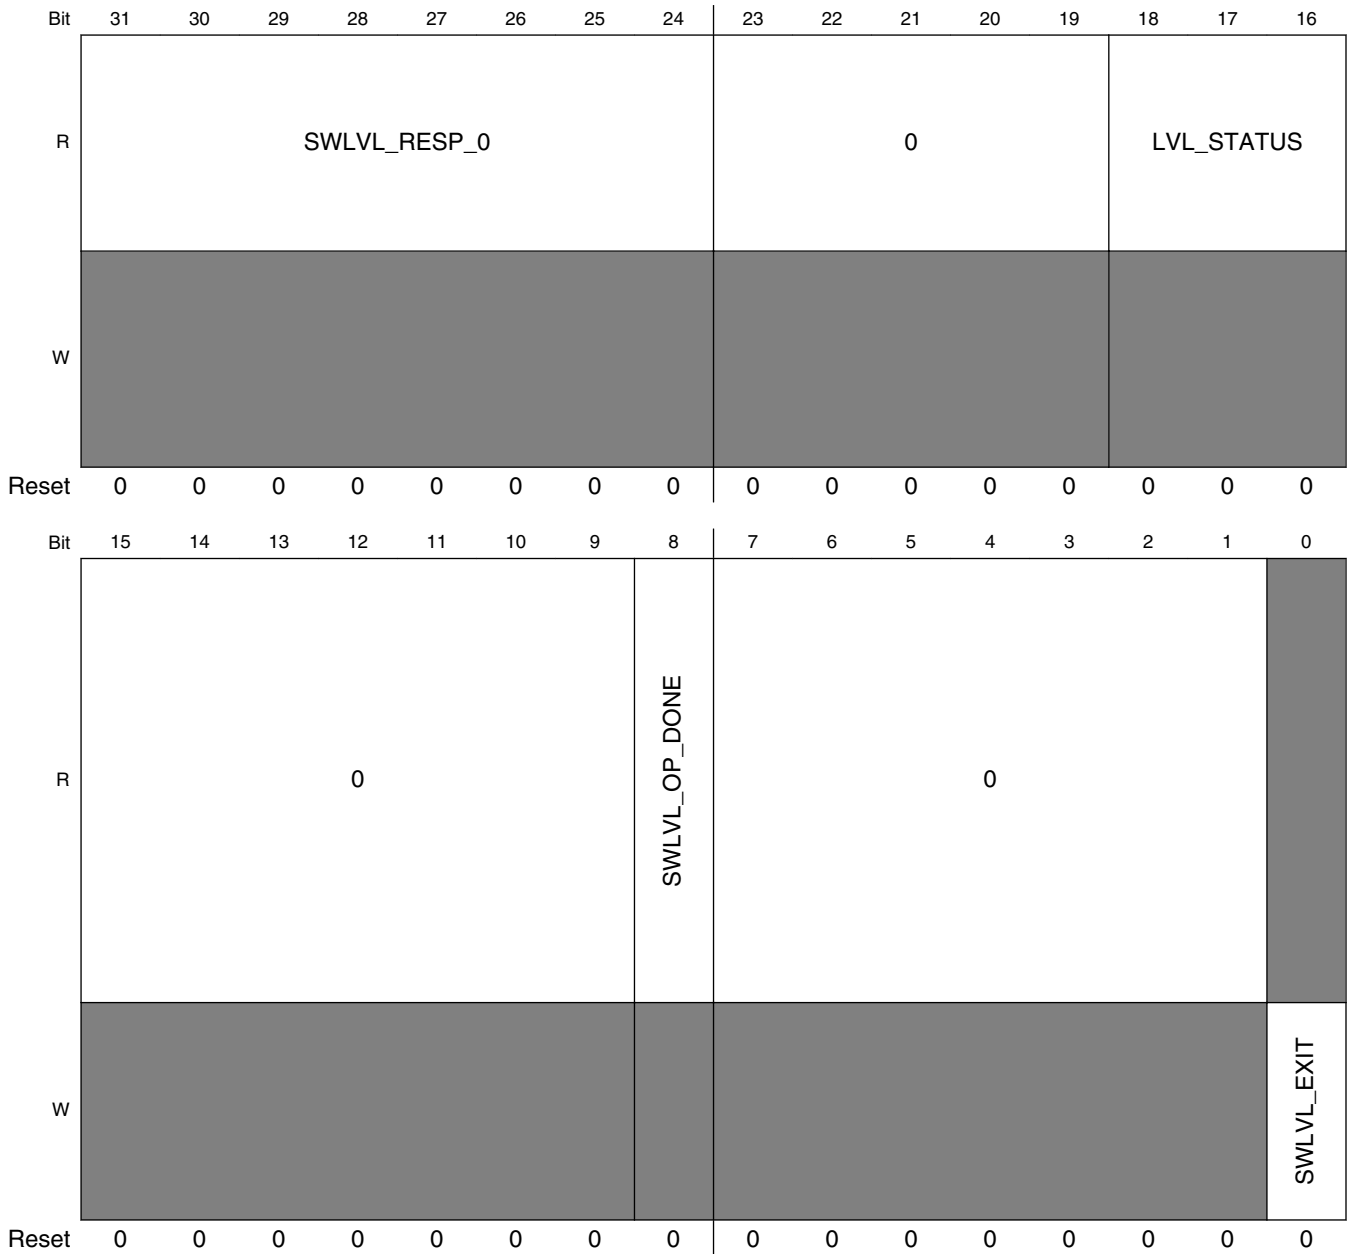

**DDRMC\_CR93 field descriptions (continued)**

Field	Description
	Triggers the delays set in the appropriate registers to be loaded into the PHY delay lines and then initiates a read burst or write strobe for software leveling. This parameter is write-only and will always read back as 0x0. This parameter is only applicable when the MC is programmed for the following memory systems:DDR3 (dram_class = 0110)  0 No action 1 Load delays and start software leveling
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 SW_LVL_MODE	Defines the type of software leveling operation to be performed when a software leveling operation is triggered.  This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)  00 No Leveling 01 Write Leveling (aligns the arrival of the DQS strobe edge with the CLK edge) 10 Read Leveling (centers the input DQS Strobe edge to the middle of the window of valid data bits) 11 Gate Training (Gates the incoming READ DQS strobe until one-half clock cycle before arrival of first valid strobe edge.)
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.1.5.95 Control Register 94 (DDRMC\_CR94)

Address: 400A\_E000h base + 178h offset = 400A\_E178h

DDRMC\_CR94 field descriptions

Field	Description
31–24 SWLVL_RESP_0	Response for the software leveling process for data slice 0 (Byte0). <ul style="list-style-type: none"><li>This parameter is read-only.</li></ul> <b>For DDR3:</b>

## DDRMC\_CR124 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>A parameter value of 'b1 indicates that the Memory Controller is able to regain control of the memory RESET and CKE signals and that the Memory Controller RESET signal to the PHY is valid and stable.</li> <li>The Command Channel and Output Drivers of the PHY are assumed enabled when the combined number of Memory Controller clock cycles specified in PHY_INI_COM (<b>DDRMCR39</b>) and PHYCTL_DL (<b>DDRMCR137</b>) have elapsed after this field goes high. (i.e., the PHY is ready to accept commands).</li> <li>This field is normally used only when the Memory Controller is powering up and the PWUP_SREF_EX (<b>DDRMCR33 bit[0]</b>) parameter is set to 'b1.</li> </ul> <p><b>For LPDDR2:</b></p> <ul style="list-style-type: none"> <li>This field has no meaning.</li> </ul>
23–17 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
16 CKE_STAT	<p>Indicates the output status of the CKE pin as it is being driven by the PHY. This field can be used to indicate if a DDR memory device is in either their self-refresh or power down modes.</p> <ul style="list-style-type: none"> <li>This signal is being reported by the PHY to the Memory Controller, delayed by the number of Memory Controller clocks specified in the CKE_DELAY (<b>DDRMCR33</b>) parameter.</li> <li>This parameter is read-only.</li> <li><b>0</b> - The memory device(s) are in power-down or self-refresh.</li> <li><b>1</b> - The memory device(s) are active.</li> </ul>
15–10 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
AXI1_PRI1RLX	<p>Holds the counter value for AXI port 1 at which the priority relax condition is triggered in weighted round robin arbitration. The counter increments down with every Memory Controller clock. When the counter reaches zero, if there are any commands waiting on AXI port 1, regardless of any other assigned priority, the first command will immediately get placed. If no commands are waiting, nothing happens. When the counter reaches zero, it immediately resets and begins counting again.</p> <ul style="list-style-type: none"> <li>The counter value is in Memory Controller clock cycles.</li> <li>When this field is cleared to 'b00_0000_0000, priority relaxing for AXI port 1 is turned off.</li> <li>For normal operations, set this field to 'b00_0110_0100.</li> </ul>

## 10.1.5.126 Control Register 125 (DDRMCR125)

#### DDRMC\_CR154 field descriptions

Field	Description
31–27 PAD_ZQ_EARLY_CMP_EN_TIMER	<p>This timer defines the time between the enabling of the comparator in the ZQ calibration pad and the beginning of the calibration process with the pad.</p> <p>0x0 - 0x6 - Reserved</p> <p>0x7 - 8 cycles</p> <p>..</p> <p>0x0D - 14 cycles (recommended setting)</p> <p>..</p> <p>0x1E - 31 cycles</p> <p>0x1F - 32 cycles</p>
26–23 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
22–21 PAD_ZQ_MODE	<p>PAD calibration modes</p> <p>0x0 No pad calibration issued (Default)</p> <p>0x1 Pad calibration issued whenever memory controller issues a external memory short or Long (ZQCL or ZQCS) commands, including during memory initialization and after self refresh exit (provided controller has been configured for this).</p> <p>0x2 pad calibration issued whenever memory controller drives only long calibration command to the external memory (ZQCL), including during memory initialization.</p> <p>0x3 reserved</p>
20 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

Table continues on the next page...

## DDRMC\_CR154 field descriptions (continued)

Field	Description
19–18 DDR_SEL_PAD_ Contr	DDR Mode select for all PHY pads (except ZQ-pad): <ul style="list-style-type: none"> <li>• DDR_SEL = 11 (DDR3 mode).</li> <li>• DDR_SEL = 10 (LPDDR2 mode).</li> <li>• All other settings are Reserved.</li> </ul>
17–16 DDR_SEL_ZQ_ PAD_Contr	DDR mode select for ZQ-pad: <ul style="list-style-type: none"> <li>• DDR_SEL = 00 (DDR3 mode)</li> <li>• DDR_SEL = 00 (LPDDR2 mode)</li> <li>• All other settings are Reserved.</li> </ul>
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 PAD_ZQ_HW_ FOR	Writing a 1 to this bit forces the processor ZQ pad to perform one long ZQ calibration cycle. It is the user responsibility to ensure that this bit is asserted at the correct time and when there is no traffic on the DDR interface. The HW PAD calibration status bit in DDR_CR 156[PAD_ZQ_HW_IN_PROG] is set during the duration of the Pad calibration seq. When the H/W calibration is done, DDR_CR 156[AD_ZQ_HW_IN_PROG] will be cleared by the logic and the pad calibration values in DDR_CR 156[PAD_ZQ_HW_PU_RES] and PAD_ZQ_HW_PD_RES are valid.  <b>NOTE:</b> It is not required to explicitly clear this bit before the next write. Writing a 0 in this bit has no effect on the PAD calibration logic. Even if this bit is left uncleared after last write, user needs to write a 1 again to this bit to force H/W pad calibration.
13–12 PAD_ZQ_CMP_ OUT_SMP	Defines the amount of cycles between driving the calibration signals to the ZQ calibration pad and sampling the comparator output for result.  00 7 cycles (Default) 01 15 cycles 10 23 cycles 11 31 cycles
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 10.1.5.156 Control Register 155 (DDRMC\_CR155)

Address: 400A\_E000h base + 26Ch offset = 400A\_E26Ch

W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**DDRMC\_CR155 field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 PAD_IBE1	Input buffer enable state for DDR pads corresponding to byte lane 1 (DQ[15:8], DQS[1] and DM[1]). This value takes effect only when PAD_IBE_SEL1 (bit 17) is high, otherwise the buffer enable signal is controlled by the logic.
18 PAD_IBE0	Input buffer enable state for DDR pads corresponding to byte lane 0 (DQ[7:0], DQS[0] and DM[0]). This value takes effect only when PAD_IBE_SELO (bit 16) is high, otherwise the buffer enable signal is controlled by the logic.
17 PAD_IBE_SEL1	DDR pad input buffer select override from software for signals corresponding to Byte lane1(DQ[15:8], DQS[1] and DM[1]). If this bit is set then DDR pad IBE is controlled by the state of PAD_IBE1 bit otherwise it is controlled by logic.
16 PAD_IBE_SELO	DDR pad input buffer select override from software for signals corresponding to Byte lane0(DQ[7:0], DQS[0] and DM[0]). If this bit is set then DDR pad IBE is controlled by the state of PAD_IBE0 bit otherwise it is controlled by logic.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 AXI1_AWCACHE	When this bit is set, it forces the AXI port 1 AWCACHE[0] signal for the DDR controller to be set. If this bit is 0, AXI bus AWCACHE signal works as usual.
10 AXI0_AWCACHE	When this bit is set, it forces the AXI port 0 AWCACHE[0] signal for the DDR controller to be set. If this bit is 0, AXI bus AWCACHE signal works as usual.
9 AXI1_COBUF	Control for AXI1_COBUF signal.

*Table continues on the next page...*

**DDRMC\_CR155 field descriptions (continued)**

Field	Description
	<p>AXI port 1 coherent bufferable selection. If the AXI1_AWCACHE bit is set to 'b1 for Bufferable operation, this signal determines exactly what type of bufferable response is returned to the user interface. For guaranteed data coherency across all ports, the user should send all commands with AXI1 Coherent Bufferable signal set to 'b1.</p> <p>0 Response returned when command and data have been received by the port.</p> <p>1 Response returned when command accepted into the memory controller core command queue and all associated data has been received by the AXI data port.</p>
8 AXI0_COBUF	<p>Control for AXI0_COBUF signal.</p> <p>AXI port 0 coherent bufferable selection. If the AXI0_AWCACHE bit is set to 'b1 for Bufferable operation, this signal determines exactly what type of bufferable response is returned to the user interface. For guaranteed data coherency across all ports, the user should send all commands with AXI0 Coherent Bufferable signal set to 'b1.</p> <p>0 Response returned when command and data have been received by the port.</p> <p>1 Response returned when command accepted into the memory controller command queue and all associated data has been received by the AXI data port.</p>
7–6 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

**DDRMC\_CR161 field descriptions**

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ODT_EN	Enables the use of the DRAM ODT pin.  This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 'b0110')  0 The DRAM ODT pin will not be used. 1 The Controller will assert and deassert the ODT output to DRAM as needed
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 TODTH_RD	Defines the DRAM timing for the minimum ODT high time after an ODT assertion for read data. When these bits are programmed to a value larger than the number of cycles required for a burst, the command-to-command delays must be adjusted to delay commands as needed. <b>For DDR3 memories:</b> <ul style="list-style-type: none"> <li>This timing is only in effect if ODT_RD_MAPCS0 (DDRMC_CR87 bit [16]) = 1.</li> <li>Program to the tODTH8 value from the memory specification. Use the value specified for a WRITE Command if no separate value for a READ Command is specified.</li> </ul> <b>For LPDDR2 memories:</b> <ul style="list-style-type: none"> <li>This parameter has no meaning for this memory type.</li> <li>Set field to 0x0.</li> </ul>
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TODTH_WR	Defines the DRAM timing for the minimum ODT high time after an ODT assertion for write data. When these bits are programmed to a value larger than the number of cycles required for a burst, the command-to-command delays must be adjusted to delay commands as needed. <b>For DDR3 memories:</b> <ul style="list-style-type: none"> <li>This timing is only in effect if ODT_WR_MAPCS0 (DDRMC_CR87 bit [24]) = 1.</li> <li>Program to the tODTH8 value from the memory specification.</li> </ul>

## DDRMC\_PHY02 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 EN_HALF_CAS	<p>Adds 1/2 cycle to the DQS gate value programmed into PHY_GATE_CFG. Default 0x0. This is used when the gate is being aligned to the first DQS, and then is removed to move the gate back into the center of the preamble.</p> <ul style="list-style-type: none"> <li>This field is used for Gate Training only. Set field for b'0' for normal operations.</li> <li>Total delay in clock cycles used for Gate training will be: <math>GATE\_CFG + 0.5 \times EN\_HALF\_CAS + RDLVL\_GTDL\_0/128</math></li> </ul> <p>0 No adjustment to DQS Gate Delay value. 1 Adjust the DQS gate by 1/2 clock</p>
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SW_HALF_CYCLE_SHIFT	<p>Write level half-clock cycle shift.</p> <p>When set to 'b1, this field will add a one-half clock period delay to the DQS0 strobe.</p> <ul style="list-style-type: none"> <li>This field is used for Write Level Training only. Set field for b'0' for normal operations.</li> <li>Total delay in clock cycles used for Write Level will be: <math>WRLVL\_CLKDL + 0.5 \times SW\_HALF\_CYCLE\_SHIFT + WLLVL\_DL\_0/128</math></li> </ul> <p>0 No adjustment to WRLVL_DL value. 1 Adds a half clock delay to the write level delay line.</p>
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 WRLVL_CLKDL	<p>Write level full-clock cycle shift.</p> <p>When set to 'b1, this field will add a full clock period delay to the DQS0 strobe.</p> <ul style="list-style-type: none"> <li>This field is used for Write Level Training only. Set field for b'0' for normal operations.</li> <li>Total delay in clock cycles used for Write Level will be: <math>WRLVL\_CLKDL + 0.5 \times SW\_HALF\_CYCLE\_SHIFT + WLLVL\_DL\_0/128</math></li> </ul> <p>0 No adjustment to WRLVL_DL value 1 Adds a full clock delay to the write level delay line.</p>
24–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–19 RD_DL_SET	<p>Read Delay Select setting. Used to synchronize Read Data across two different time domains. Provides a delay in N clock cycles between the time the Memory Controller signals the PHY to send Read Data (dfi_rddata_en) and when the PHY signals the Memory Controller that Read Data is valid (dfi_rddata_valid) and can be clocked into the Read FIFOs of the Memory Controller. See 34.6.15.7 Synchronize Read Data From delayed_dqs to PHY_CLK domain for additional details.</p> <ul style="list-style-type: none"> <li>Settings in this field are in clock cycles.</li> <li>Use a setting of 0x4 for normal operations.</li> </ul>
18–16 WR_DB_ADJ	<p>Write Leveling Delay Dead Band Adjustment</p> <p>The delay applied to the entire Data Slice to align the slice with the SDCLK is calculated and applied outside of the DLL block. The required delay is calculated using the Lock Value supplied by the Master DLL (DDRMC_PHY11[15:8]), and the WRLVL_DL_0 value (DDRMC_CR98[15:0]). Since this value is constantly being recalculated, a dead band is used to prevent the delay block from oscillating between two very close values. The value specified in this field is the required minimum difference between the new</p>

Table continues on the next page...

## DDRMC\_PHY02 field descriptions (continued)

Field	Description
	<p>calculated value delay value and the number of delay elements currently in use. The physical number of delay elements used will only be updated when the difference in required delay elements meet the minimum number specified in this field.</p> <ul style="list-style-type: none"> <li>Set to 0x1 for normal operations.</li> <li>For designs specifying a large number in the WRLVL_DL_0 field, the user may consider increasing the value in this field.</li> <li>Most designs should not have to change this field.</li> </ul> <p>'b000 One delay element (Default)  'b001 Two delay elements  'b010 Three delay elements  'b011 Four delay elements  'b100 Five delay elements  'b101 Six delay elements  'b110 Seven delay elements  'b111 Eight delay elements</p>
15–5 Reserved	<p>This field is reserved.  This read-only field is reserved and always has the value 0.</p>
4–3 GATE_CLOSE_CFG	<p>DQS GATE Open period adjustment.  <b>For DDR3:</b>  Adds full clock cycles to the "un-gated" period of the DQS0 pad input.</p> <ul style="list-style-type: none"> <li>Recommended Setting: 0x0</li> <li>This parameter may be optimized with a DDR Stress Test SW Program</li> <li>Normal Gate open period is BL/2 +1 clock cycles.</li> </ul> <p><b>For LPDDR2:</b>  Adds full clock cycles to the maximum "un-gated" period of the DQS0 pad input.</p> <ul style="list-style-type: none"> <li>Recommended Setting: 0x3</li> <li>This parameter may be optimized with a DDR Stress Test SW Program</li> <li>Gate signal is closed when the required number of DQS0 strobe edges have been received.</li> </ul>
GATE_CFG	<p>Coarse adjust of gate open time.  DQS GATE level full-clock cycle adjustment.  Adds full clock cycle delays to the calculated gate timing for DQS0 pad input.</p> <ul style="list-style-type: none"> <li>Total delay in clock cycles used for DQS GATE level will be: <math>GATE\_CFG - 0.5 \times EN\_HALF\_CAS + RDLVL\_GTDL\_0/128</math></li> <li>Recommended Setting: 0x0</li> <li>This parameter may be optimized with a DDR Stress Test SW Program</li> </ul>

### 10.1.5.166 PHY Register 03 (DDRMC\_PHY03)

PHY DLL Master Control Register for data slice 0.

Address: 400A\_E000h base + 40Ch offset = 400A\_E40Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### DDRMC\_PHY03 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PARAM_HALF_CLOCK_MODE	Determines if the master delay line locks on a full clock cycle or a half clock cycle.  Within the Master DLL there are only 128 delay elements that can be used to determine a lock. For frequencies of operation below 300 MHz, it is necessary to limit the lock period to only a half clock cycle so that the master delay line does not become saturated. <ul style="list-style-type: none"> <li>For frequencies above 300 MHz, set this bit to 'b0.</li> <li>For frequencies below 300 MHz, set this bit to 'b1.</li> </ul> <b>For both LPDDR2 and DDR3:</b> <ul style="list-style-type: none"> <li>'b0 - Master DLL locks on full clock cycle delay</li> <li>'b1 - Master DLL locks on half clock cycle delay</li> </ul>
23 PARAM_DLL_BYPASS_MODE	Places the Master DLL in bypass mode.  In bypass mode, the Master DLL will not attempt to achieve a lock. The Master DLL will report zero delay elements used in a clock cycle. <ul style="list-style-type: none"> <li>The PHY will ignore the calibration settings for RDLVL_GTDL_0 and WRLVL_DL_0, and set delay settings for these parameters to 0 time delay.</li> </ul>

Table continues on the next page...

## DDRMC\_PHY03 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>The PHY will ignore the calibration setting for RDLVL_DL_0, but instead will use the number of delay elements specified in field PHY_04[DLL_READ_DL]</li> <li>The PHY will set the write DQS strobe delay to the number of delay elements specified in PHY_04[DLL_WRITE_DL] instead of treating this value as a 1/128 fraction of a clock cycle.</li> </ul> <p><b>For both LPDDR2 and DDR3:</b></p> <ul style="list-style-type: none"> <li>'b0 - Master DLL operates normal.</li> <li>'b1 - Master DLL is placed in bypass mode.</li> </ul>
22–20 DLL_PHASE_ DET	<p>DLL Phase Detect Selector for DQS0 Output Enable Generation</p> <p>Used to compensate for clock domain differences between the DLL for the SDCLK signal and the DLL for the DQS Strobe.</p> <ul style="list-style-type: none"> <li>Selects the number of delay elements to be inserted between the phase detect flip-flops. Default value is 0b000 (is 1 delay element).</li> <li>For designs having trouble in getting a DLL lock, consider increasing the value of this field.</li> <li>Set according to the jitter of the clock source. Increasing the number of delay elements increases the window in which a lock can be obtained/maintained. A larger window also means that more jitter will propagate to the output. This jitter will reduce the margins for read and write timing. Therefore, this should be used with caution. 0b010 is considered a good starting value for most of design.</li> </ul> <p>'b000 One delay element (Default)  'b001 Two delay elements  'b010 Three delay elements  'b011 Four delay elements  'b100 Five delay elements  'b101 Six delay elements  'b110 Seven delay elements  'b111 Eight delay elements</p>
19–16 DLL_LOCK_ NUM	<p>Specifies the number of lock indications which are required in the last 8 cycles for the lock detection circuit to indicate an overall lock.</p> <p>'b000 One lock detect (Default)  'b001 Two lock detects  'b010 Three lock detects  'b011 Four lock detects  'b100 Five lock detects  'b101 Six lock detects  'b110 Seven lock detects  'b111 Eight lock detects  - All other bit settings are reserved.</p>
15–8 DLL_INCREM	<p>Specifies the increments of delay elements used by the DLL in searching for a DLL lock. A smaller value allows for a more gradual search, but increases the time required for a DLL lock.</p> <ul style="list-style-type: none"> <li>Set this field to 0x01 for normal operations.</li> </ul>
DLL_START_ POINT	<p>Specifies the number of delay elements used at the start of the DLL sequence to search for a lock.</p> <ul style="list-style-type: none"> <li>Set this field to a value greater than or equal to 0x04 and less than lock number in whole PVT range</li> </ul>

### 10.1.5.167 PHY Register 04 (DDRMC\_PHY04)

PHY DLL Slave Control Register for data slice 0.

Address: 400A\_E000h base + 410h offset = 400A\_E410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY04 field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 DLL_WRITE_DL	DLL Write delay  This is delay setting for the dll line that controls the phase relationship between DQS0 and write data D[7:0].  <b>NOTE:</b> Value programmed in this field delays the strobe by (period of strobe/128)x the programmed value. For e.g, if the value programmed is 0x20h, the the strobe is delayed by period of strobe/4.  <b>NOTE:</b> This field is not to be confused with WRLVL_DL_0 (DDRMC_CR98 bits [15:0]). DLL_WRITE_DL adjusts the DQS strobe into the center of the valid data window. WRLVL_DL_0 adjusts the DQS strobe with respect to the SDCLK signal.  <b>NOTE:</b> If the Master DLL is placed in bypass mode (PHY_03[PARAM_DLL_BYPASS_MODE]), then the value specified in this field will be the number of 30 picosecond delay element used in the delay of the Write DQS0 strobe.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DLL_READ_DL	Bypass mode DLL Read delay  Specifies the number of 30 picosecond delay elements used to delay the Read DQS0 strobe.  <b>NOTE:</b> This field is used only if the Master DLL is placed in bypass mode (PHY_03[PARAM_DLL_BYPASS_MODE]).

10.1.5.168    PHY Register 10 (DDRMC\_PHY10)

PHY Loopback Status Register. Reports status for the PHY for data slice 0

Address: 400A\_E000h base + 428h offset = 400A\_E428h

### DDRMC\_PHY10 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DQS_ERROR_STATUS	Status signal to indicate that the DQS READ Gate had to be forced closed in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> <li>'b0 = Normal operation</li> <li>'b1 = Reserved</li> </ul>
23–8 LPBK_DQ_DATA	Reports data bit values in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> </ul>
7–4 LPBK_DM_DATA	Reports data mask values in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> </ul>
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 LPBK_STATUS	Reports status of loop back errors. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> </ul>
0 LPBK_START	Reports status of loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> <li>'b0 = Normal operation</li> <li>'b1 = Reserved</li> </ul>

10.1.5.169 PHY Register 11 (DDRMC\_PHY11)

PHY DLL Status Register 0 for data slice 0.

Address: 400A\_E000h base + 42Ch offset = 400A\_E42Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC\_PHY11 field descriptions

Field	Description
31–24 DLL_UNLOCK_VALUE	Reports the dll_lock_value if the DLL has become unlocked after being locked. This field will be cleared to 0x0 following a system reset. A value of 0x0 indicates that once the dll achieved lock, it has always remained locked.  This field is read only.
23–16 LOCK	Holds the last 8 samples of the lock indicator  This field is read only.
15–8 DLL_LOCK_VALUE	Reports the DLL encoder value from the master DLL to the slave DLL's. <ul style="list-style-type: none"><li>This field is read only.</li></ul>

Table continues on the next page...

**DDRMC\_PHY11 field descriptions (continued)**

Field	Description
	<ul style="list-style-type: none"> <li>The contents of this register is only valid if DLL_LOCK = 1.</li> <li>If the DLL loses lock, the value of this register will transfer to the DLL_UNLOCK_VALUE register</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DLL_LOCK	Indicates status of the DLL This field is read only. 0 DLL has not locked 1 DLL is locked

**10.1.5.170 PHY Register 12 (DDRMC\_PHY12)**

PHY DLL Status Register 1 for data slice 0.

Address: 400A\_E000h base + 430h offset = 400A\_E430h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DDRMC\_PHY12 field descriptions**

Field	Description
31–24 Reserved	This field is reserved.
23–16 DEC_OUT_WR	Holds the encoded value for the clock write delay line for this slice. After the DQS0 DLL has locked, this field reports the number of delay elements used by the DLL to achieve the delay programmed in DLL_WRITE_DL (DDRMC_PHY04 bits [14:8]). This field is read only.
15–8 Reserved	This field is reserved.
DEC_OUT_RD	Holds the encoded value for the read delay line for this slice. After the DQS0 DLL has locked, this field reports the number of delay elements used by the DLL to achieve the delay programmed in RDLVL_DL_0 (DDRMC_CR105 bits [23:8]). This field is read only.

### 10.1.5.171 PHY Register 13 (DDRMC\_PHY13)

PHY DLL Status Register 2 for data slice 0.

Address: 400A\_E000h base + 434h offset = 400A\_E434h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	0										GATE_CLOSE_CFG			GATE_CFG		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY18 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 EN_HALF_CAS	<p>Adds 1/2 cycle to the DQS gate value programmed into PHY_GATE_CFG. Default 0x0. This is used when the gate is being aligned to the first DQS, and then is removed to move the gate back into the center of the preamble.</p> <ul style="list-style-type: none"> <li>This field is used for Gate Training only. Set field for b'0' for normal operations.</li> <li>Total delay in clock cycles used for Gate training will be: <math>GATE\_CFG + 0.5 \times EN\_HALF\_CAS + RDLVL\_GTDL\_1/128</math></li> </ul> <p>0 No adjustment to DQS Gate Delay value. 1 Adjust the DQS gate by 1/2</p>
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SW_HALF_CYCLE_SHIFT	<p>Write level half-clock cycle shift.</p> <p>When set to 'b1, this field will add a one-half clock period delay to the DQS1 strobe.</p> <ul style="list-style-type: none"> <li>This field is used for Write Level Training only. Set field for b'0' for normal operations.</li> <li>Total delay in clock cycles used for Write Level will be: <math>WRLVL\_CLKDL + 0.5 \times SW\_HALF\_CYCLE\_SHIFT + WLLVL\_DL\_1/128</math></li> </ul> <p>0 No adjustmen to WRLVL_DL value 1 Adds a half clock delay to the write level delay line.</p>

Table continues on the next page...

## DDRMC\_PHY18 field descriptions (continued)

Field	Description
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 WRLVL_CLKDL	Write level full-clock cycle shift.  When set to 'b1', this field will add a full clock period delay to the DQS1 strobe. <ul style="list-style-type: none"> <li>This field is used for Write Level Training only. Set field for b'0' for normal operations.</li> <li>Total delay in clock cycles used for Write Level will be: <math>WRLVL\_CLKDL + 0.5 \times SW\_HALF\_CYCLE\_SHIFT + WLLVL\_DL\_1/128</math></li> </ul> 0 No adjustment to WRLVL_DL value. 1 A full clock delay to the write level delay line.
24–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–19 RD_DL_SET	Read Delay Select setting. Used to synchronize Read Data across two different time domains. Provides a delay in N clock cycles between the time the Memory Controller signals the PHY to send Read Data (dfi_rddata_en) and when the PHY signals the Memory Controller that Read Data is valid (dfi_rddata_valid) and can be clocked into the Read FIFOs of the Memory Controller. See 34.6.15.7 Synchronize Read Data From delayed_dqs to PHY_CLK domain for additional details. <ul style="list-style-type: none"> <li>Settings in this field are in clock cycles.</li> <li>Use a setting of 0x4 for normal operations.</li> </ul>
18–16 WR_DB_ADJ	Write Leveling Delay Dead Band Adjustment  The delay applied to the entire Data Slice to align the slice with the SDCLK is calculated and applied outside of the DLL block. The required delay is calculated using the Lock Value supplied by the Master DLL (DDRMC_PHY27[15:8]), and the WRLVL_DL_1 value (DDRMC_CR99[15:0]). Since this value is constantly being recalculated, a dead band is used to prevent the delay block from oscillating between two very close values. The value specified in this field is the required minimum difference between the new calculated value delay value and the number of delay elements currently in use. The physical number of delay elements used will only be updated when the difference in required delay elements meet the minimum number specified in this field. <ul style="list-style-type: none"> <li>Set to 0x1 for normal operations.</li> <li>For designs specifying a large number in the WRLVL_DL_1 field, the user may consider increasing the value in this field.</li> <li>Most designs should not have to change this field.</li> </ul> 'b000 One delay element (Default) 'b001 Two delay elements 'b010 Three delay elements 'b011 Four delay elements 'b100 Five delay elements 'b101 Six delay elements 'b110 Seven delay elements 'b111 Eight delay elements
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–3 GATE_CLOSE_CFG	DQS GATE Open period adjustment. <b>For DDR3:</b> Adds full clock cycles to the "un-gated" period of the DQS1 pad input. <ul style="list-style-type: none"> <li>Recommended Setting: 0x0</li> <li>This parameter may be optimized with a DDR Stress Test SW Program</li> <li>Normal Gate open period is <math>BL/2 + 1</math> clock cycles.</li> </ul>

Table continues on the next page...

**DDRMC\_PHY18 field descriptions (continued)**

Field	Description
	<b>For LPDDR2:</b> Adds full clock cycles to the maximum "un-gated" period of the DQS1 pad input. <ul style="list-style-type: none"> <li>Recommended Setting: 0x3</li> <li>This parameter may be optimized with a DDR Stress Test SW Program</li> <li>Gate signal is closed when the required number of DQS1 strobe edges have been received.</li> </ul>
GATE_CFG	DQS GATE level full-clock cycle adjustment.  Adds full clock cycle delays to the calculated gate timing for DQS1 pad input. <ul style="list-style-type: none"> <li>Total delay in clock cycles used for DQS GATE level will be: <math>GATE\_CFG - 0.5 \times EN\_HALF\_CAS + RDLVL\_GTDL\_1/128</math></li> <li>Recommended Setting: 0x0</li> <li>This parameter may be optimized with a DDR Stress Test SW Program</li> </ul>

**10.1.5.175 PHY Register 19 (DDRMC\_PHY19)**

PHY DLL Master Control Register for data slice 1.

Address: 400A\_E000h base + 44Ch offset = 400A\_E44Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DDRMC\_PHY19 field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PARAM_HALF_CLOCK_MODE	Determines if the master delay line locks on a full clock cycle or a half clock cycle.

*Table continues on the next page...*

## DDRMC\_PHY19 field descriptions (continued)

Field	Description
	<p>Within the Master DLL there are only 128 delay elements that can be used to determine a lock. For frequencies of operation below 300 MHz, it is necessary to limit the lock period to only a half clock cycle so that the master delay line does not become saturated.</p> <ul style="list-style-type: none"> <li>For frequencies above 300 MHz, set this bit to 'b0.</li> <li>For frequencies below 300 MHz, set this bit to 'b1.</li> </ul> <p><b>For both LPDDR2 and DDR3:</b></p> <ul style="list-style-type: none"> <li>'b0 - Master DLL locks on full clock cycle delay</li> <li>'b1 - Master DLL locks on half clock cycle delay</li> </ul>
23 PARAM_DLL_ BYPASS_MODE	<p>Places the Master DLL in bypass mode.</p> <p>In bypass mode, the Master DLL will not attempt to achieve a lock. The Master DLL will report zero delay elements used in a clock cycle.</p> <ul style="list-style-type: none"> <li>The PHY will ignore the calibration settings for RDLVL_GTDL_1 and WRLVL_DL_1, and set delay settings for these parameters to 0 time delay.</li> <li>The PHY will ignore the calibration setting for RDLVL_DL_1, but instead will use the number of delay elements specified in field PHY_20[DLL_READ_DL]</li> <li>The PHY will set the write DQS strobe delay to the number of delay elements specified in PHY_20[DLL_WRITE_DL] instead of treating this value as a 1/128 fraction of a clock cycle.</li> </ul> <p><b>For both LPDDR2 and DDR3:</b></p> <ul style="list-style-type: none"> <li>'b0 - Master DLL operates normal.</li> <li>'b1 - Master DLL is placed in bypass mode.</li> </ul>
22–20 DLL_PHASE_ DET	<p>DLL Phase Detect Selector for DQS1 Output Enable Generation</p> <p>Used to compensate for clock domain differences between the DLL for the SDCLK signal and the DLL for the DQS Strobe.</p> <ul style="list-style-type: none"> <li>Selects the number of delay elements to be inserted between the phase detect flip-flops. Default value is 0b000 (is 1 delay element).</li> <li>For designs having trouble in getting a DLL lock, consider increasing the value of this field.</li> <li>Set according to the jitter of the clock source. Increasing the number of delay elements increases the window in which a lock can be obtained/maintained. A larger window also means that more jitter will propagate to the output. This jitter will reduce the margins for read and write timing. Therefore, this should be used with caution. 0b010 is considered a good starting value for most of design.</li> </ul> <p>'b000 One delay element (Default)  'b001 Two delay elements  'b010 Three delay elements  'b011 Four delay elements  'b100 Five delay elements  'b101 Six delay elements  'b110 Seven delay elements  'b111 Eight delay elements</p>
19–16 DLL_LOCK_ NUM	<p>Specifies the number of lock indications which are required in the last 8 cycles for the lock detection circuit to indicate an overall lock.</p> <p>'b000 One lock detect (Default)  'b001 Two lock detects  'b010 Three lock detects  'b011 Four lock detects  'b100 Five lock detects  'b101 Six lock detects</p>

Table continues on the next page...

## DDRMC\_PHY19 field descriptions (continued)

Field	Description
	'b110 Seven lock detects 'b111 Eight lock detects - All other bit settings are reserved.
15–8 DLL_INCREM	Specifies the increments of delay elements used by the DLL in searching for a DLL lock. A smaller value allows for a more gradual search, but increases the time required for a DLL lock. <ul style="list-style-type: none"> <li>Set this field to 0x01 for normal operations.</li> </ul>
DLL_START_POINT	Specifies the number of delay elements used at the start of the DLL sequence to search for a lock. <ul style="list-style-type: none"> <li>Set this field to a value greater than or equal to 0x04 and less than lock number in whole PVT range</li> </ul>

## 10.1.5.176 PHY Register 20 (DDRMC\_PHY20)

PHY DLL Slave Control Register for data slice 1.

Address: 400A\_E000h base + 450h offset = 400A\_E450h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	DLL_WRITE_DL							0	DLL_READ_DL						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## DDRMC\_PHY20 field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 DLL_WRITE_DL	DLL Write delay This is delay setting for the dll line that controls the phase relationship between DQS1 and write data D[15:8].  <b>NOTE:</b> Value programmed in this field delays the strobe by (period of strobe/128)x the programmed value. For e.g, if the value programmed is 0x20h, the the strobe is delayed by period of strobe/4.  <b>NOTE:</b> This field is not to be confused with WRLVL_DL_1 (DDRMC_CR99 bits [15:0]). DLL_WRITE_DL adjusts the DQS strobe into the center of the valid data window. WRLVL_DL_1 adjusts the DQS strobe with respect to the SDCLK signal.  <b>NOTE:</b> If the Master DLL is placed in bypass mode (PHY_19[PARAM_DLL_BYPASS_MODE]), then the value specified in this field will be the number of 30 picosecond delay element used in the delay of the Write DQS1 strobe.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

## DDRMC\_PHY20 field descriptions (continued)

Field	Description
DLL_READ_DL	<p>Bypass mode DLL Read delay</p> <p>Specifies the number of 30 picosecond delay elements used to delay the Read DQS1 strobe.</p> <p><b>NOTE:</b> This field is used only if the Master DLL is placed in bypass mode (PHY_19[PARAM_DLL_BYPASS_MODE]).</p>

10.1.5.177 PHY Register 26 (DDRMC\_PHY26)

PHY Loopback Status Register. Reports status for the PHY for data slice 1.

Address: 400A\_E000h base + 468h offset = 400A\_E468h

### DDRMC\_PHY26 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DQS_ERROR_STATUS	Status signal to indicate that the DQS READ Gate had to be forced closed in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> <li>'b0 = Normal operation</li> <li>'b1 = Reserved.</li> </ul>
23–8 LPBK_DQ_DATA	Reports data bit values in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> </ul>
7–4 LPBK_DM_DATA	Reports data mask values in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> </ul>
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 LPBK_STATUS	Reports status of loop back errors. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implementation of the PHY.</li> </ul>
0 LPBK_START	Reports status of loop back mode.

*Table continues on the next page...*

**DDRMC\_PHY26 field descriptions (continued)**

Field	Description
	<ul style="list-style-type: none"> <li>• This field is read only.</li> <li>• Loop back mode is not enabled in this implementation of the PHY.</li> <li>• 'b0 = Normal operation</li> <li>• 'b1 = Reserved.</li> </ul>

**10.1.5.178 PHY Register 27 (DDRMC\_PHY27)**

PHY DLL Status Register 0 for data slice 1.

Address: 400A\_E000h base + 46Ch offset = 400A\_E46Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DLL_UNLOCK_VALUE								LOCK							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DLL_LOCK_VALUE								0							DLL_LOCK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DDRMC\_PHY27 field descriptions**

Field	Description
31–24 DLL_UNLOCK_VALUE	Reports the dll_lock_value if the DLL has become unlocked after being locked. This field will be cleared to 0x0 following a system reset. A value of 0x0 indicates that once the dll achieved lock, it has always remained locked.

*Table continues on the next page...*

**DDRMC\_PHY27 field descriptions (continued)**

Field	Description
	This field is read only.
23–16 LOCK	Holds the last 8 samples of the lock indicator. This field is read only.
15–8 DLL_LOCK_ VALUE	Reports the DLL encoder value from the master DLL to the slave DLL's. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>The contents of this register is only valid if DLL_LOCK = 1.</li> <li>If the DLL loses lock, the value of this register will transfer to the DLL_UNLOCK_VALUE register</li> </ul>
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DLL_LOCK	Indicates status of the DLL. This field is read only. <ul style="list-style-type: none"> <li>0 DLL has not locked</li> <li>1 DLL is locked</li> </ul>

**10.1.5.179 PHY Register 28 (DDRMC\_PHY28)**

PHY DLL Status Register 1 for data slice 1

Address: 400A\_E000h base + 470h offset = 400A\_E470h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**DDRMC\_PHY28 field descriptions**

Field	Description
31–24 Reserved	This field is reserved.
23–16 DEC_OUT_WR	Holds the encoded value for the clock write delay line for this slice.  After the DQS1 DLL has locked, this field reports the number of delay elements used by the DLL to achieve the delay programmed in DLL_WRITE_DL1 (DDRMC_PHY20 bits [14:8]).  This field is read only.
15–8 Reserved	This field is reserved.
DEC_OUT_RD	After the DQS1 DLL has locked, this field reports the number of delay elements used by the DLL to achieve the delay programmed in RDLVL_DL_1 (DDRMC_CR105 bits [15:0]).  This field is read only.

### 10.1.5.180 PHY Register 29 (DDRMC\_PHY29)

PHY DLL Status Register 2 for data slice 1.

Address: 400A\_E000h base + 474h offset = 400A\_E474h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																DEC_OUT_WR_DQS															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY29 field descriptions

Field	Description
31–16 Reserved	This field is reserved.
DEC_OUT_WR_DQS	After the DQS1 DLL has locked, this field reports the number of delay elements used by the DLL to achieve the delay programmed in WRLVL_DL_1 (DDRMC_CR99 bits [15:0]).

### 10.1.5.181 PHY Register 32 (DDRMC\_PHY32)

PHY DQ timing register for slice 2.

Address: 400A\_E000h base + 480h offset = 400A\_E480h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TSEL_START				TSEL_END				OE_START				OE_END			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY32 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 TSEL_START	This field has no meaning in this implementation of the PHY.
11–8 TSEL_END	This field has no meaning in this implementation of the PHY.
7–4 OE_START	Adjusts the starting point of the SDCLK pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. Recommended setting for this field is 0 x 1.
OE_END	Adjusts the ending point of the SDCLK pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution. This field must be set to at least the value of bits [7:4]+2 to prevent disabling the pad before the data is completely written. Recommended setting for this field is 0x3.

### 10.1.5.182 PHY Register 33 (DDRMC\_PHY33)

PHY DQS timing register for slice 2.

Address: 400A\_E000h base + 484h offset = 400A\_E484h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### DDRMC\_PHY33 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 TSEL_START	This field has no meaning in this implementation of the PHY.
11–8 TSEL_END	This field has no meaning in this implementation of the PHY.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 OE_START	Adjusts the starting point of the Command/Address pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 1.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
OE_END	Adjusts the ending point of the Command/Address pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. This field must be set to at least the value of bits [6:4]+2 to prevent disabling the pad before the data is completely written. Recommended setting is 0x5.

### 10.1.5.183 PHY Register 34 (DDRMC\_PHY34)

PHY Gate Control Register for data slice 2.

Address: 400A\_E000h base + 488h offset = 400A\_E488h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0			0		0		0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY34 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 EN_HALF_CAS	This field has no meaning for Command/Address signals. Set to default value of 'b0. 0 Normal operations. 1 Reserved
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SW_HALF_CYCLE_SHIFT	This field has no meaning for Command/Address signals. Set to default value of 'b0. 0 Normal operations 1 Reserved
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 WRLVL_CLKDL	This field has no meaning for Command/Address signals. Set to default value of 'b0. 0 Normal operations 1 Reserved
24–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–19 RD_DL_SET	Read Delay Select setting. Used to synchronize Read Data across two different time domains.

Table continues on the next page...

## DDRMC\_PHY34 field descriptions (continued)

Field	Description
	<p>Provides a delay in N clock cycles between the time the Memory Controller signals the PHY to send Read Data (dfi_rddata_en) and when the PHY signals the Memory Controller that Read Data is valid (dfi_rddata_valid) and can be clocked into the Read FIFOs of the Memory Controller. See 34.6.15.7 Synchronize Read Data From delayed_dqs to PHY_CLK domain for additional details.</p> <ul style="list-style-type: none"> <li>Settings in this field are in clock cycles.</li> <li>Use a setting of 0x4 for normal operations.</li> </ul>
18–16 WR_DB_ADJ	<p>Write Leveling Delay Dead Band Adjustment</p> <p>The delay applied to the entire Data Slice to align the slice with the SDCLK is calculated and applied outside of the DLL block. For the Command/Address Slice, this block has little meaning, and is only included in the design for similarity with the other Data Slices.</p> <ul style="list-style-type: none"> <li>Set to 0x1 for normal operations.</li> <li>Most designs should not have to change this field.</li> </ul> <p>'b000 One delay element (Default)  'b001 Two delay elements  'b010 Three delay elements  'b011 Four delay elements  'b100 Five delay elements  'b101 Six delay elements  'b110 Seven delay elements  'b111 Eight delay elements</p>
15–5 Reserved	<p>This field is reserved.  This read-only field is reserved and always has the value 0.</p>
4–3 GATE_CLOSE_CFG	<p>-</p> <p>This field has no meaning for Command/Address signals. Set to default value of 0x0.</p>
GATE_CFG	<p>-</p> <p>This field has no meaning for Command/Address signals. Set to default value of 0x0.</p>

### 10.1.5.184 PHY Register 35 (DDRMC\_PHY35)

PHY DLL Master Control Register for data slice 2.

Address: 400A\_E000h base + 48Ch offset = 400A\_E48Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							PARAM_HALF_CLOCK_MODE	PARAM_DLL_BYPASS_MODE	DLL_PHASE_DET				DLL_LOCK_NUM		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	DLL_INCREM								DLL_START_POINT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY35 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PARAM_HALF_CLOCK_MODE	Determines if the master delay line locks on a full clock cycle or a half clock cycle.  Within the Master DLL there are only 128 delay elements that can be used to determine a lock. For frequencies of operation below 300 MHz, it is necessary to limit the lock period to only a half clock cycle so that the master delay line does not become saturated. <ul style="list-style-type: none"> <li>For frequencies above 300 MHz, set this bit to 'b0.</li> <li>For frequencies below 300 MHz, set this bit to 'b1.</li> </ul> <b>For both LPDDR2 and DDR3:</b> <ul style="list-style-type: none"> <li>'b0 - Master DLL locks on full clock cycle delay</li> <li>'b1 - Master DLL locks on half clock cycle delay</li> </ul>
23 PARAM_DLL_BYPASS_MODE	Places the Master DLL in bypass mode.  In bypass mode, the Master DLL will not attempt to achieve a lock. The Master DLL will report zero delay elements used in a clock cycle. <ul style="list-style-type: none"> <li>For LPDDR2 only, the PHY will set the SDCLK delay to the number of delay elements specified in PHY_49[PHY_WRLV_DL] instead of treating this value as a 1/128 fraction of a clock cycle.</li> </ul> <b>For both LPDDR2 and DDR3:</b>

Table continues on the next page...

## DDRMC\_PHY35 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>'b0 - Master DLL operates normal.</li> <li>'b1 - Master DLL is placed in bypass mode.</li> </ul>
22–20 DLL_PHASE_ DET	<p>DLL Phase Detect Selector for SDCLK Output Enable Generation</p> <p>For the Command/Address Slice, this field has no meaning since there is no phase difference between the DLL for the SDCLK and the DLL for the SDCLK. It is only included in the design for similarity with the other Data Slices.</p> <ul style="list-style-type: none"> <li>Selects the number of delay elements to be inserted between the phase detect flip-flops. Default value is 0b000 (is 1 delay element).</li> <li>For designs having trouble in getting a DLL lock, consider increasing the value of this field.</li> <li>Set according to the jitter of the clock source. Increasing the number of delay elements increases the window in which a lock can be obtained/maintained. A larger window also means that more jitter will propagate to the output. This jitter will reduce the margins for read and write timing. Therefore, this should be used with caution. 0b010 is considered a good starting value for most of design.</li> </ul> <p>'b000 One delay element (Default)  'b001 Two delay elements  'b010 Three delay elements  'b011 Four delay elements  'b100 Five delay elements  'b101 Six delay elements  'b110 Seven delay elements  'b111 Eight delay elements</p>
19–16 DLL_LOCK_ NUM	<p>Specifies the number of lock indications which are required in the last 8 cycles for the lock detection circuit to indicate an overall lock.</p> <p>'b000 One lock detect (Default)  'b001 Two lock detects  'b010 Three lock detects  'b011 Four lock detects  'b100 Five lock detects  'b101 Six lock detects  'b110 Seven lock detects  'b111 Eight lock detects  - All other bit settings are reserved.</p>
15–8 DLL_INCREM	<p>Specifies the increments of delay elements used by the DLL in searching for a DLL lock. A smaller value allows for a more gradual search, but increases the time required for a DLL lock.</p> <ul style="list-style-type: none"> <li>Set this field to 0x01 for normal operations.</li> </ul>
DLL_START_ POINT	<p>Specifies the number of delay elements used at the start of the DLL sequence to search for a lock.</p> <ul style="list-style-type: none"> <li>Set this field to a value greater than or equal to 0x04 and less than lock number in whole PVT range</li> </ul>

### 10.1.5.185 PHY Register 36 (DDRMC\_PHY36)

PHY DLL Slave Control Register for data slice 2.

Address: 400A\_E000h base + 490h offset = 400A\_E490h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																DLL_WRITE_DL								0							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY36 field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 DLL_WRITE_DL	SDCLK Strobe Delay  This field has no meaning in this implementation of the PHY. SDCLK strobe delay is set in field PHY_WRLV_DL (DDRMC_PHY49 bits [23:16]).  Set field to default value of 0x0 for proper operation.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.1.5.186 PHY Register 42 (DDRMC\_PHY42)

PHY Loopback Status Register. Reports status for the PHY for data slice 2.

Address: 400A\_E000h base + 4A8h offset = 400A\_E4A8h

### DDRMC\_PHY42 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DQS_ERROR_STATUS	Status signal to indicate that the DQS READ Gate had to be forced closed in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implantation of the PHY.</li> <li>'b0 = Normal operation</li> <li>'b1 = Reserved</li> </ul>
23–8 LPBK_DQ_DATA	Reports data bit values in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implantation of the PHY.</li> </ul>
7–4 LPBK_DM_DATA	Reports data mask values in loop back mode. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implantation of the PHY.</li> </ul>
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 LPBK_STATUS	Reports status of loop back errors. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>Loop back mode is not enabled in this implantation of the PHY.</li> </ul>
0 LPBK_START	Reports status of loop back mode.

*Table continues on the next page...*

## DDRMC\_PHY42 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> <li>• This field is read only.</li> <li>• Loop back mode is not enabled in this implementation of the PHY.</li> <li>• 'b0 = Normal operation</li> <li>• 'b1 = Reserved</li> </ul>

## 10.1.5.187 PHY Register 43 (DDRMC\_PHY43)

PHY DLL Status Register 0 for data slice 2 .

Address: 400A\_E000h base + 4ACh offset = 400A\_E4ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DLL_UNLOCK_VALUE								LOCK							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DLL_LOCK_VALUE								Reserved							DLL_LOCK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DDRMC\_PHY43 field descriptions**

Field	Description
31–24 DLL_UNLOCK_VALUE	Reports the dll_lock_value if the DLL has become unlocked after being locked. This field will be cleared to 0x0 following a system reset. A value of 0x0 indicates that once the dll achieved lock, it has always remained locked. This field is read only.
23–16 LOCK	Holds the last 8 samples of the lock indicator. This field is read only.
15–8 DLL_LOCK_VALUE	Reports the DLL encoder value from the master DLL to the slave DLL's <ul style="list-style-type: none"> <li>This field is read only.</li> <li>The contents of this register is only valid if DLL_LOCK=1.</li> <li>If the DLL loses lock, the value of this register will transfer to the DLL_UNLOCK_VALUE register</li> </ul>
7–1 Reserved	This field is reserved.
0 DLL_LOCK	Indicates status of the DLL. This field is read only. <ul style="list-style-type: none"> <li>0 DLL has not locked</li> <li>1 DLL is locked</li> </ul>

**10.1.5.188 PHY Register 44 (DDRMC\_PHY44)**

PHY DLL Status Register 1 for data slice 2

Address: 400A\_E000h base + 4B0h offset = 400A\_E4B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								DEC_OUT_WR								Reserved								DEC_OUT_RD							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**DDRMC\_PHY44 field descriptions**

Field	Description
31–24 Reserved	This field is reserved.
23–16 DEC_OUT_WR	Holds the encoded value for the clock write delay line for this slice.  After the SDCLK DLL has locked, this field reports the number of delay elements used by the DLL to achieve the delay programmed in PHY_WRLV_DL (DDRMC_PHY49 bits [23:16]).  This field is read only.
15–8 Reserved	This field is reserved.
DEC_OUT_RD	Holds the encoded value for the read delay line for this slice. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>This field has no meaning for Command/Address slice.</li> </ul>

### 10.1.5.189 PHY Register 45 (DDRMC\_PHY45)

PHY DLL Status Register 2 for data slice 2.

Address: 400A\_E000h base + 4B4h offset = 400A\_E4B4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### DDRMC\_PHY45 field descriptions

Field	Description
31–16 Reserved	This field is reserved.
DEC_OUT_WR_DQS	Reports the encoded value for the clock write SDCLK delay line. <ul style="list-style-type: none"> <li>This field is read only.</li> <li>This field has no meaning for Command/Address slice.</li> </ul>

### 10.1.5.190 PHY Register 49 (DDRMC\_PHY49)

PHY DLL Slave Control LPDDR2 Register

Address: 400A\_E000h base + 4C4h offset = 400A\_E4C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								PHY_WRLV_DL								0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### DDRMC\_PHY49 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 PHY_WRLV_DL	SDCLK Strobe Delay This field delays the SDCLK edges in relation to CA[9:0] signals so that the clock strobe arrives at the LPDDR2 device in the center of the valid CA window. <b>For DDR3:</b> <ul style="list-style-type: none"> <li>This field is not used.</li> <li>Set field to default value of 0x0 for proper operation.</li> </ul> <b>For LPDDR2:</b> <ul style="list-style-type: none"> <li>Value programmed in this field delays the clock by (period of clock/128)x the programmed value. For example, if the value programmed is 0x20h, SDCLK is delayed by a period of clock/4.</li> </ul>

Table continues on the next page...

**DDRMC\_PHY49 field descriptions (continued)**

Field	Description
	<b>NOTE:</b> If the Master DLL is placed in bypass mode (PHY_35[PARAM_DLL_BYPASS_MODE]), then the value specified in this field will be the number of 30 picosecond delay element used in the delay of the SDCLK strobe in LPDDR2 mode only.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**10.1.5.191 PHY Register 50 (DDRMC\_PHY50)****PHY Control register**

Address: 400A\_E000h base + 4C8h offset = 400A\_E4C8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

## 10.1.6 Functional Description

This section discusses the programming model and operation of the memory controller.

### 10.1.6.1 Address Mapping

The memory controller automatically maps user addresses to the DRAM memory in a contiguous block. Addressing for all VFxxx Controller versions starts at 0x80000000 and ends at the highest available address according to the size and number of DRAM devices present. The maximum address that can be used is 0xFFFFFFFF, for a total space of 2048 MB.

The mapping of the address space to the internal data storage structure of the DRAM devices is based on the actual size of the DRAM devices available. The size is stored in user-programmable parameters that must be initialized at power up. Certain DRAM devices allow for different mapping options to be chosen, while other DRAM devices depend on the chosen burst length.

#### 10.1.6.1.1 DDR SDRAM Address Mapping Options

The address structure of DDR SDRAM devices contains the following five fields:

- Chip select
- Row
- Bank
- Column
- Datapath

Each of these fields can be individually addressed when accessing the DRAM.

The maximum widths of the fields are based on the configuration settings. The actual widths of the fields may be smaller if the device address width parameters (CR73[ROW\_DIFF], CR73[BANK\_DIFF], and CR73[COL\_DIFF]) are programmed differently.

#### 10.1.6.1.2 Maximum Address Space

The maximum user address range is determined by the width of the memory datapath, the number of chip select pins, and the address space of the DRAM device. The maximum amount of memory can be calculated by the following formula:

$$\text{Maximum Memory Size} = \text{Chip Selects} \times 2^{\text{Address}} \times \text{Banks} \times \text{Datapath Width}$$

See the chip configuration section of the reference manual for the maximum address space calculated for this device.

#### 10.1.6.1.3 Memory Mapping to Address Space

The *col\_diff* and *row\_diff* parameters can each range from the maximum configured for the memory controller to seven bits smaller than the maximum configured. This allows the Memory Controller to function with a wide variety of memory sizes. The settings for the *col\_diff* and *row\_diff* parameters control how the address map is used to decode the user address to the DRAM chip selects and row and column addresses. The *bank\_diff* parameter controls the DRAM bank address information. It is assumed that the values in these parameters never exceed the maximum values configured.

#### 10.1.6.2 AXI Interface

This Memory Controller (MC) contains 2 internal AXI ports which communicate on the AXI bus. Each AXI port uses an AXI interface block to connect to the MC core. An arbitration scheme is required to control the traffic between the buses and the core.

### 10.1.6.2.1 Architecture Overview

The Multi-Port Memory Controller was designed for high memory bandwidth utilization and efficient arbitration for high priority requests.

Multi- Port system consists of the following subsystems:

- 2 AXI Interfaces
- Arbiter
- Command Queue with Placement Logic
- Write Data Latency Queue
- Read Data Queues
- DRAM Command Processing
- Register Port

### 10.1.6.2.2 AXI Interfaces

The Memory Controller core interfaces with 2 AXI ports and 1 AHB register port. The AXI data ports function as AXI slaves to external AXI masters such as CPUs, DMAs, DSPs, and other slave peripherals. Transfers are burst-based of variable byte counts. The transfer types INCR (incrementing) and WRAP (wrapping) are fully supported. The 2 AXI ports may accept commands from other AXI bus ports (Master or Slave) as shown in Section 9.5.3.1. All commands on the AXI bus are assigned a 13-bit AXI ID by the AXI Bus ID-Master from a pool of available IDs as soon as they enter the bus. A series of similar Reads and/or Writes entering the AXI bus from the same port may be assigned the same AXI ID for ordering purposes. The AXI ID will stay with the commands until all the commands in the series are completed. At that point, the AXI ID will be returned back to the available pool of IDs. This AXI ID is concatenated with an originating Master/Slave port identifier and other unique identifying information such as thread ID to allow the Memory Controller core to maintain originator information. The uppermost bit/s of the source ID represent the port number. There are no restrictions on mapping of AXI IDs to AXI bus masters.

The AXI Controller Core interfaces handle all communication between the AXI and the core at the boundary between the AXI bus and the Memory Controller. Each interface contains five separate channels of traffic to/from the AXI bus which support simultaneous two-way data flow: Read Command/Address, Read Data, Write Command/Address, Write data and Write Response. The Write channel is connected to an incoming FIFO (Write Data Latency Queue) and the Read channel is connected to an outgoing

FIFO (Read Data Queue). The remaining three channels are connected to the Arbiter which will place the commands into the Command Queue in accordance with the placement logic specified by the user.

Each port will always support full-size transfers where the full data port width is utilized on each beat. In addition, each port can be independently programmed to support narrow transfers, where not all the bits of the data port width are used. This translates to a bytes-per-beat size that is less than the port data width. For a multiport configuration where the port data widths are not uniform, the transfer size that defines a narrow transfer will vary based on each port's data width. There are no fixed timing requirements on a port between the traffic channels when the narrow transfer option is disabled, and in this case, write data may arrive before, with, or after the write command. When the narrow transfer option is enabled, a port will not accept write data until it has received the command and is aware of the total byte count associated with that command.

### 10.1.6.2.3 Restrictions on the AXI Bus

For this Memory Controller, the following restrictions exist:

- FIXED burst types are not supported.
- The response signals will never respond with a DECERR response type.
- Cacheable, read allocate or write allocate commands are not supported.
- WRAP commands must be aligned.
- Write data can not be interleaved. Write data must be presented to the memory controller in the same order as the write commands.
- Each port may only issue a fixed number of narrow transfers at a time. This implementation requires that each requestor must be individually enabled for narrow transfers, and that all commands from these requestors be counted in this limit, whether they are narrow transfers or not.
- Each ports may only monitor the exclusivity of a limited number of transactions at any time. In addition, each port will only maintain one exclusive monitor per requestor at a time.
- Locked access is not configured for this memory controller

### 10.1.6.2.4 Internal Command Handling

The Arbiter Module of the Memory Controller uses placement logic to fill the command queue with a command order that maximizes the throughput and efficiency of the core. Re-ordering of commands depends on the restrictions of the AXI bus. If the placement logic is being used, the Memory Controller will optimize bandwidth by re-ordering read and write commands as necessary. Read and write commands from individual ports are not affected by other ports. The following re-ordering rules apply to any one port on this memory controller:

- Two read commands with the same AXI ID on a port will not be re-ordered and will always execute in the same order as they were accepted into their port.
- Two read commands with different AXI IDs on a port may be automatically re-ordered in the core to execute out-of-order.
  - When commands with different AXI IDs are re-ordered, read data returned to the AXI port interfaces will also be out-of-order and may be interleaved. To avoid re-ordering within a port, the AXI bus master should use one AXI ID for all similar Read or Write commands from any port.
- Two write commands with the same AXI ID on a port must remain sequential and will not be reordered. These transactions will always occur in the order that the commands were received at the port.
- Two write commands with different AXI IDs on a port must remain sequential and will not be re-ordered. These transactions will always occur in the order that the commands were received at the port.
- A read command that follows a write command with the same AXI ID may be re-ordered to execute in an optimal order, as long as there are no collisions between the commands.
- A read command that follows a write command with a different AXI ID on a port may be reordered to execute in an optimal order, as long as there are no collisions between the commands.
- A write command that follows a read command with the same AXI ID may be re-ordered to execute in an optimal order, as long as there are no collisions between the commands.
- A write command that follows a read command with a different AXI ID on a port may be reordered to execute in an optimal order, as long as there are no collisions between the commands.

Command handling is summarized in the following table.

**Table 10-6. Re-Ordering / Interleaving Behavior**

Commands	AXI IDs	Can Commands be Re-Arranged and Data be Interleaved?
Two Read Commands from 1 port	Same	No
Two Read Commands from 1 port	Different	Yes
Two Read Commands from Different Ports	Same or Different	Yes
Two Write Commands from 1 port	Same	No
Two Write Commands from 1 port	Different	No
Two Write Commands from Different Ports	Same or Different	Yes
Read following a Write from 1 port	Same	Yes
Read following a Write from 1 port	Different	Yes
Read following a Write from different ports	Same or Different	Yes
Write following a Read from 1 port	Same	Yes
Write following a Read from 1 port	Different	Yes
Write following a Read from different ports	Same or Different	Yes

An incoming AXI transaction is mapped into a core-level transaction, then synchronized from the AXI clock domain to the core clock domain and stored in the AXI port FIFOs. Each instruction consists of an address, size, length and AXI ID. Since a port may utilize multiple AXI IDs, the Port Arbitration block of the AXI interface creates a source ID for a command, which is a combination of the originating AXI port and other thread ID information that can be extracted from the incoming AXI ID. This source ID is then retained alongside the command in the Command FIFO to be used in the placement logic of the Memory Controller Arbiter, which arbitrates requests from both ports and forwards the command to a single command queue in the Memory Controller Core.

#### 10.1.6.2.5 Controller configuration

- **Datapath Width** - Each port has a data interface width of 64 bits.
- **Width of the ID** - Each port is configured with a AXI ID of 13 bits.
- **Priority Definition** - Command priority is defined based on the port and the command type. For each port Y, there is an AXIY\_R\_PRI bit which defines priorities for all read commands and an AXIY\_W\_PRI bit which defines priorities for all write commands. Supported priority values range from 0 to 3, with 0 as the highest priority.
- **Register Port** - The Register Port is a 32-bit wide, asynchronous interface on the AHB bus.

- **Buffering** - Each data port contains a command, a read and a write FIFO, and a response storage array that services the port channels in the AXI-Controller Core Interfaces. In addition, each programmable port contains an asynchronous response Write Response FIFO to synchronize the memory response to the port time domain when operating asynchronously. The depth of these various FIFOs are as follows:
  - Command FIFO Depth – 8
  - Write FIFO Depth – 16
  - Read FIFO Depth – 8
  - Write Response FIFO Depth – 4
  - Write Response Storage Array Depth - 8
- **Narrow Transfer FIFO** - Since any command could be a full-size or narrow transfer, an entry is created in the port narrow transfer FIFO with the address, bytes-per-beat and a narrow transfer flag for each command. Each port has been configured with an 8-deep FIFO. If a port receives 8 narrow transfer commands and fills this FIFO, the associated port command FIFO may be stalled from accepting more commands. The user should judiciously limit the number of narrow transfers in software so that this FIFO never becomes full.
- **Exclusive Access Buffer Depth** - This feature allows individual sources to monitor activity on memory locations. This type of access will only be used if exclusive access commands are issued to the memory controller by driving the AXI port Y atomic access indicator to 'b01 with a read command. Each port of this Memory Controller contains 1 exclusive buffer and therefore each port may monitor the exclusivity of up to 1 transaction at any time. Refer to [Exclusive Access Option](#) for more information. This exclusivity buffer is shared by all the Masters/Slaves assigned to the port. If the exclusivity buffer is being used, a new request for exclusivity will overwrite the previous request, and the older exclusivity will be lost.
- **Error Detection** When an illegal operational condition is detected on a new AXI transaction entering the port, the port responds through an AXI error signal, by asserting the interrupt signal from the memory controller, and recording the error signature in the register space.

The AXI error signal flagged is dependent on the type of transaction that caused the error (read or write). If the error was associated with the command, the port command error interrupt will be set in INT\_STAT (DDRMC\_CR80 bit [7]), and the address, source ID and type related to the error will be saved in P\_CMDERRADD (DDRMC\_CR85 bits [31:0]), P\_CMDERR\_TYP (DDRMC\_CR86 bits [17:16]), and P\_CMDERRID (DDRMC\_CR86 bits [13:0]).

### 10.1.6.2.6 Port Clocking

There are two user-selectable modes of operation for each of the AXI port interfaces. The mode is set by programming AXI0\_FITYPREG (DDRMC\_CR117 bits [17:16] for AXI0 and AXI1\_FITYPREG (DDRMC\_CR119 bits [1:0] for AXI1. The two settings are:

- **Asynchronous ('b00)**

The AXI interface port and the core operate on clocks that are mismatched in frequency and phase. The AXI interface port FIFOs use two stages of synchronization logic to synchronize commands, write data and read data to the appropriate clock domain.

- **1:2 Port: Core Pseudo-Synchronous ('b10)**

The AXI interface port operates at half of the frequency of the core frequency, with clocks that are aligned in phase. Only one stage of the two-stage synchronization logic of the FIFOs will be utilized to synchronize commands, write data and read data to the appropriate clock domain.

### 10.1.6.2.7 AXI Port FIFOs

Incoming transactions from the AXI interfaces are processed by the interface logic and mapped into equivalent transactions on the core bus. These transactions are queued into each port's command FIFO. As the incoming transactions on the Read and Write Command channels are being processed by the Port Arbitration, the associated Read Data and Write Data enter their respective FIFOs and wait to pass to the Memory Controller Core when accepted by the MC Arbiter. [Figure 10-2](#) shows the relationship between the FIFOs in the AXI-Controller Core Interface and the Controller Core.

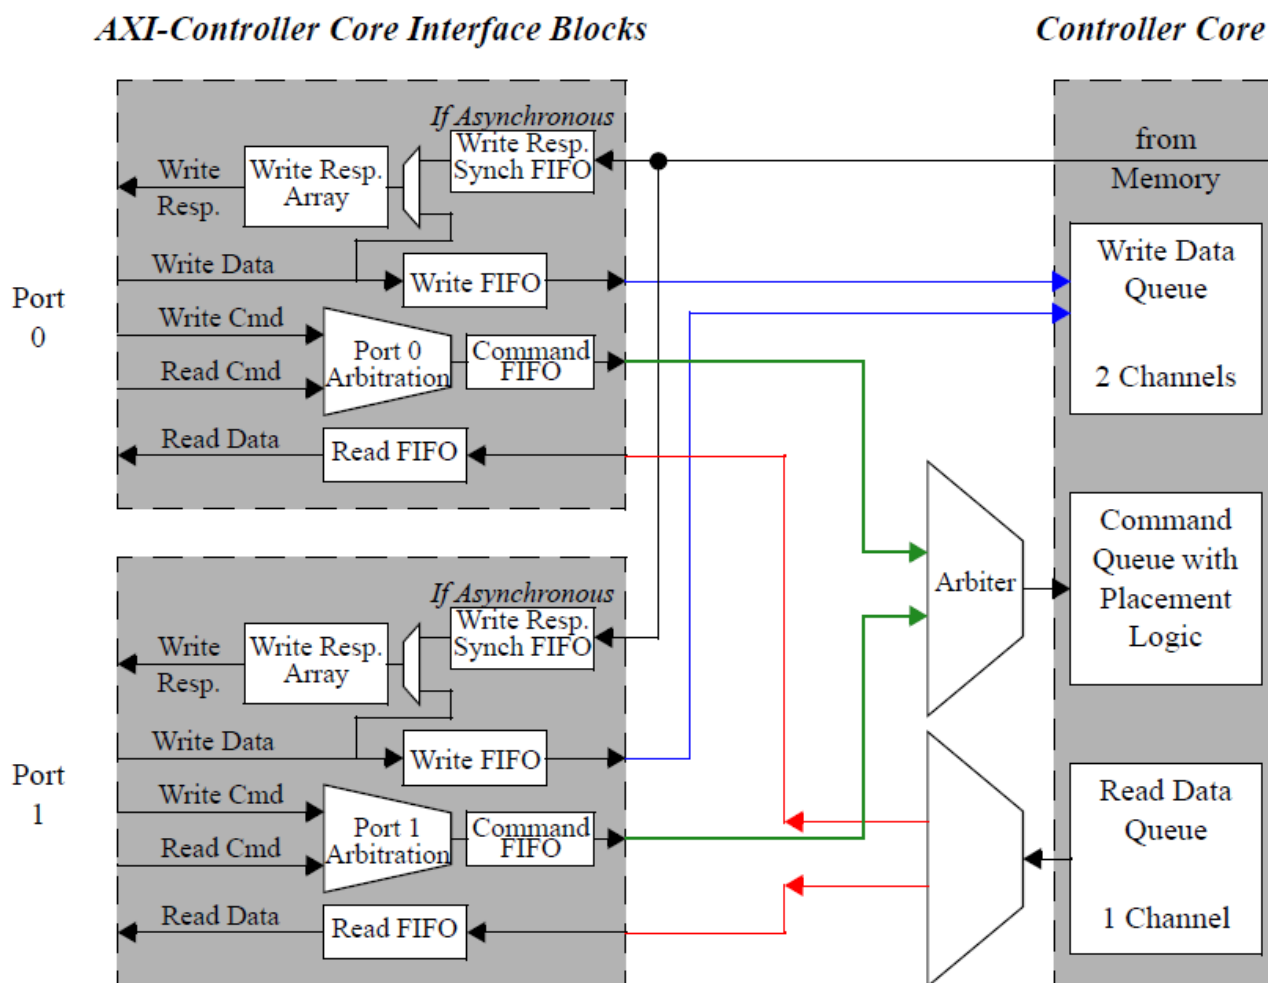

Figure 10-2. FIFOs in the AXI-Controller Core Interface

#### 10.1.6.2.8 Command FIFO

Prior to entering the port command FIFO, the AXI port interface blocks convert the AXI transactions into core transactions and generate the source ID. Commands enter the Command FIFO via the Port Interface Arbitration block.

##### 10.1.6.2.8.1 In-Port Arbitration

Within each port, it is possible that both the read and write command channels of the AXI bus are active concurrently. If this occurs, each port performs a simple arbitration to select the command to pass through to the Arbiter. This arbitration is based on the following factors, in order of importance:

1. Priority of read commands versus priority of write commands for this port as set by the user in AXI0\_R\_PRI (DDRMCR117 bits [1:0]) and AXI0\_W\_PRI (DDRMCR117 bits [9:8]) for AXI0 and AXI1\_R\_PRI (DDRMCR118 bits [17:16]) and AXI1\_W\_PRI (DDRMCR118 bits [25:24]) for AXI1.
2. Default Read over Write preference. If both read and write commands are accepted simultaneously, and their priorities are identical, then the read channel will be selected first.

The following table shows the system behavior when the port FIFO is full, allowing commands to accumulate on both read and write channels. The commands will be arbitrated into the port command FIFO based on the order that they are accepted at the port.

**Table 10-7. Port Arbitration Example 1**

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
1	FULL	1st Read	Any			None (FIFO full)
2	FULL			1st Write	Any	None (FIFO full)
3	Available					1st Read (Arrived First)
4	Available	2nd Read	Any			1st Write (Arrived First)
5	Available					2nd Read

The following table shows the system behavior when read and write commands are accepted simultaneously. The commands will be arbitrated into the port command FIFO based on priority for that type of command. When the commands are not simultaneous, they will be arbitrated based on the order that they are accepted at the port.

**Table 10-8. Port Arbitration Example 2**

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
1	Available	1st Read	Lower	1st Write	Higher	1st Write (Higher Priority)
2	Available			2nd Write	Higher	1st Read (Arrived First)

*Table continues on the next page...*

**Table 10-8. Port Arbitration Example 2 (continued)**

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
3	Available					2nd Write
4	Available	2nd Read	Lower	3rd Write	Higher	3rd Write (Higher Priority)
5	Available					2nd Read

The following table shows the system behavior when read and write commands are accepted simultaneously and their port priorities are the same. Read commands will automatically be arbitrated ahead of write commands when both other conditions match. When the commands are not simultaneous, they will be arbitrated based on the order that they are accepted at the port.

**Table 10-9. Port Arbitration Example 3**

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
1	Available	1st Read	Same	1st Write	Same	1st Read (Read over Write Priority)
2	Available	2nd Read	Same			1st Write (Arrived First)
3	Available			2nd Write	Same	2nd Read (Arrived First)
4	Available					2nd Write
5	Available	3rd Read	Same	3rd Write	Same	3rd Read (Read over Write Priority)
6	Available					3rd Write

#### 10.1.6.2.9 Read FIFO

There is only one streaming read data interface out from the Memory Controller Core servicing both AXI ports, regardless of the number of ports or the number of AXI IDs being serviced by either port. The Memory Controller maps this data stream back to the proper port using the source ID. The AXI bus master must map the data back to originating AXI port by using the AXI ID.

With this singular data interface, the AXI port Read Data channel must be ready to accept the read data as soon as it is available on the internal core bus to avoid stalling the memory controller. The AXI port read data valid indicator output signal will be asserted whenever the port has received valid data from memory that can be passed back to the originator associated with that AXI ID. The Read Data FIFO can hold up to 8 Read transactions before it will stop accepting more Read data from the Memory Controller Core.

If the Read Data FIFO stops accepting transactions from the Memory Controller Core, the core will stall with read data still waiting in the Controller read data queue waiting to be off loaded. The performance across both ports in the system will be affected. Users should never rely on AXI bus FIFOs to buffer data requested by a thread.

#### **10.1.6.2.10 Write FIFO**

The depth of the Write FIFO is set to 16 in this implementation of the Controller IP. This should allow enough Write transactions to complete a Write Burst to accumulate in the FIFO during most use cases. Note that there is a write data queue inside the core as well. Therefore, the purpose of the write FIFO is to allow the AXI bus to off load its write data completely before the data is transferred to the core buffers. Each port has a distinct write channel into the core write data queue. If there are multiple AXI IDs for a port, they will all share the channel for that port.

While an AXI write may begin at any address, aligned or un-aligned, AXI-bus protocol specifies that it must complete at an address that is aligned to the beat size.

Depending on the type of transfer, the write data may arrive before the command. However, if the originator associated with the AXI ID sending the data is capable of sending narrow transfers, then the write data will not be accepted until the command has been received.

#### **10.1.6.2.11 Response Interface**

When a write request is accepted into the AXI interface, an entry will be created in the Response Storage Array for that command. The array will maintain information on the order of received commands from each AXI ID for each port. Write responses will be returned in the same order as the commands were received, regardless of the AXI ID or the type of response requested (bufferable, coherent bufferable or non-bufferable). When a write response is ready, the array will verify that this is oldest command for that port and if so, the response will be sent out. The timing of this response is dependent on the type of response requested and the contents of the command queue. Responses for bufferable commands will be available when the port has received all of the data, responses for coherent bufferable commands will be available when the core has received

the command and the port has received all the data associated with that command, and responses for non-bufferable commands will be available when all data has been sent to the PHY via the DFI interface. It is possible that a response for a newer command for that port will be ready before a response for an older command, but it will not be sent to the user interface until all older commands are sent out. Write responses will be returned to the AXI master through a standard AXI Bus Response signal, along with its associated AXI Bus Valid Indicator signal.

#### **10.1.6.2.12 Bufferable, Coherent Bufferable and Non-Bufferable Response Types**

The Write Data channel of each AXI port is configured with two signal bits that work together to determine when an instruction is considered complete and the write completion response is to be returned to the originator. These bits are the Cache Bit (AWCACHE\_0) and the Coherent Bufferable Bit (AWCOBUF).

If the Cache Bit is set to 'b0, the setting for the Coherent Bufferable Bit is not relevant. The command is designated a Non-Bufferable Write Command, and the response will only be ready once the write data has been issued to the PHY via the DFI.

If the Cache Bit is set to 'b1 and the Coherent Bufferable Bit is set to 'b0, the command is designated a Standard Bufferable Write Command. The response will be ready when the write command is received and all the associated write data is received in the Write FIFO. There is no guarantee of data coherency across all of the AXI ports. If data coherency is not required across the ports, this setting will provide the fastest response time for bufferable write requests.

If both the Cache Bit and the Coherent Bufferable Bit are set to 'b1, the command is designated a Coherent Bufferable Write Command. The response will be ready when the command has been accepted into the Command Queue of the Controller Core and all the associated write data is received in the Write FIFO. This guarantees data coherency across all of the AXI ports, but reduces the overall write response latency relative to the non-bufferable option.

#### **10.1.6.2.13 Exclusive Access Option**

The exclusive access feature allows a master to monitor if a memory area has been altered since it was last read by that master. Exclusive access does not imply that the memory area is locked; other AXI IDs of that port, or the other port, may access the area for reads or writes even though an exclusive access exists. If any writes occur to a memory area with a valid exclusive access request, the master will lose exclusivity and be informed of this status when it attempts to write to the area again. A loss of exclusivity does not trigger an immediate interrupt or any error conditions. If an exclusive write fails

its exclusivity check, the AXI protocol only requires that the write data is not written to memory before the master determines how to proceed. The master that lost exclusivity may determine to either restart the sequence by requesting another exclusive read, or to write the data to the memory without an exclusive write.

### 10.1.6.3 Multi-Port Arbiter

The Arbiter is responsible for arbitrating requests from the ports and sending requests to the MC core. Each transaction received at the Arbiter logic has an associated priority, which works with each port's arbitration logic to determine how ports issue requests to the MC core. This Memory Controller supports the Weighted Round-Robin arbitration scheme. The Arbiter logic routes read data from the MC core to the appropriate port. The requesting port is assumed able to receive the data. Write data from each port is connected directly to its own write data interface in the MC core, allowing the ports to independently pass write data to the MC core buffers.

#### 10.1.6.3.1 Arbitration Overview

The weighted round-robin arbitration scheme is a three-step arbitration system. All commands are routed into priority groups based on the priority of the requests. Then, within each priority group, requests are serviced according to the "weight" (relative priority) of each port. Finally, each priority group presents a single command to the priority select module, which passes the highest priority command on to the MC core. This arbitration scheme also supports two additional features. For situations where the priority and the relative priority for multiple commands are identical, a port ordering system is included whereby the user may adjust the order in which the ports are considered. Secondly, for situations where two ports may be related, a mechanism is included which allows a pair of ports to share arbitration bandwidth for bandwidth efficiency. Weighted round-robin arbitration is a complex arbitration scheme. To understand the operation, each concept must be first understood individually.

[Understanding Round-Robin Operation](#) through [Understanding Port Ordering](#) describe the various components of weighted round-robin arbitration. Note that the examples may utilize a greater number of ports and a larger number of priority levels than are available in this Memory Controller. This is done intentionally for explanation.

#### 10.1.6.3.2 Understanding Round-Robin Operation

Round-robin operation is the simplest form of arbitration and is ideal for systems that do not require requests to be treated preferentially to maintain bandwidth or minimize latency. This scheme uses a counter that rotates through the port numbers, incrementing every time a port request is granted. If the port that the counter is referencing has an

active request, and the MC core command queue is not full, then this request will be sent to the MC core. If there is not an active request for that port, then the port will be skipped and the next port will be checked. The counter will increment by one whenever any request has been processed, regardless of which port's request was arbitrated. Round-robin arbitration ensures that each port's requests can be successfully arbitrated into the MC core every N cycles, where N is the number of ports in the Memory Controller. No port will ever be locked out, and any port can have its requests serviced on every cycle as long as all other ports are quiet and the command queue is not full. An example of the round-robin scheme is shown in the following table. Cycles 0, 2 and 6 show the system behavior when the command queue is full. Cycle 8 and 11 show the system behavior when the port addressed by the arbitration counter does not have an active request. In particular, note cycle 11: The port addressed by the arbitration counter (0) is not requesting, so the counter scans through the other ports, in incrementing order, to find an active request. Port 2 is requesting and therefore wins arbitration, but the counter only increments to port 1 which was the next port in the sequence. All other cycles show normal behavior.

**Table 10-10. Round-Robin Operation Example**

Cycle	Port Addressed by the Arbitration Counter	Ports Requesting				Command Queue Full?	Arbitration Winner	Value of Counter at Next Cycle
		P0	P1	P2	P3			
0	0	Y	Y	Y	Y	Yes	None	0
1	0	Y	Y	Y	Y	No	P0	1
2	1		Y	Y	Y	Yes	None	1
3	1	Y	Y	Y	Y	No	P1	2
4	2	Y		Y	Y	No	P2	3
5	3	Y			Y	No	P3	0
6	0	Y		Y		Yes	None	0
7	0	Y		Y		No	P0	1
8	1			Y		No	P2	2
9	2			Y	Y	No	P2	3
10	3	Y			Y	No	P3	0
11	0			Y		No	P2	1

### 10.1.6.3.3 Understanding Port Priority

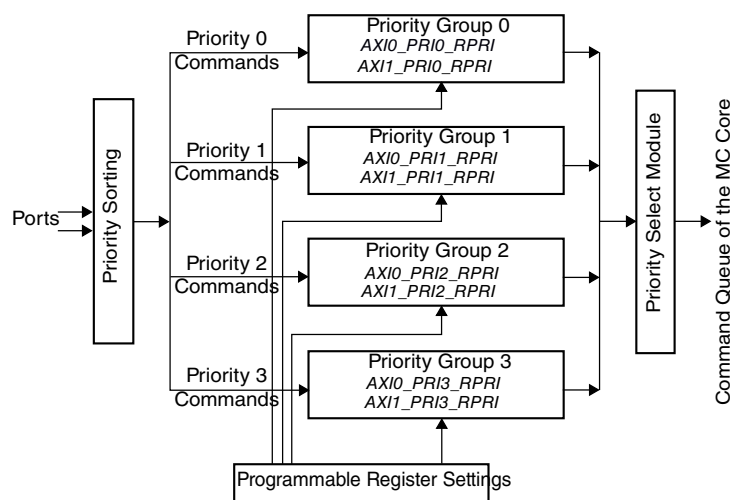

For AXI ports, the priority is associated with a port and each port has separate priority parameter for reads and writes. These values are stored into the programmable bits *axiY\_r\_pri* and *axiY\_w\_pri* (where Y represents the port number) at controller initialization. Internally, the ports are organized into priority groups based on their priority setting. The priority value is also used by the placement logic inside the MC core

when filling the command queue. A priority value of 0 is highest priority, and a priority value of (decimal) 3 is the lowest priority in the Memory Controller. The user may program at priority level 0; however, it is best to reserve this priority value so that the placement queue can elevate to this level through aging.

#### 10.1.6.3.4 Understanding Relative Priority

Inside each priority group, the relative priority is used to determine arbitration. The Memory Controller contains 4 identical priority groups with logic that selects between the requests from all commands at that priority level. The relative priority parameters *axiY\_priZ\_rpri* (where Y is the port number and Z is the priority group) "weight" the ports for each level and determine how the priority group will be arbitrated. The following figure shows this type of arbitration system.

**Figure 10-3. Weighted Round-Robin Priority Group Structure**

By using the relative priority concept, the arbitration is skewed in favor of certain ports based on user programming. Note that the relative priority bits have a minimum acceptable value of 1 to prevent port lockout. A '0' value will cause an error condition.

If the relative priorities are all programmed to the same value within any priority group, then the arbitration will mimic a version of simple round-robin scheme within that priority group. Instead of incrementing whenever any request is processed, the simple round-robin counter will only increment to the next port after the value in the *axiY\_priZ\_rpri* bits number of requests are processed.

Each port Y for priority level Z will be allocated the ratio of that port's relative priority bits (*axiY\_priZ\_rpri*) to the sum of all requesting port's relative priority values. If a particular port is not requesting, then it is not included in the sum calculation, which means that the arbitration will be split with relative proportions among the requesting ports.

As an example, consider a system with 4 ports where all requests are at priority 0. This system is described in the following table.

**Table 10-11. Relative Priority Example**

Memory Controller bits	System A
AXI0_PRI0_RPRI	1
AXI1_PRI0_RPRI	2
AXI2_PRI0_RPRI	3
AXI3_PRI0_RPRI	4

For this system, port 0 will be serviced  $1/(1+2+3+4) = 1/10$  of the time and Port 3 will be serviced  $4/(1+2+3+4) = 4/10$  of the time. However, if Port 2 is not actively requesting, then port 0 will be serviced  $1/(1+2+4) = 1/7$  of the time and port 3 will be serviced  $4/(1+2+4) = 4/7$  of the time.

In order to ensure that relative priorities are maintained, there is a weight counter for each port within each priority group. These counters track the number of transactions accepted for that port in that priority group. When any counter value reaches the programmed relative port priority, the scan order for that priority group will be internally modified. The port that has met its relative priority will be dynamically positioned to the bottom of the scan order (and its counter will be reset), allowing other ports a preferential position.

For ports that are not expected to issue requests at a certain priority level, the associated relative priority parameter should be programmed to 0x1. This allows for minimum allocation without the risk of lock out in case a command appears.

#### 10.1.6.3.5 Understanding Port Ordering

With simple round-robin arbitration, the ports are scanned based on their port number in incrementing order in the system. Assuming that the command queue is not full, the port referenced by the counter is examined for valid incoming transactions. If there is an active request, it will be accepted. Otherwise, the next port in the scan order will be checked, and its request accepted. For the Memory Controller with weighted round-robin arbitration, the user has the option of adjusting the order that the ports are scanned. This is useful if requests from certain ports are more critical, or if a specific order may reduce contention between ports. The *axiY\_p\_odr* bits are used to set this new scan order. A value of 'b0 gives the highest listing in the scan order, and a value of 'b1 is the lowest listing in the scan order. If the 2 *axiY\_p\_odr* bits are programmed with unique values, then the scan order will be modified to proceed sequentially in this new order. If any of the port ordering parameters have the same value, then those ports will still be equal in the arbitration test. In this case, the port number will select between these ports, with the lower-numbered port automatically being selected first. To demonstrate this concept, consider a system with 8 ports and the two port orders as shown in the following table.

For System B, the port ordering bits all contain unique values, so the resulting order is entirely based on the values of the parameters. For System C, three ports have the same programmed values for the port order. For these three ports, the port number sets the order. Remaining ports follow the port ordering parameters. If all of the port ordering bits are programmed with the same value, then the scan order will default to the numbered port order.

**Table 10-12. Port Ordering Example**

Memory Controller Parameter	System B	System C
<i>axi0_p_odr</i>	3	3
<i>axi1_p_odr</i>	4	0
<i>axi2_p_odr</i>	5	5
<i>axi3_p_odr</i>	6	6
<i>axi4_p_odr</i>	7	7
<i>axi5_p_odr</i>	0	1
<i>axi6_p_odr</i>	2	0
<i>axi7_p_odr</i>	1	0
Port Scan Order	P5-P7-P6-P0-P1-P2-P3-P4	P1-P6-P7-P5-P0-P2-P3-P4

### 10.1.6.3.6 Weighted Round-Robin Arbitration Summary

The MC weighted round-robin arbitration system combines the concepts of round-robin operation, priority, relative priority and port ordering. The incoming commands are separated into priority groups based on the priority of the associated port for that type of command. Within each priority group, the relative priority values are examined to determine the arbitration winner. If the relative priority values are identical and no individual command can be selected, then the scan order is used to select between the requests. In the end, the highest priority command, from the highest relative priority port, with the highest location in the scan order will be selected and sent to the MC core. As an example, consider the system described in [Table 10-13](#). The counters refer to the counters that exist for each port within each priority group to ensure that relative priorities are maintained. For simplification, the command queue is considered to never be full and commands are only received at priority level 0. The behavior is shown in [Table 10-14](#). The highest port in the scan order that is requesting always wins arbitration, and the scan order is dynamically modified when any port counter reaches its allocated relative priority value. Note that if the command queue was considered, then cycles where the command queue was full would not have any arbitration winner and therefore, the counter values and scan order would not change on that cycle.

**Table 10-13. System D Specification**

Memory Controller Parameter	Port 0	Port 1	Port 2	Port 3
AXIY_PRI0_RPRI	4	3	2	1
AXIY_P_ODR	0	1	2	3

**Table 10-14. System D Operation**

Cycle	Ports Requesting				Arbitration Winner	Next Counter				Next Scan Order
	P0	P1	P2	P3		P0	P1	P2	P3	
										P0-P1-P2-P3
0	Y			Y	P0	1	0	0	0	P0-P1-P2-P3
1	Y		Y	Y	P0	2	0	0	0	P0-P1-P2-P3
2	Y	Y	Y	Y	P0	3	0	0	0	P0-P1-P2-P3
3	Y	Y	Y	Y	P0	4	0	0	0	P1-P2-P3-P0
4	Y	Y	Y	Y	P1	0	1	0	0	P1-P2-P3-P0
5	Y	Y	Y	Y	P1	0	2	0	0	P1-P2-P3-P0
6	Y	Y	Y	Y	P1	0	3	0	0	P2-P3-P0-P1
7	Y		Y	Y	P2	0	0	1	0	P2-P3-P0-P1
8	Y		Y	Y	P2	0	0	2	0	P3-P0-P1-P2
9	Y			Y	P3	0	0	0	1	P0-P1-P2-P3
10	Y		Y	Y	P0	1	0	0	0	P0-P1-P2-P3
11			Y	Y	P2	1	0	1	0	P0-P1-P2-P3
12			Y	Y	P2	1	0	2	0	P0-P1-P3-P2

If the same system also contains two ports that only request at priority level 1, then the system behavior will be slightly altered. The addition of these 2 ports creates the second priority group structure that adds to the arbitration complexity. [Table 10-15](#) describes this system. Again, for simplification, the command queue is considered to never be full and it is assumed that commands from ports 0, 1, 2 and 3 are only received at priority level 0. The behavior is shown in [Table 10-16](#). Note that if any of the priority 0 ports (P0, P1, P2, P3) are requesting, the system behavior will match the behavior when there is only one priority group, as in [Table 10-14](#). Ports 4 and 5 can only win arbitration when no higher-priority commands exist.

**Table 10-15. System E Specification**

Memory Controller bits	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5
AXIY_PRI0_RPRI	4	3	2	1	1	1
AXIY_PRI1_RPRI	1	1	1	1	3	2
AXIY_P_ODR	0	1	2	3	4	5

Table 10-16. System E Operation

Cycle	Ports Requesting						Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5		P0	P1	P2	P3	P4	P5	
														Priority 0: P0-P1-P2-P3 Priority 1: P4-P5
0			Y			Y	P2	0	0	1	0	0	0	P0-P1-P2-P3 P4-P5
1	Y		Y			Y	P0	1	0	1	0	0	0	P0-P1-P2-P3 P4-P5
2			Y			Y	P2	1	0	2	0	0	0	P0-P1-P3-P2 P4-P5
3	Y		Y		Y	Y	P0	2	0	0	0	0	0	P0-P1-P3-P2 P4-P5
4			Y		Y	Y	P2	2	0	1	0	0	0	P0-P1-P3-P2 P4-P5
5					Y	Y	P4	2	0	1	0	1	0	P0-P1-P3-P2 P4-P5
6		Y			Y	Y	P1	2	1	1	0	1	0	P0-P1-P3-P2 P4-P5
7					Y	Y	P4	2	1	1	0	2	0	P0-P1-P3-P2 P4-P5
8					Y	Y	P4	2	1	1	0	3	0	P0-P1-P3-P2 P5-P4
9					Y	Y	P5	2	1	1	0	0	1	P0-P1-P3-P2 P5-P4
10					Y		P4	2	0	1	0	1	1	P0-P1-P3-P2 P5-P4

### 10.1.6.3.7 Priority Relaxing

From [Table 10-16](#), it is evident that ports at lower priority levels will not win arbitration in weighted round-robin arbitration unless there are no higher priority requests. This could mean that, in a situation where high priority requests are being received continuously, lower priority requests could be locked out indefinitely. To avoid this scenario and control the arbitration latency for lower-priority commands, it is possible to disable priority groups temporarily. This is known as priority relaxing, and it is a time-controlled function. Each higher priority group will be temporarily disabled when the pre-set counter value for the lower priority group has been reached and a request is

waiting. The *axiY\_prirlx* bits set the counter value for port Y at which the priority relax condition will be triggered. The timing counters inside each port are controlled by the CR119[WRR\_LATCTL]. When the latency control bit is set to 'b1, the timing counters are free-running. Any timing counter may hit its *axiY\_prirlx* bits value at any point. When this occurs, higher-priority groups are disabled to allow a waiting request for this port to be processed. This results in a random latency for each port, but the maximum latency is fixed at the *axiY\_prirlx* bits value. If the current port does not have any commands waiting when the timing counter hits the relax value, then the counter will be reset and the Arbiter will function normally. When the WRR\_LATCTL bit is cleared to 'b0, the timing counters only count while that port has a waiting request that is not being processed. In this case, when the port's *axiY\_prirlx* bits value is reached, all priority groups at priority levels higher than the waiting request are disabled. This port's command is granted arbitration and is moved through to the MC core. Since the priority relax parameters and counters are associated with individual ports, it is possible that multiple priority relax counters could reach their specified value simultaneously. In this case, the lower priority command will be arbitrated first and then the higher priority command. This situation could alter the arbitration latency slightly, causing it to be longer than the expected value in the priority relax parameter. Consider the System F as described in [Table 10-17](#). The same conditions apply as for the previous example. The command queue is considered to never be full, commands from ports 0, 1, 2 and 3 are only received at priority level 0, and commands from ports 4 and 5 are only received at priority 1.

**Table 10-17. System F Specification**

Memory Controller bits	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5
AXIY_PRI0_RPRI	4	3	2	1	1	1
AXIY_PRI1_RPRI	1	1	1	1	2	1
AXIY_P_ODR	0	1	2	3	4	5

[Table 10-18](#) shows the system behavior. The exact settings of the latency control and priority relax parameters are not shown. Instead, the "Relaxed Ports" column indicates which, if any, ports have hit their priority relax values. The following cycles are important to observe:

- Cycles 1 and 7: A port relaxes while a higher priority request and a higher scan order request are both present. The relaxed port still wins arbitration.
- Cycle 4: Two ports of the same priority relax. The higher scan order request wins arbitration.
- Cycle 5: Two ports of different priorities relax.

The lower priority port that relaxed wins arbitration. The higher priority port that relaxed will maintain its relax condition, and win arbitration in the next cycle.

**Table 10-18. System F Operation with Priority Relaxing**

Cycle	Ports Requesting						Relaxed Ports	Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5			P0	P1	P2	P3	P4	P5	
															Priority 0: P0-P1-P2-P3 Priority 1: P5-P4
0			Y		Y	Y		P2	0	0	1	0	0	0	P0-P1-P2-P3 P5-P4
1			Y		Y	Y	P5	P5	0	0	1	0	0	1	P0-P1-P2-P3 P4-P5
2			Y		Y	Y		P2	0	0	2	0	0	0	P0-P1-P3-P2 P4-P5
3		Y			Y	Y		P1	0	1	0	0	0	0	P0-P1-P3-P2 P4-P5
4	Y				Y	Y	P4,P5	P4	0	1	0	0	1	0	P0-P1-P3-P2 P4-P5
5	Y				Y	Y	P0,P5	P5	0	1	0	0	1	1	P0-P1-P3-P2 P4-P5
6	Y				Y		P0	P0	1	1	0	0	1	0	P0-P1-P3-P2 P4-P5
7	Y				Y	Y	P4	P4	1	1	0	0	2	0	P0-P1-P3-P2 P5-P4
8	Y	Y	Y			Y		P0	2	1	0	0	0	0	P0-P1-P3-P2 P5-P4
9		Y	Y	Y		Y		P1	2	2	0	0	0	0	P0-P1-P3-P2 P5-P4
10		Y	Y	Y		Y	P2	P2	2	2	1	0	0	0	P0-P1-P3-P2 P5-P4

Priority relaxing allows low priority commands to be able to move through the Arbiter to the MC core. This will ensure that the system can meet maximum latency requirements.

### 10.1.6.3.8 Port Pairing

The Memory Controller Arbiter incorporates a feature which allows adjacent ports to be grouped together and considered jointly for arbitration. The CR120[W\_RR\_WSHR] controls this function, with 1 bit per pair of ports in the Memory Controller. Bit 0 controls ports 0 and 1, Bit 1 controls ports 2 and 3, etc. If the Memory Controller interfaces to an odd number of ports, the highest numbered port is excluded from the port pairing system. Since the ports are grouped together, their relative priorities are not considered separately. Referring to [Understanding Relative Priority](#), the general formula for port priority allocation is the ratio of that port's relative priority bits (AXIY\_PRIYZ\_RELPRI) to the sum of all requesting port's relative priority values. In this case, the relative priority value of only one of the paired ports is used for the sum calculation. This means that the bandwidth will be divided differently among the ports. If the port pair is at the top of the scan order, and either of the ports is requesting, then the requesting port will win arbitration. If both are requesting, port ordering is used to determine which port wins arbitration. Note that when the ports are paired, their scan order can never be altered and they will always remain together in the scan order. Their counters increment together, and so when they reach their relative priority value, the port pair will dynamically be placed at the bottom of the scan order for that priority group.

In order for port weight sharing to be used, the relative priority parameters for the port pair must be programmed to the same value and the port order of the paired ports should be sequential. If either condition is not followed, an error bit will be set to 'b1.

Consider System G as described in [Table 10-19](#). Again, for simplification, the command queue is considered to never be full, commands from ports 0, 1, 2 and 3 are only received at priority level 0 and commands from ports 4 and 5 are always at priority 1. However, now ports 0 and 1 and ports 4 and 5 are paired.

**Table 10-19. System G Specifications**

Memory Controller bits	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5
AXIY_PRI0_RELPRI	4	3	2	1	1	1
AXIY_PRI1_RELPRI	1	1	1	1	2	1
AXIY_P_ODR	0	1	2	3	4	5
W_RR_WSHR	1 (Paired)		0 (Not Paired)		1 (Paired)	

[Table 10-20](#) shows the system behavior with port pairing. Since ports 4 and 5 are still at a lower priority, they will be ignored unless none of the higher priority ports (P0, P1, P2 or P3) are requesting. Note the following points:

- When either port of a port pair wins arbitration, the counters for both ports of the pair increment.
- In Cycle 3, the port pair P0/P1 reaches its allocated relative priority. Note that the port pair dynamically moves to the bottom of the scan order.
- In Cycle 8, the port pair P4/P5 reaches its allocated relative priority. However, since these are the only requests at priority 1, the scan order does not change.

**Table 10-20. System G Operation**

Cycle	Ports Requesting						Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5		P0	P1	P2	P3	P4	P5	
														Priority 0: P0-P1-P2-P3 Priority 1: P5-P4
0	Y		Y				P0	1	1	0	0	0	0	P0-P1-P2-P3 P5-P4
1	Y		Y			Y	P0	2	2	0	0	0	0	P0-P1-P2-P3 P5-P4
2			Y			Y	P2	2	2	1	0	0	0	P0-P1-P2-P3 P5-P4
3	Y	Y		Y		Y	P0	3	3	1	0	0	0	P2-P3-P0-P1 P5-P4
4		Y		Y		Y	P3	0	0	1	1	0	0	P2-P3-P0-P1 P5-P4
5		Y		Y		Y	P3	0	0	1	2	0	0	P2-P0-P1-P3 P5-P4
6		Y				Y	P1	1	1	1	0	0	0	P2-P0-P1-P3 P5-P4
7						Y	P5	1	1	1	0	1	1	P2-P0-P1-P3 P5-P4
8					Y		P4	1	1	1	0	2	2	P2-P0-P1-P3 P5-P4
9					Y	Y	P5	1	1	1	0	1	1	P2-P0-P1-P3 P5-P4
10		Y	Y		Y	Y	P2	1	1	2	0	1	1	P0-P1-P3-P2 P5-P4
11		Y			Y	Y	P1	2	2	0	0	1	1	P0-P1-P3-P2 P5-P4

### 10.1.6.3.9 Error Conditions

With the programming complexities of the weighted round-robin arbitration scheme, an error reporting mechanism is included to notify users of illegal programming scenarios. These error conditions will each set a bit in the CR120[WRR\_ERR] to 'b1. The potential error conditions are:

- Bit 0 = The 2 *axiY\_p\_odr* bits do not all contain unique values.
- Bit 1 = Any of the *axiY\_priz\_relpri* bits have been programmed with a zero value. A 0 value leads to unknown behavior. The minimum allowable value is 1.
- Bit 2 = Any ports, whose related bit of the CR120[W\_RR\_WSHR] is set to 'b1, do not have the same values in their *axiY\_priz\_relpri* bits.
- Bit 3 = For ports whose related bit of the W\_RR\_WSHR bit is set to 'b1, the values of the *axiY\_p\_odr* bits are not sequential.

If bit 0, 2 or 3 is set to 'b1 in the WRR\_ERR, and any of the ports are paired in the W\_RR\_WSHR, then all weight sharing data will be ignored during Memory Controller initialization and the ports will be prioritized by port number. If port pairing is not being used, but the bit 0 error condition is set to 'b1, then ports with a non-unique port ordering are prioritized by port number.

#### Note

The user is strongly cautioned against modifying the values of the port ordering or relative priority parameters during active port usage.

### 10.1.6.3.10 Programmable Options for Weighted Round Robin Arbitration

The Memory Controller's weighted round-robin arbitration scheme provides a great deal of programmable control for the user. The parameters are referenced throughout this chapter and are summarized here for clarity:

- *axiY\_r\_pri* (DDR117[AXI0\_R\_PRI] and DDR118[AXI1\_R\_PRI])
- *axiY\_w\_pri* (DDR117[AXI0\_W\_PRI] and DDR118[AXI1\_W\_PRI])
- *axiY\_priz\_relpri* ((DDR120[AXI0\_PRI1\_RPRI], DDR120[AXI0\_PRI0\_RPRI], DDR121[AXI0\_PRI3\_RPRI], DDR121[AXI0\_PRI2\_RPRI], DDR122[AXI1\_PRI1\_RPRI], DDR122[AXI1\_PRI0\_RPRI], DDR123[AXI1\_PRI3\_RPRI] and DDR123[AXI1\_PRI2\_RPRI])
- *axiY\_p\_odr* (DDR121[AXI0\_P\_ODR] and DDR123[AXI1\_P\_ODR])

- *axiY\_prirlx* (DDR122[AXI0\_PRIRLX] and DDR124[AXI1\_PRIRLX])
- DDR119[WRR\_LATCTL]
- DDR120[W\_RR\_WSHR]
- DDR120[WRR\_ERR]

### 10.1.6.4 Core Command Queue with Placement Logic

The MC core contains a command queue that accepts commands from the Arbiter. This command queue uses a placement algorithm to determine the order that commands will be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at the time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. In addition, the placement logic attempts to maximize efficiency of the MC core through command grouping, write-to-read splitting and bank splitting. Many of the rules used in placement may be individually enabled/disabled. In addition, the command queue may be disabled by clearing the CR75[PLEN] bit, resulting in an in-line queue that services requests in the order they are received. If the CR75[PLEN] is cleared to 'b0 and the CR79[INODR\_ACT] is set to 'b1, the placement algorithm will be ignored.

#### 10.1.6.4.1 Rules of the Placement Algorithm

The factors affecting command placement all work together to identify where a new command fits into the execution order. They are listed in order of importance.

##### 10.1.6.4.1.1 Address Collision/Data Coherency Violation

The order in which read and write commands are processed in the memory controller is critical to proper system behavior. While reads and writes to different addresses are independent and may be re-ordered without affecting system performance, reads and writes that access the same address are significantly related. If the port requests a read after a write to the same address, then repositioning the read before the write would return the original data, not the changed data. Similarly, if the read was requested ahead of the write but accidentally positioned after the write, then the read would return the new data, not the original data prior to being overwritten. These are significant data coherency mistakes.

To avoid address collisions, reads or writes that access the same chip select, bank and row as a command already in the command queue will be inserted into the command queue after the original command, even if the new command is of a higher priority. This rule is ignored when comparing a new read command to an existing read. Even if an address collision occurs between these reads, there is no data integrity issue and the data may be returned in any order.

This factor may be enabled/disabled through the CR74[ADDR\_CMP\_EN] and should only be disabled if the system can guarantee coherency of reads and writes.

#### 10.1.6.4.2 Source ID Collision

Each port is assigned a specific source ID that is a combination of the port and thread ID information, and identifies the source uniquely. This allows the memory controller to map data from/ to the correct source/destination.

Note that a source ID does contain port identification information which means that the rules for placement are dependent on the requesting port. There will not be source ID collisions between ports.

In general, read commands from the same source ID will be placed in the command queue in order. Therefore, a read command with the same source ID as a read command already in the command queue will be processed after the original read command. All write commands from a port, even with different source IDs, will be executed in order.

The behavior of commands of different types from the same source ID is dependent on the user configuration. For this Memory Controller, the placement of new read/write commands that collide in terms of source ID with existing entries in the command queue will only depend on other commands of the same type, not on different types. This means that, if there are no address conflicts, a read command could be executed ahead of a write command with the same source ID, and likewise a write command could be executed ahead of a read command with the same source ID.

This feature will always be enabled.

#### 10.1.6.4.3 Priority

Priorities are used to distinguish important commands from less important commands. Each command is given a priority based on the command type through the programmable bits AXIx\_R\_PRI and AXIx\_W\_PRI in registers CR117 and CR118.

The placement algorithm will attempt to place higher priority commands ahead of lower priority commands, as long as they have no source ID or address collisions. Higher priority commands will be placed lower in the command queue if they access the same address, are from the same requestor or use the same buffer as lower priority commands already in the command queue.

This feature is enabled through the CR75[PRI\_EN].

#### **10.1.6.4.4 Bank Splitting**

Before accesses can be made to two different rows within the same bank, the first active row must be closed (pre-charged) and the new row must be opened (activated). Both activities require some timing overhead; therefore, for optimization, the placement logic will attempt to insert the new command into the command queue such that commands to other banks may execute during this timing overhead. The placement of the new commands will still follow priority, source ID and address collision rules.

This feature is enabled through the CR74[BANKSPLT\_EN].

#### **10.1.6.4.5 Write-to-Read Splitting**

When a read command follows a write command to the same chip select, there is some timing overhead to switch command types. For optimization, the placement logic will attempt to insert the new command into the command queue to separate two commands addressing the same chip select of different types where the write is going to execute before the read. The placement of the new commands will still follow priority, source ID and address collision rules. This feature is enabled through the CR76[W2R\_SPLT\_EN].

#### **10.1.6.4.6 Read/Write Grouping**

The memory suffers a small timing overhead when switching from read to write mode. For efficiency, the placement logic will attempt to place a new read command sequentially with other read commands in the command queue, or a new write command sequentially with other write commands in the command queue. Grouping will only be possible if no priority, source ID or address collision rules are violated. This feature is enabled through the CR75[RW\_EN].

#### 10.1.6.4.6.1 Bank Conflicts and Read/Write Grouping

If the new command addresses the same chip select and same bank, but a different row, as a command currently in the command queue, these commands are considered to have a bank conflict. As described in [Bank Splitting](#), the placement logic will attempt to separate commands with bank conflicts. For this memory controller, certain placements are prohibited for read/write grouping to support ideal bank splitting.

These checks are controlled through the CR76[D\_RW\_G\_BKCN]. If bit [0] of this parameter is set to 'b1, a new command will be prohibited from placement in the entry directly before or directly after the command with a bank conflict. If bit [1] of this parameter is also set to 'b1, the new command will also be prohibited from being placed two entries before or two entries after the command with a bank conflict. The following table shows a simplified command queue.

**Table 10-21. Simple Command Queue Example**

PQ Entry	Read/write	Bank	Row
0	Rd	0	0
1	Rd	0	0
2	Rd	0	0
3	Rd	1	0
4	Rd	0	0
5	Rd	0	0

For this example, a new entry is received that is a READ to BANK 1, Row 1. Assume that no priority, source ID or address collision rules are violated. This new command would have a bank conflict with PQ Entry 3.

- If D\_RW\_G\_BKCN [0] = 'b1, the new command could not be placed immediately before or after the conflicting command. If the command was placed into entry 3, entries 3-5 would be moved to entries 4-6, and the bank conflicts would occur between entries 3 and 4. If the command was placed into entry 4, entries 4-5 would be moved to entries 5-6 and the bank conflict would still occur between entries 3 and 4. Therefore, entries 3 and 4 are prohibited for placement.
- If D\_RW\_G\_BKCN [1] = 'b1, the new command could not be placed two entries before or two entries after the conflicting command. If the command was placed into entry 2, entries 2-5 would move to entries 3-6, and the bank conflict would occur between

entries 2 and 4. If the command was placed into entry 5, the bank conflict would occur with between entries 3 and 5. Therefore, entries 2 and 5 are also prohibited for placement.

- Therefore, if the D\_RW\_G\_BKCN bit was set to 'b11, the new entry could only be placed at entry 0, 1 or 6, allowing at least 2 commands in between the conflicting commands.

### Note

It is not meaningful to set bit [1] of the CR76[D\_RW\_G\_BKCN] without bit [0].

#### 10.1.6.4.6.2 Chip Select Grouping with Read/Write Grouping

When attempting to group read and write commands, the placement logic will also consider the chip select for the commands. If possible, read commands will be grouped with read commands to the same chip select, and write commands with write commands to the same chip select. If chip select grouping is not possible, commands will still be grouped by command type if the CR75[RW\_EN] is set to 'b1. If read/write grouping is disabled (CR75[RW\_EN] is cleared to 'b0), chip select grouping will have no effect. This feature is enabled through the CR76[CS\_EN].

#### 10.1.6.4.6.3 Page Grouping with Read/Write Grouping

When attempting to group read and write commands, the placement logic will also consider the page for the commands. If possible, read commands will be grouped with read commands to the same page, and write commands with write commands to the same page. If page grouping is not possible, commands will still be grouped by command type if the CR75[RW\_EN] is set to 'b1. If read/ write grouping is disabled (CR75[RW\_EN] is cleared to 'b0), page grouping will have no effect. This feature is enabled through the CR75[RW\_PG\_EN] parameter.

#### 10.1.6.4.7 Command Execution Order After Placement

Once a command has been placed in the command queue, selection logic will be used to determine how to pull commands from the queue for execution. This logic may be disabled by setting INODR\_ACT (DDRMCR79 bit [0]) to 'b1, resulting in the command queue executing the commands in the order that they are placed relatively in the command queue. If INODR\_ACT is cleared to 'b0, the selection logic will be utilized.

Regardless of the setting of this parameter, high-priority command swapping and command aging are provided which may affect commands after they have been placed into the command queue.

#### 10.1.6.4.7.1 Command Selection Logic

On each clock cycle, the selection logic will scan the top 4 entries of the command queue to determine which command to execute. This value is defined at configuration.

Commands are considered for execution based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing (JEDEC-specified and programmable) and conflicts. Similar to the placement rules, a command will not be executed before a command that was placed ahead of it in the command queue if there are any address, source ID or bank conflicts.

All placement rules mentioned in this chapter are followed by the selection logic other than priority. It is possible that lower priority commands may be executed ahead of higher priority commands if the higher priority commands are not ready to execute, provided that there are no conflicts with commands ahead in the command queue. The memory controller will also not execute a read/ modify/write sequence before another read/modify/write sequence ahead of it in the command queue due to limited storage in the core.

The selection feature is disabled through the CR79[INODR\_ACT] . If this bit is set to 'b1, only the top entry of the command queue will be considered for execution. The following figure shows the command selection logic relative to the rest of the placement logic.

**Figure 10-4. Selection logic**

#### 10.1.6.4.7.2 High-Priority Command Swapping

Commands are assigned priority values to ensure that critical commands are executed more quickly in the memory controller than less important commands. Therefore, it is desirable that high-priority commands pass into the MC core as soon as possible. The placement algorithm takes priority into account when determining the order of commands, but still allows a scenario in which a high-priority command sits waiting in

the command queue while another command, perhaps of a lower priority, is in process. The high-priority command swapping feature allows this new high-priority command to be executed more quickly. If the user has enabled the swapping function through the CR79[SWAP\_EN] parameter, then the behavior of the swapping logic will be dependent on the value of the CR79[INODR\_ACT]. If the command queue must be executed in order (INODR\_ACT = 'b1), the entry at the top of the command queue will be compared with the current command in progress. If the selection logic is being used (INODR\_ACT = 'b0), the top 4 entries of the command queue will be compared with the current command in progress to determine which command may need to be executed first. If the selected command queue entry is of a higher priority (not the same priority), from a different ID, and it does not have an address or source ID conflict with the current command being executed, then the original command will be interrupted. If the command is to be interrupted, it will be halted after completing the current burst, stored and placed at the top of the command queue, and the new command will begin executing. As long as the command queue is not full, new commands may continue to be inserted into the command queue based on the placement rules, even at the top of the queue ahead of the interrupted command. The selection logic will determine the command to execute next. Whenever the interrupted command is resumed, it will start from the point at which it was interrupted. Note that priority 0 commands will never be interrupted, so the user should set any commands that should not be interrupted to priority 0.

#### 10.1.6.4.7.3 Command Aging

Since commands can be inserted ahead of existing commands in the command queue, the situation could occur where a low priority command remains at the bottom of the queue indefinitely. To avoid such a lockout condition, aging counters have been included in the placement logic that measure the number of cycles that each command has been waiting. If an aging counter hits its maximum, the priority of the associated command will be decremented by one (lower priority commands are executed first). This increases the likelihood that this command will be picked by the selection logic and execute. Note that this command does not move relative positions in the command queue when it ages; the new priority will be considered when placing new commands into the command queue.

Aging is controlled through a master aging counter and command aging counters associated with each command in the command queue. The CR74[AGE\_CNT] and CR74[CMD\_AGE\_CNT] hold the initial values for each of these counters, respectively. When the master counter counts down the AGE\_CNT bit value, a signal is sent to the command aging counters to decrement. When the command aging counters have expired, the priority of the associated command is decremented and the counter is reset. Therefore, a command does not age by a priority level until the total elapsed cycles has reached the product of AGE\_CNT bit value + 1 and CMD\_AGE\_CNT bit value + 1. The

maximum number of cycles that any command can wait in the command queue until reaching the top priority level is the product of the AGE\_CNT bit value +1, the CMD\_AGE\_CNT bit value +1, and the number of priority levels in the system.

If command swapping is enabled, it is possible that a command in progress could be interrupted by a higher priority command in the command queue. This situation could arise if a new higher-priority command arrives and is placed while the current command is in progress, or by a command in the queue aging to a lower priority while the current command is in progress. An interrupted command will be placed at the top of the command queue.

This feature will always be enabled.

#### 10.1.6.4.8 ACT Request Control

The Memory Controller provides a means to limit which commands of the command queue may issue ACT requests. This can be used to prevent situations in which an ACT is issued for a command in the queue, and before that command can be executed, a new command is placed ahead of it which accesses the same bank but a different row. This would require a PRE-ACT sequence that may have been avoided if the first ACT was never issued.

This functionality is controlled through the CR76[NQENT\_ACTDIS], which specifies the number of entries of the command queue in which ACT requests are not allowed. For this 8-deep command queue, the entries are numbered 0-7, where entry 0 is the command next to execute.

**Table 10-22. Programming of the NQENT\_ACTDIS bits**

Value	Effect
0x0	ACT request can occur from entries 0-7
0x1	ACT request can occur from entries 0-6
0x2	ACT request can occur from entries 0-5
0x3	ACT request can occur from entries 0-4
0x4	ACT request can occur from entries 0-3
0x5	ACT request can occur from entries 0-2
0x6	ACT request can occur from entries 0-1
0x7	ACT request can occur from entries 0

### 10.1.6.5 ECC Options

Memory Controllers provide an optional error reporting and correcting circuitry that can be used to verify data in memory and correct memory errors if they occur. The logic will check for errors in both the data and the check code on all read transactions.

ECC, or error checking and correcting, is the process of detecting bit errors in the memory data and if possible, correcting them. This function can confirm the accuracy of data and remove or at least identify bit errors.

ECC works by storing unique "check codes" in memory. A check code is a mathematical description of the information in an aligned segment of memory known as an "ECC data word". The check code is always related to the entire ECC data word, and is used inside the Memory Controller on all memory reads to control data accuracy. Check codes are not input from, or output to, the user interface.

An ECC data word can not start and end at any random address; these words are memory aligned to their size. The starting addresses of ECC data words are defined as ECC word boundaries and the alignment of user transactions to these boundaries determines how transactions are processed inside the Memory Controller. If the user does not wish to use the ECC option, the ECC module may be disabled by setting the control bit CR57[CTRL\_RAW] to 'b10.

This Memory Controller supports a 32-bit ECC data word size. A 7-bit check code is maintained for each 32-bit memory area. ECC word boundaries fall on each 4-byte address (0xN0, 0xN4, 0xN8, 0xNc).

When ECC is used DRAM controller have to be reconfigured to 8-bit bus width in CR078. Data are transfered on lines [7:0] and ECC are on lines [9:8] then.

#### **Write operation:**

A write command to DDR controller may be processed as a simple write, or may trigger an internal read command before the write occurs. A read will be required if not all bytes of an ECC data word are being changed; this allows the controller knowledge of the entire ECC data word for accurate check code generation.

The ECC logic will initiate a RMW operation for narrow transactions . For example, if 8bit write access introduced towards memory ( which is not aligned with ECC-write-word boundary), this logic will activate the additional Read operation on full ECC- word-boundary and merge the read data with write bytes and will calculate the ECC on word boundary for updated/merged data.

#### **Read operation:**

A read command to the DDR controller will always result in reading complete ECC data words of information, and their associated check codes, from the DRAM memory. The check code is always related to the entire ECC data word, and is used inside the DDR controller on all memory reads to control data accuracy.

#### 10.1.6.5.1 Initialization of memory when using ECC

When using ECC, or error checking and correcting, additional steps are required to configure the memory and all ECC values after the controller has been initialized.

The entire memory region that will be used should be written once. This write is required so that a correct ECC tag can be written for each memory location. There are two recommended methods for performing this initialization.

- Using the DMA to initialize the memory.

The DMA controller is usually the most efficient means of writing the initial data and ECC values to the memory. The DMA should be configured to perform a 32-byte write to DDR destination addresses with the NBYTES field configured so that any memory locations that will be used by the system are initialized.

- Using the CPU to initialize the memory.

A CPU can also be used to write the initial data and ECC values to memory; however, when using a CPU to perform the writes the accesses can actually trigger ECC errors. To avoid this, set the DDRMC\_CR058[ECC\_DIS\_WCRER] bit, then perform the writes to set the initial values. After all of the memory locations have been initialized, the ECC\_DIS\_WCRER bit can be cleared.

#### 10.1.6.6 Low Power Operation

The Memory Controller provides various user-configurable low power options to address power savings.

There are seven low power states available in the Memory Controller and managed by the LPC module. The low power states are listed from least to most power saving.

##### Note

Transitions will only be made into deeper low power states. If the user requires to switch to a higher power state, the current state must be exited and then the new state entered.

## Note

Low power state transitions that may be completed without a low power exit will be performed when possible. The system will include low power exits if necessary when switching from one low power state to another. Low power modes entry exit is controlled through the register interface

### 1. Active Power-Down

The memory controller sets the memories into power-down while any row is active in the bank. This state reduces the overall power consumption of the system, but has the least effect of all the low power states. In this state, the memory controller and memory clocks are fully operational, but the CKE input bit to the memories is de-asserted. If entry into the "Active Power-Down" state was requested, the memory will enter either active or pre-charge power-down mode depending on the state of the rows. If there are no open rows, pre-charge power-down mode will be entered. If the CR34[LP\_REFEN] is set to 'b1, the memory controller will continue to monitor memory refresh needs and will automatically bring the memory out of power-down to perform these refreshes. When a refresh is required, the CKE input bit to the memories will be re-enabled. This action brings the memories out of power-down. Memory that has been transitioned into active power-down mode will automatically transition to pre-charge power-down mode after the memory controller performs a refresh since the refresh process includes a pre-charge all command.

### 2. Active Power-Down with Memory Clock Gating

The memory controller sets the memories into power-down while any row is active in the bank, and gates off the clock to the memories. Refreshes will be handled as in the "Active Power-Down" state, with the exception that gating on the memory clock will be removed before asserting the CKE pin. Memory that has been transitioned into active power-down mode will automatically transition to pre-charge power-down mode (with the clock gated) when the memory controller performs a refresh since the refresh process includes a pre-charge all command. Before the memories are removed from power-down, the clock will be gated on again.

This low power state is only valid for LPDDR2 memory. The user should not use this state for memories that do not support memory clock gating. Clock gating is not supported for standard DDR3 memories. When set into this state, the memory controller will attempt to place the memories in power-down and gate off the memory clock. The memory will function unpredictably and may hang.

### 3. Pre-Charge Power-Down

The memory controller sets the memories into power-down once all banks are idle. If any rows are active, prior to issuing the power-down mode command, the memory controller will issue a pre-charge all command. If the CR34[LP\_REFEN] is set to 'b1, the memory controller will continue to monitor memory refresh needs and will automatically bring the memory out of power-down to perform these refreshes. When a refresh is required, the CKE input bit to the memories will be re-enabled. This action brings the memories out of power-down. Once the refresh has been completed, the memories will be returned to pre-charge power-down mode following the de-assertion the CKE input bit. For DDR3, pre-charge power-down mode supports both fast and slow exit modes depending on how the memory mode registers are programmed. If the pre-charge power-down bit (MR0 [A12]) is cleared to 'b0 (slow exit), the timing parameter *txpdll\_fN* will define the exit time from this low power state to a read command. If the pre-charge power-down parameter is set to 'b1 (fast exit), the timing parameter *tpdex\_fN* will be used.

#### 4. Pre-Charge Power-Down with Memory Clock Gating

The memory controller sets the memories into power-down once all banks are idle, and gates off the clock to the memories. Refreshes will be handled as in the "Pre-Charge Power-Down" state, with the exception that gating on the memory clock will be removed before asserting the CKE pin. After the refresh has been completed, the memories will be returned to pre-charge power-down mode with the clock gated. Before the memories are removed from power-down, the clock will be gated on again. This low power state is only valid for LPDDR2 memory.

The user should not use this state for memories that do not support memory clock gating. Clock gating is not supported for standard DDR1, DDR2 or DDR3 memories. When set into this state, the memory controller will attempt to place the memories in power-down and gate off the memory clock. The memory will function unpredictably and may hang.

#### 5. Self-Refresh

The memory controller sets the memories into self-refresh mode. In this low power mode, the memory controller and memory clocks are fully operational and the CKE input bit to the memories is de-asserted. Since the memory automatically refreshes its contents, the memory controller does not need to send explicit refreshes to the memory.

#### 6. Self-Refresh with Memory Clock Gating

The memory controller sets the memories into self-refresh and gates off the clock to the memories. Before the memories are removed from self-refresh, the clock will be gated on again. This low power state is only valid for LPDDR2 memory.

## 7. Self-Refresh with Memory and Controller Clock Gating

This is the deepest low power state of the memory controller. The memory controller sets the memories into self-refresh and gates off the clock to the memories. In addition, the clock to the memory controller will be gated off.

Before the memories are removed from self-refresh, the memory controller and memory clocks will be gated on. If automatic exit from this state is enabled, a new transaction that addresses a memory device in this state will wake up the memory to process the transaction. This low power state is only valid for LPDDR2 memory.

### Note

This state should not be entered when a read or write command is being processed. The user should ensure that the controller is idle before requesting entry into this state by checking the CR79[CTLBUSY].

### Note

When the controller clock is gated through the low power control module, writes to any of the programmable command parameters - parameters that result in command execution within the controller - will be ignored and not result in execution of the associated commands. Any commands issued while the controller clock is gated may or may not be executed once the controller clock is un-gated. In general, command registers should not be programmed during controller clock gating as the commands will have undefined results.

### 10.1.6.6.1 Automatic Interface

There are seven low power states available in the Memory Controller, which are managed by the Low Power Controller (LPC) module. The LPC module functions as the state control machine within the MC.

The LPC module supports automatic entry into each of the low power states based on programmable enables and idle state monitors. Each low power state has a separate enable bit and counter. As with the external pin interface and software programmable interface, the automatic interface must win arbitration of the LPC module to issue requests. The automatic interface has the lowest priority for arbitration.

When the memory controller is idle, each of the seven timing counters that are enabled begin counting down the cycles of inactivity. Idle time requires that no read or write commands are executing or pending in the memory controller core command queue or

any of the ports. For the power-down states, idle time begins when no commands are waiting to be sent to memory. For the self-refresh states, idle time begins only after all the read data for outstanding read commands has been retrieved; this restriction ensures that all read data is received even if the automatic request includes gating off the memory controller clock.

#### 10.1.6.6.1.1 Automatic Entry

If any of the counters expire, the automatic interface will request arbitration. The timing counters are initially loaded with the values in the associated parameters, and will only decrement if the associated CR36[LPAUTO] parameter bit is set to 'b1 and the counters are loaded with a non-zero value. If no other interface has control of the LPC module (CR35[LP\_ARBST] = 'b00 or 'b11), the automatic interface will win arbitration and the specified low power state will be compared to the current state of the memories. If the memory is already in a low power state, and the expired counter is associated with a deeper low power state than the current state, the LPC module will trigger an entry into the new low power state. If the expired counter is associated with a higher power usage state, the counter expiration will be ignored.

If a counter expires while the LPC module is being controlled by the external pin interface or the software programmable interface, the automatic request will remain pending until the arbiter returns to idle (LP\_ARBST = 'b00) and the automatic interface is granted control of the LPC module. A pending request will also be cancelled if a read or write command enters the Memory Controller core command queue, resetting the automatic counters to the programmed values.

Multiple automatic low power idle counters may expire at the same time. When this happens, the counter associated with the deepest low power state will be entered. No state change will occur if current low power state is deeper than the states associated with any of the expired counters.

#### 10.1.6.6.1.2 Automatic Exit

The automatic interface also supports automatic exit from a low power state if the system requires, with separate enable bits for each low power state. During an automatic exit, all of the idle counters are reset to their programmed values and the memories are returned to normal operation. When a new read or write command enters the memory controller command queue, if the current low power state's associated CR36[LP\_AEXEN] is set to 'b1, the automatic interface will request arbitration. If no other interface has control of the

LPC module (CR35[LP\_ARBST] = 'b00 or 'b11), the automatic interface will win arbitration and a low power exit will be triggered. If the current state is not enabled for automatic exit in the CR36[LP\_AEXEN], the LPC module will not exit low power.

If the LPC module is being controlled by the external pin interface or the software programmable interface when the new read or write command appears, the automatic request will remain pending until the arbiter returns to idle (CR35[LP\_ARBST] = 'b00) and the automatic interface is granted control of the LPC module.

Only new read or write commands will cause the counters to be reloaded to their programmed values and trigger an exit. Other commands, including MRR, MRW, low power entry and exit commands, register accesses, refresh, ZQ, etc., do not reset the counters and do not trigger an exit from low power. When the memory controller is idle and the memories have automatically entered a low power state, these commands may be prevented from executing.

It is generally expected that any state that is defined for automatic entry CR36[LPAUTO] should also be enabled for automatic exit CR36[LP\_AEXEN]. Automatic exit may also be used for low power states that are not defined for automatic entry, but are expected to be entered manually through the software programmable interface CR35[LP\_CMD]. If it is desirable to use both manual and automatic entry/ exit into the same low power state, then the user may need to re-program the CR36[LP\_AEXEN] parameter prior to issuing a request through the software programmable interface.

#### 10.1.6.6.2 Refresh Masking

Regular refresh commands will be issued at the same intervals while the memory controller is operating normally, is idle, or is in any of the low power states. However, for memory arrays with multiple chip selects, the Memory Controller supports the ability to mask refreshes while in any of the power-down low power states. By setting bits of the CR34[LP\_REFEN] parameter to 'b1, auto-refreshes will be masked for the associated chip selects.

It is the user's responsibility to ensure that refreshes are not constantly masked, and that each chip select is refreshed periodically.

#### 10.1.6.6.3 LPDDR2 SDRAM Memories

#### 10.1.6.6.3.1 Enabling Mobile Usage

When using LPDDR2 (mobile memory), bit 0 of the CR00[DRAM\_CLASS] must be set to 1. This enables the memory controller to use the initialization sequence and mode register addressing appropriate to LPDDR2. When bit 0 of the CR00[DRAM\_CLASS] is cleared to 'b0, a standard DDRSDRAM or SDRAM memory may be used.

#### 10.1.6.6.3.2 Partial Array Self-Refresh

For LPDDR2, the Memory Controller is capable of supporting refreshes to subsections of the memory array. To facilitate this capability, separate parameters are provided to supply the mode register data for each chip select. These parameters are named *mrY\_data\_X*, where X represents the chip select and Y represents 0, 1, 2 or 3 - depending on the memory type being used.

Having separate control parameters for the mode register data allows the individual chips to set their own masked refresh. The CR45[WRMD] controls the writing of this mode register data into the registers. When the CR45[WRMD] is set to 'b1 initially, the mode register of chip select 0 will be written. Each subsequent setting of the CR45[WRMD] to 'b1 will write the mode register of the next chip select (1, 2, 3, etc.).

Note that the memory controller does not check if operations attempt to access addresses outside of the refresh ranges set by the memory mode registers. Any accesses to these addresses may result in corrupt or lost data.

#### 10.1.6.7 Out-of-Range Address Checking

It is possible that the master attempts to write to an invalid address. For this reason, all incoming addresses are always checked against the addressable physical memory space. If a transaction is addressed to an out-of-range memory location, then bit 1 of the CR80[INT\_STAT] will be set to 'b1 to alert the user of this condition. The memory controller will record the address, source ID, length and type of transaction that caused the out-of-range interrupt in the CR83[OORAD], CR84[OORID], CR84[OORLEN] and CR84[OORTYP].

Reading the out-of-range parameters will initiate the Memory Controller to empty these parameters and allow them to store out-of-range access information for future errors. The interrupt should be acknowledged by setting bit 1 of the CR81[INT\_ACK] parameter to 'b1, which will in turn cause bit 1 of the CR80[INT\_STAT] to be cleared to 'b0.

If a second out-of-range access occurs before the first out-of-range interrupt is acknowledged, then bit 2 of the CR80[INT\_STAT] will be set to 'b1 to indicate that multiple out-of-range accesses have occurred. If the out-of-range parameters have been read when the second out-of-range error occurs, then the details for this transaction will be stored in the out-of-range parameters. If they have not been read, then the details of the second error will be lost.

Even though the address has been identified as erroneous, the Memory Controller will still process the read or write transaction. A read transaction will return random data which the user must receive to avoid stalling the memory controller. A standard, non-exclusive write transaction will write the associated data to an unknown location in the memory array, potentially over-writing other stored data. A command can not be aborted once accepted into the Memory Controller.

A special situation occurs with AXI exclusive accesses. For an exclusive write access only, if the exclusivity check fails, then the command will automatically be flushed internally. This is the only situation in which the erroneous data is NOT written to memory but is cleared out of the memory controller FIFOs. The CR84[OORTYP] bits [5:4] maintain status on AXI exclusive accesses.

**Table 10-23. Out of Range Access Parameter**

Memory Controller bit	Description
CR83[OORAD][31:0] Out of range address	Transaction Address
CR84[OORID] [13:0] Out of range source id	Bits [13:13] = Port ID Bits [12:0] = AXI Thread ID
CR84[OORLEN] [6:0] Out of range length	Total byte count of the transaction. <ul style="list-style-type: none"> <li>For write commands: <math>(\text{AXI port Y encoded write command length} + 1) \times 2^{(\text{AXI port Y encoded write command size})}</math>.</li> <li>For read commands: <math>(\text{AXI port Y encoded read command length} + 1) \times 2^{(\text{AXI port Y encoded read command size})}</math>.</li> </ul>
CR84[OORTYP] [5:0] Out of range type	<ul style="list-style-type: none"> <li>'b000000 = Non-Exclusive Write</li> <li>'b000001 = Non-Exclusive Read</li> <li>'b000010 = Non-Exclusive Masked Write</li> <li>'b000100 = Wrapped Write</li> <li>'b000101 = Wrapped Read</li> <li>'b000110 = Wrapped Masked Write</li> <li>'b001000 = Exclusive Write</li> <li>'b001001 = Exclusive Read</li> <li>'b001010 = Exclusive Masked Write</li> <li>'b010000 = Flushed Write</li> </ul>

**Table 10-23. Out of Range Access Parameter**

	<ul style="list-style-type: none"> <li>• 'b100000 = Non-Exclusive Write with Auto-Precharge</li> <li>• 'b100001 = Non-Exclusive Read with Auto-Precharge</li> <li>• 'b100010 = Non-Exclusive Masked Write with Auto- Precharge</li> <li>• 'b100100 = Wrapped Write with Auto-Precharge</li> <li>• 'b100101 = Wrapped Read with Auto-Precharge</li> <li>• 'b100110 = Wrapped Masked Write with Auto-Precharge</li> <li>• 'b101000 = Exclusive Write with Auto-Precharge</li> <li>• 'b101001 = Exclusive Read with uto-Precharge</li> <li>• 'b101010 = Exclusive Masked Write with Auto-Precharge</li> <li>• 'b110000 = Flushed Write with Auto-Precharge</li> <li>• All other settings Reserved</li> </ul>

### 10.1.6.8 Command to Command Timing

For flexibility and maximum user control, the Memory Controller provides a set of timing parameters to control the bus turnaround timing between commands of different types. In many systems, extended pad or PCB board delays may cause interference with the controller default timings when changing chip selects or command types. These timing parameters allow the user to add additional clock cycles between a particular command combination by increasing the associated command to command parameter value based on the physical PCB design and the software applications used by the customer. Each of the command to command parameters listed below can be changed individually to achieve timing which prevents bus contentions that could slow down the Memory Controller throughput. The user should program each parameter with the minimum number of clocks required for these transaction combinations on the data bus.

The memory controller will automatically account for the burst length and memory timing requirements. The additional command to command parameters below do not compensate for these delays, but rather should be used to account for any additional delay needed such as variance in the pads, board or system. In addition, more delay may be needed to turn the bi-directional DQ/DQS bus around for commands of different types; For example, switching a pad between High-Z, input, and output states. The "same CS" parameters may also be used to account for termination timing.

These command to command parameters should also be used to account for any constants in the timing equations in the JEDEC specification. For example, the LPDDR2 specification lists the R2W same CS delay as:

$$RL + tDQCK\_MAX + BL/2 + 1 - WL$$

The memory controller will account for all of these terms, other than the "+1". Therefore, for this memory system, the R2W\_SMCSDL parameter would need to be programmed to at least a value of 0x1.

The command to command delay bits are:

- AODT\_WRSMCS (DDRMC\_CR89 bits [11:8])
- AODT\_RWSMCS (DDRMC\_CR89 bits [3:0])
- W2R\_SMCSDL (DDRMC\_CR91 bits [26:24])
- R2W\_SMCSDL (DDRMC\_CR91 bits [18:16])
- R2R\_SMCSDL (DDRMC\_CR91 bits [10:8])
- W2W\_SMCSDL (DDRMC\_CR92 bits [2:0])

### 10.1.6.9 Writing Mode Registers

The Memory Controller provides several options to program the mode registers in the memories. This functionality is controlled through the CR45[WRMD]. The encoding of this parameter defines which mode register(s) and which chip select(s) will be written. When the write has been completed (or if an invalid request was programmed), the mode register write complete interrupt (bit 21) will be set in the CR80[INT\_STAT]. Any errors will be reported in the CR46[MRW\_STAT] parameter. This parameter will be reset to 0x0 on the cycle after it is changed and can not be reprogrammed until the interrupt occurs.

#### 10.1.6.9.1 WRMD (write mode register) bit fields

The fields of the CR45[WRMD] are:

- Bit [25] = Trigger the MRW sequence with the settings defined in bits [24:0].
- Bit [24] = Write all chip selects
  - 'b0 = Only the chip select identified in bits [15:8] will be written for the mode register(s) specified in bits [23:16].
  - 'b1 = Bits [15:8] will be ignored and all chip selects will be written for the mode register(s) specified in bits [23:16].

- Bits [23:16] = Mode register write type. Only one of these bits should be set when bit [25] is set. If no bits are set, an error will be flagged in the CR46[MRW\_STAT]. If bit [24] is set to 'b1, all chip selects will be programmed. If bit [24] is cleared to 'b0, bits [15:8] will specify which chip select will be programmed.

As shown in [Table 10-24](#), the memory controller may provide mode register parameters that have no meaning for a particular memory system or chip select. If the user attempts a write to a mode register that is not relevant to the memory system for which the MC is programmed (through the CR00[DRAM\_CLASS] parameter), the memory controller will only perform the write when applicable. For example, an all-chip select write to MR16 and MR17 will only write these mode registers when programmed for LPDDR2 memory systems.

- Bit [23] = Write a single MRz

The mode register specified in bits [7:0] will be written with the data in the associated mrsingle\_data\_X parameters. Even if an associated mrZ\_data\_X parameter exists (refer to [Table 10-24](#)), the data from that parameter will NOT be used for the write and the mrZ\_data\_X parameter will not be updated with this command. This setting can be used to write mode registers for which the Memory Controller does not provide a specific parameter.

- Bit [18] = Write MR16, MR17
- Bit [17] = Write MR0, MR1, MR2, MR3
- All other bits reserved
- Bits [15:8] = Chip select number to be written. This field is only valid when bit [24] is cleared to 'b0 specifying that only a single MRz will be written.
- Bits [7:0] = Mode register number to be written. This field is only valid when bit [23] is set to 'b1 specifying that only a certain MRz will be written.

The mode register write(s) will be issued when the trigger bit (bit [25]) is set. Once the memory controller has completed all of the writes, the mode register write complete interrupt (bit 21) will be set in the CR80[INT\_STAT] and errors will be reported in the CR46[MRW\_STAT]. The CR45[WRMD] will be reset to 0x0 on the cycle after it is changed.

- Bit [16] = Write MR0, MR1, MR2, MR3, MR16, MR17

### 10.1.6.9.2 MRW Module and Arbiter

The mode register write (MRW) module initiates the required mode register writes for any memory type. These MRWs are initiated from several modules including the initialization state machine, frequency scaling logic, low power logic and software. Since requests originate from different sources, multiple MRW requests may occur at the same time. To manage these requests, the MRW module contains an arbiter. If multiple requests occur, they will be serviced in the following priority order:

- ZQ Calibration
- Hardware Frequency Changes (MRW to MR0, MR1 and MR2 in order for each memory)
- Power-on initialization
- Power-on MR0 for initialization of non-LPDDR2 memories
- Power-on DLL reset

If a lower priority request is being serviced when a higher priority request is issued, the lower priority request will complete entirely before the higher priority request will be serviced. This is true even if the request must write to multiple mode registers and/or multiple chip selects. Software will initiate MRWs by programming the CR45[WRMD].

### 10.1.6.9.3 Programming Errors

If the CR45[WRMD] field was programmed incorrectly, the memory controller state machine may or may not issue the request. In either case, the mode register write complete interrupt (bit 21) will be set to 'b1 in the CR80[INT\_STAT] and then the CR46[MRW\_STAT] should be read for error information. If any bits are set in this parameter, an error occurred. This is a read-only parameter, with the following bit settings:

- Bits [7:3] = Reserved
- Bit [2] = Reserved
- Bit [1] = A mode register write was requested for the PASR mode registers (MR16, MR17) when the memory controller is not programmed for LPDDR2 memory systems (CR00[DRAM\_CLASS] is not set to 'b0101).
- Bit [0] = CR45[WRMD] programming error. This bit will be set if no mode register write type is specified (CR45[WRMD] bits [23:16]) but the mode register write was triggered (CR45[WRMD] bit [25] = 'b1).

#### 10.1.6.9.4 Mode Register Storage in the Memory Controller

There are specific parameters in the register map to hold the data to write into the mode registers. The parameters that are not listed as read-only may be written at any time, and will be programmed into the memory mode registers when the CR45[WRMD] is programmed with the specified settings.

**Table 10-24. Mode Register Parameters**

Memory Controller Parameter	write_modereg Associated Mode Write Type Bit	Memory System Correlations
MR0_DAFN_X	Bit [16] = 'b1 Bit [17] = 'b1	<ul style="list-style-type: none"> <li>LPDDR2 (S2): MR0 (read-only)</li> <li>LPDDR2 (S4): MR0 (read-only)</li> <li>DDR3: MR0</li> </ul>
MR1_DAFN_X	Bit [16] = 'b1 Bit [17] = 'b1	<ul style="list-style-type: none"> <li>LPDDR2 (S2): MR1</li> <li>LPDDR2 (S4): MR1</li> <li>DDR3: MR1</li> </ul>
MR2_DAFN_X	Bit [16] = 'b1 Bit [17] = 'b1	<ul style="list-style-type: none"> <li>LPDDR2 (S2): MR2</li> <li>LPDDR2 (S4): MR2</li> <li>DDR3: MR2</li> </ul>
MR3_DAX	Bit [16] = 'b1 Bit [17] = 'b1	<ul style="list-style-type: none"> <li>LPDDR2 (S2): MR3</li> <li>LPDDR2 (S4): MR3</li> <li>DDR3: MR3</li> </ul>
MR8_DAX	Read Only	<ul style="list-style-type: none"> <li>LPDDR2 (S2): MR8 (read-only)</li> <li>LPDDR2 (S4): MR8 (read-only)</li> <li>DDR3: <a href="#">_a</a></li> </ul>
MR16_DAX	Bit [16] = 'b1 Bit [18] = 'b1	<ul style="list-style-type: none"> <li>LPDDR2 (S2): MR16</li> <li>LPDDR2 (S4): MR16</li> <li>DDR3: <a href="#">_a</a></li> </ul>
MR17_DAX	Bit [16] = 'b1 Bit [18] = 'b1	<ul style="list-style-type: none"> <li>LPDDR2 (S2): <a href="#">_b</a></li> <li>LPDDR2 (S4): MR17</li> <li>DDR3: <a href="#">_a</a></li> </ul>
MR_SINDAX	Bit [23] = 'b1	-

a There is no corresponding mode register for this memory system. Any attempt to write this mode register for this memory system will be ignored.

b This mode register should not be written for this memory system.

### 10.1.6.10 Refresh Per Command Timing

The TREF parameter is used to define the number of DRAM cycles allowed between refresh commands from the memory controller. This parameter sets the average interval between refreshes.

The actual interval may vary by up to 8 cycles from refresh to refresh, depending on other activities that are occurring in the controller at the time.

Over an infinite time period, the average interval will be equal to the number of clocks set by this parameter; however, if the user sets this parameter to be exactly equal to the specification value  $tREFi$ , then local variations might mean that the memory tREF value may be violated by a very small amount.

The amount of this violation would be  $8tCK/tREF$ . For example, for a 400 MHz memory and  $tREF=64$  ms, the amount of the violation would be  $2.5 \text{ ns}/64 \text{ ms} = 0.000004\%$ .

### 10.1.6.11 LPDDR2 Memories DQS

For these memories, all accesses to memory must be memory burst-aligned in both address and length. The Memory Controller still processes all transactions even if the starting and/or ending address is unaligned. Therefore, for a x4 memory, a write that begins or ends on an unaligned address will result in memory corruption. Such an access may also result in taking more data from the write FIFO than what correlates to the current transaction.

### 10.1.6.12 DRAM Refresh

While memory refresh operations are necessary for DRAM data integrity, they unfortunately draw a significant current and temporarily disable the memory from accepting other commands. A memory refresh may be initiated from the user interface by setting the AREF parameter (DDRMCR25 bit[0]) to 'b1 or through an internal source such as the expiration of the TREF counter (DDRMCR26 bits[31:16]) or an exit from Self-Refresh. Regardless of the source, when the refresh command is received, all transactions will be inhibited and a refresh sequence will be initiated.

TRFC (DDRMCR26 bits[9:0]) sets the time that a DRAM memory must wait between receiving a refresh command to when a data transaction or the next refresh command can be processed. When each refresh command is issued, the TRFC counter inside the MC core begins a countdown from the programmed value TRFC. With each refresh command, the counter is reset and the memory controller will only accept commands

TRFC cycles after when the final refresh command has been issued. Once the TRFC time expires and no further refresh commands are required, normal read/write traffic and behavior resumes in the memory controller.

#### 10.1.6.12.1 Programming of the TREF field

The TREF (CR26[31:16]) field sets the average interval between refreshes. The actual interval may vary by up to 8 cycles from refresh to refresh, depending on other activities that are occurring in the controller at the time. Over an infinite time period, the average interval will be equal to the number of clocks set by this bit; however, if the user sets this bit to be exactly equal to the specification value  $tREFi$ , then local variations might mean that the memory  $tREF$  value may be violated by a very small amount.

The amount of this violation would be  $8tCK/tREF$ . For example, for a 400 MHz memory and  $tREF=64$  ms, the amount of the violation would be  $2.5 \text{ ns}/64 \text{ ms} = 0.000004\%$ .

#### 10.1.6.12.2 Programming of the tref\_INT bits

The interval is a critical value in achieving real current savings. The following considerations should be taken for programming the CR28[TREF\_INT] bits.

- A larger interval will increase the time that the memory controller is held off from processing data transactions.
- Peak current restrictions will guide the interval value. The interval should be defined to the minimum value that still meets peak current restrictions.
- Programming the interval to zero will disable the refresh per chip select logic and refresh commands will be issued simultaneously to all chip selects.
- The refresh per chip select logic requires at least one dead cycle between refresh commands, and therefore the minimum interval used is actually 4 cycles. Programming the TREF\_INT bits to 1, 2 or 3 will default to 4 cycles.
- The Memory Controller runs at half the frequency as the memories. Therefore, if the TREF\_INT bits is programmed to an odd number of clocks, the actual interval used will be the one clock longer than programmed

- Other factors in the design also affect timing, and therefore the actual delay between refresh commands may exceed the programmed value. This is particularly likely when the interval value programmed is very low, such as 'b004.
- When the  $t_{RFC}$  counter completes its countdown, the memory controller will accept any pending commands. Since no read or write commands may occur during the entire refresh sequence, the `TREF_INT` bits should always be set to a value lower than the `TRFC_F0` bits.

Figure 10-5 shows a refresh sequence for a system with four chip selects and a `TREF_INT` of four clocks ('b100).

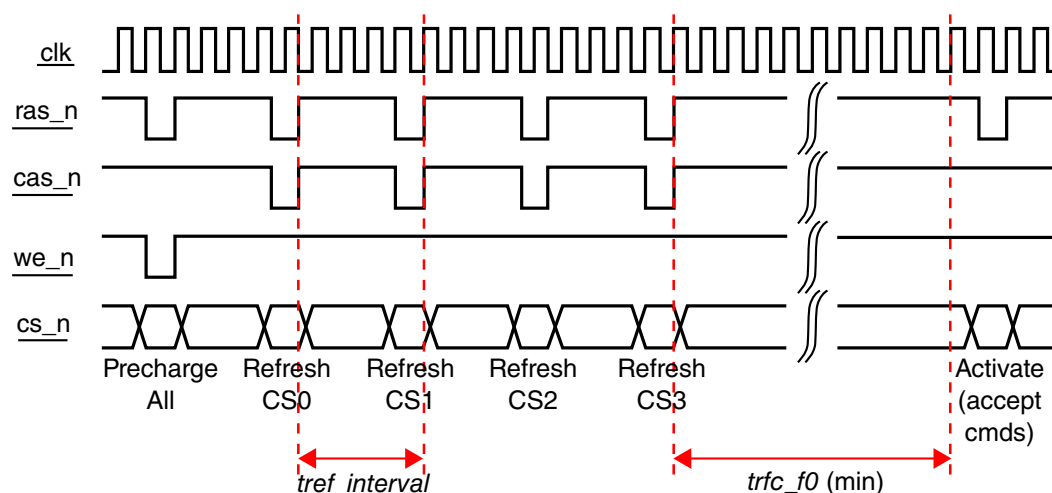

Figure 10-5. Refresh per CS Example

### 10.1.6.13 Half Data path option

The memory controller can be made to operate in half datapath mode (8 bit memory mode) by setting `REDUC (DDRM_CCTL78[8]) = '1b`. This option must be used to enable ECC, or can be used if only an 8-bit wide DRAM memory is desired.

### 10.1.6.14 ZQ pad calibration

ZQ pad calibration logic handles the calibration of the drivers and termination resistances in DDR pads. The auto mode is handled by the logic on its own and is the mode that would be used during functional operation of DDR. Software calibration can be used to override the pad calibration process. Software calibration is very slow and at best is useful for debug purposes.

When ZQ pad calibration is enabled in the CR154[PAD\_ZQ\_MODE], the calibration is done in parallel to the memory ZQ calibration. Pad calibration will either be done with both short and long ZQ calibration commands issued to the memory or only when long calibration is done (including during memory initial sequence and refresh exit). Memory controller must be separately programmed to control how it issues the ZQ calibration commands to the external memory.

There is provision to issue a separate one time hardware calibration. The Memory Controller will automatically perform ZQ calibrations on the Processor Pads before attempting to program the DRAM Mode Registers. In addition, the Memory Control will issue an initial ZQ calibration command to the DRAM memories as part of the Mode Register setting sequence.

### 10.1.6.15 DDR PHY

The DDR PHY includes all the functionality required at the Physical Layer Level to interface the Memory Controller to external DDR DRAM devices. The PHY is used drive signals to and receive signals from external memories in accordance with the JEDEC memory standards.

Basic functionality includes:

- DFI compliant interface with the Memory Controller
- Command and Address control path to external memories
- Bi-Directional Data Interface with external memories
- DLL for timing, which includes accurately generating necessary delays for aligning strobes to data

#### 10.1.6.15.1 High Level Block Diagram

The DDR PHY, together with the Memory Controller Core, uses a slice-based architecture to manage the flow of data to and from the external DRAM memory. Each slice manages a byte (8 bits) of data and its corresponding DQS and DM signals.

A high level block diagram of the PHY is provided in [Figure 10-6](#).

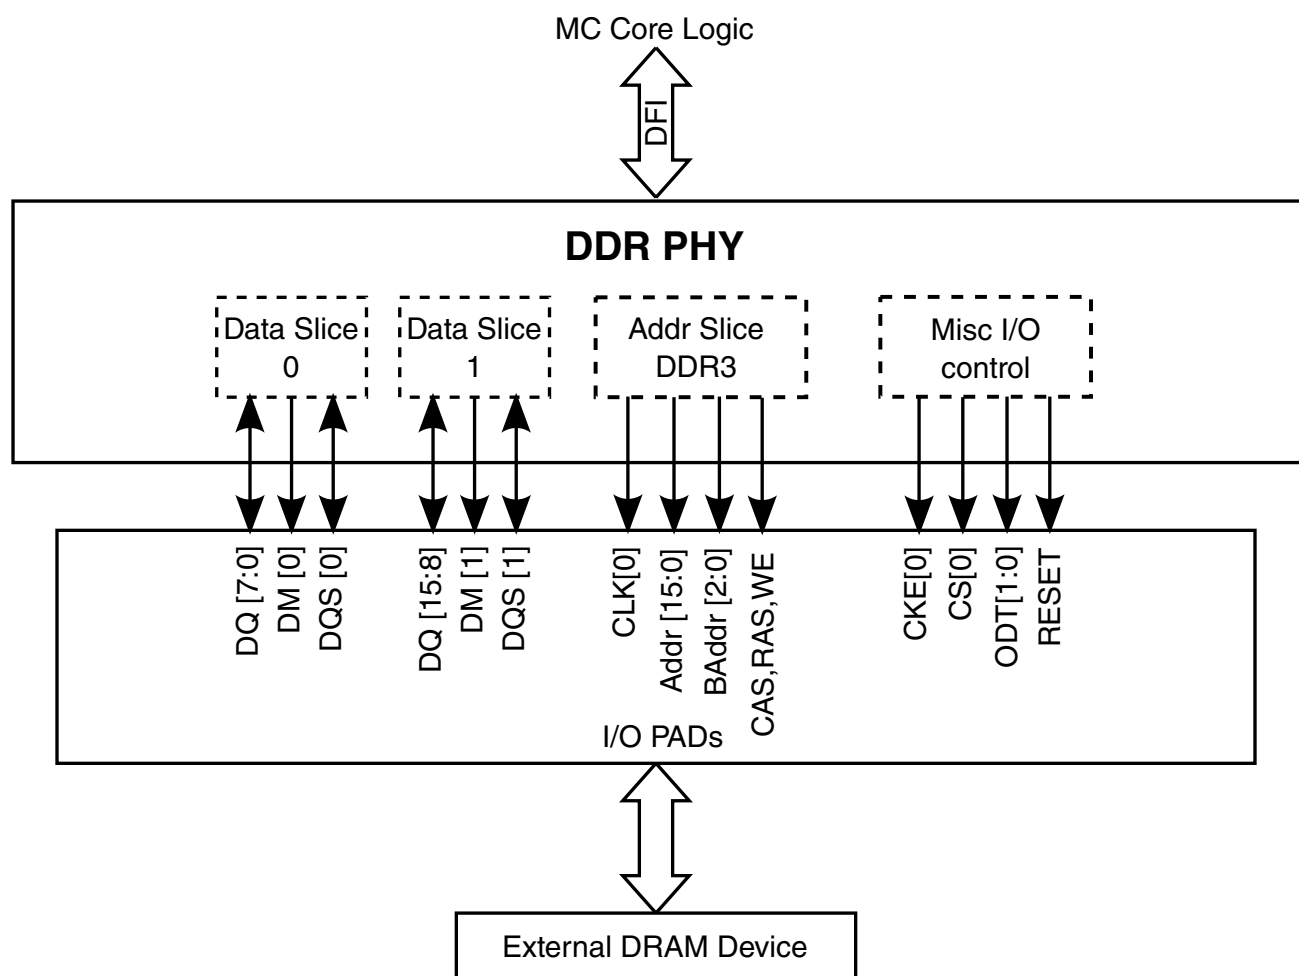

Figure 10-6. DDR PHY High Level Block Diagram

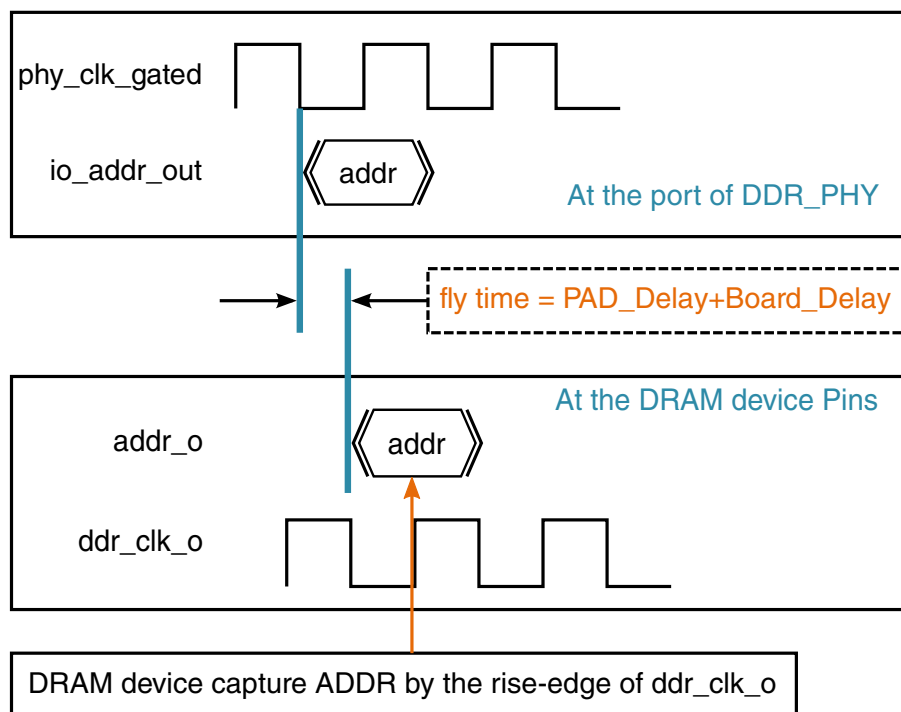

#### 10.1.6.15.2 DFI

The interface between the DRAM Memory Controller core logic and the PHY is called "DFI". The "D" stands for "DRAM Controller" and "FI" is a reference to "PHY". The DFI seamlessly interfaces the Controller with the PHY and requires no user settings to configure correctly. All signals required by the DFI have been connected, and some additional optional signals shared by both the Controller and the PHY IP have also been connected. The DFI standards can be found at [www.ddr-phy.org](http://www.ddr-phy.org).

#### 10.1.6.15.3 Command and Address Timing for DDR3

Unlike the two Data Slices, the CA Slice differs depending on whether the PHY is configured for LPDDR2 or DDR3 DRAM devices. All slices have the same basic structure, including a DLL, but the CA slice does not use delays for Read Leveling or Read Gate Leveling since the CA slice never inputs a signal from the external memories.

In addition, the PHY\_CLK is always aligned to itself, so it does not use the Write Level delay. But when configured for LPDDR2 devices, the CA slice does use PHY\_WRLV\_DL (DDRMC\_PHY49[23:16]) for offsetting the PHY\_CLK with respect to the CA signals. When configured for DDR3 devices, all DLL delays are bypassed in the slice.

**Figure 10-7. The DDR3 I/O Timing of Address Traces**

The Command and Address signals include all of the external DRAM interface signals except the DQS, DM, and DQ signals: Clock-Enable (CKE), chip-select, bank-address, row/column\_address, CASn, RASn, WEn, etc.

1. The Command and Address signals are latched out by the falling-edge of the PHY\_CLK and they remain at that logic level until the next falling edge of the PHY\_CLK latches in the next value. This scheme naturally places the rising edge of the PHY\_CLK in the center of the valid Command and Address signals.
2. “Fly-time” refers to the signal propagation time from the point that the signals pass out of the PHY, through the I/O pads, traveling through the signal traces on the PCB, and then arriving at the pins of the DDR3 device. For a proper layout, all the Command and Address traces should be trace length matched with the PHY\_CLK trace so that each trace has the same “fly-time.”
3. The DRAM device captures the CA signals by the rising edge of the ddr\_clk\_o signal at the pads of the DDR3 device.
4. [Figure 10-7](#) illustrates the address timing for DDR3.

#### 10.1.6.15.4 Command and Address Timing for LPDDR2

When the PHY is configured for LPDDR2 operations, the Command & Address slice operates differently in two major ways from the description in the previous section for DDR3. First, the 16 Address, 3 Bank-Address, CAS<sub>n</sub>, RAS<sub>n</sub> and WEn signals are encoded into a smaller set of 10 Command & Address (CA[9:0]) signals. This encoding logic is done automatically by the CA slice, and requires no configuration by the user. To transmit the same amount of Command & Address information on the reduce number of signals, the CA slice will double the data rate of the CA slice. It does this by latching out the CA signals on both the rising and falling edges of the PHY\_CLK.

The second major difference from the DDR3 configuration is that the clock signal output from the CA slice (ddr\_clk\_o) must be delayed from the PHY\_CLK by one-quarter a clock cycle so that it will strobe the CA signals at the pins of the LPDDR2 device in the center of the data window. The amount of delay is adjustable, and allows the user to tune the clock edges to best match a particular board design. This value can be determined on a random sample of customer boards early in the development cycle, and can be fixed for the remainder of the product lifetime. The field that controls this timing parameter is PHY\_WRLV\_DL (DDRMCMC\_PHY49 bits [23:16]). The following figure illustrates the address timing for LPDDR2.

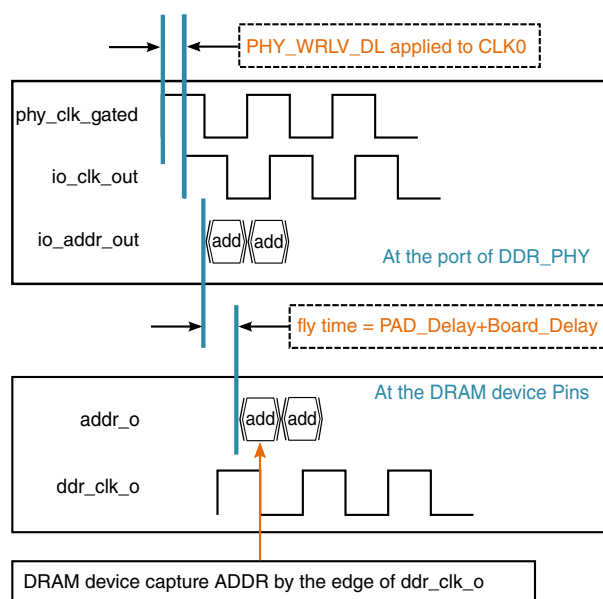

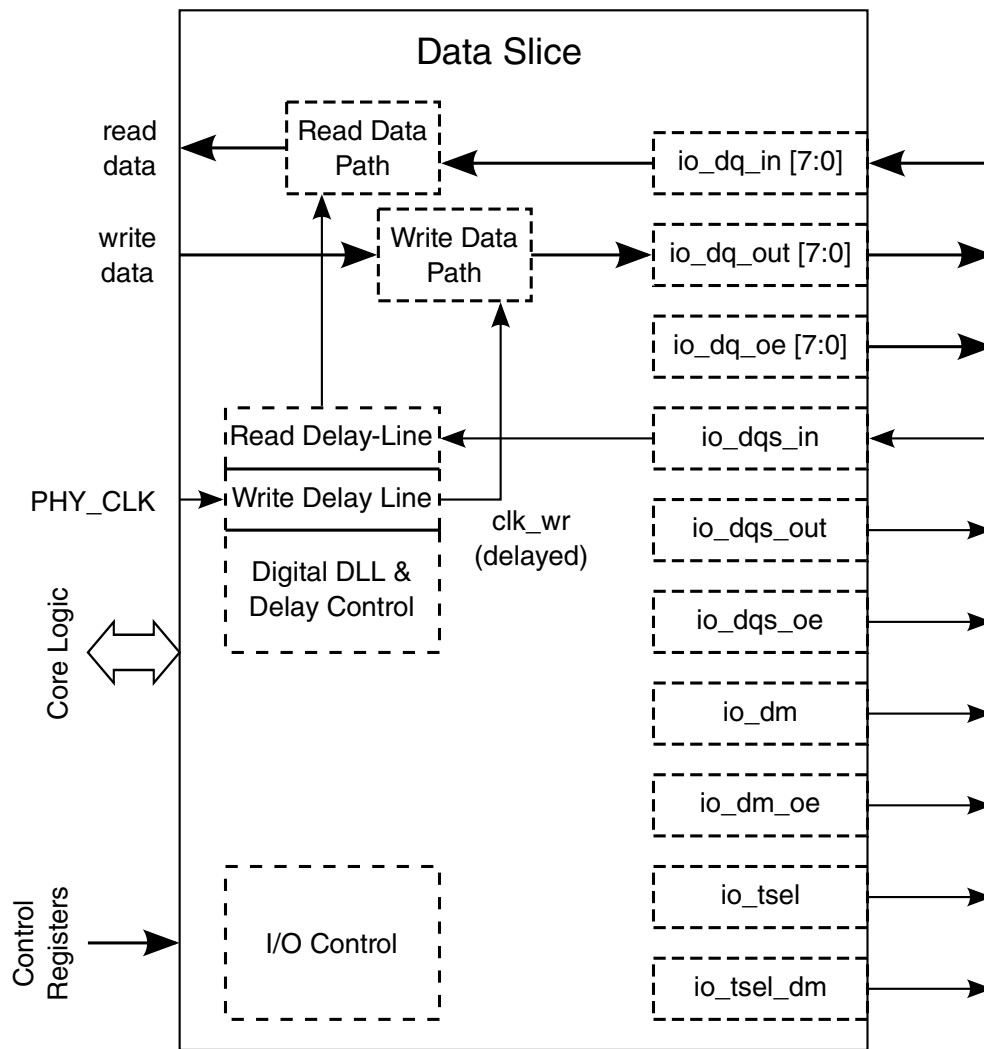

Figure 10-8. The LPDDR2 I/O Timing of Address Traces

#### 10.1.6.15.5 Data Slice Overview

**Figure 10-9. DDR PHY Data Slice**

Each data-slice manages a byte (8-bit) of data and its corresponding signals.

The "Read Data Path" captures read data by latching it into read data buffers by using both the posedge & negedge of the "delayed\_dqs" signal. The read data is then moved out of the "delayed\_dqs" clock domain of the PHY and synchronized into the `PHY_CLK` domain of the core logic. Systems with longer DQ traces may need to adjust the `RD_DLY_SEL` to a higher value to properly synchronize the data across the two clock domains.

The "Write Data Path" creates the write data mask signal ("dm") to match the valid data ("dq") window, and delays the `PHY_CLK` signal a quarter of a clock period to create the "dqs\_out" strobe properly synchronized to the write data.

### 10.1.6.15.6 Read Data Capture

When reading, DDR (dual data rate) devices send a data strobe (DQS) signal coincident with the read data. The edges of this DQS strobe are aligned (edge-aligned) with the data output by the DDR devices.

To latch read data into DRAM MC read data buffer, it requires that the latch clock edge is center-aligned with the data. Thus, a delayed version of the DQS strobe signal must be used to capture the data. Because the frequency of the DQS strobe signal is matched to the PHY\_CLK, the delay is a relative number based on the period of the PHY\_CLK. In the example shown in Figure 10-10, the delay is set to approximately 25% of the PHY\_CLK cycle.

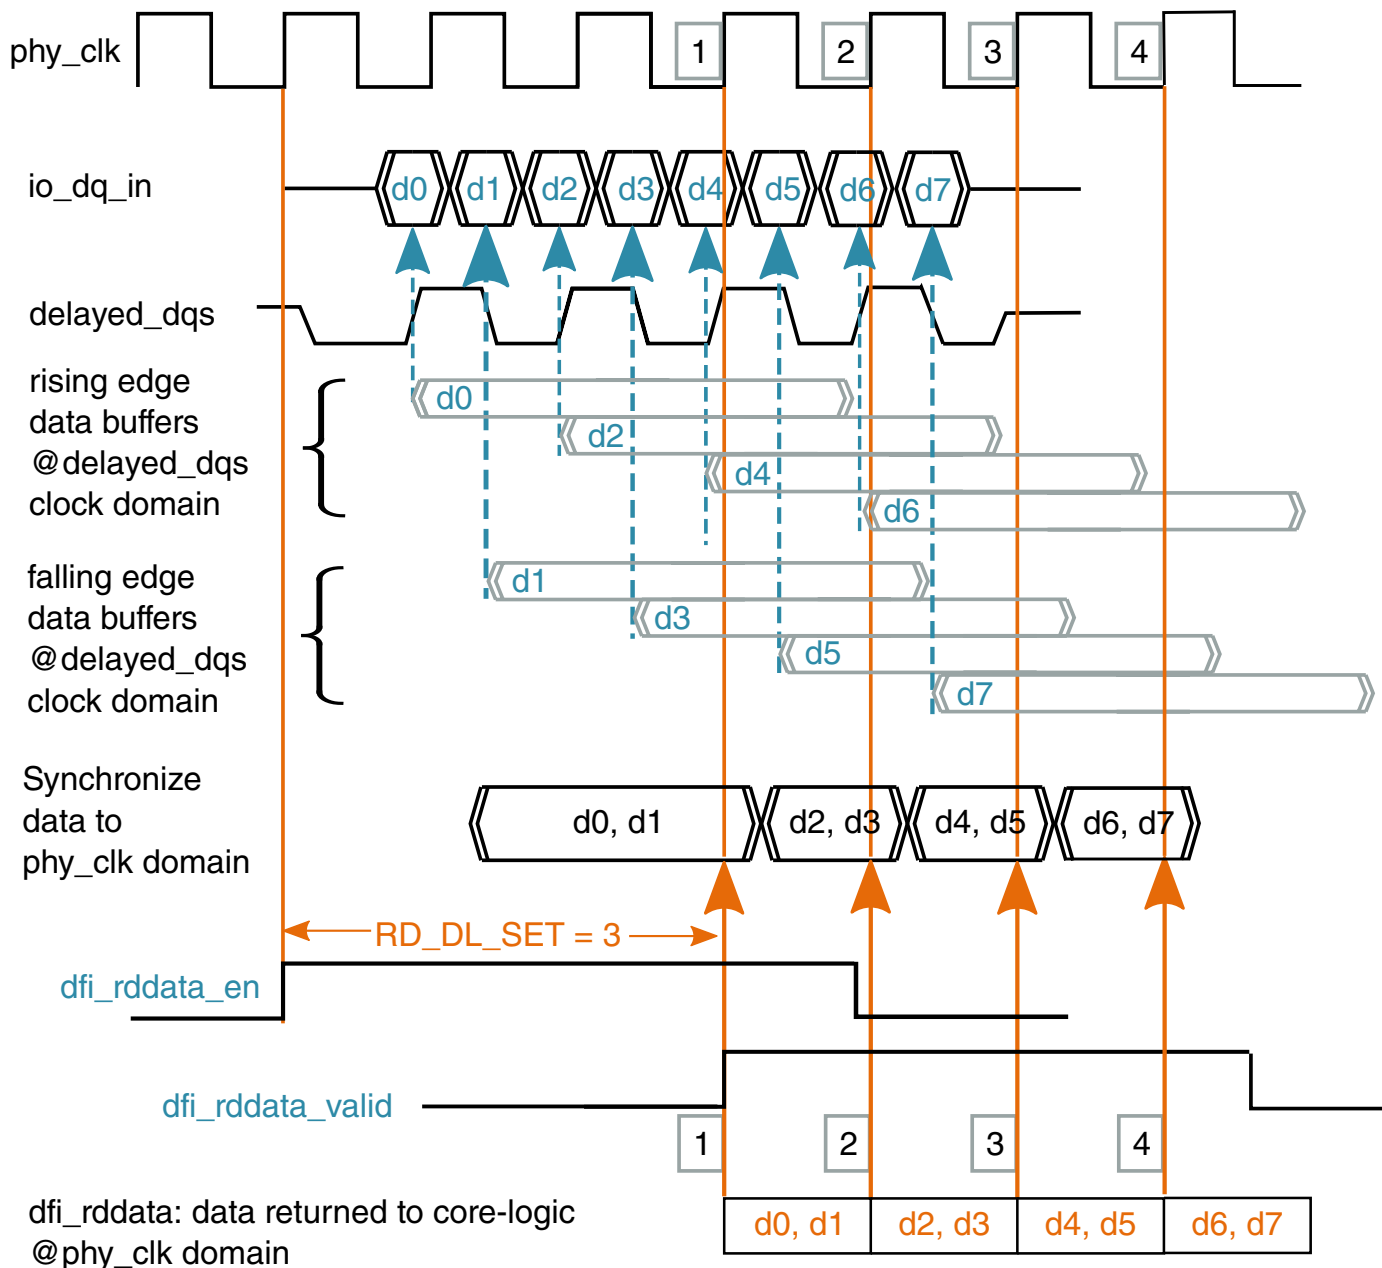

**Figure 10-10. Read Data Capture**

The actual delay values used are specified in **RDLVL\_DL\_0** (DDRMCR105[23:8]) and **RDLVL\_DL\_1** (DDRMCR110[15:0]). Delay values should be determined for each hardware design using a calibration routine. It is not necessary to compensate these values for process variations inherent to the individual ICs or the PCB manufacturing process. Once the values are determined for a specific board design, the values are valid until the PCB design is altered.

### 10.1.6.15.7 Synchronize Read Data From **delayed\_dqs** To PHY\_CLK domain

Read data is captured into data buffers by the "delayed\_dqs". It must be synchronized into PHY\_CLK domain, then returned to DRAM MC core logic.

Figure 10-11 illustrates how the read data from the external DRAM device is captured and synchronized to DRAM MC core logic.

**Figure 10-11. Synchronize Read Data**

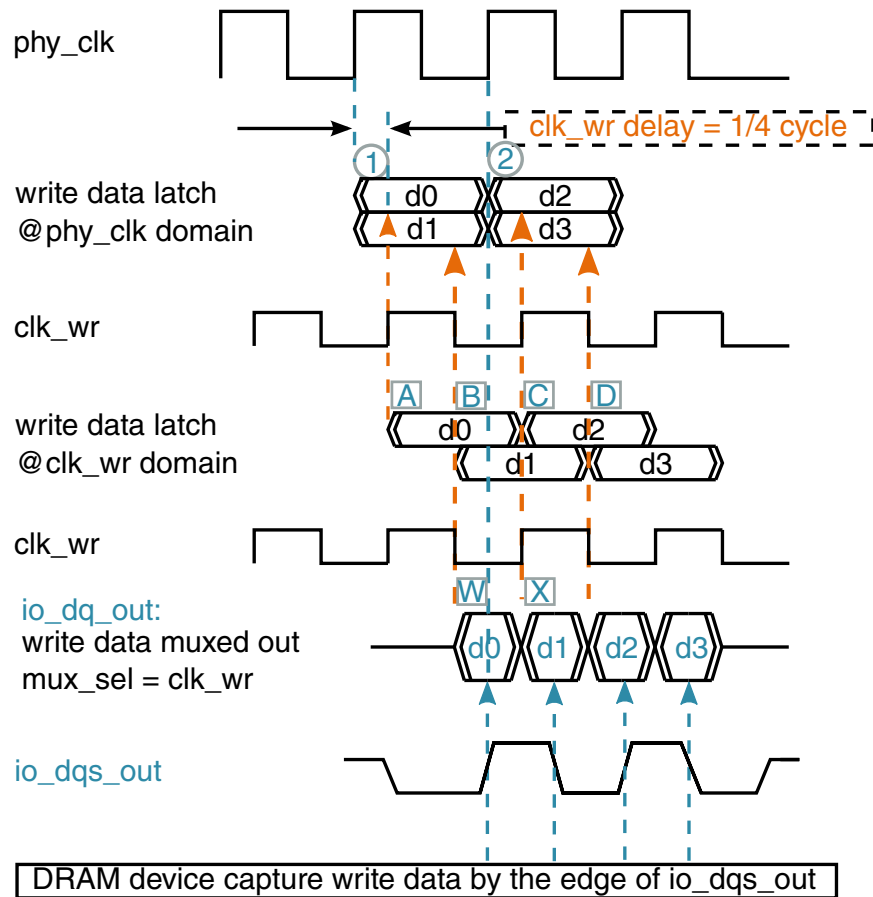

1. **io\_dq\_in** & **io\_dqs\_in** are not aligned with the **PHY\_CLK** when they are in the PHY. Many factors affect the phase of **io\_dq/dqs\_in**, such as voltage, temperature, board layout, manufacture process, and so on.
2. The PHY is responsible for delaying the “**io\_dqs\_in**” and creating the “**delayed\_dqs**” strobe used to correctly latch the “**io\_dq\_in**” values into the PHY Read FIFOs. There are two Read FIFOs for each data slice: One is used to buffer the read data latched in

on the rising edge of the “delayed\_dqs” strobe, and one is used to buffer the read data latched in on the falling edge of the “delayed\_dqs” strobe. The depth of each FIFO is 8-words, which allows the FIFO to hold data from two 8-word bursts before the oldest data is overwritten with data from the next read burst.

3. The data path width of the @PHY\_CLK domain in the Memory Controller is twice the data path width of the @delayed\_dqs domain. This conversion is accomplished by latching the current buffers of all the Read FIFOs in the PHY domain at the same time. Since there is an independent FIFO for both the rising and falling edges of the DQS, this results in a doubling of the external data bus width.
4. The DRAM MC core logic fetches the Read Data from the PHY by using only the rising edge of the PHY\_CLK. Since the data bus width is now doubled, the MC only needs to latch in data on a single clock edge to maintain the same data bandwidth. The DRAM MC core logic fetches read data by using two signals defined by the DFI standards: dfi\_rddata & dfi\_rddata\_valid.
5. The timing of the data transfer between the PHY FIFOs and the MC FIFOs can be controlled by RD\_DL\_SET fields for each data slice (DDRMC\_PHY02[21:19] and DDRMC\_PHY18[21:19]). Higher values of this field will result in delaying the FIFO fetch signal by increasing amount. For most designs, a value of 0x4 is sufficient delay. For boards using longer data trace lengths, a higher value may be needed.
6. In this example, d0 is clocked in by the rising edge of the delayed\_dqs strobe and d1 is clocked in by the falling edge of the delayed\_dqs strobe. The data remains in the Read FIFO for three clock periods. The Memory Controller will calculate a time when it expects Read Data to be available from the PHY based on the CAS\_Latency register value. The Memory Controller will then signal the PHY to enable Read Data to be sent to Memory Controller (dfi\_rddata\_en). Since the PHY must account for timing differences outside of the processor’s control, the PHY applies a delay in whole PHY\_CLK cycles to the rd\_data\_en signal before it signals back to the Memory Controller that the Read Data on the bus is valid and should be clocked in on the rising edge of the PHY\_CLK. In the example shown, d0 and d1 have been made available on the Read bus to the Memory Controller for approximately one and one-half clock cycles before the Memory Controller latches in the data (Cycle 1), and readies itself for the next data (Cycle 2). This example shows Read Data that is clocked in within one PHY\_CLK of the time that the Memory Controller expects the data to have arrived. On designs with longer data traces, the arrival of io\_dq\_in may be further delayed, resulting a shorter time for d0 and d1 to wait before the data is synchronized to the PHY\_CLK domain. For designs with relatively longer data traces, it may be necessary to increase the RD\_DL\_SET value.

### 10.1.6.15.8 Write Data Path

Figure 10-12 illustrates the write data path.

**Figure 10-12. Write Data Path**

#### NOTE

The marker "1" indicates the "setup time" for data "d0", which is approximately 1/4 cycle. While "d1" data is valid from the MC core at the same time, it does not get clocked out of the PHY until the falling edge of the clk\_wr signal.

1. Data from the MC enters the PHY on a 32-bit wide data bus (dfi\_wrdata). This data is latched into four 8-bit wide registers in the PHY\_CLK domain: Two for the rising edge of the phy\_clk corresponding to data slice 0 and data slice 1, and two for the falling edges of the phy\_clk for each data slice.
2. The rising edge of the clk\_wr signal for each data slice will then latch in the d0 value of the first register into the first register in the clk\_wr clock domain (A). The next falling edge of the clk\_wr signal will then latch the d1 value from the second register into the second register in the clk\_wr clock domain (B). The next rising edge of

clk\_wr will latch in data d2 into the clk\_wr domain, replacing the previous data d0 (C). And the next falling edge of clk\_wr will latch in data d3 into the clk\_wr clock domain, replacing data d1 (D). When data is in the registers of the clk\_wr domain, the data will last for one clock cycle before it is replaced with newer data.

3. Once the Write Data is latched into the clk\_wr domain, the opposite wr\_clk edge is used to latch the data out to the DDR pads (io\_dq\_out). In this example, data d0 was latched into the wr\_clk domain using the rising clock edge. The next falling edge of wr\_clk is used to latch data d0 out to the DDR pads (W). The next rising edge of the wr\_clk will then latch d1 out to the DDR pads (X). At this point, the data stream is  $\frac{3}{4}$  of a clock period out of phase with the PHY\_CLK (270 degrees).
4. Each data slice will then create the DQS Strobe by branching off the clk\_wr, inverting the clock signal (ie, add a  $\frac{1}{2}$  clock phase shift), and further delaying the clock by the amount specified in DLL\_WRITE\_CL (DDRMC\_PHY04[14:8] and DDRMC\_PHY20[14:8]) which is approximately an additional  $\frac{1}{4}$  of a clock cycle. The resultant “io\_dqs\_out” strobe signal will now be back in phase with the SDCLK at the DRAM device (Marker “2”), and will be used by the DRAM device to strobe in valid data. The “io\_dqs\_out” and the “io\_dq\_out” are center-aligned, as required by the DRAM device.

#### 10.1.6.15.9 Digital DLL and the Delay-Line

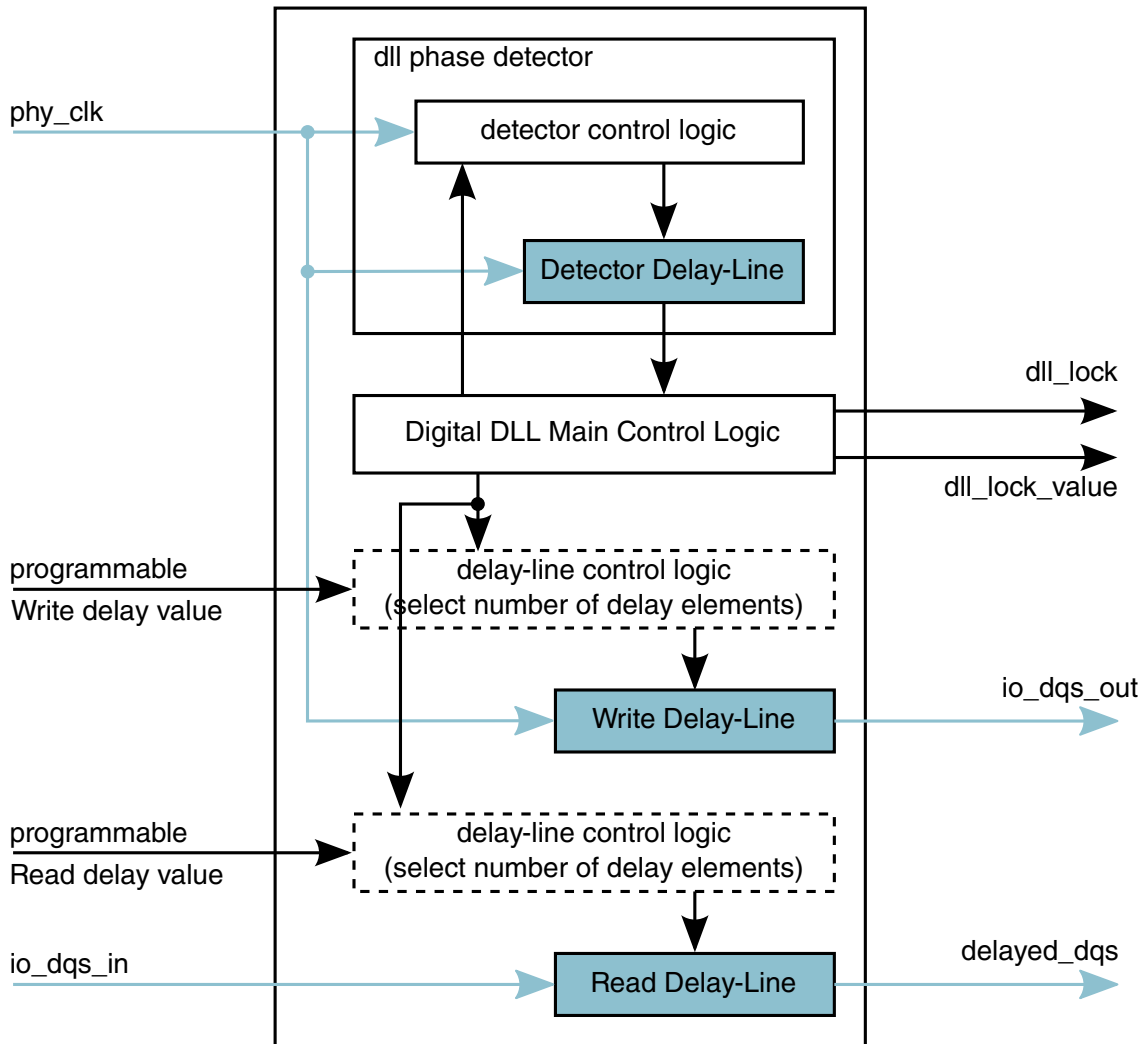

In a DRAM memory system, the Memory Controller is the master of the system and is responsible for ensuring that proper timing is maintained by all signals on a particular slice in relation to the strobe/clock signals. Designers are free to create systems in a wide range of physical layouts, but the variable nature of trace lengths and the time required to pass through them causes the MC to necessarily deal with an inherently asynchronous system. To give the MC the ability to delay signals in fractions of a clock cycle, the PHY contains a Delay-Locked Loop (DLL) for each of the slices. The delay compensating circuit of the DLL is designed with the following features:

- Programmable read strobe delay specified as a percentage of a clock cycle.
- Programmable write data delays specified as percentages of a clock cycle.
- Delay compensation and re-synchronous circuitry which is activated during refresh cycles to compensate for temperature and voltage drift of the DLL.
- Separate delay chains for each of the slices.

The delay compensation circuitry relies on a master/slave approach. There is a master delay line which is used to determine how many delay elements constitute a complete cycle. This count is used, along with the programmable fractional delay settings, to determine the actual number of delay elements to program into the slave delay lines. The

master and slave delay lines are identical. This approach allows the memory controller to observe a clock and then delay other signals a fixed percentage of that clock. The DLL logic does not actively generate clock signals.

Figure 10-13 shows the block diagram for a digital DLL.

**Figure 10-13. Digital DLL**

The delay-line is comprised by 255 tiny delay-elements. The delay value of each delay element are almost the same. And the number of delay elements which is in use to form a delay result is configurable.

There is one mode for the delay-line control :

1. Auto-configure mode:

The process begins with a “phase-detector” which measures the number of delay elements in a clock period by matching the phase between the input clock and a clock that has been delayed by a known number of delay elements. Once the phase-detector successfully completes the detection, it will raise the “dll\_lock” signal and output “dll\_lock\_value” which indicates the number of delay elements determined by the phase-detector. The number of elements that are needed to capture an entire clock cycle is then converted into an unsigned integer stored in fields

DDRMC\_PHY11[DLL\_LOCK\_VALUE],

DDRMC\_PHY27[DLL\_LOCK\_VALUE], and

DDRMC\_PHY43[DLL\_LOCK\_VALUE]. This integer is used as the dividend for the read and write delay parameters. The actual delay setting for the delay lines is calculated by multiplying the DLL\_LOCK\_VALUE integer by the parameter settings for each delay line and then dividing by 128 and rounding. These values are then encoded into a one-hot counter and updated at initialization and at every refresh interval.

#### 10.1.6.15.10 Configure the "output enable" of I/O Control

The Memory Controller has direct control over when the DQ and the DQS pads are enabled for Input and Output. This is independent of any Write Latency or Read Latency values programmed into the PHY for controlling the attached DRAM devices. The timing for enabling the output of the DQ/DQS pad for a Write is set in field

DDRMC\_CR132[WRLAT\_ADJ], and the timing for enabling the input of the DQ/DQS pad for a Read is set in field DDRMC\_CR132[RDLAT\_ADJ]. Since the Read Pre-Amble is typically not included in the DRAM memory Read Latency value, the value for RDLAT\_ADJ should be set to one less than the value of

DDRMC\_CR12[CASLAT\_LIN]. The value for WRLAT\_ADJ automatically has one subtracted from it by the Memory Controller for DDR3 memories, so no manual adjustment is necessary. (See DDRMC\_CR125[PHY\_WRLAT]). When the enable signal is triggered by the Memory Controller, it will last for exactly (Burst Length)/2 clock cycles.

#### NOTE

In the case of LPDDR2 memories, RDLAT\_ADJ should not be manually adjusted since there is no "un-gate" feature on the read data.

In addition to the enabling signal from the Memory Controller, the PHY has the ability to delay the enable signal start point and the end point on a Byte Lane basis, and adjust the DQS strobe independently of the DQ pads. These are the OE\_START and OE\_END

fields in the PHY registers for each data slice. Only when the resulting “output enable” signal is active low, will the I/O pads be able to drive or receive signals. The relationship between the “output enable” signal is shown in [Figure 10-14](#).

**Figure 10-14. Output Enable of DRAM MC i/Os**

There are 3 kinds of output enable signals in this DRAM MC design:

- `io_dq_out_oen`  
output enable for write data.
- `io_dqm_oen`  
output enable for write data mask. Please configure it exactly the same as `io_dq_out_oen`.
- `io_dqs_oen`  
output enable for write data strobe.

The suffix “\_oen” means the output enable signal is active low. The start time and the end time of a output enable signal can be configured separately. The start time and the end time can be adusted by 1/4 clock cycle in unit.

To meet the timing requirement of the I/O circuits, the start time of each output enable must be prior to it's corresponding output signal, and, the end time must be later than it's corresponding signal. In another word, the output enable signal must be “wider” than the output signal. The margin at start time is named “pre-amble” and the margin at end time is named “post-amble”. In the example of [Figure 10-14](#), pre-amble = 1/2 cycle while post-amble = 1/4 cycle.

### 10.1.6.15.11 Low Frequency Options

The DDR PHY has been optimized for operating at 400 MHz. In its default setting, the PHY will be able to reliably operate down to a frequency of 300 MHz, provided that all of the Memory Controller timing settings are made correctly from the DDR datasheet. For frequencies below 300 MHz, it is necessary to modify the settings of the Master DLLs to measure the timing of only one-half the SDCLK clock cycle, or completely bypass the Master DLL. When operating above 300 MHz, it is recommended to use the full clock period to determine a base number of delay elements because the larger number of delay elements leads to a more accurate fractional placement of the DQS strobes, and for SDCLK (LPDDR2 only).

The critical component of the Master DLL used to measure the SDCLK clock cycle is a bank of 128 delay elements, each of which provides approximately 30 picosecond of delay. This bank can measure a clock cycle with a period up to 3.84 nanoseconds (260 MHz). Since it is desired to leave a small number of delay elements for production variations, 300 MHz is a good cutoff frequency. When the DLL is set to measure a half clock cycle, the delay elements are sufficient to measure a clock cycle with a period of 7.68 nanoseconds (130 MHz). Again, to leave a margin of variance, the cutoff frequency for half-cycle mode should be limited to 150 MHz. Below this frequency, the Master DLL should be placed in bypass mode, which then requires that the number of delay elements used in the Slave DLLs be specified instead of using a fractional value of the clock cycle.

#### 10.1.6.15.11.1 Operating between 150 MHz and 300 MHz

When operating in this frequency range, the only necessary additional register changes are to put the Master DLLs in half-clock cycle measurement mode. This is accomplished by setting `PHY03[PARAM_HALF_CLOCK_MODE] =`  
`PHY19[PARAM_HALF_CLOCK_MODE] =`  
`PHY35[PARAM_HALF_CLOCK_MODE] = 'b1`. The PHY will automatically adjust the specified DQS Write, DQS Read Leveling, Read Gate Leveling and Write Leveling calibration parameters for the half-clock cycle measurement condition.

#### 10.1.6.15.11.2 Operating below 150 MHz

When operating below 150 MHz, it is necessary to place the Master DLLs in bypass mode. This is done by setting `PHY03[PARAM_DLL_BYPASS_MODE] =`  
`PHY19[PARAM_DLL_BYPASS_MODE] =` `PHY35[PARAM_`

DLL\_BYPASS\_MODE] = 'b1. In this mode, the Master DLLs will not attempt to lock, nor will they provide a base number of Delay Elements to be used in calculating calibration parameters.

Therefore, the following register fields will switch from specifying the fraction of a clock cycle to be delayed to specifying a specific number of Delay Elements:

PHY04[DLL\_WRITE\_DL], PHY20[DLL\_WRITE\_DL], and PHY49[PHY\_WRLV\_DL]. In addition, the PHY will ignore the Read Leveling values sent from the Memory Controller and use the specified number of Delay Elements in the following fields: PHY04[DLL\_READ\_DL], PHY20[DLL\_READ\_DL]. The Memory Controller fields for Write Leveling and Read Gate Leveling should be set to 0x00.

If operating in this frequency range, the user needs to manually calculate the number of delay elements that would equal one-quarter a clock cycle, and use this as the desired number of delay elements. Because valid data windows are so wide at these low frequencies, precise values are not required, so manual calculations are sufficient.

**Example:** For operations at 100 MHz, a clock period is 10 nanoseconds. One-quarter clock cycle is 2.5 nanoseconds, which would require  $2500 \text{ ps} / 30 \text{ ps} = 83$  delay elements

### NOTE

Even if operating at higher frequencies, placing the Master DLLs in bypass can be used for debug purposes. This may be useful for cases where a design is having trouble locking the DLLs. Use of the debug mode is not recommended for normal production units unless it is desired to operate below 150 MHz.

#### 10.1.6.16 Levelling Operations through Software

DDR3 memories feature leveling capabilities that allow more accurate alignment of critical timing signals for read and write operations. DDR3 PHYs must account for the delays induced by the fly-by topology to properly align the write DQS with the memory clock at the memory interface and to properly time the gate signal for read data capture. There are three different leveling delays which may be tuned in the DDRMC in DDR3 mode:

- Write leveling: Used to locate the delay at which the write DQS rising edge aligns with the rising edge of the memory clock.
- Gate training: Used to correctly time the opening of the gate for the read DQS.
- Read leveling: Used to center the read DQS in the DQ data eye on a memory read. This process assumes that gate training has been completed.

The DDRMC supports all of the leveling operation modes through software. Software write leveling refers to a mode of operation where software must handle the leveling sequences including setup. When placing the DDRMC in a leveling operation mode, communications across AXI0 and AXI1 will be suspended. Therefore it is necessary to execute software out of OCRM or through an external source (ie, JTAG) to obtain leveling values.

### NOTE

The Write DQS delay value used by `io_dqs_out` is specified in the PHY registers. There is no procedure for the Memory Controller to determine this value.

#### 10.1.6.16.1 Detailed Software Leveling Procedure

Leveling operations should be performed on new customer board designs, and repeated every time physical DDR trace layouts are changed. In addition, it might be considered to run leveling operation during memory initialization periods, by software at any point, or as a response to a hardware interrupt as long as the operating system can support a period of suspended communications with the DRAM. The DDRMC will inform the user interface of a leveling request by hardware through the leveling request interrupt `CR80[INT_STAT]`. This bit is tied to the `CR94[LVL_STAT]`, which contains a single bit per type of leveling operation and is set whenever a leveling request is sent from the PHY, if the periodic refresh timers for a leveling request are triggered, or if the request parameter is set.

Software is not required to use the `CR94[LVL_STAT]` or respond to a hardware interrupt for leveling requests. However, if the user wishes to count refreshes between leveling operations, then this bit will inform the user when the refresh counter expires. If desired, software may respond to a leveling interrupt by reading the `CR94[LVL_STAT]` and then programming the `CR93[SW_LVL_MODE]` with the type of leveling procedure requested. If the interrupt and `lvl_status` bit are not being used, software must program the `CR93[SW_LVL_MODE]` with the operation being implemented. The encoding of the 2-bit `CR93[SW_LVL_MODE]` is:

- 'b00: No leveling
- 'b01: Write leveling
- 'b10: Read leveling
- 'b11: Gate training

After specifying the type of leveling, the software algorithm should initiate the procedure by setting the `CR90[SW_LVL_START]` to 'b1. This triggers the memory controller (MC) to complete any commands in progress, inhibit the command queue from accepting additional requests, and issue a `precharge_all` command to the memory to close all banks

(if necessary). The memory controller will then issue the appropriate mode register commands to place the memories into write leveling mode or to enable read leveling through the MPR register. After meeting any applicable timing parameters, the MC will also assert one of the DFI leveling enable signals which enables the appropriate logic in the PHY.

The CR94[SWLVL\_OP\_DONE] is used to inform the software of the status of any active operations. This parameter will be cleared to 'b0 during any initialization, load or exit operation is being performed and set to 'b1 when the operation is complete. The leveling operation complete interrupt (bit 18) will also be set to 'b1 in the CR80[INT\_STAT] when the CR94[SWLVL\_OP\_DONE] is set. The software may wait for the interrupt or monitor this parameter to indicate that the operation in process has completed, and another action may be performed. The interrupt may be disabled by setting the associated bit in the CR82[INT\_MASK] to 'b1 if it is preferable not to have the interrupt firing.

The procedures for write and read leveling are influenced by the type of write leveling, gate training and read leveling support provided by the PHY and defined through the MC input signals. The procedures described in this document are only applicable for the MC Evaluation mode, which is the only mode supported by the PHY.

To run leveling mode operations, the MMDC and PHY should be initialized, and the appropriate delay parameters should be written with the value of delay that is needed for each data slice X in the PHY. The delay parameters used by the software leveling option are:

- Write Leveling: WRLVL\_DL\_X bits
- Gate Training: RDLVL\_GTDL\_X bits
- Read Leveling: RDLVL\_DL\_X bits

At this point, the software should set the CR93[SWLVL\_LOAD] to 'b1. This action will trigger the MC to de-assert the CR94[SWLVL\_OP\_DONE] and the MC will initiate a loading of the delay values into the data slices. The MC will then wait for the load operation to complete, and initiate a write level strobe or a read burst. The MC will wait for the response from the memory and save the response into CR95[SWLVL\_RESP\_1] and CR94[SWLVL\_RESP\_0] for each slice X. Once all responses are saved, the MC will assert the CR94[SWLVL\_OP\_DONE] and generate an interrupt. This informs the user that the response data is available for the initial delay values.

The software should use the response values in CR95[SWLVL\_RESP\_1] and CR94[SWLVL\_RESP\_0] to determine the next operation. For MC Evaluation mode, the response will indicate if the delay is appropriate, or must be increased or decreased. If the delay must be changed, the new delay value should be written to the associated parameter and the load sequence should be performed again.

If the delays are accurate, the software should now exit leveling by setting the CR94[SWLVL\_EXIT] to 'b1. This triggers the MC to clear the mode registers in the memories, de-assert the DFI leveling enable signal and enable the command queue for normal operation. The software is not required to complete the entire procedure prior to exiting. The user may exit after initialization or after a load operation, even if the response does not indicate completion or accurate values. Any writes to the CR94[SWLVL\_EXIT] while the CR94[SWLVL\_OP\_DONE] is clear will be ignored. As with other operations, the CR94[SWLVL\_OP\_DONE] will be de-asserted at the start of the exiting process and asserted with an interrupt generation when exit has completed.

The value in the CR93[SW\_LVL\_MODE] is sampled when the CR93[SWLVL\_START] is asserted, and must remain at the same value until the CR94[SWLVL\_EXIT] operation has been completed. If this parameter is changed during any load operations, the MC may exhibit unstable behavior.

### NOTE

Although an interrupt is generated at the end of each step in the leveling process, the system does not have access to the memory served by the controller. The command queue is disabled during this time and the memory is in a state in which it will not accept read or write commands. Any interrupt-servicing routine will need to be developed with the knowledge that it will not have access to this memory, or the user may first mask interrupt(s) by setting the associated bits in the CR82[INT\_MASK] to 'b1 before performing leveling through software.

#### 10.1.6.16.2 Software Write Leveling

Write leveling is a feature of DDR3 memories that is used to align the rising edge of the memory clock and the rising edge of the write data strobe relative to each other at the memory interface, accounting for system skew. Write leveling must be done per data slice to allow proper alignment of clock and DQS.

The procedure outlined in the above mentioned Detailed Software Leveling Procedure Detailed section will be followed for write leveling, gate training and read leveling. This section details the specific procedure for write leveling through software.

The CR93[SW\_LVL\_MODE] must also be programmed to 'b01 to indicate the desire to perform a write leveling operation through software.

**10.1.6.16.2.1 Software Write Leveling in MC Evaluation Mode**

The software should perform the following sequence:

1. Software may initiate a write leveling operation at any time, or as a response to the leveling request interrupt (bit 17) being set to 'b1 in the CR80[INT\_STAT]. Software is not required to respond to the hardware interrupt.

If the hardware interrupt is being used, the refresh timer may have expired. Read the CR94[LVL\_STATUS] parameter to determine the type of leveling operation being requested. If bit [16] is set, then a write leveling operation is being requested.

2. Ensure that appropriate values are programmed in the CR139[PHY\_WRLV\_DLL], CR139[PHY\_WRLV\_EN], CR139[PHY\_WRLV\_LOAD], CR139[PHY\_WRLV\_RESPLAT], CR140[PHY\_WRLV\_WW], CR17[TMOD], CR96[WLDQSEN], CR96[WLMRD].
3. Ensure that CR95[WRLVL\_CS] is set to 'b0.
4. Program the CR93[SW\_LVL\_MODE] to 'b01.
5. Set the CR93[SWLVL\_START] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], complete the current command, inhibit the command queue and issue a precharge\_all to the memory banks if necessary. A mode register write (MR1 bit A7) will place the memory into write leveling mode and, wait TMOD cycles, the PHY write level enable signal will be asserted to enable the PHY write leveling logic. After WLDQSEN cycles, the DQS strobe is sent.

6. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.
7. Program delay values for each data slice X into the WRLVL\_DL\_X bits.
8. Set the CR93[SWLVL\_LOAD] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], wait PHY\_WRLV\_EN cycles and then pass the initial WRLVL\_DL\_X values to the PHY. After PHY\_WRLV\_LOAD cycles have passed, the controller will then send a signal to the PHY to load the delay values into the slave DLLs. The MC will ensure that PHY\_WRLV\_DLL cycles have elapsed and then initiate a write level strobe. After PHY\_WRLV\_RESPLAT cycles, the MC will load the returned values from the PHY into the SWLVL\_RESP\_X bits for each data slice X.

9. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.
10. Read the responses from the SWLVL\_RESP\_X bits.

A “1” indicates the rising edge of the strobe occurred during the high phase of the clock and a “0” indicates the rising edge of the strobe occurred during the low phase of the clock. In general, the user will want to increase the delay if a “0” response was received or decrease the delay if a “1” response was received.

11. Based on the response for each slice, a higher or lower delay value should be programmed into each WRLVL\_DL\_X bits. Note that the software must track the “previous” value of the response for future evaluation
12. Set the CR93[SWLVL\_LOAD] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], pass the updated WRLVL\_DL\_X values to the PHY, wait PHY\_WRLV\_LOAD clock cycles and then send a signal to the PHY to load the updated values into the slave DLLs. The MC will wait PHY\_WRLV\_DLL cycles and ensure that PHY\_WRLV\_RR cycles have elapsed before issuing another write level strobe. After PHY\_WRLV\_RESPLAT cycles, the MC will load the values returned by the PHY into the SWLVL\_RESP\_X bits for each data slice X.

13. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt CR80[INT\_STAT] until the operation has completed
14. Read the responses from the SWLVL\_RESP\_X bits. The meaning of the response is based on the previous response and how the delay was changed for this iteration. [Table 10-25](#) below can be used to help the user determine the next actions to be used in Step 15.
15. Repeat steps 11 through 14 until the transition point has been located, or the delay value has reached the maximum or minimum possible.
16. Set the CR94[SWLVL\_EXIT] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], perform a mode register write to disable the write leveling mode for the memory and de-assert the PHY write level enable signal. The command queue will be enabled for normal operation.

17. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.

**Table 10-25. Write Leveling Responses in MC Evaluation Mode**

Previous	Current	Delay Change	Suggested Action
0	0	Incremented	Increment delay value
0	0	Decrement	Decrement delay value
0	1	Incremented	Rising edge transition point has been located.
0	1	Decrement	Decrement delay value (leveling is attempting to locate rising edge.)

*Table continues on the next page...*

**Table 10-25. Write Leveling Responses in MC Evaluation Mode (continued)**

Previous	Current	Delay Change	Suggested Action
1	0	Incremented	Increment delay value (leveling is attempting to locate rising edge.)
1	0	Decrement	Rising edge transition point has been located.
1	1	Incremented	Increment delay value
1	1	Decrement	Decrement delay value

### 10.1.6.16.2.2 Software Write Leveling Software Considerations

When conducting Write Leveling Operations, the software should be prepared for some of these anomalous conditions should they be encountered.

1. The delay value may reach the minimum or maximum possible without finding the edges of the clock relative to the strobe. In this case, the software should determine whether the smallest or largest value of the delay line is most appropriate, or whether another adjustment is required to place the signal within the range of the delay line.
2. If the initial delay value causes the strobe to just miss the rising edge of the clock, a full cycle of delay may be required to find the next rising edge. However, this full cycle of delay may cause the data to ultimately be delayed a cycle longer than needed. If the initial strobe just misses the clock edge, the initial value may be the correct value of delay. For example, if the initial delay tested responded with a “1”, then the correct delay may be 0x0.
3. The software must be aware of any limitations of the delay lines in the PHY, including maximum delay values that can be programmed.
4. Once the data slices have been leveled, incremental re-leveling may be accomplished more quickly by starting with the previous value and incrementing or decrementing the delay based on the responses.
5. Ideally, the signal should be placed away from the edges of the delay line to allow flexibility in adjustment.

### 10.1.6.16.3 Software Gate Training

Gate training is a feature of DDR3 memories that is used to align the rising edge of the read data strobe gate in the middle of the preamble of the read data strobe signal at the memory interface. The procedure outlined in above mentioned Detailed Software Leveling Procedure section will be followed for write leveling, gate training and read leveling. This section details the specific procedure for gate training through software.

Since the gate is being aligned to the first read DQS, the user should adjust the gate by a 1/2 cycle forward prior to performing gate training. Then, the 1/2 cycle delay should be removed, aligning the gate in the center of the preamble. In addition, the DFI specification requires that the gate signals must assert during the preamble or first high phase of the read DQS.

The DFI training interface timing parameters must be defined for the system. The CR93[SW\_LVL\_MODE] must also be set to 'b11 to indicate the desire to perform a gate training operation through software.

#### 10.1.6.16.3.1 Software Gate Training in MC Evaluation Mode

The software should perform the following sequence:

1. Software may initiate a gate training operation at any time, or as a response to the leveling request interrupt (bit 17) being set to 'b1 in the CR80[INT\_STAT]. Software is not required to respond to the hardware interrupt.

If the hardware interrupt is being used, the refresh timer may have expired. Read the CR94[LVL\_STATUS] parameter to determine the type of leveling operation being requested. If bit [18] is set, then a gate training operation is being requested.

2. Ensure that appropriate values are programmed in the CR144[PHY\_RDLV\_DLL], CR144[PHY\_RDLV\_EN], CR144[PHY\_RDLV\_LOAD], CR144[PHY\_RDLV\_RES], CR146[PHY\_RDLV\_RESP], CR145[PHY\_RDLV\_RR].
3. Add a 1/2 clock cycle increment to the DQS gate by setting PHY02[EN\_HALF\_CAS], PHY18[EN\_HALF\_CAS], PHY02[GATE\_CFG] and PHY18[GATE\_CFG] = 1.
4. Set the CR93[SW\_LVL\_MODE] to 'b11.
5. Set the CR93[SWLVL\_START] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], complete the current command, inhibit the command queue and issue a precharge\_all to the memory banks if necessary. An MPR write (MR3 bit A2) will enable read leveling for the memory and the PHY read level gate enable signal will be asserted to enable the PHY gate training logic.

6. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.
7. Program delay values for each data slice X into the RDLVL\_GTDL\_X bits.
8. Set the CR93[SWLVL\_LOAD] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], wait PHY\_RDLV\_EN cycles and then pass the initial RDLVL\_GTDL\_X values to the PHY. After PHY\_RDLV\_LOAD cycles, the MC will send a signal to the PHY to load the initial values into the slave DLLs. The MC will ensure that PHY\_RDLV\_DLL cycles have elapsed and then initiate a read burst. After PHY\_RDLVL\_RESP cycles, the MC will load the responses from the PHY into the SWLVL\_RESP\_X bits for each data slice X.

9. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.

The value returned will be the sampled value of DQS at the rising edge of the gate signal. In general, the user will want to increase the delay if a “0” response was received or decrease the delay if a “1” response was received.

10. Based on the response for each slice, a higher or lower delay value should be programmed into each RDLVL\_GTDL\_X bits. Note that the software must track the “previous” value of the response for future evaluation.
11. Set the CR93[SWLVL\_LOAD] to 'b1. The MC will clear the CR94[SWLVL\_OP\_DONE], pass the updated RDLVL\_GTDL\_X values to the PHY, for PHY\_RDLV\_LOAD clock cycles, and then send a signal to the PHY to load the updated values into the slave DLLs. The MC will wait PHY\_RDLV\_DLL clock cycles and ensure that PHY\_RDLV\_RR cycles have elapsed before issuing another read burst. After PHY\_RDLV\_RESP cycles, the MC will load the returned values from the PHY into the SWLVL\_RESP\_X bits for each data slice X.
12. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt CR80[INT\_STAT] until the operation has completed.
13. Read the responses from the SWLVL\_RESP\_X bits. The meaning of the response is based on the previous response and how the delay was changed for this iteration. [Table 10-26](#) below can be used to help the user determine the next actions to be used in Step 14.
14. Repeat steps 10 through 13 until the gate is aligned to the rising edge of the read DQS for each data slice, or the delay value has reached the maximum or minimum possible
15. Remove the ½ clock cycle increment to the DQS gate by setting PHY02[EN\_HALF\_CAS], PHY18[EN\_HALF\_CAS], PHY02[GATE\_CFG] and PHY18[GATE\_CFG] = 0.
16. Set the CR94[SWLVL\_EXIT] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE] , perform a mode register write to disable the read leveling mode for the memory and de-assert the PHY read level gate enable signal. The command queue will be enabled for normal operation.

17. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.

**Table 10-26. Gate Training Responses in MC Evaluation Mode**

Previous	Current	Delay Change	Suggested Action
0	0	Incremented	Increment delay value
0	0	Decrement	Decrement delay value
0	1	Incremented	Rising edge transition point has been located.
0	1	Decrement	Decrement delay value
1	0	Incremented	Increment delay value
1	0	Decrement	Rising edge transition point has been located.
1	1	Incremented	Increment delay value
1	1	Decrement	Decrement delay value

#### 10.1.6.16.3.2 Software Gate Training Software Considerations

When conducting Gate Training Operations, the software should be prepared for some of these anomalous conditions should they be encountered.

1. If the delay value reaches the minimum or maximum possible without finding the edge of the DQS, an error has occurred in gate training.
2. Once the data slices have been leveled, incremental re-leveling may be accomplished more quickly by starting with the previous value and incrementing or decrementing the delay based on the responses.
3. Once gate training has been completed, the user should use read and write data patterns to verify that the gate was placed correctly within the preamble.
4. Ideally, the signal should be placed away from the edges of the delay line to allow flexibility in adjustment.

#### 10.1.6.16.4 Software Read Leveling

Read leveling training is a feature of DDR3 memories that is used to align the rising edge of the read data strobe in the middle of the data eye at the memory interface. The procedure outlined in Software Leveling Procedure Detailed section, will be followed for write leveling, gate training and read leveling. This section details the specific procedure for read leveling through software.

Several parameters in the Controller must be programmed to appropriate values prior to initiating a software read leveling operation. The leveling edge must be identified in the CR101[RDLVL\_EDGE]. The DFI training interface timing parameters must be defined for the system. The CR93[SW\_LEVELING\_MODE] must also be programmed to 'b10 to indicate the desire to perform a read leveling operation through software.

#### 10.1.6.16.4.1 Software Read Leveling in MC Evaluation Mode

The software should perform the following sequence:

1. Software may initiate a write leveling operation at any time, or as a response to the leveling request interrupt (bit 17) being set to 'b1 in the CR80[INT\_STAT]. Software is not required to respond to the hardware interrupt.

If the hardware interrupt is being used, the refresh timer may be have expired. Read the CR94[LVL\_STATUS] parameter to determine the type of leveling operation being requested. If bit [17] is set, then a read leveling operation is being requested.

2. Ensure that appropriate values are programmed in the CR144[PHY\_RDLV\_DLL], CR144[PHY\_RDLV\_EN], CR144[PHY\_RDLV\_LOAD], CR144[PHY\_RDLV\_RES], CR146[PHY\_RDLV\_RESP], CR145[PHY\_RDLV\_RR].
3. Program the leveling edge in the CR101[RDLVL\_EDGE] parameter
4. Program the CR93[SW\_LVL\_MODE] to 'b01.
5. Set the CR93[SWLVL\_START] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], complete the current command, inhibit the command queue and issue a precharge\_all to the memory banks if necessary. An MPR write (MR3 bit A2) will enable read leveling for the memory and the PHY read level enable signal will be asserted to enable the PHY read levelling logic.

6. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.
7. Program delay values for each data slice X into the RDLVL\_DL\_X bits.
8. Set the CR93[SWLVL\_LOAD] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], wait PHY\_RDLV\_EN clock cycles and then pass the RDLVL\_DL\_X values into the PHY. After PHY\_RDLV\_LOAD cycles, the MC will send a signal to the PHY to load the delay values into the slave DLLs. The MC will ensure that PHY\_RDLV\_DLL cycles have elapsed and then initiate a read burst. After PHY\_RDLV\_RESP cycles, the MC will load the responses from the PHY into the SWLVL\_RESP\_X bits for each data slice X.

9. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the int\_status parameter until the operation has completed.
10. Based on the response for each slice, a higher or lower delay value should be programmed into each RDLVL\_DL\_X bits. Note that the software must track the “previous” value of the response for future evaluation.
11. Read the responses from the SWLVL\_RESP\_X bits. The value returned will be the value of DQ sampled by DQS for each data slice X.
12. Set the CR93[SWLVL\_LOAD] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE], pass the updated RDLVL\_DL\_X values to the PHY, wait PHY\_RDLV\_LOAD cycles and then signal the PHY to load the updated delay values in the slave DLLs. The MC will wait PHY\_RDLV\_DLL cycles and ensure that PHY\_RDLV\_RR has elapsed before issuing another read burst. After PHY\_RDLV\_RESP cycles, the MC will load the responses returned from the PHY into the SWLVL\_RESP\_X bits for each data slice X.

13. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt CR80[INT\_STAT] until the operation has completed.
14. Read the responses from the SWLVL\_RESP\_X bits. The meaning of the response is based on the previous response and how the delay was changed for this iteration. [Table 10-27](#) below can be used to help the user determine the next actions to be used in Step 15.
15. Repeat steps 11 through 14 until the gate is aligned to the rising edge of the read DQS for each data slice, or the delay value has reached the maximum or minimum possible.
16. The ideal delay value for this system will be the midpoint between the rising and falling edge transition points. The midpoint values should be calculated and stored in the RDLVL\_DLL\_X bits for each data slice X. This operation should be completed prior to Step 17 to ensure that the desired calibration value is used by the controller upon exiting the calibration routine.
17. Set the CR94[SWLVL\_EXIT] to 'b1.

The MC will clear the CR94[SWLVL\_OP\_DONE] , perform a mode register write to disable the read leveling mode for the memory and de-assert the PHY read level gate enable signal. The command queue will be enabled for normal operation.

18. Poll the CR94[SWLVL\_OP\_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT\_STAT] until the operation has completed.

**Table 10-27. Read Leveling Responses in MC Evaluation Mode**

Previous	Current	Delay Change	Suggested Action
0	0	Incremented	Increment delay value
0	0	Decrement	Decrement delay value
0	1	Incremented	Rising edge transition point has been located.
0	1	Decrement	Falling edge transition point has been located.
1	0	Incremented	Falling edge transition point has been located.
1	0	Decrement	Rising edge transition point has been located.
1	1	Incremented	Increment delay value
1	1	Decrement	Decrement delay value

#### 10.1.6.16.4.2 Software Read Leveling Software Considerations

When conducting Read Leveling Operations, the software should be prepared for some of these anomalous conditions should they be encountered.

1. Depending on the resolution of the delay elements, as the DQS edge gets near the data edge, the response values may oscillate. This effect should be considered when evaluating whether a specific edge has been found. This is particularly relevant when the first delay adjustment seems to indicate an edge: several samples may be required to determine which edge has been found.
2. The software must be aware of any limitations of the delay lines in the PHY, including maximum delay values that can be programmed.
3. Once the data slices have been leveled, incremental re-leveling may be accomplished more quickly by starting with the previous value and incrementing or decrementing the delay based on the responses.
4. Ideally, the signal should be placed away from the edges of the delay line to allow flexibility in adjustment.

### 10.1.7 Initialization and Application Information

The memory controller requires a sequence for correct operation after power to the microcontroller and memory devices is stable. When power is stable, the memory controller automatically initializes the memory devices.

The procedure to initialize the memory controller is as follows:

1. Assert system reset (managed by device logic) and wait for the reset to get deasserted.
2. Issue write register commands to configure the DRAM protocols and the settings for the memory. Keep the CR00[START] de-asserted during this initialization step.
3. Assert the CR00[START]. This triggers the memory controller to execute the initialization sequence using the bits written into the registers.

The MC will set the initialization complete interrupt (bit [8]) in the CR80[INT\_STAT] when it is ready for commands. In addition, the user should check that the CCM\_CCSR[DDRC\_CLK\_SEL] is enabled before accessing the DDR memory.

### CAUTION

Attempting to access the DRAM DDR devices before the PHY\_CLK is turned on will cause the device to hang.

### NOTE

Each data/CA slice uses its own DLLs. All three master DLLs have to be locked for successful PHY init and following MC init. The lock status can be checked in appropriate PHY status register (registers PHY11/27/43). It is recommended to increase default number of delay elements in lock detector (registers PHY03/19/35). Good starting point is three elements. For safe lock please also set number of lock indications to three (registers PHY03/19/35).

## 10.2 Quad Serial Peripheral Interface (QuadSPI)

### 10.2.1 Introduction

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to four bidirectional data lines.

#### 10.2.1.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices.
- Single, dual, quad modes of operation.

- DDR/DTR mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and SDR mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- DMA support to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access).
  - Inner loop size of DMA access can be configured.
- Multimaster accesses with priority
  - Flexible and configurable buffer for each master
- Multiple interrupt conditions (see [Table 10-37](#))
- Memory mapped read access to connected flash devices.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations.
  - Supports 3-byte and 4-byte addressing.

### 10.2.1.2 Block Diagram

The following figure is a block diagram of the Quad Serial Peripheral Interface (QuadSPI) module.

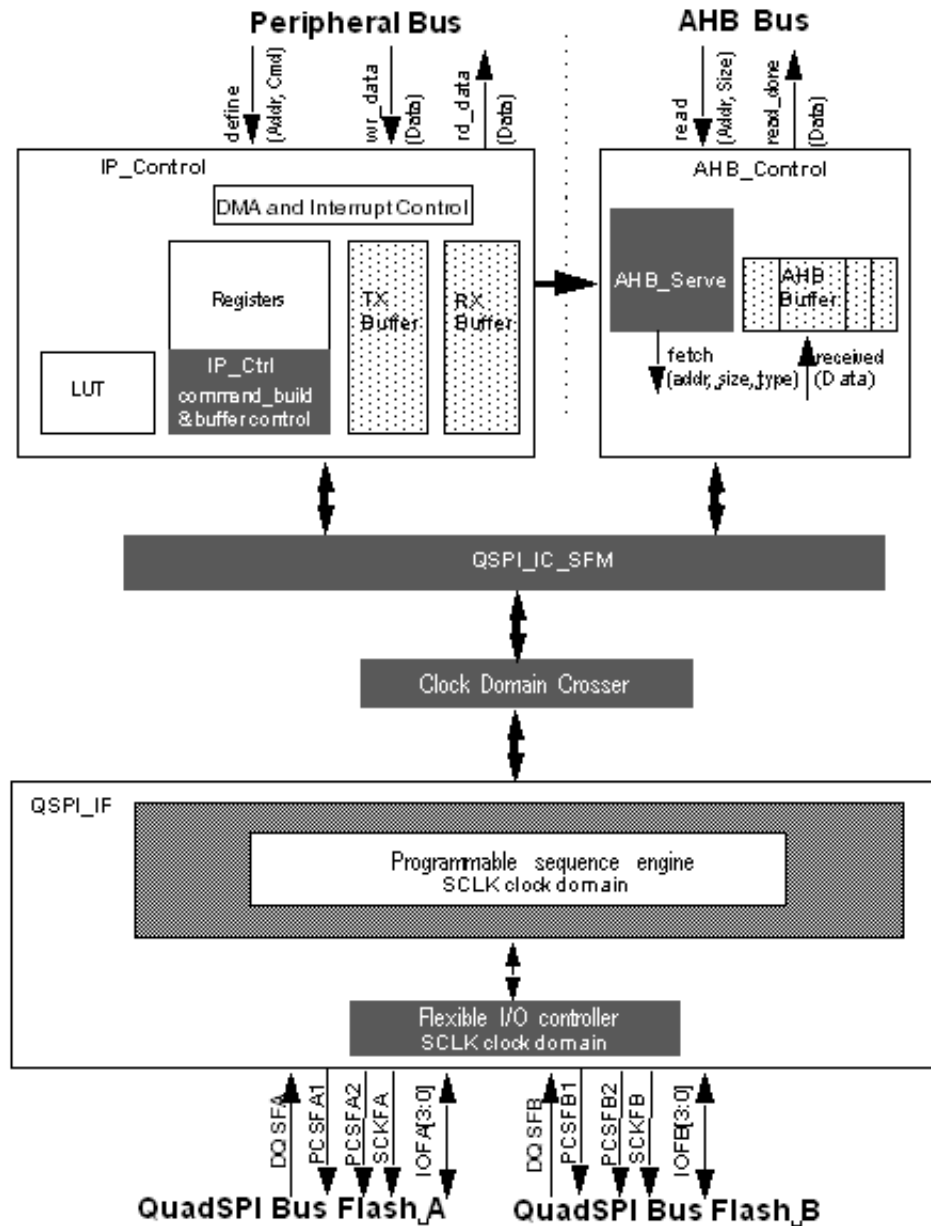

Figure 10-15. QuadSPI Block Diagram

### 10.2.1.3 QuadSPI Modes of Operation

This section provides information about the modes in which the QuadSPI module can be used.

#### 10.2.1.3.1 Normal Mode

In this mode, one or two external serial flash memory devices can be accessed. Further details about this mode of operation can be found in [Modes of Operation \(Normal Mode\)](#).

### 10.2.1.3.2 Module Disable Mode

This mode is used for power management of the device containing the QuadSPI module. It is controlled by signals external to the QuadSPI. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode.

### 10.2.1.3.3 Stop Mode

This mode is also used for power management. When a request is made to enter Stop Mode, the QuadSPI block completes the action currently being processed, before the request is acknowledged.

## 10.2.1.4 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

**Table 10-28. Acronyms and Abbreviations**

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select
DMA	Direct Memory Access
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a 1 to this field resets the flag

## 10.2.1.5 Glossary for QuadSPI module

**Table 10-29. Glossary**

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in <a href="#">Table 10-34</a> . Refer to <a href="#">AHB Commands</a> for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
QSPI_AMBA_BASE	First address of QuadSPI address space on system memory map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
RX Buffer PUSH Event	<p>Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added.</p> <p>The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.</p>
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to <a href="#">Serial Flash Access Schemes</a> for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to <a href="#">Serial Flash Access Schemes</a> for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to <a href="#">Table 10-47</a> for details on errors.
Single/Dual/Quad Instructions	<p>Depending on the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines.</p> <ul style="list-style-type: none"> <li>• Single: Single line I/O with one data out and one data in line to/from the serial flash device.</li> </ul>

*Table continues on the next page...*

**Table 10-29. Glossary (continued)**

Term	Definition
	<ul style="list-style-type: none"> <li>Dual: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module</li> <li>Quad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI</li> </ul>
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode-and/or dummy bytes, transmit and/or receive data.
LUT	Look-up table.

## 10.2.2 External Signal Description

This section provides the external signal information of the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

**Table 10-30. Signal Properties**

Signal Name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash A1	O	This signal is the chip select for the serial flash device A1. A1 represents the first device in a dual-die package flash A or the first of the two flash devices that share IOFA. Refer to <a href="#">Dual Die Flashes</a> for more details.
PCSFA2	Peripheral Chip Select Flash A2	O	This signal is the chip select for the serial flash device A2. A2 represents the second device in a dual-die package flash A or the second of the two flash devices that share IOFA. Refer to <a href="#">Dual Die Flashes</a> for more details.
PCSFB1	Peripheral Chip Select Flash B1	O	This signal is the chip select for the serial flash device B1. B1 represents the first device in a dual-die package flash B or the first of the two flash devices that share IOFB. Refer to <a href="#">Dual Die Flashes</a> for more details.
PCSFB2	Peripheral Chip Select Flash B2	O	This signal is the chip select for the serial flash device B2. B2 represents the second device in a dual-die package flash B or the second of the two flash devices that share IOFB. Refer to <a href="#">Dual Die Flashes</a> for more details.
SCKFA	Serial Clock Flash A	O	This signal is the serial clock output to the serial flash device A.
SCKFB	Serial Clock Flash B	O	This signal is the serial clock output to the serial flash device B.
IOFA[3:0]	Serial I/O Flash A	I/O	These signals are the data I/O lines to/from the serial flash device A. Refer to <a href="#">Driving External Signals</a> for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as control inputs when Single and Dual Instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1].
IOFB[3:0]	Serial I/O Flash B	I/O	These signals are the data I/O lines to/from the serial flash device B. Refer to <a href="#">Driving External Signals</a> for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as

*Table continues on the next page...*

**Table 10-30. Signal Properties (continued)**

Signal Name	Function	Direction	Description
			control inputs when Single and Dual Instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFB[0] and expects data on IOFB[1].
DQSFA	Data Strobe signal Flash A	I	Data strobe signal for port A. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.
DQSFB	Data Strobe signal Flash B	I	Data strobe signal for port B. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.

### 10.2.2.1 Driving External Signals

The different phases of the serial flash access scheme are shown in the following figure.

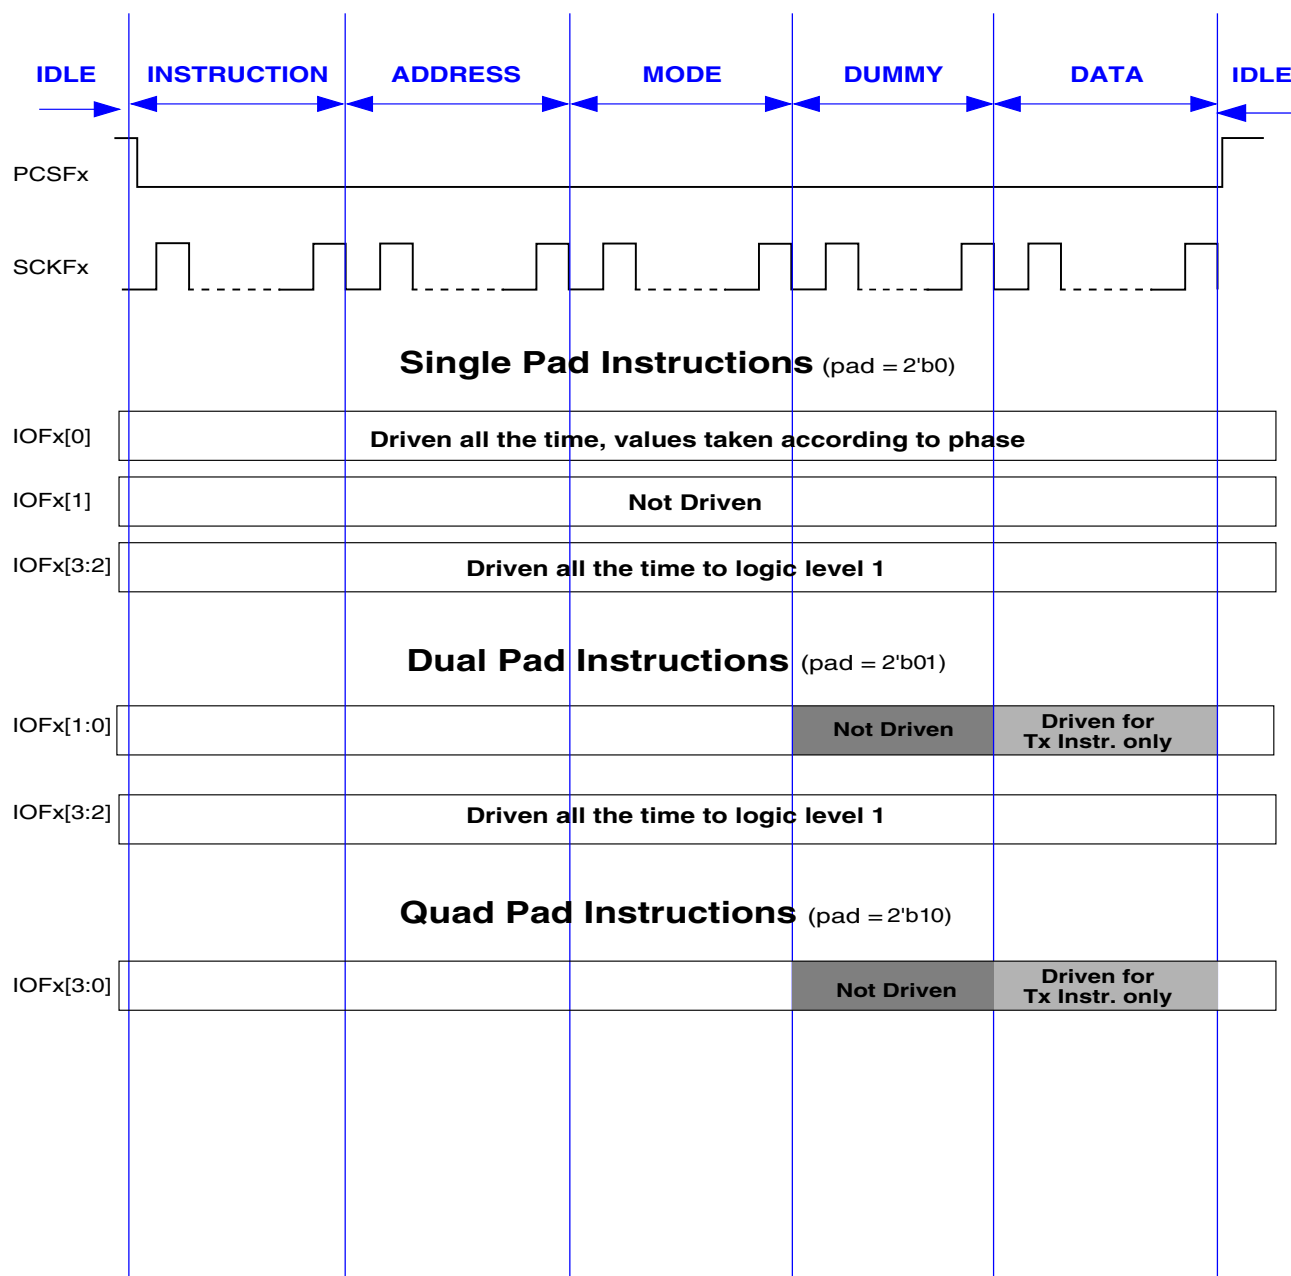

Figure 10-16. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- **IDLE:** Serial flash device not selected. No interaction with the serial flash device. All IOFx signals driven.
- **INSTRUCTION:** Serial flash device selected. The instruction is sent to the serial flash device. All IOFx signals are driven.

- **ADDRESS:** Serial Flash Address is sent to the device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- **MODE:** Mode bytes are sent to the serial flash device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- **DUMMY:** Dummy clocks are provided to the serial flash device. Refer to the [Figure 10-16](#) for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- **DATA:** Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device. In Parallel Flash Mode this applies to both serial flash devices simultaneously.

## 10.2.3 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

### 10.2.3.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

**Table 10-31. Register Write Access Restrictions**

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if <i>QSPI_MCR[MDIS] = 1</i> .
Normal Mode	Write access only if the module is in <i>Normal Mode</i> .

### • Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

## 10.2.3.2 Peripheral Bus Register Descriptions

This section provides the memory map and register definitions of the QuadSPI module.

**QuadSPI memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4004_4000	Module Configuration Register (QuadSPI0_MCR)	32	R/W	000F_4000h	<a href="#">10.2.3.2.1/1624</a>
4004_4008	IP Configuration Register (QuadSPI0_IPCR)	32	R/W	0000_0000h	<a href="#">10.2.3.2.2/1626</a>
4004_400C	Flash Configuration Register (QuadSPI0_FLSHCR)	32	R/W	0000_0303h	<a href="#">10.2.3.2.3/1627</a>
4004_4010	Buffer0 Configuration Register (QuadSPI0_BUF0CR)	32	R/W	<a href="#">See section</a>	<a href="#">10.2.3.2.4/1627</a>
4004_4014	Buffer1 Configuration Register (QuadSPI0_BUF1CR)	32	R/W	<a href="#">See section</a>	<a href="#">10.2.3.2.5/1628</a>
4004_4018	Buffer2 Configuration Register (QuadSPI0_BUF2CR)	32	R/W	<a href="#">See section</a>	<a href="#">10.2.3.2.6/1629</a>
4004_401C	Buffer3 Configuration Register (QuadSPI0_BUF3CR)	32	R/W	<a href="#">See section</a>	<a href="#">10.2.3.2.7/1630</a>
4004_4020	Buffer Generic Configuration Register (QuadSPI0_BFGENCR)	32	R/W	0000_0000h	<a href="#">10.2.3.2.8/1631</a>
4004_4024	SOC Configuration Register (QuadSPI0_SOCCR)	32	R/W	0000_0000h	<a href="#">10.2.3.2.9/1632</a>

*Table continues on the next page...*

## QuadSPI memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4004_4030	Buffer0 Top Index Register (QuadSPI0_BUF0IND)	32	R/W	0000_0000h	<a href="#">10.2.3.2.10/1632</a>

**QuadSPIx\_MCR field descriptions**

Field	Description
31–24 SCLKCFG	Serial Clock Configuration. This field configuration is chip specific. For details, refer to chip-specific QuadSPI information. It may be used for dividing clocks.
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state.  0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.

*Table continues on the next page...*

## QuadSPIx\_MCR field descriptions (continued)

Field	Description
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidates the TX Buffer content. This is a self-clearing field.  0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidates the RX Buffer. This is a self-clearing field.  0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable  0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable. This field is valid for both SDR and DDR mode. For more details, refer to <a href="#">Data Strobe (DQS) sampling method</a> .  0 DQS disabled. 1 DQS enabled. When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5–4 Reserved	This field is reserved.
3–2 Reserved	This field is reserved.
1 SWRSTHD	Software reset for AHB domain  0 No action 1 AHB domain flops are reset. Does not reset configuration registers.  It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.  <b>NOTE:</b> The software resets need the clock to be running to propagate to the design. The MCR[MDIS] should therefore be set to 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTHD] to 0), it is recommended to set the MCR[MDIS] bit to 1. Once the software resets have been deasserted, the normal operation can be started by setting the MCR[MDIS] bit to 0.
0 SWRSTSD	Software reset for serial flash domain  0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers.  It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

*Table continues on the next page...*

## QuadSPIx\_MCR field descriptions (continued)

Field	Description
	<b>NOTE:</b> The software resets need the clock to be running to propagate to the design. The MCR[MDIS] should therefore be set to 0 when the software reset bits are asserted. Also, before they can be deasserted again (by setting MCR[SWRSTSD] to 0), it is recommended to set the MCR[MDIS] bit to 1. Once the software resets have been deasserted, the normal operation can be started by setting the MCR[MDIS] bit to 0.

## 10.2.3.2.2 IP Configuration Register (QuadSPIx\_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to [Normal Mode](#), for details about the command triggering and command execution.

Write:

- $QSPI\_SR[IP\_ACC]=0$

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				SEQID				Reserved							PAR_EN
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IDATSZ															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## QuadSPIx\_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up table. This field defines bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to <a href="#">Look-up Table</a> for more details. A write to this field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to <a href="#">Parallel Flash Mode</a> for more details.
IDATSZ	IP data transfer size. Defines the data transfer size in bytes of the IP command.

### 10.2.3.2.3 Flash Configuration Register (QuadSPIx\_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$
- $QSPI\_SR[IP\_ACC] = 0$

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																TCSH					Reserved				TCSS						
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	

#### QuadSPIx\_FLSHCR field descriptions

Field	Description
31–12 -	This field is reserved. Reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles.  <b>NOTE:</b> The actual delay between chip select and clock is defined as: <ul style="list-style-type: none"> <li>• <math>TCSH = 1 \text{ SCK clk}</math> if <math>N = 0/1</math> else, <math>N \text{ SCK clk}</math> if <math>N &gt; 1</math>, where <math>N</math> is the setting of TCSH</li> </ul>
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles.  <b>NOTE:</b> <ol style="list-style-type: none"> <li>1. The actual delay between chip select and clock is defined as: <ul style="list-style-type: none"> <li>• <math>TCSS = 0.5 \text{ SCK clk}</math> if <math>N = 0/1</math> else, <math>N + 0.5 \text{ SCK clk}</math> if <math>N &gt; 1</math>, where <math>N</math> is the setting of TCSS.</li> </ul> </li> <li>2. Any update to the TCSS register bits is visible on the flash interface only from the second transaction following the update.</li> </ol>

### 10.2.3.2.4 Buffer0 Configuration Register (QuadSPIx\_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP\_EN field of this register.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

## Quad Serial Peripheral Interface (QuadSPI)

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

\* Notes:

- MSTRID field: See the module configuration for reset value.

### QuadSPIx\_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable. When set, the master/projects/Modules/D_IP_QUADSPI_Vybrid/topics/flexible_ahb_buffers associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to <a href="#">Flexible AHB Buffers</a> for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size  Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

### 10.2.3.2.5 Buffer1 Configuration Register (QuadSPIx\_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																ADATSZ								Reserved				MSTRID			
W

\* Notes:

- MSTRID field: See the module configuration for reset value.

### QuadSPIx\_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size  Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

### 10.2.3.2.6 Buffer2 Configuration Register (QuadSPIx\_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*	*

\* Notes:

- MSTRID field: See the module configuration for the device specific reset value.

### QuadSPIx\_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size  Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.

Table continues on the next page...

## QuadSPIx\_BUF2CR field descriptions (continued)

Field	Description
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

## 10.2.3.2.7 Buffer3 Configuration Register (QuadSPIx\_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be considered as an illegal programming. This kind of programming is not allowed.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ALLMST	Reserved														
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*	*

\* Notes:

- MSTRID field: See the module configuration for the device specific reset value.

## QuadSPIx\_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable. When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.

Table continues on the next page...

## QuadSPIx\_BUF3CR field descriptions (continued)

Field	Description
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size  Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. Software should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID. The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer. It must be ensured that the master IDs associated with all buffers must be different.

## 10.2.3.2.8 Buffer Generic Configuration Register (QuadSPIx\_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR\_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## QuadSPIx\_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to <a href="#">Parallel Flash Mode</a> for more details.

Table continues on the next page...

## QuadSPIx\_BFGENCR field descriptions (continued)

Field	Description
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to <a href="#">Look-up Table</a> .  <b>NOTE:</b> If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

## 10.2.3.2.9 SOC Configuration Register (QuadSPIx\_SOCCR)

This register is programmed at chip level for QuadSPI delay chain configuration. For details, refer to chip-specific QuadSPI information.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 24h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## QuadSPIx\_SOCCR field descriptions

Field	Description
31–8 Reserved	This field is reserved.
SOCCFG	This field configuration is chip specific. For details, refer to chip-specific QuadSPI information.

## 10.2.3.2.10 Buffer0 Top Index Register (QuadSPIx\_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned, as each buffer entry is 64 bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 gives 16 bytes etc.

The size of buffer0 is the difference between BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TPINDX0																Reserved															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### QuadSPIx\_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

#### 10.2.3.2.11 Buffer1 Top Index Register (QuadSPIx\_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned as each buffer entry is 64 bits long.

The size of buffer1 is the difference between BUF1IND and BUF0IND. The register value should be entered in bytes. For example, If BUF0IND = 0x100 then setting BUF1IND = 0x130 will set buffer1 size to 0x30 bytes.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

*Write:*

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TPINDX1																Reserved															
W

#### QuadSPIx\_BUF1IND field descriptions

Field	Description
31–3 TPINDX1	Top index of buffer 1.
Reserved	This field is reserved.

10.2.3.2.12 Buffer2 Top Index Register (QuadSPIx\_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that the 3 LSBs of this register are set to zero. This ensures that the buffer is 64-bit aligned as each buffer entry is 64 bits long.

The size of buffer2 is the difference between the BUF2IND and BUF1IND. The register value should be entered in bytes. For example, if BUF1IND = 0x130 then setting BUF2IND = 0x180 will set buffer2 size to 0x50 bytes.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 38h offset

QuadSPIx\_BUF2IND field descriptions

Field	Description
31–3 TPINDX2	Top index of buffer 2.
Reserved	This field is reserved.

10.2.3.2.13 Serial Flash Address Register (QuadSPIx\_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24-bit mode, only bits 23-0 are sent to the flash. In 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 Refer to [Table 10-32](#) for the mapping between the access mode and the QSPI\_SFAR content and to [Normal Mode](#) for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI\_SFAR register lies in the valid flash address range as defined in [Table 10-32](#).

Write:

- $QSPI\_SR[IP\_ACC] = 0$

Address: Base address + 100h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## QuadSPIx\_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter. Indicates how many entries of 4 bytes have been removed from the RX Buffer. For example, a value of 0x2 would indicate 8 bytes have been removed.  It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDP]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details, refer to <a href="#">AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)</a> and "Data Transfer from the QuadSPI Module Internal Buffers" section in <a href="#">Flash Read</a> .
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level. Indicates how many entries of 4 bytes are still available in the RX Buffer. For example, a value of 0x2 would indicate 8 bytes are available.
Reserved	This field is reserved.

## 10.2.3.2.16 RX Buffer Control Register (QuadSPIx\_RBCT)

This register contains control data related to the receive data buffer.

Write:

- $QSPI\_SR[IP\_ACC] = 0$

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## QuadSPIx\_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout. This field specifies the access scheme for the RX Buffer readout.  0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to <a href="#">Exclusive Access to Serial Flash for AHB Commands</a> .  1 RX Buffer content is read using the IP Bus registers QSPI_RBDRO to QSPI_RBDRI31.

Table continues on the next page...

**QuadSPIx\_RBCT field descriptions (continued)**

Field	Description
7–5 Reserved	This field is reserved.
WMRK	RX Buffer Watermark. This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted. The value should be entered as the number of 4-byte entries minus 1. For example, a value of 0x0 would set the watermark to 4 bytes, 1 to 8 bytes, 2 to 12 bytes, and so on. For details, refer to <a href="#">DMA Usage</a> .

**10.2.3.2.17 TX Buffer Status Register (QuadSPIx\_TBSR)**

This register contains information related to the transmit data buffer.

Address: Base address + 150h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**QuadSPIx\_TBSR field descriptions**

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written to QSPI_MCR[CLR_TXF]. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to <a href="#">TX Buffer Data Register (QuadSPI_TBDR)</a> for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

**10.2.3.2.18 TX Buffer Data Register (QuadSPIx\_TBDR)**

The QSPI\_TBDR register provides access to the circular TX Buffer of depth 64 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to [Table 10-41](#) for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of one data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

*Write:*

- $QSPI\_SR[TXFULL] = 0$

32-bit write access required

Address: Base address + 154h offset

QuadSPIx\_TBDR field descriptions

Field	Description
TXDATA	<div>TX Data</div> <div>On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSTR[TRBFL] field is updated accordingly.</div> <div>On a read access, the last data written to the register is returned.</div>

10.2.3.2.19 Status Register (QuadSP1x\_SR)

The QSPI\_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer, TX Buffer, and the AHB Buffer.

Address: Base address + 15Ch offset

QuadSPiX\_SR field descriptions

Field	Description
31–29 DLPSMP	Data learning pattern sampling point. The sampling point found by the controller with the data learning pattern. <ul style="list-style-type: none"> <li>This is used for DDR only.</li> <li>If the learning fails, this field will return garbage and DLPFF bit will be set.</li> </ul>
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full. Asserted when no more data can be stored.
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXNE	TX Buffer Not Empty: Asserted when TX Buffer contains data.
23 RXDMA	RX Buffer DMA. Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.

Table continues on the next page...

## QuadSPIx\_SR field descriptions (continued)

Field	Description
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full. Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded. Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full. Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full. Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full. Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full. Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty. Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty. Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty. Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty. Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending. Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to <a href="#">Command Arbitration</a> .
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access. Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access. Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy. Asserted when module is currently busy handling a transaction to an external flash device.

### 10.2.3.2.20 Flag Register (QuadSPIx\_FR)

The QSPI\_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

*Write: Enabled Mode*

Address: Base address + 160h offset

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## QuadSPIx\_FR field descriptions

Field	Description
31 DLPFF	Data Learning Pattern Failure Flag. Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern. The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30–29 RESERVED	This field is reserved.
28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag. Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to <a href="#">Tx Buffer Operation</a> for details.
26 TBUF	TX Buffer Underrun Flag. Set when the module tried to pull data although TX Buffer was empty. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is undefined). The application must clear the TX Buffer in response to this event by writing a 1 to the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag. Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to <a href="#">Table 10-39</a> for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag. Set when not all the data read from the serial flash device could be pushed into the RX Buffer.  The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device.  The content of the RX Buffer is not changed.
16 RBDF	RX Buffer Drain Flag. Will be set if the QuadSPI_SR[RXWE] status bit is asserted.  Writing 1 into this bit triggers one of the following actions: <ul style="list-style-type: none"> <li>• If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared.</li> <li>• If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered.</li> </ul> <p>The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>Refer to "Receive Buffer Drain Interrupt or DMA Request" section in <a href="#">Normal Mode Interrupt and DMA Requests</a>, for details.</p>
15 ABSEF	AHB Sequence Error Flag. Set when the execution of an AHB Command is started with a WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register. (QSPI_BUFxCR implies any one of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR.)  Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.  The AHB bus request which triggered this command is answered with an ERROR response.
14 Reserved	Reserved  This field is reserved.

Table continues on the next page...

**QuadSPIx\_FR field descriptions (continued)**

Field	Description
13 Reserved	Reserved  This field is reserved.
12 ABOF	AHB Buffer Overflow Flag. Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly.  The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device.  The content of the AHB Buffer is not changed.
11 IUEF	IP Command Usage Error Flag. Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to <a href="#">Table 10-39</a> table for the related commands.  Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.
10–8 Reserved	This field is reserved.
7 IPAEF	IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs: <ul style="list-style-type: none"> <li>A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAEF flag is ignored.</li> </ul>
6 IPIEF	IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs: <ul style="list-style-type: none"> <li>Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored</li> <li>Write access to the QSPI_SFAR register.</li> <li>Write access to the QSPI_RBCT register.</li> </ul>
5 Reserved	This field is reserved.
4 IPGEF	IP Command Trigger during AHB Grant Error Flag. Set when the following condition occurs: <ul style="list-style-type: none"> <li>A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.</li> </ul>
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag. Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

**10.2.3.2.21 Interrupt and DMA Request Select and Enable Register (QuadSPIx\_RSER)**

The QuadSPI\_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

**NOTE**

Each flag of the QuadSPI\_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

10.2.3.2.22 Sequence Suspend Status Register (QuadSP1x\_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: Base address + 168h offset

Quad Serial Peripheral Interface (QuadSPI)

QuadSPIx\_SPNDST field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

### 10.2.3.2.23 Sequence Pointer Clear Register (QuadSPIx\_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP\_ON\_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI\_IPCR or QSPI\_BFGENCR.

Address: Base address + 16Ch offset

**QuadSPIx\_SPTRCLR field descriptions**

Field	Description
31–9 Reserved	This field is reserved.
8 IPPTRC	IP Pointer Clear: 1: Clears the sequence pointer for IP accesses as defined in QuadSPI_IPCR This is a self-clearing field.
7–1 Reserved	This field is reserved. Reserved.
0 BFPTRC	Buffer Pointer Clear: 1: Clears the sequence pointer for AHB accesses as defined in QuadSPI_BFGENCR. This is a self-clearing field.

### 10.2.3.2.24 Serial Flash A1 Top Address (QuadSPIx\_SFA1AD)

The QSPI\_SFA1AD register provides the address mapping for the serial flash A1. The difference between QSPI\_SFA1AD[TPADA1] and QSPI\_AMBA\_BASE defines the size of the memory map for serial flash A1.

*Write:*

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 180h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### QuadSPIx\_SFB2AD field descriptions

Field	Description
31–10 TPADB2	Top address for Serial Flash B2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

### 10.2.3.2.28 RX Buffer Data Register (QuadSPIx\_RBDRn)

The QuadSPI\_RBDR registers provide access to the individual entries in the RX Buffer. Refer to [Table 10-41](#) for the byte ordering scheme.

QuadSPI\_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI\_RBDR0 to QuadSPI\_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI\_RBSR[RDBFL] is 5. In this case an access to QuadSPI\_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: Base address + 200h offset + (4d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### QuadSPIx\_RBDRn field descriptions

Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in <a href="#">Byte Ordering of Serial Flash Read Data</a> .

### 10.2.3.2.29 LUT Key Register (QuadSPIx\_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to [Look-up Table](#) for details.

*Write: Anytime*

Address: Base address + 300h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### QuadSPIx\_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

### 10.2.3.2.30 LUT Lock Configuration Register (QuadSPIx\_LCKCR)

The LUT lock configuration register is used along with QSPI\_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI\_LUTKEY register for the lock or unlock operation to be successful. Refer to [Look-up Table](#) for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

*Write: Just after writing the LUT Key Register*

*(QSPI\_LUTKEY)*

Address: Base address + 304h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### QuadSPIx\_LCKCR field descriptions

Field	Description
31–2 Reserved	This field is reserved.
1 UNLOCK	Unlocks the LUT when the following two conditions are met: 1. This register is written just after the <a href="#">LUT Key Register (QuadSPI_LUTKEY)</a> 2. The LUT key register was written with 0x5AF05AF0 key

*Table continues on the next page...*

**QuadSPIx\_LCKCR field descriptions (continued)**

Field	Description
0 LOCK	Locks the LUT when the following condition is met: 1. This register is written just after the <a href="#">LUT Key Register (QuadSPI_LUTKEY)</a> 2. The LUT key register was written with 0x5AF05AF0 key

**10.2.3.2.31 Look-up Table register (QuadSPIx\_LUTn)**

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI\_LUT[0], QSPI\_LUT[4], QSPI\_LUT[8] ..... QSPI\_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT63. A maximum of 16 sequences can be defined at one time. [Look-up Table](#) describes the LUT registers in detail.

**NOTE**

The reset values for LUT0 and LUT1 are 0818\_0403h and 2400\_1C08h, respectively.

*Write: Once the LUT is unlocked*

Address: Base address + 310h offset + (4d × i), where i=0d to 63d

\* Notes:

- The reset values for LUT0 and LUT1 are 0818\_0403h and 2400\_1C08h respectively.

**QuadSPIx\_LUTn field descriptions**

Field	Description
31–26 INSTR1	Instruction 1
25–24 PAD1	Pad information for INSTR1.  00 1 Pad 01 2 Pads

*Table continues on the next page...*

**QuadSPIx\_LUTn field descriptions (continued)**

Field	Description
	10 4 Pads 11 NA
23–16 OPRND1	Operand for INSTR1.
15–10 INSTR0	Instruction 0
9–8 PAD0	Pad information for INSTR0.  00 1 Pad 01 2 Pads 10 4 Pads 11 NA
OPRND0	Operand for INSTR0.

**10.2.3.3 Serial Flash Address Assignment**

The serial flash address assignment may be modified by writing into [Serial Flash A1 Top Address \(QuadSPI\\_SFA1AD\)](#) and [Serial Flash A2 Top Address \(QuadSPI\\_SFA2AD\)](#) for device A and into [Serial Flash B1 Top Address \(QuadSPI\\_SFB1AD\)](#) and [Serial Flash B2 Top Address \(QuadSPI\\_SFB2AD\)](#) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

**Table 10-32. Serial Flash Address Assignment**

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(T PADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to <b>Serial Flash A1</b>
TOP_ADDR_MEMA2(T PADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to <b>Serial Flash A2</b>
TOP_ADDR_MEMB1(T PADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to <b>Serial Flash B1</b>
TOP_ADDR_MEMB2(T PADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to <b>Serial Flash A2</b>

### 10.2.3.4 AMBA Bus Register Memory Map

QSPI\_AMBA\_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map..

**Table 10-33. QuadSPI AMBA Bus Memory Map**

Address	Register Name
<b>Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A</b>	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to <a href="#">Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A</a> for details and to <a href="#">Table 10-41</a> and <a href="#">Table 10-45</a> for information about the byte ordering.
<b>Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B</b>	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to <a href="#">Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B</a> for details and to <a href="#">Table 10-41</a> and <a href="#">Table 10-45</a> for information about the byte ordering.
<b>Parallel Flash Mode</b>	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to <a href="#">Parallel Flash Mode</a> for details and to <a href="#">Table 10-44</a> and <a href="#">Table 10-45</a> for information about the byte ordering.
<b>AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)</b>	
QSPI_ARDB_BASE to... (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) Refer to <a href="#">Table 10-41</a> and <a href="#">Table 10-43</a> for information about the byte ordering.

#### Note

Any read access to non-implemented addresses will provide undefined results.

In case single die flash devices, TOP\_ADDR\_MEMA2 and TOP\_ADDR\_MEMB2 should be initialized/programmed to TOP\_ADDR\_MEMA1 and TOP\_ADDR\_MEMB1 respectively- in effect, setting the size of these devices to 0. This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read from the serial flash. The first device of flash A has to be paired with the first device of flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the QSPI\_BFGENCR[PAR\_EN] bit for all masters in AHB driven

mode and via the QSPI\_IPCR[PAR\_EN] in IP driven mode. In parallel mode, the incoming address (SFAR address in case of IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI\_FR[IUEF] flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI\_FR[ABSEF] flag.

In the Individual Flash Modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0] as given in the table above.

In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

### 10.2.3.5 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

#### 10.2.3.5.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI\_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA\_AHB specification. The resulting AHB Command is ignored.

- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

### 10.2.3.5.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI\_AMBA\_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI\_AMBA\_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 10-41](#) and for 64 bit read access the byte ordering is given in [Table 10-45](#).

**Table 10-34. Memory Mapped Individual Flash Mode - Flash A Address Scheme**

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
QSPI_AMBA_BASE + 0x00	QSPI_AMBA_BASE + 0x00	0x00_0000 to 0x00_0003	A1
QSPI_AMBA_BASE + 0x04		0x00_0004 to 0x00_0007	
...	...	...	
TOP_ADDR_MEMA1 - 0x08	TOP_ADDR_MEMA1 - 0x08	(TOP_ADDR_MEMA1 - 0x08) to (TOP_ADDR_MEMA1 - 0x04 - 0x01)	
TOP_ADDR_MEMA1 - 0x04		(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)	
TOP_ADDR_MEMA1 + 0x00	TOP_ADDR_MEMA1 + 0x00_0000	0x00_0000 to 0x00_0003	A2
TOP_ADDR_MEMA1 + 0x04		0x00_0004 to 0x00_0007	
.....	...	...	
TOP_ADDR_MEMA2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMA2 - 0x04		(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

### 10.2.3.5.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP\_ADDR\_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP\_ADDR\_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 10-41](#) and for 64 bit read access the byte ordering is given in [Table 10-45](#).

**Table 10-35. Memory Mapped Individual Flash Mode - Flash B Address Scheme**

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
...	...	...	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	B2
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
.....	...	...	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

### 10.2.3.5.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI\_BFGENCR[PAR\_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 10-43](#) and for 64 bit read access the byte ordering is given in [Table 10-45](#).

**Table 10-36. Memory Mapped Parallel Flash Mode Address Scheme**

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to <a href="#">Parallel mode</a> and <a href="#">Dual Die Flashes</a> .	0x00_0000	0x00_0000
		-	-
		0x00_0001	0x00_0001
		0x00_0002	0x00_0002
QSPI_AMBA_BASE + 0x0000_0004	QSPI_AMBA_BASE + 0x08	-	-
		0x00_0003	0x00_0003
		0x00_0004	0x00_0004
		-	-
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0005	0x00_0005
		-	-
		0x00_0006	0x00_0006
		-	-
QSPI_AMBA_BASE + 0x0000_000C	QSPI_AMBA_BASE + 0x08	0x00_0007	0x00_0007
		-	-
		0x00_0008	0x00_0008
		-	-
...	...	...	...
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

### 10.2.3.5.5 AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)

#### NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

#### memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

**10.2.3.5.5.1 AHB RX Data Buffer register (ARDBn)**

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI\_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in [Flash Read](#) section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to [Byte Ordering of Serial Flash Read Data](#) for the byte ordering scheme.

Valid address range accessible in the QSPI\_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI\_ARDB0 to QSPI\_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI\_RBSR[RDBFL] is 5. In this case an access to QSPI\_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

### ARDBn field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

## 10.2.4 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

**Table 10-37. Assignment of Interrupt Request Lines**

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overn		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
ipi_int_ored	IUEF	Peripheral Command Usage Error
	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF	Logical OR from all the QSPI_FR flags mentioned

## 10.2.5 Functional Description

This section provides the functional information of the QuadSPI module.

### 10.2.5.1 Serial Flash Access Schemes

The following access schemes are possible, depending on the serial flash devices attached to the QuadSPI module.

**Table 10-38. Access Schemes for Serial Flash Data Access**

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	Yes	N/a	Yes
Individual Flash Mode: Access to Flash B	N/a	Yes	Yes
Parallel Flash Mode: Read from Flash A and Flash B	N/a	N/a	Yes

#### Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI\_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI\_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

### 10.2.5.2 Modes of Operation

Refer to [QuadSPI Modes of Operation](#) for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.
  - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to [Flash Programming](#) for further details.
  - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see [Flash Read](#).
- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI\_MCR[MDIS].

### 10.2.5.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

#### 10.2.5.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

**Table 10-39. Instruction set**

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2		Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions .
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads <sup>1</sup> specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads <sup>2</sup> specified
READ	6'd7	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of <a href="#">IP Configuration Register (QuadSPI_IPCR)</a> for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads specified. The data size may be overwritten by writing to the IDATSZ field of <a href="#">IP Configuration Register (QuadSPI_IPCR)</a> register
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions .
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash <sup>3</sup>

Table continues on the next page...

**Table 10-39. Instruction set (continued)**

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
MODE4_DDR	6'd13	$N=2^d\{0,1\}$	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash <sup>4</sup> .
READ_DDR	6'd14	$N=2^d\{0,1,2\}$ 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of <a href="#">IP Configuration Register (QuadSPI_IPCR)</a> for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of <a href="#">IP Configuration Register (QuadSPI_IPCR)</a> register
DATA_LEARN	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the <a href="#">QSPI_SMPR[DDRSMP]</a> values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern. <sup>5</sup>
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2\_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4\_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4\_DDR will take half a cycle on the serial flash interface.
5. It is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

### 10.2.5.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated. The size of buffer 0 is defined as being from 0 to QSPI\_BUF0IND. The Size of buffer 1 is from QSPI\_BUF0IND to

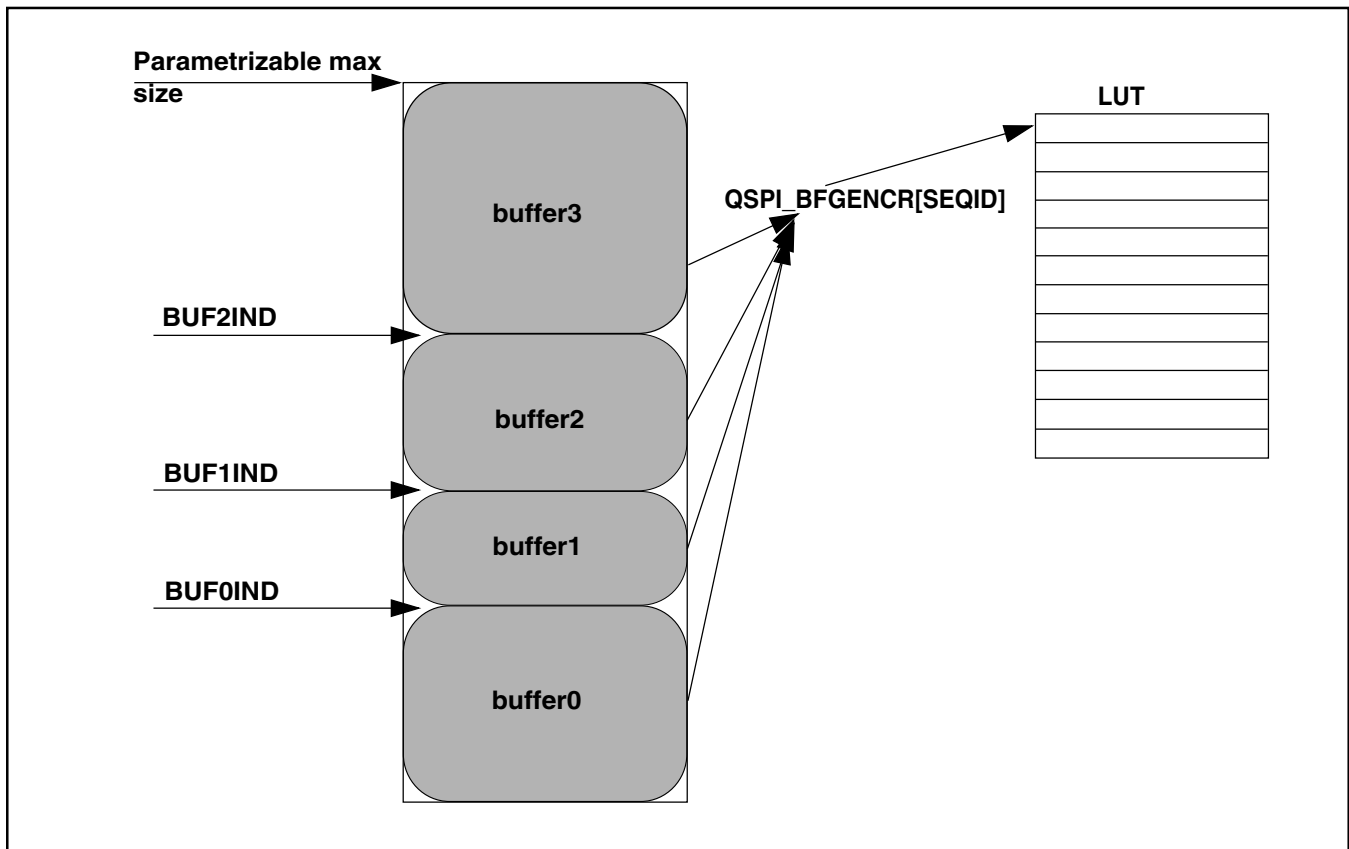

QSPI\_BUF1IND, buffer2 is from QSPI\_BUF1IND to QSPI\_BUF2IND and buffer 3 is from QSPI\_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI\_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI\_BUFxCR[ADATSZ] amount of data from the serial flash. As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI\_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. [Figure 10-17](#) shows the flexible AHB buffers.

The QSPI\_BFGENCR[SEQID] field points to an index of the LUT. Refer to [Look-up Table](#) for details.

**Figure 10-17. Flexible AHB Buffers**

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU\_BUF0CR[HP\_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from [Sequence Suspend Status Register \(QuadSPI\\_SPNDST\)](#).

### 10.2.5.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

### 10.2.5.3.4 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

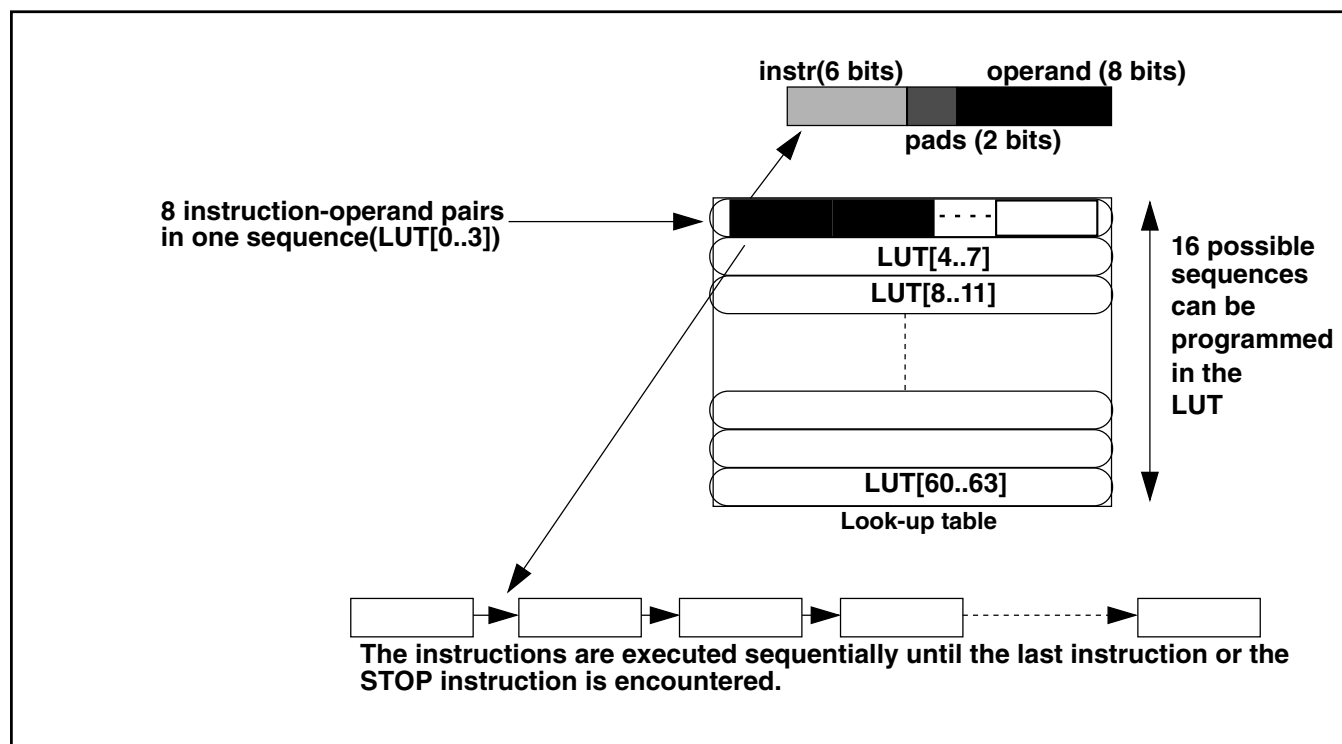

Figure 10-18. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in [Table 10-40](#). After reset the complete LUT may be reprogrammed according to the device connected on board. In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

#### Locking the LUT

1. Write the key (**0x5AF05AF0**) in to the [LUT Key Register \(QuadSPI\\_LUTKEY\)](#).
2. Write 0b01 to the [LUT Lock Configuration Register \(QuadSPI\\_LCKCR\)](#). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

## Unlocking the LUT

1. Write the key (**0x5AF05AF0**) into the [LUT Key Register \(QuadSPI\\_LUTKEY\)](#)
2. Write 0b10 to the [LUT Lock Configuration Register \(QuadSPI\\_LCKCR\)](#). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from QSPI\_LCKCR[UNLOCK] and QSPI\_LCKCR[LOCK] bit.

Some example sequences are defined in [Example Sequences](#). The reset sequence at LUT index 0 is given in the following table.

**Table 10-40. Reset sequence**

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

### 10.2.5.3.5 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI\_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI\_SR[BUSY] is reset. In case of an IP Command the QSPI\_FR[TFF] flag is asserted.

Further details are given in below in [Flash Programming](#) and [Flash Read](#).

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

For IP Commands the required components need to be written into the following registers:

- Write the serial flash address to be used by the instruction into QSPI\_SFAR, refer to [Serial Flash Address Register \(QSPI\\_SFAR\)](#). For IP Commands not related to specific addresses, the base address of the related flash need to be programmed. For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.
- Write the sequence ID and data size details in the [IP Configuration Register \(QSPI\\_IPCR\)](#).
- Note that the write into the QSPI\_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI\_IPCR into one single write. Refer to [IP Configuration Register \(QSPI\\_IPCR\)](#) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI\_IPCR[SEQID] field and the write operation itself is ignored. They are described in [Command Arbitration](#).

- **Using AHB commands**

Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in [Flexible AHB buffers](#).

An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#) and [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#).

Again the possible error conditions are described in [Command Arbitration](#).

### 10.2.5.3.6 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI\_SR[TXNE] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI\_MCR[CLR\_TXF] bit.
2. Program the address related to the command in the QSPI\_SFAR register.

3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI\_TBDR) . At least one word of data must be written into the TX Buffer up to a maximum of 16.
4. Program the QSPI\_IPCR register to trigger the command. The QSPI\_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed. The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI\_TBDR register. The QSPI\_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI\_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI\_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **16** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

#### 10.2.5.3.7 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

##### 1. Reading Serial Flash Data into the QuadSPI Module Internal Buffers

A read access to the external serial flash device can be triggered in two different ways:

- **IP Command Read:** For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI\_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI\_SFAR) and the IP Configuration Register (QSPI\_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI\_MCR[CLR\_RXF] field.

From these inputs, the complete transaction is built when the QSPI\_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command, the IP\_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI\_SR) ). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI\_RBSR[RDBFL].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

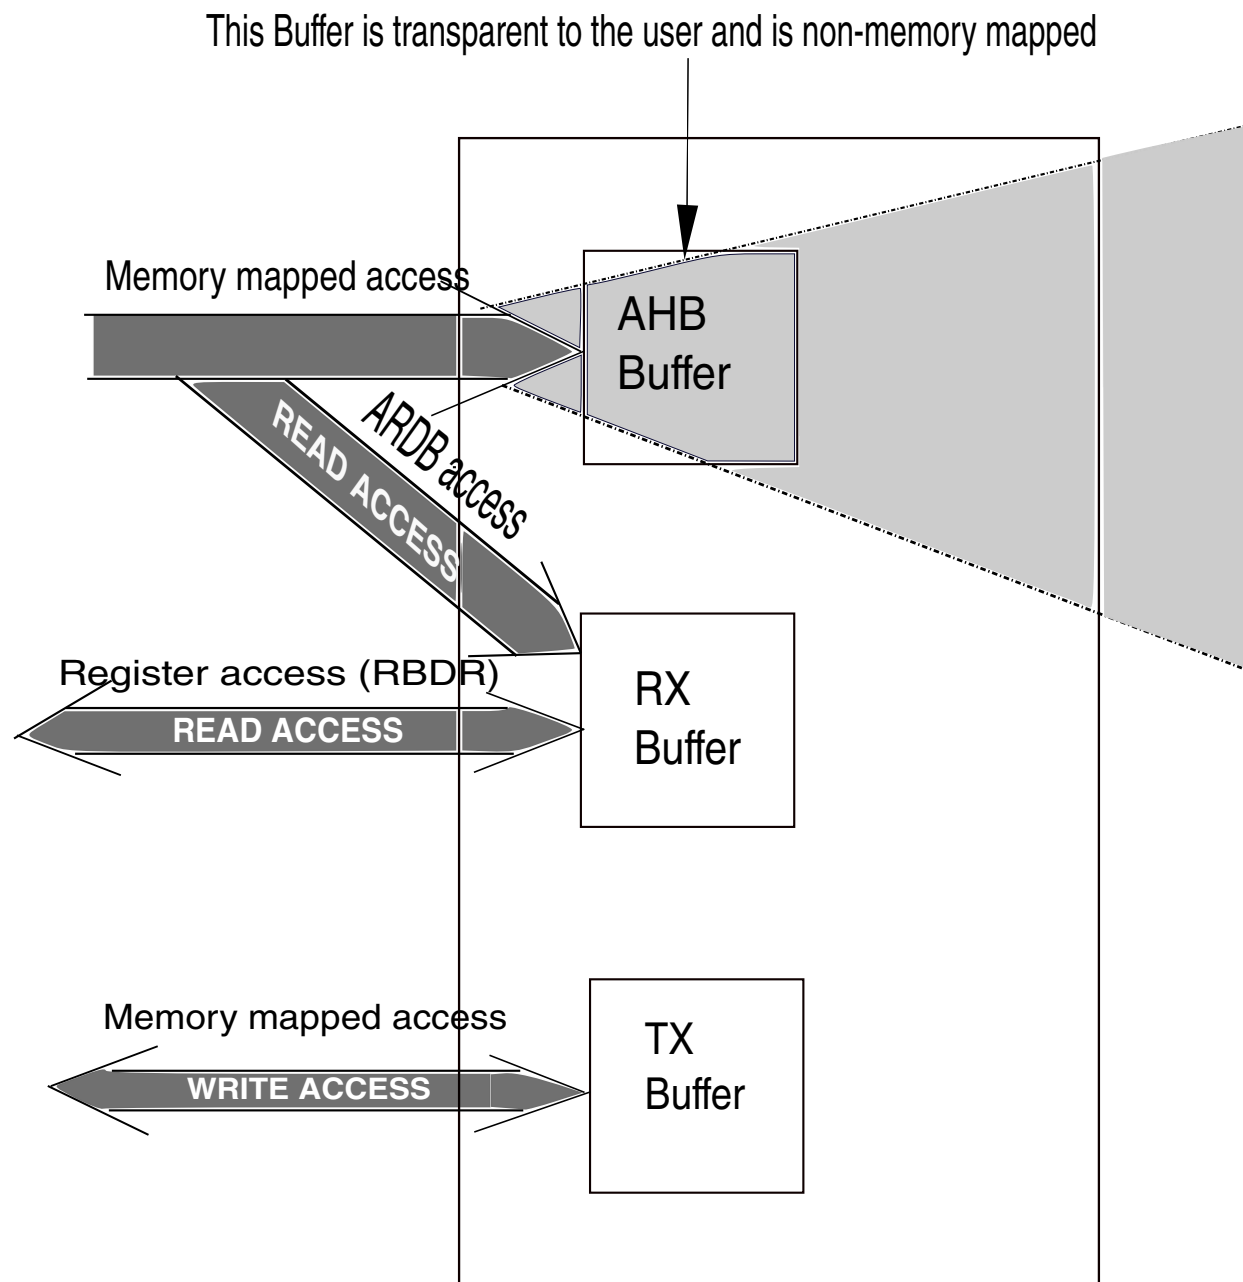

- **AHB Command Read:** For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI\_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI\_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module (refer to [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#), [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#) and [Parallel Flash Mode](#).)

On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI\_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI\_SR[AHB\_ACC] status bit is set driving in turn the QSPI\_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

## 2. Data Transfer from the QuadSPI Module Internal Buffers

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to [Block Diagram](#) for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

**Figure 10-19. QuadSPI memory map**

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

In the IPS address space in the area associated to QSPI\_RBDR0 to QSPI\_RBDR31

In the AHB address space in the area associated to QSPI\_ARDB0 to QSPI\_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI\_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI\_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI\_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI\_RBDR0 or QSPI\_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in [RX Buffer Data Register \(QuadSPI\\_RBDR<sub>n</sub>\)](#) and in [AHB RX Data Buffer \(QSPI\\_ARDB0 to QSPI\\_ARDB31\)](#).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI\_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI\_RBDR<sub>n</sub>) or the AHB address space (QSPI\_ARDB<sub>n</sub>). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI\_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module. The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in [DMA Usage](#).

DMA controlled read out is triggered fully automatically by the assertion of the QSPI\_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI\_RBDR<sub>n</sub> or QSPI\_ARDB<sub>n</sub> related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in [Table 10-33](#) table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress*. If this is not the

case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data.

Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

### 10.2.5.3.8 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI\_SFAR[SFADR] field - corresponds to bit position QSPI\_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

#### • Byte Ordering in Individual Flash Mode

The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

- Flash A or Flash B in Individual Flash Mode
- All AHB data read commands with access size of 32 bit

**Table 10-41. Byte Ordering in Individual Flash Mode**

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

## Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

### • Byte Ordering in Parallel Flash Mode

In Parallel Flash Mode each byte is combined out of 2 half bytes which are read in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI\_RBDR0 register.

**Table 10-42. Serial Flash Device Half Byte Ordering**

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbI0
1	fah1	fal1	fbh1	fbI1
2	fah2	fal2	fbh2	fbI2
3	fah3	fal3	fbh3	fbI3
4	fah4	fal4	fbh4	fbI4
5	fah5	fal5	fbh5	fbI5
6	fah6	fal6	fbh6	fbI6
7	fah7	fal7	fbh7	fbI7
8	fah8	fal8	fbh8	fbI8

The table entry naming reflects the half byte positioning in the serial flash devices:

- <fa>h0 means **Flash A**, <fb>h0 means Flash B.

- fa<**h**>0 means half byte in **high position**, fa<**l**>0 means half byte in low position.
- fah<**0**> means **physical byte address 0** in the serial flash device, fal<**1**> means physical byte address 1 in the serial flash device.

**Table 10-43. Byte Ordering in Parallel Flash Mode - RX Buffer**

<b>QSPI_SFAR[SFADR] set to 0x000_0000</b>								
<b>QSPI_RBDR0</b> <b>QSPI_ARDB0</b>	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
<b>QSPI_RBDR1</b> <b>QSPI_ARDB1</b>	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
<b>QSPI_SFAR[SFADR] set to 0x000_0001</b>								
<b>QSPI_RBDR0</b> <b>QSPI_ARDB0</b>	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
<b>QSPI_RBDR1</b> <b>QSPI_ARDB1</b>	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

### Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

**Table 10-44. Byte Ordering in Parallel Flash Mode - AHB Buffer**

<b>AHB Address</b> <b>(32 Bit Access)</b>	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
<b>AHB Address</b> <b>0x800_0004</b> <b>(32 Bit Access)</b>	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

**Note**

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Buffer Entry Ordering for 64 Bit Read Access**

For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

**Table 10-45. 64 Bit Read Access Buffer Entry Ordering**

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

### 10.2.5.3.9 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the [Flag Register \(QSPI\\_FR\)](#).

**Table 10-46. Interrupt and DMA Request Conditions**

Condition	Flag(QSPI_FR)	DMA
Data Learn pattern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-

*Table continues on the next page...*

**Table 10-46. Interrupt and DMA Request Conditions (continued)**

Condition	Flag(QSPI_FR)	DMA
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the [Flag Register \(QSPI\\_FR\)](#) and a Request Enable bit in the [DMA Request Select and Enable Register \(QSPI\\_RSER\)](#). The RX Buffer Drain Flag (RBDFF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- **Transmit Buffer Fill Interrupt Request:**

The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI\_FR[TBFF] flag is asserted and if the corresponding enable bit (QSPI\_RSER[TBFIE]) is set. Refer to [TX Buffer Operation](#), for details about the assertion of the QSPI\_FR[TBFF] flag.

- **Receive Buffer Drain Interrupt or DMA Request:**

The Receive Buffer Drain IRQ derived from the QSPI\_FR[RBDFF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI\_RBSR[RXWE] bit is set. The QSPI\_RSER[RBDIE] bit enables the related IRQ.

Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI\_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI\_RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- **Buffer Overflow/Underrun Interrupt Request:**

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI\_FR register with the related enable bits in the QSPI\_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI\_RSER[TBUIE] bit is set.

The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI\_RSER[RBOIE] bit is set.

The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI\_RSER[ABOIE] bit is set.

The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI\_FR are set, and the related interrupt enable bits in the QSPI\_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

The IP Command Transaction Finished IRQ indicates the completion of the current IP Command. It is triggered by the QSPI\_FR[TFF] flag and is masked by the QSPI\_RSER[TFIE] bit.

### 10.2.5.3.10 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least one entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI\_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI\_FR[TBUF] flag. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is undefined i.e. once the underrun flag is set, it will return the garbage value until the required number of bytes are not sent. When this Sequence Command is finished, the QSPI\_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI\_TBSR[TRBFL] field.

Refer to [TX Buffer Status Register \(QuadSPI\\_TBSR\)](#) and [Flag Register \(QuadSPI\\_FR\)](#) for details about the TX Buffer related registers.

### 10.2.5.3.11 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR\_DDR command should be programmed with 8'd32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

## 10.2.6 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

### 10.2.6.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

### 10.2.6.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI\_SR and QSPI\_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

#### 10.2.6.2.1 IP Commands

Refer to [IP Configuration Register \(QuadSPI\\_IPCR\)](#) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

Writing the QSPI\_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI\_SR[IPACC] and the QSPI\_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI\_FR[TFF] flag is set.

- **IP Commands - Error Situations**

Refer to [Table 10-47](#) below.

#### 10.2.6.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in [Flash Read](#) for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI\_SR[AHBACC] and the QSPI\_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

#### • IP Commands - Error Situations

Refer to [Table 10-47](#) below.

### 10.2.6.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI\_FR register and additional error-related details.

**Table 10-47. Overview of QSPI\_FR Error Flags**

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
<b>AHB Error Flag</b>	ABSEF	Flash transaction is aborted	AHB sequence contains <ul style="list-style-type: none"> <li>• WRITE instruction</li> <li>• WRITE_DDR instruction</li> </ul>
<b>AHB Error Flag</b>	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
<b>Miscellaneous Error Flag</b>	DLPFF	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
<b>Miscellaneous Error Flag</b>	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
<b>Command Arbitration Error</b>	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and <ul style="list-style-type: none"> <li>• write attempt to QSPI_IPCR register.</li> <li>• write attempt to QSPI_SFAR register.</li> <li>• write attempt to QSPI_RBCT register.</li> </ul>

*Table continues on the next page...*

**Table 10-47. Overview of QSPI\_FR Error Flags (continued)**

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Command Arbitration Error	IPAEF		<ul style="list-style-type: none"> <li>AHB Command already running, another IP Command could not be executed.</li> <li>AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.</li> </ul>
Command Arbitration Error	IPGEF		<ul style="list-style-type: none"> <li>Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.</li> </ul>
IP Command Error	IUEF	—	<ul style="list-style-type: none"> <li>IP Command Usage Error</li> </ul>
Buffer Related Error	RBOF	TFF is asserted on completion	<ul style="list-style-type: none"> <li>RX Buffer Overrun</li> </ul>
Buffer Related Error	TBUF		<ul style="list-style-type: none"> <li>TX Buffer Underrun</li> </ul>

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

#### 10.2.6.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI\_FR[IPAEF] and QSPI\_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for a description of the flags and [Command Arbitration](#), for details about possible command collisions.

#### 10.2.6.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR<sub>n</sub> register) and the other masters by triggering AHB Commands (via ARDB<sub>n</sub> Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer. Refer to [Figure 10-19](#) To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands.

If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI\_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI\_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

#### 10.2.6.3.1 RX Buffer Read via QSPI\_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI\_RBCT[RXBRD] bit.

In this case the QSPI\_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI\_SR[IP\_ACC] is 0), the RX Buffer has been read out completely (QSPI\_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI\_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI\_RBCT[RXBRD]) equal to 1).

#### 10.2.6.3.2 RX Buffer Read via QSPI\_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI\_RBDR0 to QSPI\_RBDR31.

For this case it is recommended to program the QSPI\_RBCT[RXBRD] bit to 1. The QSPI\_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI\_SR[IP\_ACC] is 0), the RX Buffer has been read out completely

(QSPI\_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI\_SR[RXDMA] equal to 0), allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

#### 10.2.6.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in [Exclusive Access to Serial Flash for AHB Commands](#) is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI\_FR[PIEF] flag is asserted when the host tries to write into the QSPI\_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI\_FR[IPAEF] flag is asserted. Refer to [Flag Register \(QuadSPI\\_FR\)](#) for the description of these flags.

When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI\_SR[IP\_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI\_FR[TFF] flag.

#### 10.2.6.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI\_SFAR register. Refer to [Serial Flash Address Register \(QuadSPI\\_SFAR\)](#) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to [AMBA Bus Register Memory Map](#) for details.

### 10.2.6.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

#### 10.2.6.6.1 DMA Usage in Normal Mode

##### 10.2.6.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

#### AHB Bus Side (data read):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI\_RBCT[WMRK] field, therefore the overhead given above distributes among  $(\text{QSPI\_RBCT[WMRK]} + 1) / 2$  read accesses of 64 bit each.

The following table gives some examples for typical use cases:

**Table 10-48. Access Duration Examples - Bus Clock Side**

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop <sup>1</sup>	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	12+2 = 14	~117ns
1	8	12+2 = 14	~117ns
3	16	12+4 = 16	~133ns
7	32	12+8 = 20	~167ns
11	48	12+12 = 24	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

**NOTE**

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

**Serial Flash Device Side (data read):**

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI\_RBCT[WMRK] field:

**Table 10-49. Access Duration Examples - Serial Flash side**

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop <sup>1</sup>	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM <sup>2</sup> Quad	IFM Quad DDR	PFM <sup>3</sup> Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.
3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

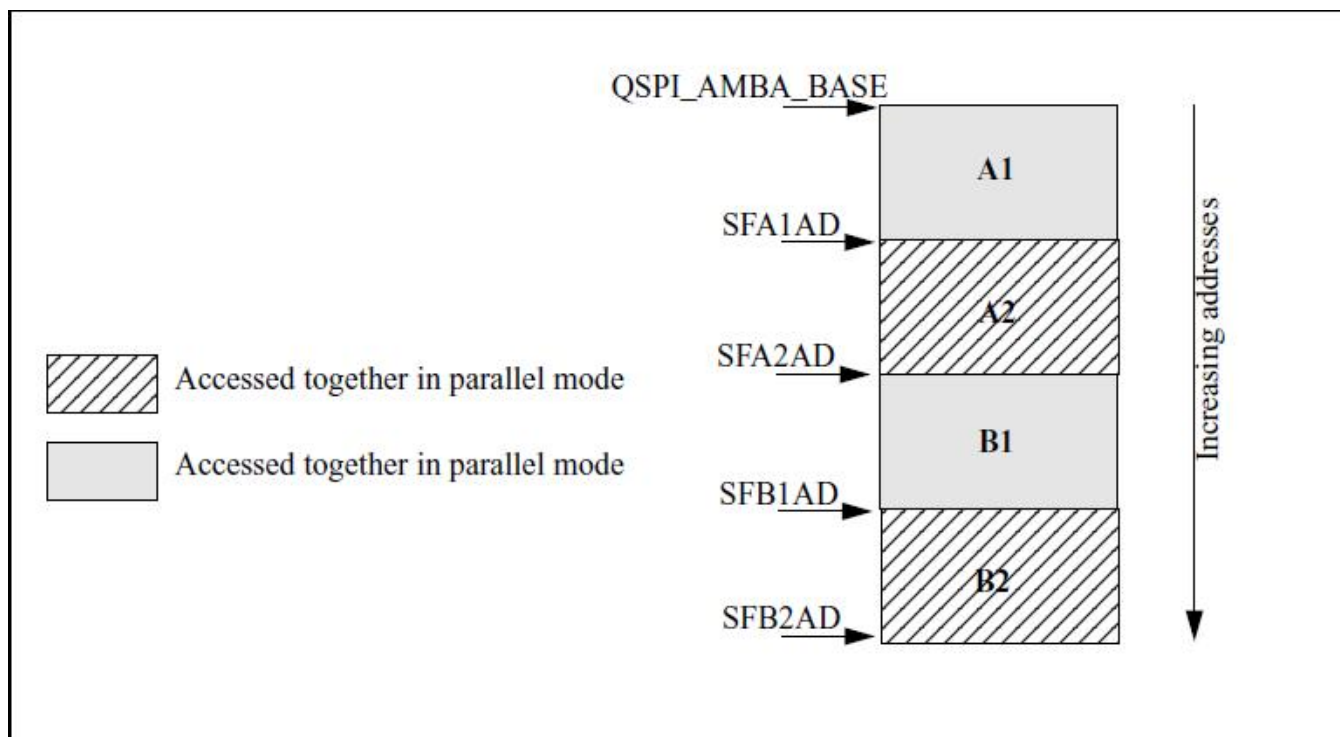

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

### NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

#### 10.2.6.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Only read operations are allowed in parallel mode. In case a write transaction is initiated in parallel mode, QSPI\_FR[IUEF] is set. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

**Figure 10-20. Flash addressing**

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI\_AMBA\_BASE - 0x10000000
- QSPI\_SFA1AD[TPADA1] - 0x20000000
- QSPI\_SFA2AD[TPADA2] - 0x30000000
- QSPI\_SFB1AD[TPADB1] - 0x40000000
- QSPI\_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI\_AMBA\_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

$$\text{Flash Address} = (\text{Memory mapped address} - \text{QSPI\_AMBA\_BASE})/2$$

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

$$\text{Flash Address} = (\text{Memory mapped address} - \text{SFA2AD})/2$$

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

**Figure 10-21. Memory map - Serial and Parallel**

Software must ensure that when multiple flashes are used, accesses should never cross a boundary between separate flash devices. For example, in the above figure, for serial mode, accesses must not cross the A1 to A2, A2 to B1 or B1 to B2 boundaries. For parallel mode, accesses must not cross the A1+B1 to A2+B2 boundary. Software can manage this via the following methods:

- Reduce the data fetch amount of the AHB buffers to 64 bit so that no prefetch occurs. This will prevent any legal access from crossing the boundary
- If prefetch is enabled then reserve a memory region, the maximum size of the prefetch, prior to the boundary. So long as no accesses are made to this region of memory, no access will cross the boundary
- Ensure that cache is not prefetching across the boundary

## 10.2.7 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

### 10.2.7.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

**Table 10-50. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status**

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

#### 10.2.7.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

**Table 10-51. Fast Read sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

### 10.2.7.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

**Table 10-52. Fast Dual I/O DT Read sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

### 10.2.7.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

**Table 10-53. Fast Read Quad output sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

### 10.2.7.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

**Table 10-54. Fast Read Quad output sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

### 10.2.7.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

**Table 10-55. Dual Command Page Program sequence**

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

### 10.2.7.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

**Table 10-56. Sector Erase sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

### 10.2.7.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

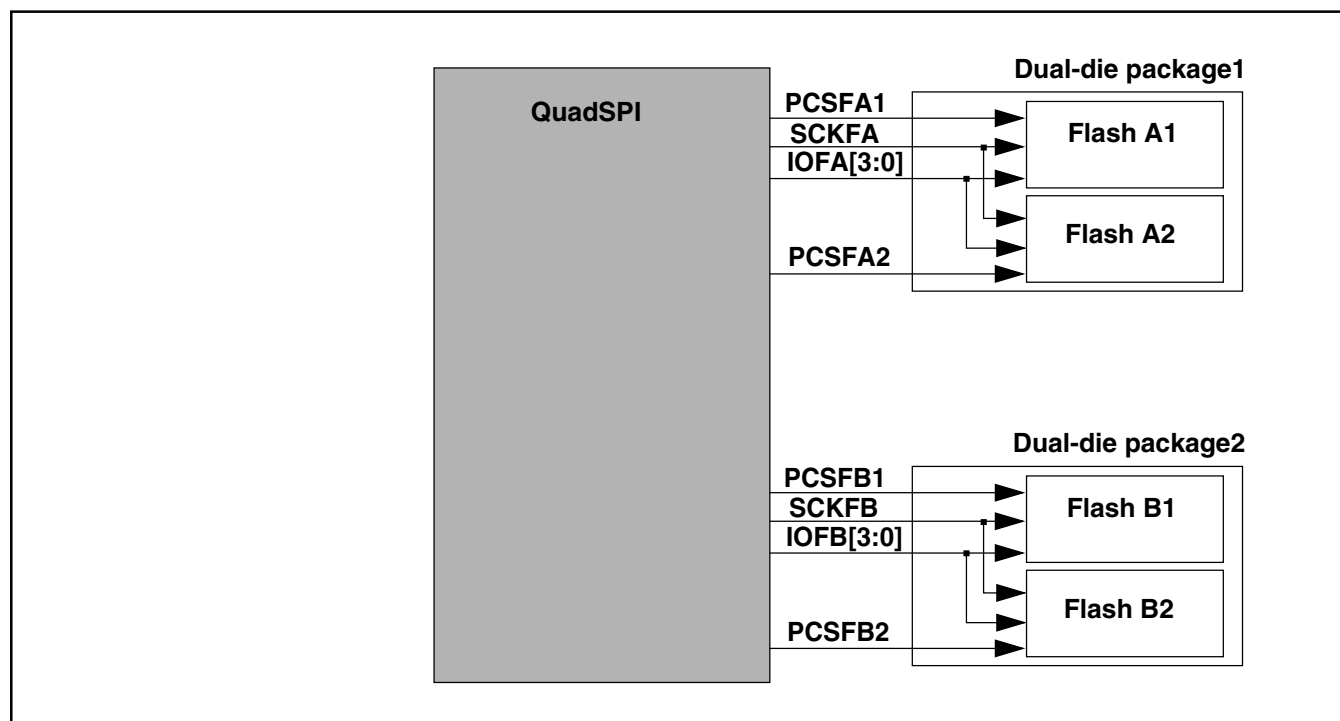

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

**Table 10-57. Read Status Register Sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

### 10.2.7.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

**Figure 10-22. Dual-die support**

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

### 10.2.7.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.

- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
  - The total sizes of all the flashes connected on board
  - Whether DDR mode supported
  - Frequency of DDR operation
  - Continuous mode entry sequence
  - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
  - Quad Mode enabled
  - Dummy reads to enter into XIP
- QuadSPI is configured
  - Parallel enable set
  - LUT configured for highest performance reads
  - DDR mode enabled (if applicable)
  - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

#### **10.2.7.4 Serial Flash Clock Frequency Limitations**

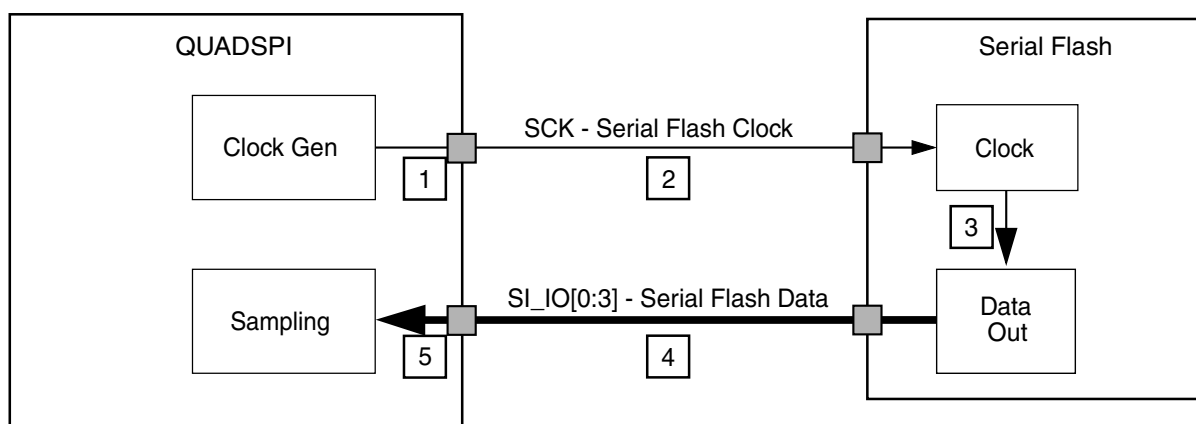

Certain commands of some serial flash devices are limited in the frequency applied to the serial flash device on command execution. In order to support these commands without having to recalibrate the module clocks, the the serial flash device clock can be divided by 2 (half speed) by setting the QSPI\_SMPR[HSENA] bit. The SCLK will return to full speed once the the QSPI\_SMPR[HSENA] bit is cleared.

#### **10.2.8 Sampling of Serial Flash Input Data**

### 10.2.8.1 Basic Description

QuadSPI is used to read data from the serial flash device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

**Figure 10-23. Serial Flash Sampling Clock Overview**

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of  $t_{\text{Del,total}}$  the data arrives at the internal sampling stage of the QuadSPI module. According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to  $t_{\text{Del,total}}$ :

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Device delay corresponding to the input data

#### NOTE

The amount of total delay  $t_{\text{Del,total}}$  is specific to the characteristics of the actual implementation. Also, the serial flash device clock (SCK) is inverted with respect to the QuadSPI internal reference clock.

10.2.8.2 SDR mode

Most flash memories operate in single data rate (SDR) mode. In SDR mode, the data is transferred only on one edge of the clock signal. The SDR serial flash memories sample the incoming data on the rising edge of serial flash clock and drive the output data on the falling edge of the serial flash clock.

10.2.8.2.1 Internal sampling

QuadSPI uses different edges of the internal reference clock for sampling the input data in SDR mode.

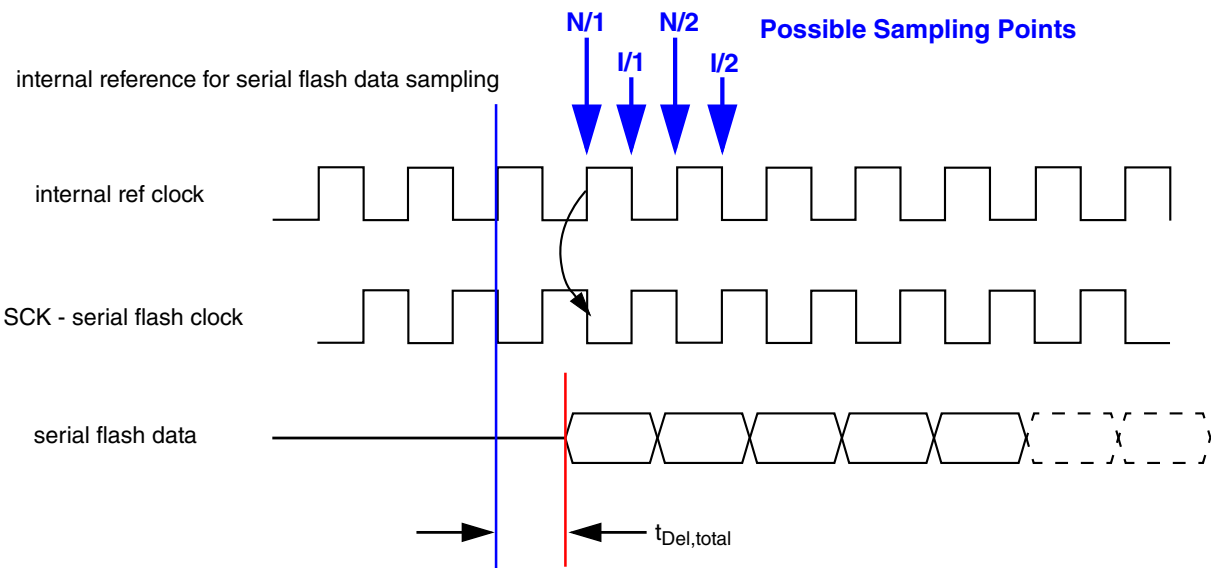

Figure 10-24. Internal sampling in SDR mode

The possible points in time for sampling incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI\_SMPR register. Refer to [Sampling Register \(QuadSPI\\_SMPR\)](#) for details. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 10-58. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting <sup>1</sup>
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x

Table continues on the next page...

**Table 10-58. Sampling Configuration (continued)**

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting <sup>1</sup>
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending on the actual delay and the serial flash clock frequency, the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be two settings possible to capture the correct data, since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending on the timing uncertainties, it may turn out in actual applications that only one possible sample position remains. This is subject to careful consideration depending on the actual implementation.
- The delay  $t_{Del,total}$  is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI\_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI\_SMPR register.

#### 10.2.8.2.2 DQS sampling method

Data sampling in SDR mode can be supported using the DQS sampling method. Refer to [Data Strobe \(DQS\) sampling method](#) for more details.

### 10.2.8.3 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

#### 10.2.8.3.1 Internal sampling (4x sampling method)

When the serial flash memories function in DDR mode, the data is valid for only half a clock cycle. This, along with the fact that the time for which the data is actually valid is smaller than half a clock cycle, requires that we provide closely spaced sampling points. The QuadSPI module provides a mechanism to sample the incoming data at multiple sampling points provided by a 4x serial flash clock in DDR mode. The figure below shows the different sampling points as configured by QuadSPI\_SMPR[DDRSMP]. The FSDLY/FSPHS and HSDLY/HSPHS bits are ignored for DDR instructions.

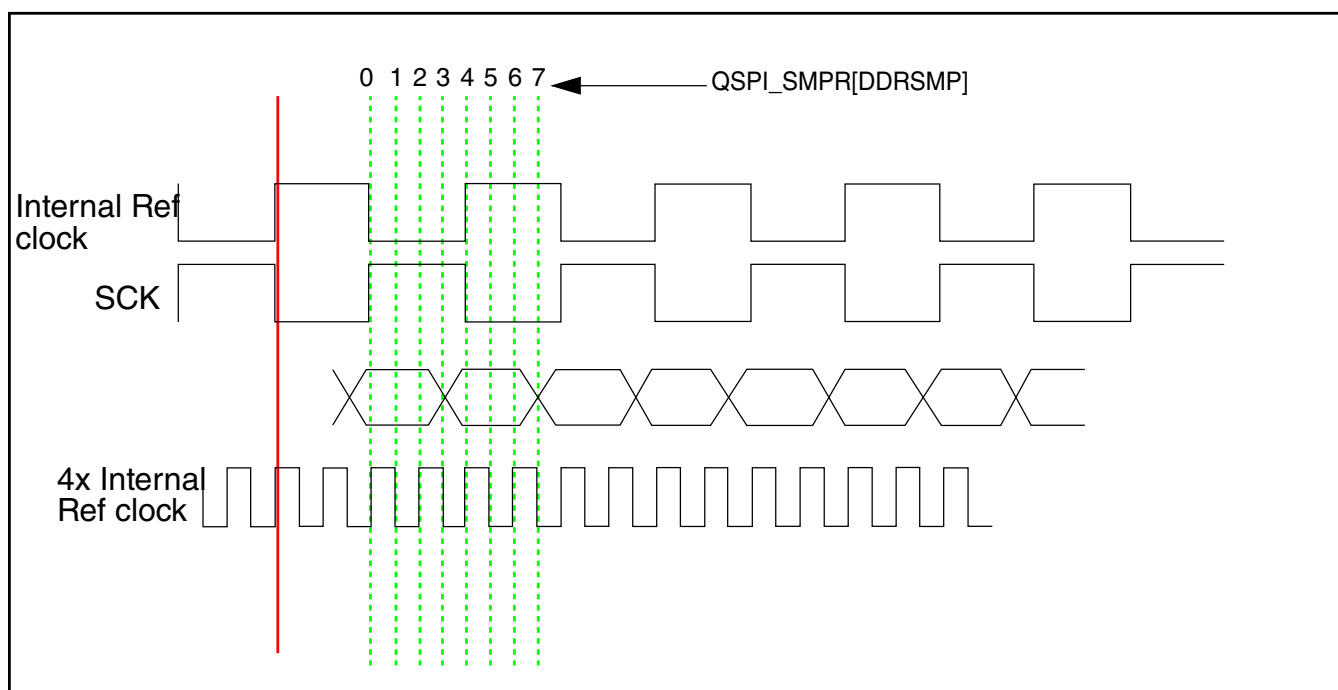

Figure 10-25. 4x sampling edges in DDR mode

Software should ensure that the correct sampling value is configured in the QuadSPI\_SMPR[DDRSMP] register.

#### 10.2.8.3.2 DQS sampling method

Data sampling in DDR mode can be supported using DQS method. Refer to [Data Strobe \(DQS\) sampling method](#) for more details.

## 10.2.8.4 Data Strobe (DQS) sampling method

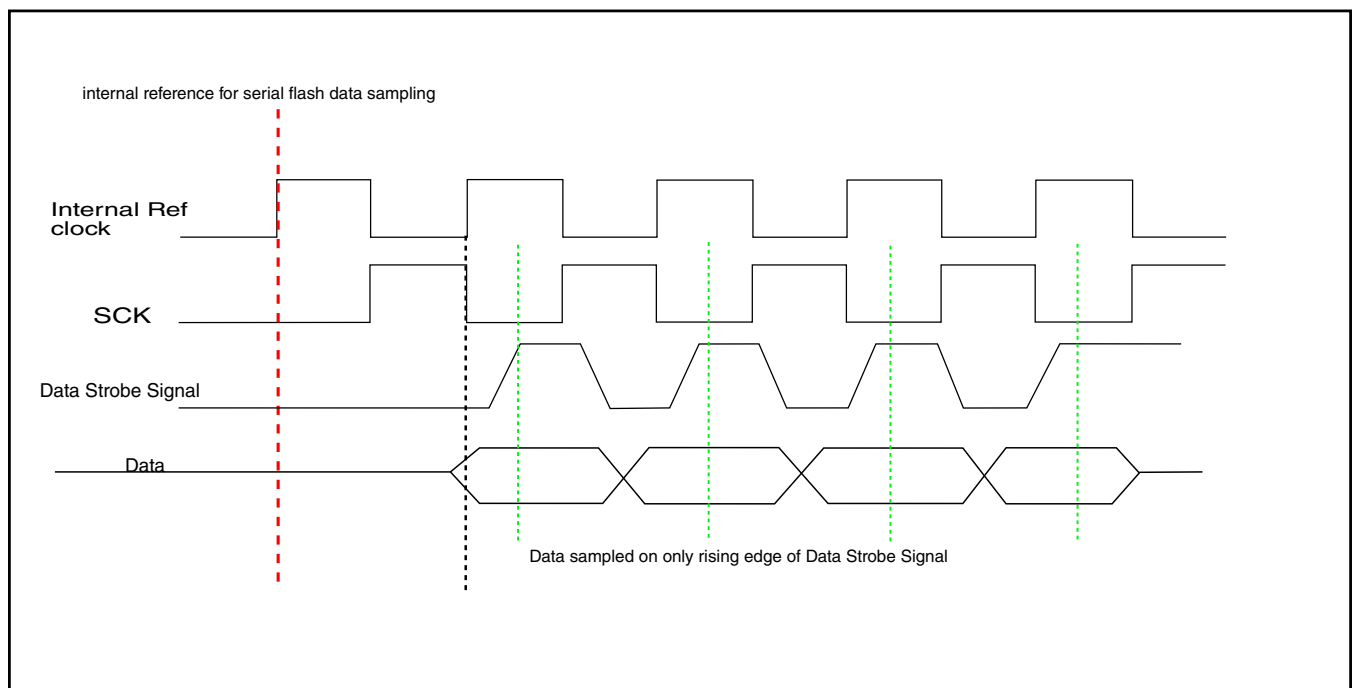

### 10.2.8.4.1 Basic Description

In DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash move in the same direction, so it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on only one of the edges (either rising edge or falling edge) of the strobe signal. The edge on which the data will be sampled depends on the setting of QuadSPI\_SMPR[FSPHS].

QSPI_SMPR[FSPHS]	Sampling edge
0	rising
1	falling

The figure below shows sampling read data in SDR mode using DQS.

**Figure 10-26. Data Strobe functionality in SDR mode**

When using DQS for DDR reads, QuadSPI internally samples the incoming data on both the edges of the strobe signal. Refer to the figure below for more detail.

**Figure 10-27. Data Strobe functionality in DDR mode**

## 10.3 NAND Flash Controller (NFC)

### 10.3.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The NAND flash controller (NFC) interfaces to standard NAND flash memory devices. It is composed of various control logic units and a 9 KB SRAM buffer. The NFC provides a glueless interface to 8- and 16-bit NAND flash devices with page sizes of 512 bytes, 2 KB, 4 KB, 8 KB and 16 KB.

Throughout this chapter the following terms are used:

- Block — (specified by device) smallest erasable unit in a NAND device, consisting of multiple pages
- Page — (specified by device) unit of flash data containing main and spare areas
- Main area of a page — stores data

- Spare area of a page — stores ECC and other software information
- Sector — an elementary transfer unit
  - For devices with pages of 2KB and smaller, this is the same size of the page
  - For devices with pages larger than 2KB, the pages are split into multiple virtual pages. In this case, the sector size is the size of the virtual page
- Virtual page — is the physical page size divided by the splitting factor, `NFC_CFG[PAGECNT]`
- ECC — error-correcting code
- BCH (Bose Chaudhuri Hocquenghem) — cyclic error-correcting code that corrects multi-bit errors

### 10.3.1.1 Block Diagram

The following is a block diagram of the NAND flash controller.

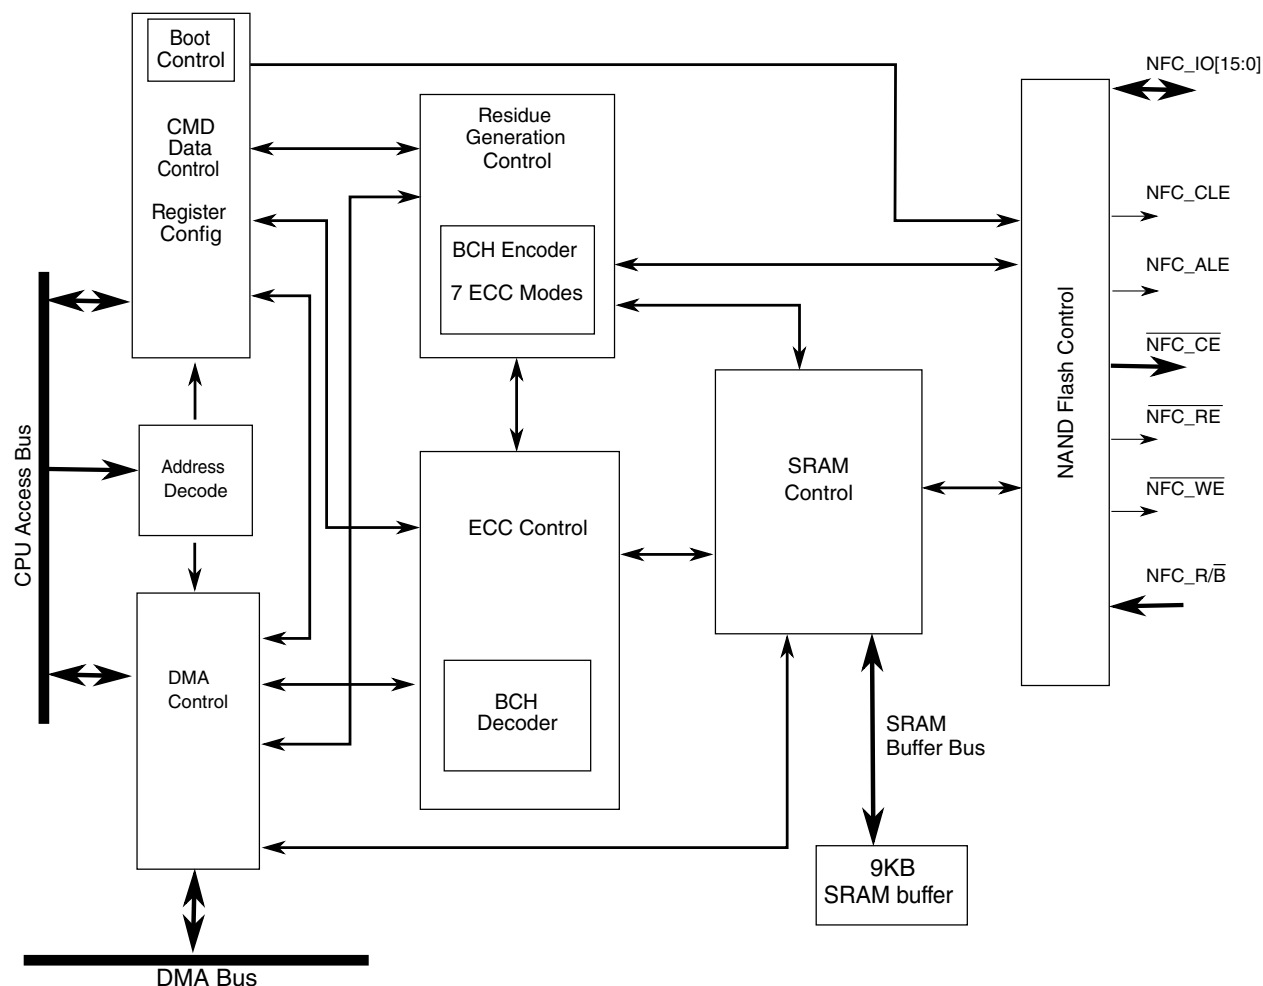

Figure 10-28. NAND Flash Controller Block Diagram

### 10.3.1.2 Features

The NAND flash controller includes the following features:

- 8- and 16-bit NAND flash interface
- 9 KB RAM buffer
  - Memory-mapped registers and SRAM buffer
- Supports all NAND flash products regardless of density/organization
- Supports flash device commands, such as page read, page program, reset, block erase, read status, read ID, copy-back, multiplane read/program, interleaved read/program, random input/output, read in EDO mode.
- Integrated DMA engine

- Two configurable DMA channels
  - Use DMA channel 1 only to read/write a page for main and spare area of a page
  - Use DMA channel 1 to read/write the main area of a page, and DMA channel 2 for the spare area
- ECC mode
  - In ECC mode, NFC supports 4/6/8/12/16/24/32-bit error correction.
  - ECC mode can be bypassed.
- Boot from page size  $\geq 2\text{KB}$  flash (x8) without extra control

### 10.3.2 External Signal Description

The signals shown in the next table are used to control NAND flash device.

**Table 10-59. NFC Signal Properties**

Name	Function	I/O	Reset
NFC_ALE	Flash address latch enable	O	1
NFC_CE	Flash chip enable	O	1
NFC_CLE	Flash command latch enable	O	1
NFC_R/ $\overline{\text{B}}$	Flash ready/busy	I	Pull up <sup>1</sup>
NFC_RE	Flash read enable	O	1
NFC_WE	Flash write enable	O	1
NFC_IO[15:0]	Flash data bus	I/O	—

1. Need to configure both PE and PS bit to 1'b1 of pin control register PORTC\_PCR18 to make NFC\_R/ $\overline{\text{B}}$  pull up, when PTC18 is configured to MUX=6 (NFC\_R/ $\overline{\text{B}}$ ).

### 10.3.3 Memory Map/Register Definition

This section defines the NAND flash controller's registers.

**NFC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
400E_3F00	Flash command 1 (NFC_CMD1)	32	R/W	30FF_0000h	<a href="#">10.3.3.1/1710</a>

*Table continues on the next page...*

## NFC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
400E_3F04	Flash command 2 (NFC_CMD2)	32	R/W	007E_E000h	<a href="#">10.3.3.2/1711</a>
400E_3F08	Column address (NFC_CAR)	32	R/W	0000_0000h	<a href="#">10.3.3.3/1712</a>
400E_3F0C	Row address (NFC_RAR)	32	R/W	1100_0000h	<a href="#">10.3.3.4/1713</a>
400E_3F10	Flash command repeat (NFC_RPT)	32	R/W	0000_0000h	<a href="#">10.3.3.5/1714</a>
400E_3F14	Row address increment (NFC_RAI)	32	R/W	0000_0001h	<a href="#">10.3.3.6/1714</a>
400E_3F18	Flash status 1 (NFC_SR1)	32	R	0000_0000h	<a href="#">10.3.3.7/1715</a>
400E_3F1C	Flash status 2 (NFC_SR2)	32	R	0000_0000h	<a href="#">10.3.3.8/1715</a>
400E_3F20	DMA channel 1 address (NFC_DMA_CH1)	32	R/W	0000_0000h	<a href="#">10.3.3.9/1716</a>
400E_3F24	DMA configuration (NFC_DMACFG)	32	R/W	0000_0000h	<a href="#">10.3.3.10/1716</a>
400E_3F28	Cach swap (NFC_SWAP)	32	R/W	0FFE_0FFEh	<a href="#">10.3.3.11/1717</a>
400E_3F2C	Sector size (NFC_SECSZ)	32	R/W	0000_0420h	<a href="#">10.3.3.12/1718</a>
400E_3F30	Flash configuration (NFC_CFG)	32	R/W	000E_A631h	<a href="#">10.3.3.13/1719</a>
400E_3F34	DMA channel 2 address (NFC_DMA_CH2)	32	R/W	0000_0000h	<a href="#">10.3.3.14/1721</a>
400E_3F38	Interrupt status (NFC_ISR)	32	R/W	6000_0000h	<a href="#">10.3.3.15/1721</a>

## 10.3.3.1 Flash command 1 (NFC\_CMD1)

Address: 400E\_0000h base + 3F00h offset = 400E\_3F00h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	CODE								0				0	BUFNO		BUSY_START
W																
Reset	1	1	1	0	0	0	0	0	0	0	0	0				

**NFC\_CMD2 field descriptions**

Field	Description
31–24 BYTE1	First command byte that may be sent to the flash device
23–8 CODE	<p>User-defined flash operation sequencer</p> <p>Each bit indicates a certain action. If the bit is set, the corresponding action is executed after writing 1 to START. The following are some configuration examples (other sequences are possible):</p> <p>0111_1110_1110_0000 Read data (BYTE1, 5x Address, BYTE2, R/ <math>\bar{B}</math> , read data)</p> <p>1111_1111_1101_1000 Write page (DMA,BYTE1, 5x Address, write data, BYTE2, R/ <math>\bar{B}</math> , BYTE3, read status)</p> <p>0100_1110_1101_1000 Block erase (BYTE1, 3x Address, BYTE2, R/ <math>\bar{B}</math> , BYTE3, read status)</p> <p>0100_1000_0000_0100 Read ID (BYTE1, 1x Address, read ID)</p> <p>0100_0000_0100_0000 Reset (BYTE1, R/ <math>\bar{B}</math> )</p> <p>0111_1110_0000_0000 CMD+address (BYTE1, 5xaddress)</p> <p>1111_1111_1100_0000 Write page burst (DMA,BYTE1,5xAddress, write data, BYTE2,R/ <math>\bar{B}</math> )</p>
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## NFC\_CMD2 field descriptions (continued)

Field	Description
3 Reserved	User should ignore writing to this field. Writes may occur, but will have no impact.  This field is reserved. This read-only field is reserved and always has the value 0.
2–1 BUFNO	Internal buffer number used for this command
0 BUSY_START	Busy indicator and start command  This busy indicator is repeated in the NFC_ISR register. <b>NOTE:</b> Read to this bitfield indicates BUSY whereas write indicates START.  0 During reads, flash controller is idle and it is okay to send next command. During writes, no action. 1 During reads, command execution is busy. During writes, start command execution.

## 10.3.3.3 Column address (NFC\_CAR)

## NOTE

Refer data organization in flash datasheet to correctly configure this register's value.

Address: 400E\_0000h base + 3F08h offset = 400E\_3F08h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																BYTE2								BYTE1							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## NFC\_CAR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–8 BYTE2	Second byte of column address
BYTE1	First byte of column address

### 10.3.3.4 Row address (NFC\_RAR)

Address: 400E\_0000h base + 3F0Ch offset = 400E\_3F0Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0			RB0	0		CS1	CS0	BYTE3							
W																
Reset	0	0	0	1	0	0	0	1	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BYTE2								BYTE1							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### NFC\_RAR field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RB0	Ready/busy 0 enable  Determines if $\overline{\text{NFC\_R}}/\overline{\text{B}}0$ is waited on a wait for $\text{R}/\overline{\text{B}}$ command. If an equal number of $\overline{\text{NFC\_CE}}$ and $\text{NFC\_R}/\overline{\text{B}}$ lines are used, the $\text{CS } n$ and $\text{RB } n$ fields must contain identical values. If only one $\text{NFC\_R}/\overline{\text{B}}$ is used, then $\text{CS } n$ determines the true chip select, and this field is always 1.  0 $\overline{\text{NFC\_R}}/\overline{\text{B}}0$ is disabled 1 $\overline{\text{NFC\_R}}/\overline{\text{B}}0$ is enabled
27–26 Reserved	User should ignore writing to these fields. Writes may occur, but will have no impact.  This field is reserved. This read-only field is reserved and always has the value 0.
25 CS1	Chip select 1 enable  0 $\overline{\text{NFC\_CE1}}$ is disabled 1 $\overline{\text{NFC\_CE1}}$ is enabled
24 CS0	Chip select 0 enable  0 $\overline{\text{NFC\_CE0}}$ is disabled 1 $\overline{\text{NFC\_CE0}}$ is enabled
23–16 BYTE3	Third byte of row address
15–8 BYTE2	Second byte of row address
BYTE1	First byte of row address

### 10.3.3.5 Flash command repeat (NFC\_RPT)

Address: 400E\_0000h base + 3F10h offset = 400E\_3F10h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### NFC\_RPT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	16-bit repeat count  Determines how many times NFC_CMD2[CODE] is executed. If 0 or 1, the flash command is executed once.

### 10.3.3.6 Row address increment (NFC\_RAI)

When auto-increment of row address is enabled (NFC\_CFG[AIAD] = 1), the row address is incremented as follows:

$$\text{new}\{\text{NFC\_RAR}[\text{BYTE3}], \text{NFC\_RAR}[\text{BYTE2}], \text{NFC\_RAR}[\text{BYTE1}]\} = \{\text{NFC\_RAR}[\text{BYTE3}], \text{NFC\_RAR}[\text{BYTE2}], \text{NFC\_RAR}[\text{BYTE1}]\} + \{\text{NFC\_RAI}[\text{INC3}], \text{NFC\_RAI}[\text{INC2}], \text{NFC\_RAI}[\text{INC1}]\}$$

Address: 400E\_0000h base + 3F14h offset = 400E\_3F14h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								INC3								INC2								INC1							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

#### NFC\_RAI field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 INC3	Increment for the third byte of row address
15–8 INC2	Increment for the second byte of row address
INC1	Increment for the first byte of row address

### 10.3.3.7 Flash status 1 (NFC\_SR1)

Address: 400E\_0000h base + 3F18h offset = 400E\_3F18h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### NFC\_DMACFG field descriptions

Field	Description
31–20 COUNT1	Number of bytes to be transferred by DMA channel 1. It should be multiple of 16 bytes.
19–13 COUNT2	Number of bytes to be transferred by DMA channel 2. It should be multiple of 16 bytes.
12–9 OFFSET2	256-byte offset for DMA channel 2. DMA channel 2 transfer starts at this offset count x 256 bytes. For example, if OFFSET2 = 0x2, DMA channel 2 transfer starts at 0x200.
8–2 Reserved	User should ignore writing to these fields. Writes may occur, but will have no impact.  This field is reserved. This read-only field is reserved and always has the value 0.
1 ACT1	DMA channel 1 status

Table continues on the next page...

**NFC\_DMACFG field descriptions (continued)**

Field	Description
	0 Inactive 1 Active, and transfers to memory when triggered
0 ACT2	DMA channel 2 status 0 Inactive 1 Active, and transfers to memory when triggered

**10.3.3.11 Cach swap (NFC\_SWAP)**

When DMA transfers data to/from the NFC cache (NFC SRAM buffer), or when the CPU reads or writes data to/from the NFC cache via the internal bus, all accesses that go to `NFC_SWAP[ADDR1]*8` are directed to `NFC_SWAP[ADDR2]*8`. Likewise, all accesses that go to `NFC_SWAP[ADDR2]*8` are directed to `NFC_SWAP[ADDR1]*8`.

The feature allows the bad block marker in the first position of the spare area of a page. Because of the way the flash controller interleaves data and ECC bytes on flash devices with page sizes larger than 2 KB, the position of the bad block marker is shifted, and does not appear in the first position of the spare area of the page. The cache swap feature allows consistent swapping of the actual bad block line with the expected bad block line, and causes the operating system to get the bad block marker in the position where it is expected.

Address: `400E_0000h` base + `3F28h` offset = `400E_3F28h`

## NFC\_SECSZ field descriptions

Field	Description
31–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SIZE	<p>Size in bytes of one elementary transfer unit</p> <p>For devices with pages of 2KB and smaller, this is the physical size of the page in bytes (data bytes + ECC bytes) transferred in one page. When pages are larger than 2KB, they must be split in multiple virtual pages. In this case, the sector size is the size of the virtual page. The virtual page size is the physical size divided by the splitting factor, NFC_CFG[PAGECNT].</p> <p><b>NOTE:</b> If only a part of a page to be programmed or read, SIZE can be set to the number of affected bytes, not the page size. Then, ECC and DMA (data bytes) are all performed on the number of bytes, indicated by SIZE.</p> <p><b>NOTE:</b> For 16-bit data width flash devices, only even SIZE is supported. If SIZE is odd number, the real implemented size is SIZE – 1. So, write size + 1 to this field. For example, if SIZE = 1, no data is written or read.</p> <p><b>NOTE:</b> When programming NAND memory for boot and using the ECC feature, ensure that SIZE is equal to number of (data + ECC bytes).</p>

### 10.3.3.13 Flash configuration (NFC\_CFG)

#### NOTE

NFC\_CFG[BTMD] resets to 0 if no boot is performed by the NFC; 1 if booting from NFC.

Address: 400E\_0000h base + 3F30h offset = 400E\_3F30h

## NFC\_ISR field descriptions

Field	Description
31 WERR	Write error interrupt Set if an error condition is detected during a flash read status command. Sticky bit.
30 DONE	DONE interrupt Set if command processing is done.
29 IDLE	Command idle interrupt Set if the command is done, and residue engine, ECC engine and DMA engine are idle.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 WERRNS	Write error status Set if an error condition was detected during the last flash read status command. Non-sticky bit.
26 CMDBUSY	Command busy Set if command execution busy, cleared otherwise.
25 RESBUSY	Residue engine busy Set if residue engine busy, cleared otherwise.
24 ECCBUSY	ECC engine busy Set if ECC engine busy, cleared otherwise.
23 DMABUSY	DMA engine busy Set if DMA engine busy, cleared otherwise.
22 WERREN	Enable bit for NFC_ISR[WERR]
21 DONEEN	Enable bit for NFC_ISR[DONE]
20 IDLEEN	Enable bit for NFC_ISR[IDLE]
19 WERRCLR	Clear bit for NFC_ISR[WERR]. Writing 1 to this bit clears NFC_ISR[WERR].
18 DONECLR	Clear bit for NFC_ISR[DONE]. Writing 1 to this bit clears NFC_ISR[DONE].
17 IDLECLR	Clear bit for NFC_ISR[IDLE]. Writing 1 to this bit clears NFC_ISR[IDLE].
16–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 RESBN	Residue buffer number Buffer number corresponding with the current residue block task.
3–2 ECCBN	ECC buffer number Buffer number corresponding with the current ECC task.
DMABN	DMA buffer number Buffer number corresponding with the current DMA task.

### 10.3.4 Functional Description

The NFC executes commands on a single or bank of external NAND flash chips. The NFC supports commands such as read, program, reset, erase, status read, read ID.

The NFC block contains a DMA engine and built-in ECC logic. For each read or write, the NFC performs ECC calculations on-the-fly. Two DMA channels are organized for each read or write: one for the main area, and one for the spare area. It is possible to disable the second DMA channel, and transfer main and spare data with only the first DMA channel.

Page size supported is 512, 2K, 4K, 8K and 16K bytes. There are 8 different ECC settings provided: 0, 4, 6, 8, 12, 16, 24 and 32 bits errors. They use 0, 8, 12, 15, 23, 30, 45 and 60 ECC bytes. The ECC works on page sizes of 512+spares bytes, 1K+spares bytes, 2K+spares bytes. The ECC algorithm used is a BCH code.

The error corrector can write ECC status to the spare area, since the read is pipelined. This means, while the current page is transferred from flash to buffer, the previous page is ECC corrected, and the page before that is transferred using DMA. Because of the pipelining, it is difficult to inform the CPU in the foreground of ECC errors. To solve this, ECC status is written to the auxiliary area of the sector, and transferred to memory. See [Error Corrector Status](#) for more information. It's up to the CPU to inspect the ECC result in memory, and act appropriately.

As described, reads are pipelined. However, writes are flow-through; no advance operations are done during a write. If there is a problem found during a write, the command sequence may be interrupted, and the CPU is informed.

Each page read, page write, page erase, read ID, or read status command sequence needs CPU attention only once. The CPU needs to prepare the DMA to point to the data, write correct values to all registers, and start the command. After command completion, the NFC block may interrupt the CPU.

The block allows command repeat, which is useful for write, read and erase, and allows processing multiple pages with just one command given by the CPU. No bank interleaving is supported during command repeat.

Booting from NAND flash is optional, and how it is activated is device-specific. See the chip-specific NFC information for how to activate NFC boot on your device.

If boot feature is activated, first the NFC issues a reset command (0xFF) to the flash, then NFC reads four pages from block 0. Each page is 1056 bytes. The boot pages are protected by 32-bit error correction, which means that of the 1056 bytes, 996 bytes are user bytes and 60 bytes are ECC bytes. When the data from the boot pages is read,

successfully error corrected, and stored in the NFC SRAM, the NFC indicates to the CPU that its boot code is visible in the NFC SRAM, and visible on addresses 0x000 to 0xF8F (3984 bytes total).

If the boot image from block 0 cannot be corrected, because there are more than 32 errors in one or several pages, boot is retried on the blocks at row addresses 256, 512, and 768. If it still fails after these retries, boot from the NFC is aborted. The device may begin execution using other memory. See the chip-specific NFC information for details on how your device behaves in this scenario.

Right after boot, a special address hashing function is active on all reads and writes DONE to NFC SRAM. This hashing function interleaves the page data from the four boot pages in such a way that all user data is visible in address range 0x000 to 0xF8F instead of four different ranges, one for each page. This hashing is controlled by NFC\_CFG[BTMD], and the hashing should be turned off by the CPU after finishing reading/executing the boot image, and before normal operations of the NFC. See [Figure 10-37](#) and [NFC Buffer Memory Space](#).

Page size at boot is set to 1056 bytes to be compatible with a large number of NFC devices, without needing additional power-on reset flags to indicate the boot device.

- Compatible with 8-wide SLC and MLC devices with page size of 2 KB + 64 bytes spare
- Compatible with 8-wide SLC and MLC devices with page size of 4 KB and larger
- Compatible with 16-wide SLC and MLC devices with page size of 2 KB + 64 bytes spare
- Compatible with 16-wide SLC and MLC devices with page size of 4 KB and larger
- Not compatible with devices with 512 bytes page size.

#### 10.3.4.1 NFC Buffer Memory Space

The next figure shows the organization of the buffer memory space in the NFC. The memory's size is  $1152 \times 64$  bit, and is separated into four buffers, each with inconsecutive physical address. For example, buffer 0's physical address is  $(0x000 + 0x20 \times i) - (0x007 + 0x20 \times i)$ .

However, when the CPU writes or reads a buffer in non-boot mode, the CPU address is continuous, since there's an address transition inside NFC:  $\text{sram\_physical\_addr}[13:3] = \{\text{cpu\_addr}[11:3], \text{cpu\_addr}[13:12]\}$

So, in non-boot mode, the address ranges are:

- Buffer 0: 0x0000 – 0x08FF
- Buffer 1: 0x1000 – 0x18FF
- Buffer 2: 0x2000 – 0x28FF
- Buffer 3: 0x3000 – 0x38FF

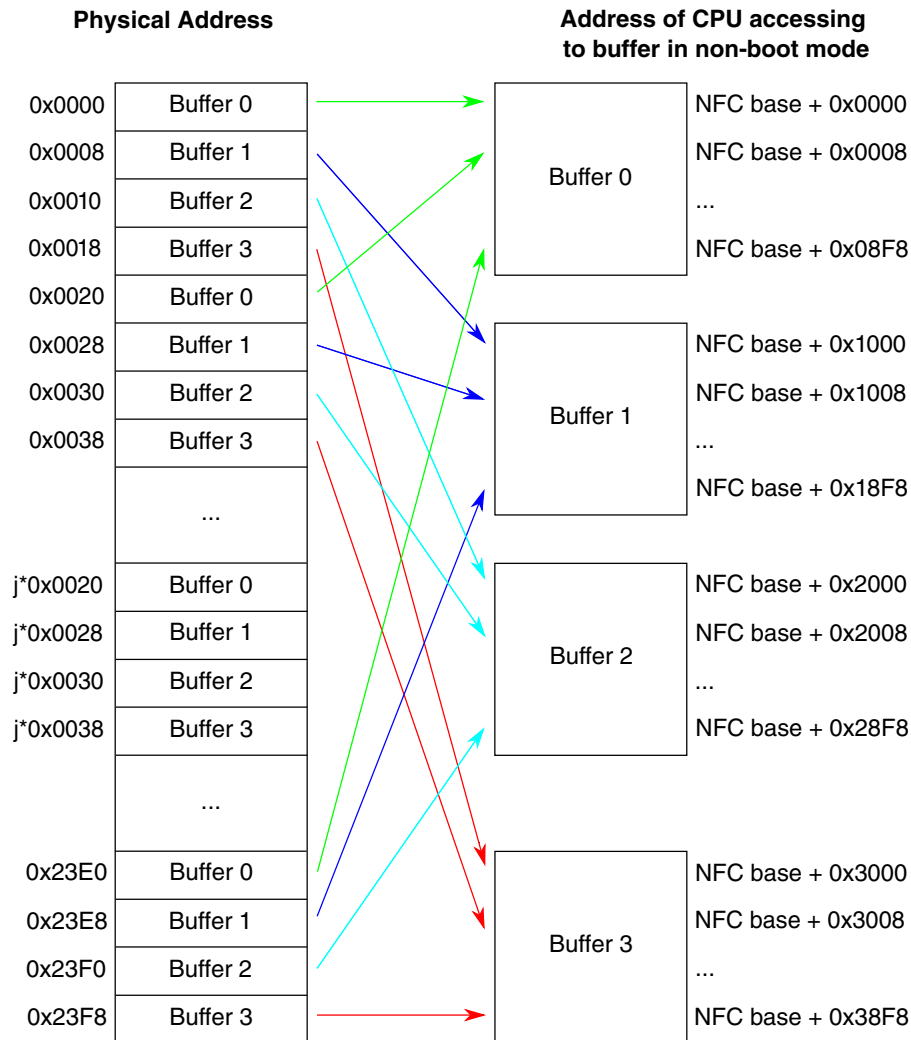

Figure 10-29. NFC Buffer Memory Space

### 10.3.4.2 Error Corrector Status

The ECC engine determines if a page is correctable. If correctable, it corrects error bits, and indicates error number. Otherwise, CORFAIL bit is asserted as shown in the next table. For a bad block management strategy to work, it may be necessary for the processor to obtain this information.

The error corrector writes the status word to a byte location to the SRAM buffer, defined by NFC\_CFG[ECCAD]. It is selectable if the status is written or not with NFC\_CFG[ECCSRAM]. If the status is written to the SRAM buffer, it becomes effectively part of the flash data, and is processed like the flash data. Most likely, the status byte is written to memory as part of the page header. Once in memory, the ECC status is visible to the CPU, while CPU parses the rest of the flash header. No interrupt on error or status is available because this increases the interrupt load on the CPU. (The interrupt would be independent of the command done interrupt.) It is not possible to stop reading when ECC fails.

The organization of the status byte is shown here.

Table 10-60. ECC Status Word

Field	Definition
7	0 Page has been successfully corrected
CORFAIL	1 Page is uncorrectable
5–0	Number of errors that have been corrected in this page
ERROR_COUNT	

NOTE

The address of the ECC status byte = Buffer n's start address + NFC\_CFG[ECCAD]\*8 + 4 (n=0,1,2,3).

10.3.4.3 NFC Basic Commands

NFC basic commands include Page Read, Page Program, Block Erase, Read ID, and Reset.

10.3.4.3.1 Page Read

This command reads pages from the NAND flash. This figure shows the general flowchart of a read operation.

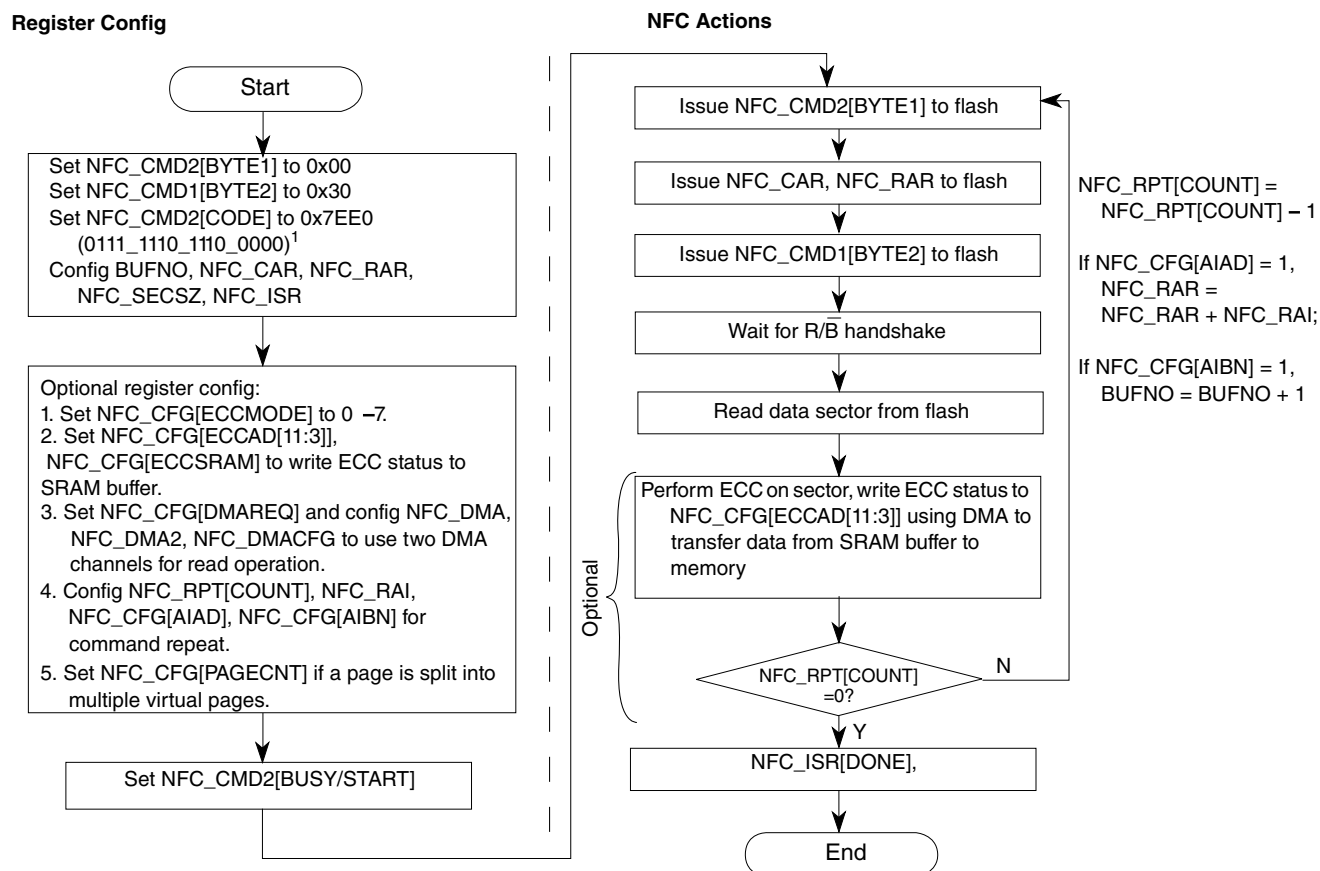

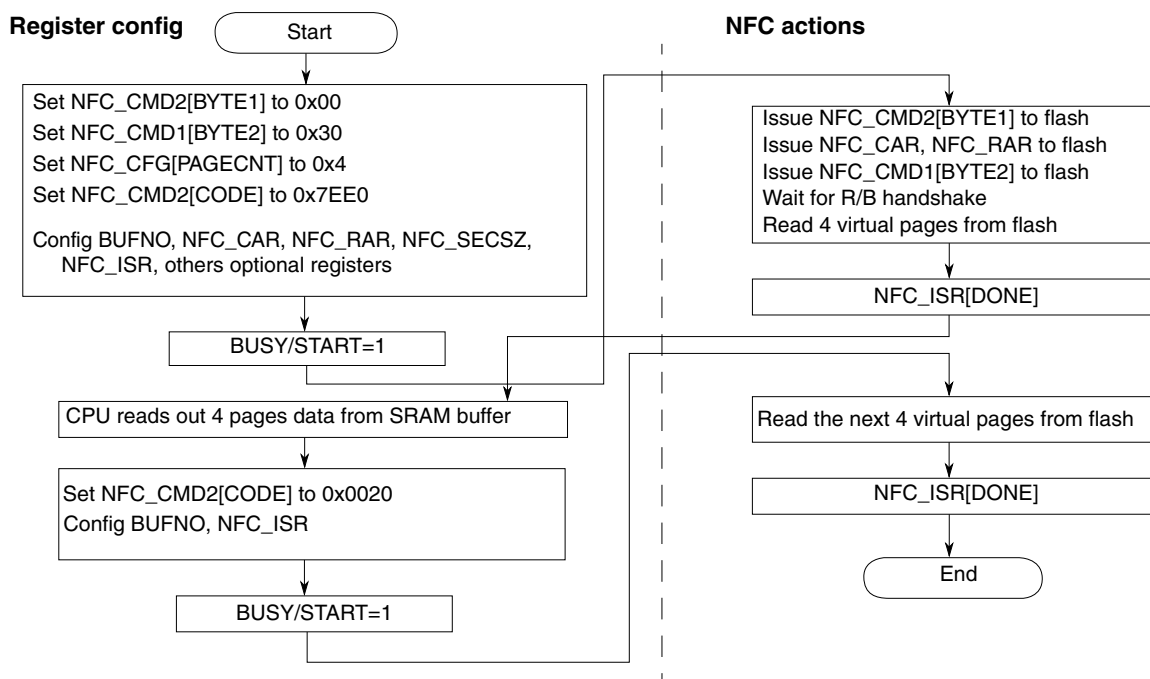

Figure 10-30. Flow Chart of Read Operation

The next figure shows a particular case: one page is split into 8 virtual pages (see [Organization of the Data in the NAND Flash](#)), and DMA is not used. The SRAM buffer can hold data for four (virtual) pages at most. The CPU must transfer data out of the SRAM buffer after the first four virtual pages are read from flash. Otherwise, the next four virtual pages data overwrite the buffer. So, the read operation has following steps:

- Configure registers as shown in the preceding figure. NFC\_CFG[PAGECNT] = 4, start commands, wait for NFC\_ISR[DONE]
- CPU reads data from buffer, set NFC\_CMD2[CODE] = 0x20 (only enable read data)
- Start commands to read out the next 4 virtual pages, wait for NFC\_ISR[DONE]

If DMA is used to transfer data from SRAM buffer to memory instead of CPU, the flow in the preceding figure is used: set `NFC_CFG[PAGECNT] = 8`, set `NFC_CFG[DMAREQ] = 1`, configure DMA registers, start commands. A pipeline ([Functional Description](#)) controls the read operation.

**Figure 10-31. Flow Chart of Read Operation, `NFC_CFG[PAGECNT] = 8`, No DMA**

### Note

See footnote in [Figure 10-30](#).

#### 10.3.4.3.2 Page Program

This command programs pages to the NAND flash. The next figure is the general flow of page program operation.

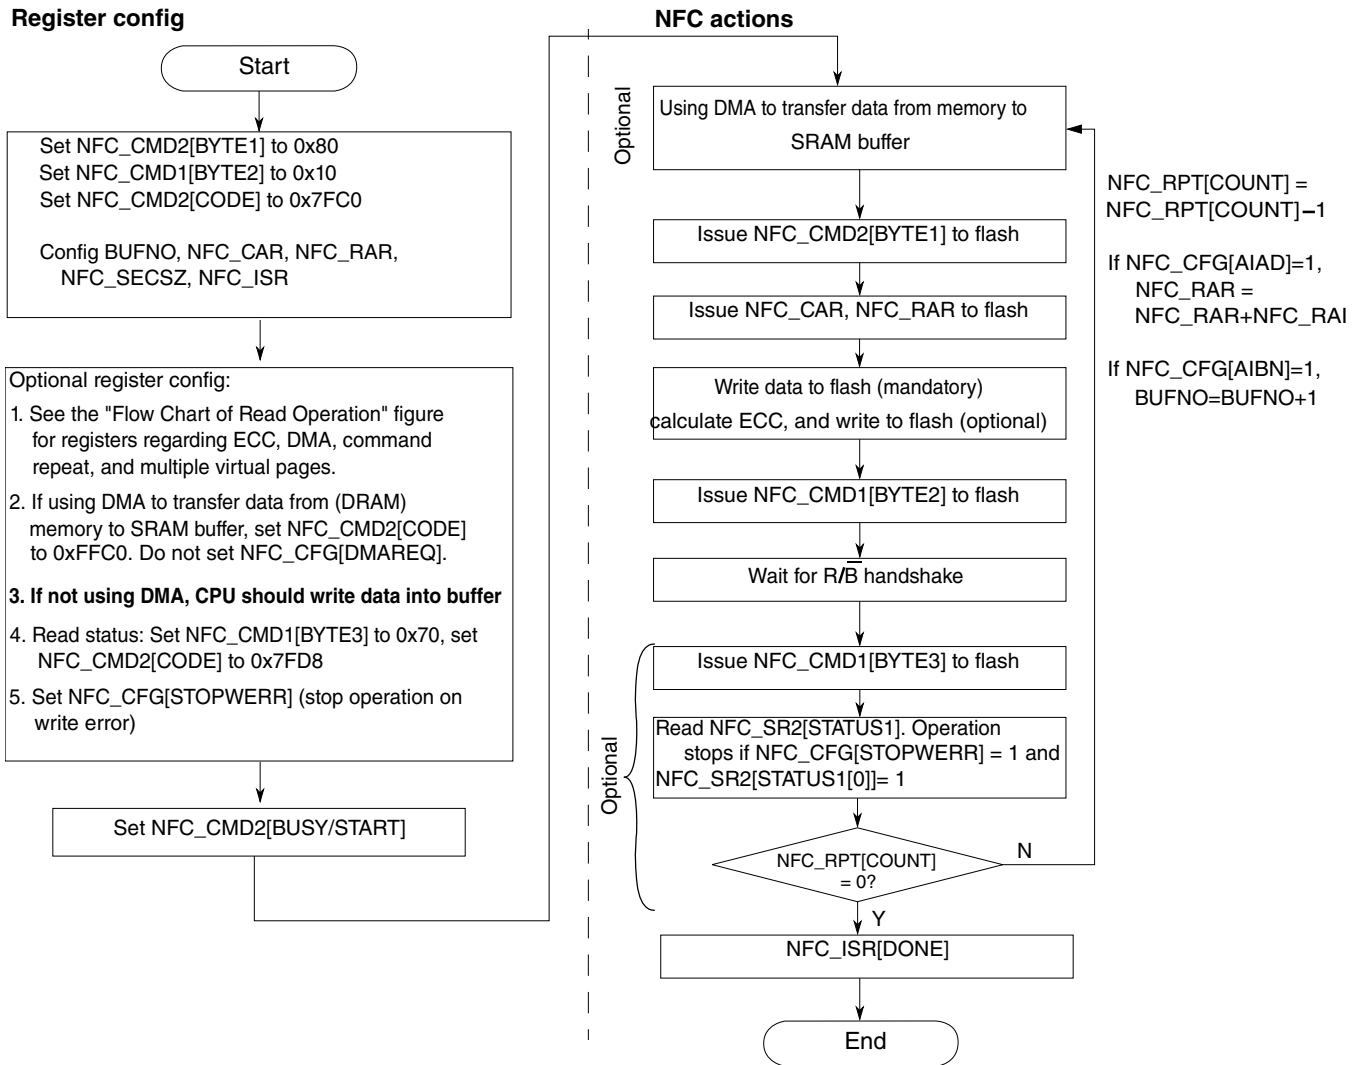

Figure 10-32. Flow Chart of Page Program Operation

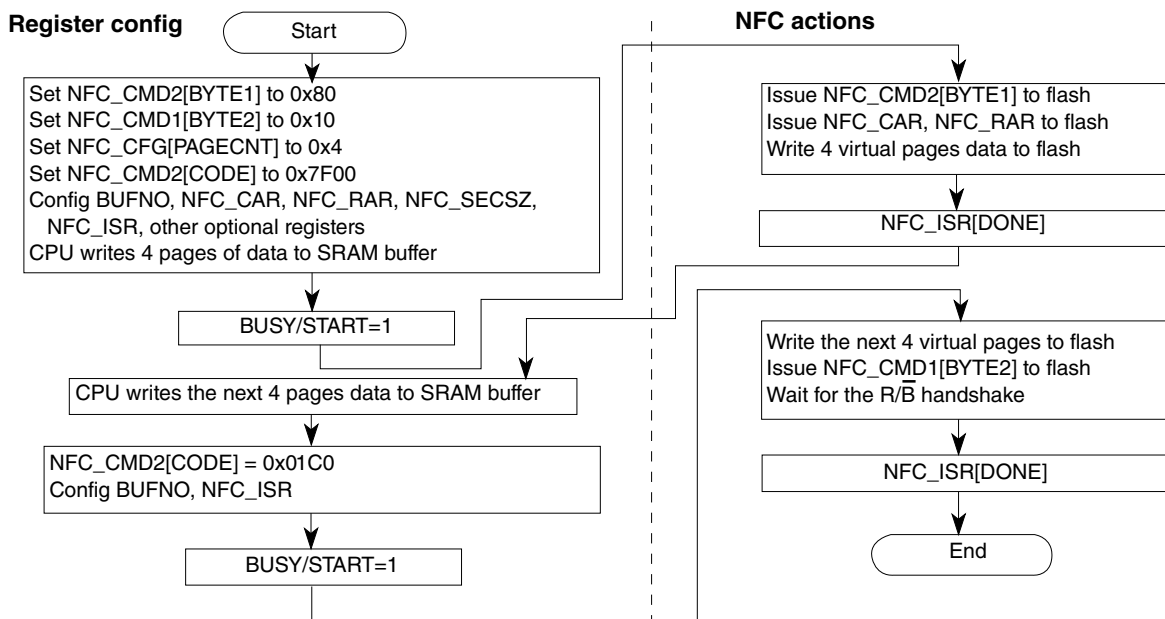

**Note**

COL\_ADDR2 and NFC\_RAR[BYTE3] (bold) are not necessary for some flash devices. See their data sheets for detail. See the footnote of [Figure 10-30](#).

The next figure shows the particular case which is similar to [Figure 10-31](#). The CPU writes at most four virtual pages of data into the buffer before the first start command. Set NFC\_CFG[PAGECNT] to 4 and set NFC\_CMD2[CODE] twice:

- First, set it to 0x7F00 (0111\_1111\_0000\_0000). The NFC issues NFC\_CMD2[BYTE1], address cycles, four virtual pages data to flash. After NFC\_ISR[DONE] is set, the CPU can write the next four virtual pages data into the SRAM buffer.
- Second, set CODE to 0x01C0 (0000\_0001\_1100\_0000). The NFC sends the next four virtual pages of data to flash, issues NFC\_CMD1[BYTE2], waits for R/B handshake, and waits for NFC\_ISR[DONE] to set.

Like the read operation, if DMA transfers data from memory to NFC SRAM buffer (instead of the CPU), the flow in the preceding figure is used and set NFC\_CFG[PAGECNT] to 0x8.

**Figure 10-33. Flow Chart of Page Program Operation, NFC\_CFG[PAGECNT] = 8, No DMA**

### Note

If you want to read the status after the second 0x10 command, set NFC\_CMD1[BYTE3] to 0x70 and NFC\_CMD2[CODE] to 0x01D8 (0000\_0001\_1101\_1000). Then, after "Wait for the R/B handshake", the NFC issues NFC\_CMD1[BYTE3] to flash, and reads the status. If NFC\_CFG[STOPWERR] is set and NFC\_SR2[STATUS1[0]]=1, operation stops. Otherwise, NFC\_ISR[DONE] comes out. The COL\_ADDR2 and NFC\_RAR[BYTE3] of the first NFC\_CMD2[CODE] may not be necessary. See note 1 of [Figure 10-30](#).

### 10.3.4.3.3 Block Erase

This command is used to erase blocks.

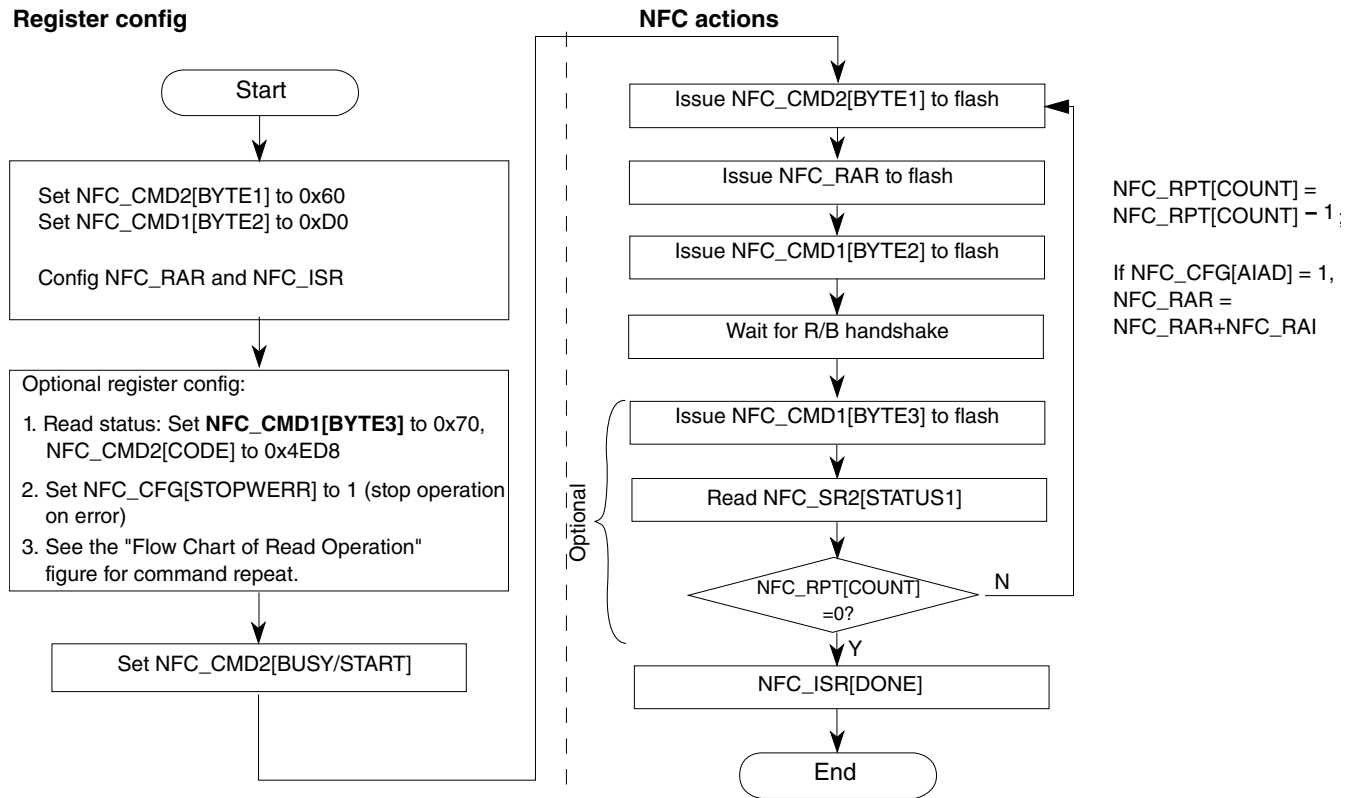

Figure 10-34. Flow Chart of Block Erase Operation

#### Note

NFC\_RAR[BYTE3] (**bold**) is not necessary for some flash devices. See their data sheets for detail.

#### Note

If NFC\_CFG[STOPWERR] is set and NFC\_SR2[STATUS1[0]]=1, operation stops.

### 10.3.4.3.4 Read ID

This command reads the flash ID.

Figure 10-35. Flow Chart of Read ID Operation

### 10.3.4.3.5 Reset

This command sends a single reset command to the flash.

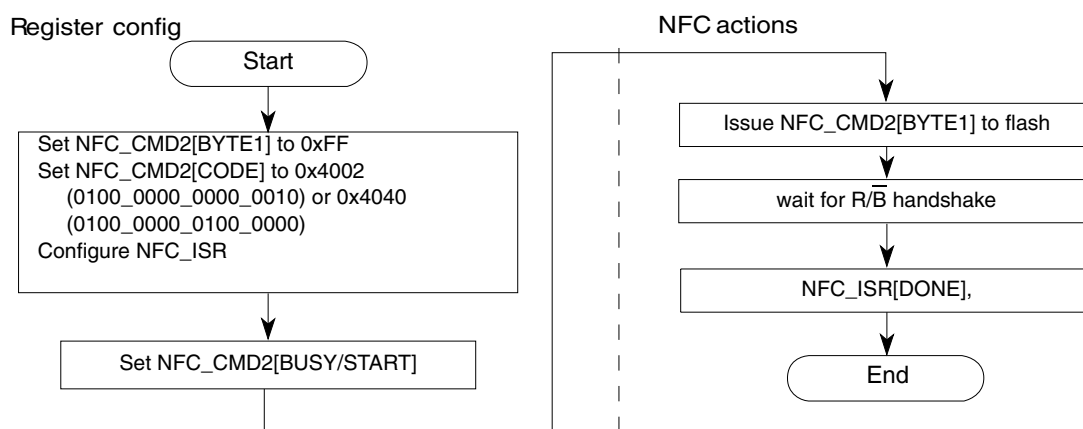

Figure 10-36. Flow Chart of Reset Operation

### 10.3.4.4 NAND Flash Boot

For booting, the power-on reset values of some registers are:

- Sector size is 1056 bytes: NFC\_SECSZ = 1056
- Flash is defined as 8-bit: NFC\_CFG[16BIT] = 0
- ECC correction depth is 32 bits errors: NFC\_CFG[ECCMODE] = 0x7
- Boot sector address is 0: NFC\_CMD2[BUFNO] = 00

Boot-up occurs after power-on reset. After boot, the following happens:

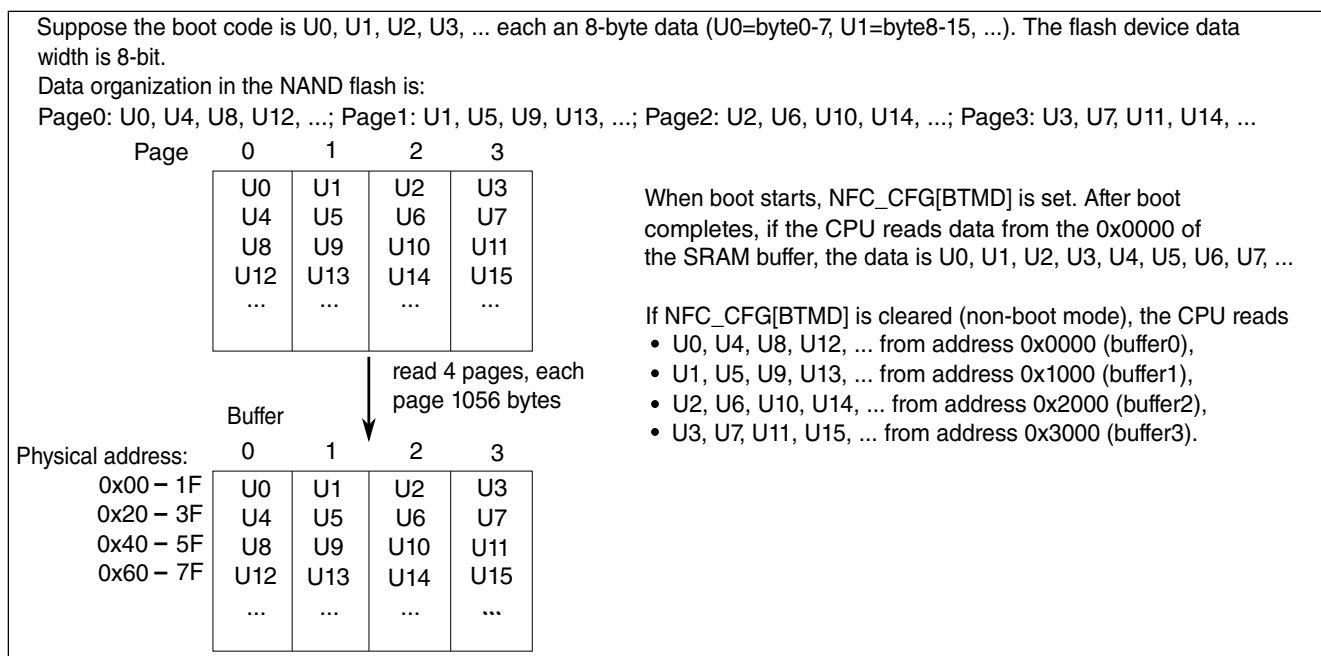

1. The NFC issues reset command 0xFF to the flash.
2. Four boot blocks are identified in the flash at row addresses 0, 256, 512, and 768.
3. The flash controller burst reads four pages from the first boot block to memory. A total of 4 KB are read in this way.
4. If there is no ECC failure during the burst read, the boot is successful.

If there is an ECC failure during the burst read, the process is started again from the next boot block. If the fourth block still has ECC failure, boot is unsuccessful, which means it is not possible to read a reliable boot image from the flash.

5. CPU access is held until boot completion.
6. After boot, the boot image is visible in the memory map at address 0x00 – 0xF8F. A special hash function is active on the NFC SRAM read to have the boot image in one continuous address range, and not in four address ranges (one for each page). The NFC\_CFG[BTMD] bit controls this hash function, and this bit should be cleared after the CPU has read/executed the boot image, and before it operates the NFC in standard mode. See the next figure.

### Note

There is no difference in how data is transferred between SRAM buffer and the flash: one page uses one buffer. But, how the CPU writes/reads the buffer is different. In non-boot mode, the write/read address is the SRAM physical address. In boot mode, the write/read address is based on the buffers. See [NFC Buffer Memory Space](#).

**Figure 10-37. Boot and NFC\_CFG[BTMD]**

The CPU boot code should be split into four pages as shown in the preceding figure. Boot sector encoding cannot be done by the NFC block itself. It must be done in software. Each page contains 996-byte boot codes and 60-byte ECC codes.

The ECC codes should be inverted because when NFC is doing a page program, it sends the inverted ECC codes to flash. When reading, it inverts them again to get the correct ECC codes for error correction. And only page reads are performed in boot operation. So, software should do the ECC code inversion after boot sector encoding.

The boot is identical for a 8- and 16-bit wide flash. If a 16-bit flash is connected, the data on the upper lane is discarded. If a 8-bit flash is connected, the upper 1 KB of data is not read.

For an 8-bit flash, the upper 1 KB of data is not read.

**Table 10-61. Boot Data's Location in a Page — 8-bit**

8-bit flash boot codes and ECC's location in a page		
	0	1056
996 bytes boot codes	60 bytes ECC (inverted)	Unused

**Table 10-62. Boot Data's Location in a Page — 16-bit**

0x083E	xx	ECC byte 59 (inverted)

### 10.3.4.5 Fast Flash Configuration for EDO

Normally, read out data goes valid after the high-to-low transition of  $\overline{RE}$ , and invalid on the low-to-high transition (as shown in the next figure)  $t_{RHOH} < t_{REH}$ . NFC sampled the read data at the negedge of flash\_clk, and because the data is invalid at that time, a latch is used here to maintain the valid data during the high period of flash\_clk, so that NFC can sample correct data.

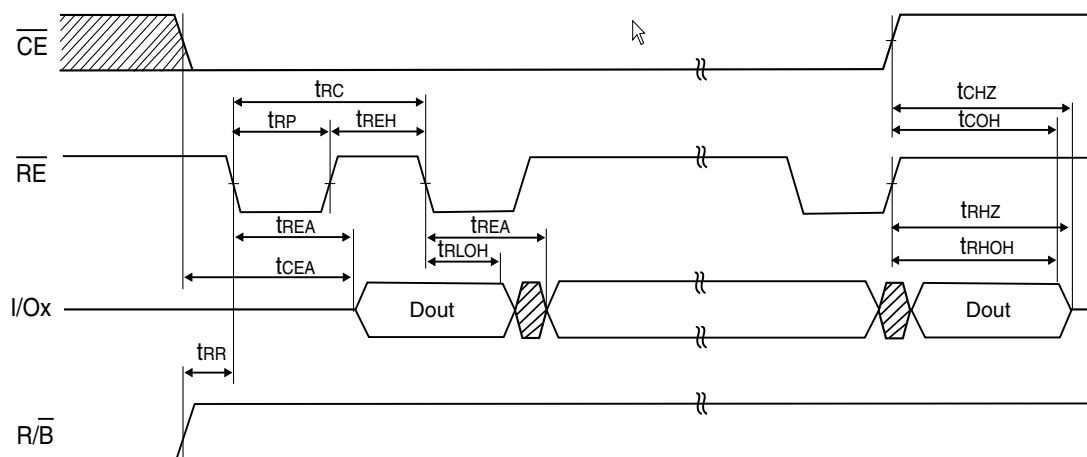

Some flash devices contain an EDO (enhanced data out) feature, where the data can be held until the next high-to-low  $\overline{RE}$  transition (see the figure after next, labeled "Read Operation, EDO type"),  $t_{RHOH} > t_{REH}$ . The read data is valid at the negedge of flash\_clk, NFC can sample data directly without latching it. To support the EDO feature, the NFC must work in fast mode (NFC\_CFG[FAST] set). The NFC clock must be configured fast enough (usually > 33 MHz) according to the data sheet of flash devices.

\* Serial access Cycle after Read(CLE=L,  $\overline{WE}$ =H, ALE=L)

**Figure 10-38. Read Operation**

Serial Access Cycle after Read(EDO Type, CLE=L,  $\overline{WE}$ =H, ALE=L)

**Figure 10-39. Read Operation, EDO type**

#### 10.3.4.6 Organization of the Data in the NAND Flash

Pages on the flash can be split into multiple virtual ECC/DMA pages. The parameter that controls this is NFC\_CFG[PAGECNT]. This parameter gives the number of virtual ECC/DMA pages in one flash page.

The virtual page is split into a user (main) area and ECC (spare) area. Data in the user area can be set or used by the application, while data in the ECC area is set and used by the ECC.

The following tables give virtual-to-physical mappings for various flash devices and their recommended settings.

**Table 10-63. Virtual-to-Physical Mappings of Different Flash,**

Flash page size (main + spare) bytes	NFC_CFG [ECC MODE]	ECC bits	NFC_CFG [PAGE CNT]	Sector size (bytes)	Virtual page user size (bytes)	Mapping
512 + 16	000	0	1	528	528	VirtualPage_0[527:0] = Physical[527:0]
512 + 16	001	4	1	528	520	VirtualPage_0[519:0] = Physical[519:0]

4096 + 208	111	32	2	2152	2092	VirtualPage_0[2091:0] = Physical[2091:0] VirtualPage_1[2091:0] = Physical[4243:2152]
4096 + 208	000	0	8	538	538	VirtualPage_0[537:0] = Physical[537:0] VirtualPage_1[537:0] = Physical[1075:538] VirtualPage_2[537:0] = Physical[1613:1076] VirtualPage_3[537:0] = Physical[2151:1614] VirtualPage_4[537:0] = Physical[2689:2152] VirtualPage_5[537:0] = Physical[3227:2690] VirtualPage_6[537:0] = Physical[3765:3228] VirtualPage_7[537:0] = Physical[4304:3766]
4096 + 208	001	4	8	538	530	VirtualPage_0[529:0] = Physical[529:0] VirtualPage_1[529:0] = Physical[1067:538] VirtualPage_2[529:0] = Physical[1605:1076] VirtualPage_3[529:0] = Physical[2143:1614] VirtualPage_4[529:0] = Physical[2681:2152] VirtualPage_5[529:0] = Physical[3219:2690] VirtualPage_6[529:0] = Physical[3757:3228] VirtualPage_7[529:0] = Physical[4295:3766]
4096 + 208	010	6	8	538	526	VirtualPage_0[525:0] = Physical[525:0] VirtualPage_1[525:0] = Physical[1063:538] VirtualPage_2[525:0] = Physical[1601:1076] VirtualPage_3[525:0] = Physical[2139:1614]

Table continues on the next page...

**Table 10-63. Virtual-to-Physical Mappings of Different Flash, (continued)**

Flash page size (main + spare) bytes	NFC_CFG [ECC MODE]	ECC bits	NFC_CFG [PAGE CNT]	Sector size (bytes)	Virtual page user size (bytes)	Mapping
						VirtualPage_4[525:0] = Physical[2677:2152] VirtualPage_5[525:0] = Physical[3215:2690] VirtualPage_6[525:0] = Physical[3753:3228] VirtualPage_7[525:0] = Physical[4291:3766]
4096 + 208	011	8	8	538	523	VirtualPage_0[522:0] = Physical[523:0] VirtualPage_1[522:0] = Physical[1060:538] VirtualPage_2[522:0] = Physical[1598:1076] VirtualPage_3[522:0] = Physical[2136:1614] VirtualPage_4[522:0] = Physical[2674:2152] VirtualPage_5[522:0] = Physical[3212:2690] VirtualPage_6[522:0] = Physical[3750:3228] VirtualPage_7[522:0] = Physical[4288:3766]

3. In most applications, this mode is of no use because user size is too small.
4. When 4KB page is split into eight virtual pages, if page program/read using DMA, set NFC\_CFG[PAGECNT] to 8. if not using DMA, set NFC\_CFG[PAGECNT] to 4. See [Page Read](#) and [Page Program](#) for details.

If flash devices with a physical page size of 4K or more are used, the bad block marker appears as the first byte of the spare area. But, because of the physical-to-virtual mapping, it does not appear in byte 2048 of the virtual page, where its logical place would be. The DMA engine contains the option to swap some bytes, and to make the bad block marker appear in the requested place.

**Table 10-64. Using the Swap Field to Move the Bad Block Marker**

Flash sector size (main + spare) bytes	Bad block marker (physical)	Bad block marker (virtual) Before swap	Bad block marker (expected) After swap	Swap
4096 + 128	4096	Page 1/byte 1984	Page 1/byte 2048	NFC_SWAP[ADDR1] = (1984/8) <sup>1</sup> NFC_SWAP[ADDR2] = (2048/8)
4096 + 208	4096	Page 1/byte 1944	Page 1/byte 2048	NFC_SWAP[ADDR1] = (1944/8) NFC_SWAP[ADDR2] = (2048/8)

1. Only works with a user page size of at least 2055 bytes. Does not work with ECC mode 111.

### 10.3.4.7 Flash Command Code Description

The 16-bit command code in NFC\_CMD2[CODE] is defined in the next table. If a bit is set, the action is executed. The command is repeated for the number of the NFC\_RPT[COUNT] value. If NFC\_RPT[COUNT] is zero or one, the command is executed once.

**Table 10-65. NFC\_CMD2[CODE] Detail**

NFC_CMD2 [CODE] bit	Action when Bit is Set
15	Start DMA transfer to read data from memory , and write to SRAM.
14	Send command byte 1 (NFC_CMD2[BYTE1]) to flash
13	Send column address 1 (NFC_CAR[BYTE1]) to flash
12	Send column address 2 (NFC_CAR[BYTE2]) to flash
11	Send row address 1 (NFC_RAR[BYTE1]) to flash
10	Send row address 2 (NFC_RAR[BYTE2]) to flash
9	Send row address 3 (NFC_RAR[BYTE3]) to flash
8	Write data to flash. Total of NFC_CFG[PAGECNT] pages is written to the flash, and equal number of starts is sent to the residue engine. Also, additional starts to the DMA engine are sent, until DMA has transferred the NFC_CFG[PAGECNT] data from memory to NFC.
7	Send command byte 2 (NFC_CMD1[BYTE2]) to flash
6	Wait for flash R/B handshake
5	Read data from flash. Read is only started if the new NFC_CMD2[BUFNO] is idle. One or more starts are sent to the residue engine, total NFC_CFG[PAGECNT] starts. <b>Note:</b> For reads, DMA is not started. Instead, to start DMA for reads, NFC_CFG[DMAREQ] must be set.
4	Send command byte 3 (NFC_CMD1[BYTE3]) to flash
3	Read flash status
2	Read ID
1	Always set. End-of-command marker used to signal done.
0	Reserved, must be cleared.

### 10.3.4.8 Interrupts

There are two interrupts to flag the end of a command execution:

1. The DONE interrupt, NFC\_ISR[DONE]. Use this interrupt if commands are sent back-to-back to the flash. It indicates when a new command can be dispatched. The DONE interrupt is given before the flash data is corrected and resident in memory, because the operation of the ECC engine and DMA engine is pipelined.

When the DONE interrupt tracks command completion, the software may also monitor the NFC\_ISR[ECCBUSY, DMABUSY, ECCBN, DMABN] fields.

- a. NFC\_ISR[ECCBUSY] indicates that the ECC block is still busy, and reports the buffer number the ECC block is working on in NFC\_ISR[ECCBN].
  - b. NFC\_ISR[DMABUSY] indicates that the DMA block is still busy, and reports the buffer number the DMA block is working on in NFC\_ISR[DMABN].
2. The command IDLE interrupt, NFC\_ISR[IDLE]. Use this interrupt if you want to use the data produced in the next process. The IDLE interrupt indicates all command processing has terminated, and the relevant data is now available in memory or the NFC SRAM buffer. When using back-to-back reads to the flash, use of the IDLE interrupt means the NFC does not operate at its maximum transfer speed, as ECC and DMA are now done in the foreground.

When using the DONE interrupt, transfer completion for write pages can be assumed when the DONE interrupt is received. When DONE is received for read pages, the data may still be in flight in the DMA or the ECC. To check this, the CPU should remember the buffer number (NFC\_CMD2[BUFNO]) associated with the command, and wait until the DMA and ECC are either idle, or are both busy on a different buffer number. (The ECC buffer number and the DMA buffer number fields do not match the BUFNO specified with the command.) You can check on any DONE interrupt or by polling the register.

## 10.4 Secured Digital Host Controller (SDHC)

### 10.4.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The chapter is intended for a module driver software developer. It describes module-level operation and programming.

### 10.4.2 Overview

#### 10.4.2.1 Supported types of cards

Different types of cards supported by the SDHC are described briefly as follows:

The multimedia card (MMC) is a universal low-cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high-speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

The secure digital card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC with some additions.

Under the SD protocol, it can be categorized into memory card, I/O card and combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the figure does not show cards with reduced size or mini cards.

**Figure 10-40. System connection of the SDHC**

### 10.4.2.2 SDHC block diagram

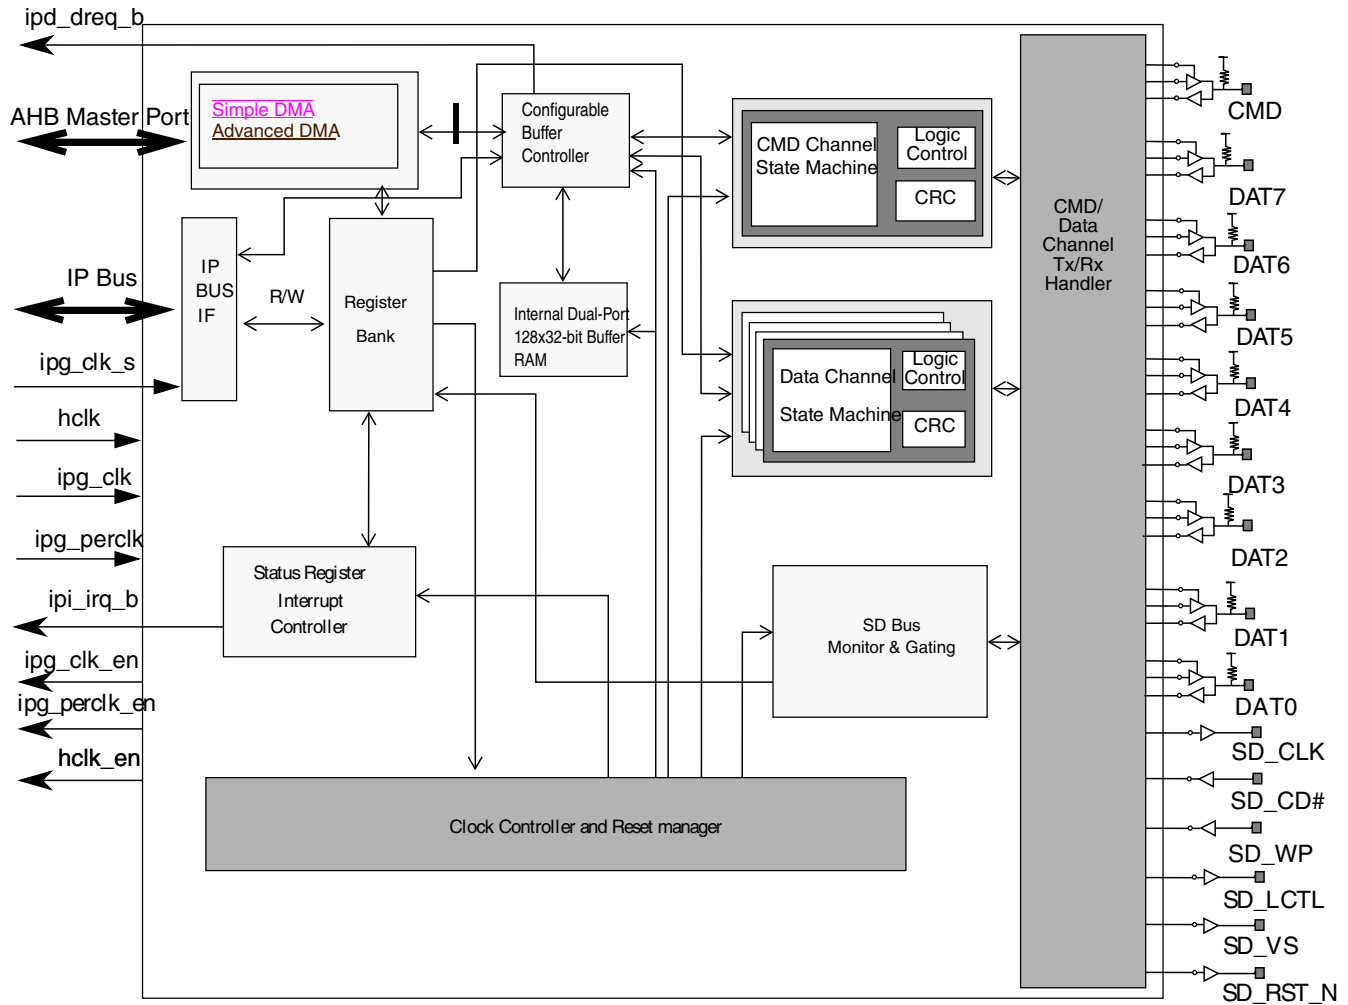

Figure 10-41. Enhanced secure digital host controller block diagram

### 10.4.2.3 Features

The features of the SDHC module include:

- Conforms to the SD Host Controller Standard Specification version 2.0 including test event register support
- Compatible with the MMC System Specification version 4.2/4.3/4.4
- Compatible with the SD Memory Card Specification version 2.0 and supports the high capacity SD memory card
- Compatible with the SDIO Card Specification version 2.0

- Designed to work with SD memory, miniSD memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 52 MHz
- Supports 1-bit/4-bit SD and SDIO modes, 1-bit/4-bit / 8-bit MMC modes devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in Single Data Rate (SDR) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in Dual Data Rate (DDR) mode
- Supports single block, multiblock read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort (both hardware and software CMD12)
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports auto CMD12 for multiblock transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities

#### **10.4.2.4 Modes and operations**

The SDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit

- MMC 4-bit
- MMC 8-bit
- Identification mode up to 400 kHz
- MMC Full Speed mode up to 20 MHz
- MMC High Speed mode up to 52 MHz
- MMC DDR mode 52 MHz both edge
- SD/SDIO Full Speed mode up to 25 MHz
- SD/SDIO High Speed mode up to 50 MHz

### 10.4.3 SDHC signal descriptions

**Table 10-66. SDHC signal descriptions**

Signal	Description	I/O
SDHC_DCLK	Generated clock used to drive the MMC, SD, SDIO or CE-ATA cards.	O
SDHC_CMD	Send commands to and receive responses from the card.	I/O
SDHC_D0	DAT0 line or busy-state detect	I/O
SDHC_D1	8-bit mode: DAT1 line 4-bit mode: DAT1 line or interrupt detect 1-bit mode: Interrupt detect	I/O
SDHC_D2	4-/8-bit mode: DAT2 line or read wait 1-bit mode: Read wait	I/O
SDHC_D3	4-/8-bit mode: DAT3 line or configured as card detection pin 1-bit mode: May be configured as card detection pin	I/O
SDHC_D4	DAT4 line in 8-bit mode Not used in other modes	I/O
SDHC_D5	DAT5 line in 8-bit mode Not used in other modes	I/O
SDHC_D6	DAT6 line in 8-bit mode Not used in other modes	I/O
SDHC_D7	DAT7 line in 8-bit mode Not used in other modes	I/O

## 10.4.4 Memory map and register definition

This section includes the module memory map and detailed descriptions of all registers.

### SDHC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400B_1000	DMA System Address register (SDHC0_DSADDR)	32	R/W	0000_0000h	<a href="#">10.4.4.1/1748</a>
400B_1004	Block Attributes register (SDHC0_BLKATTR)	32	R/W	0000_0000h	<a href="#">10.4.4.2/1749</a>

## 10.4.4.1 DMA System Address register (SDHCx\_DSADDR)

This register contains the physical system memory address used for DMA transfers.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DSADDR																														0	
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## SDHCx\_DSADDR field descriptions

Field	Description
31–2 DSADDR	<p>DMA System Address</p> <p>Contains the 32-bit system memory address for a DMA transfer. Because the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the SDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing, that is, after a transaction has stopped. Read operation during transfers may return an invalid value. The host driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver shall wait, until PRSSTAT[DLA] is cleared, before writing to this register.</p> <p>The SDHC internal DMA does not support a virtual memory system. It supports only continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, SDHC will automatically change SEQ burst type to NSEQ.</p> <p>Because this register supports dynamic address reflecting, when IRQSTAT[TC] bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when IRQSTAT[TC] is set.</p>
Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

### 10.4.4.2 Block Attributes register (SDHCx\_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BLKCNT																0		BLKSIZE													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### SDHCx\_BLKATTR field descriptions

Field	Description
31–16 BLKCNT	<p>Blocks Count For Current Transfer</p> <p>This register is enabled when XFERTYP[BCEN] is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The host driver shall set this register to a value between 1 and the maximum block count. The SDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register must be accessed only when no transaction is executing, that is, after transactions are stopped. During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p> <p>When saving transfer content as a result of a suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register must be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when suspend command is sent out, SDHC will regard the current transfer as aborted and change BLKCNT back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a resume command, the host driver shall restore the previously saved block count.</p> <p><b>NOTE:</b> Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when XFERTYP[MSBSEL] is 0, indicating a single block transfer, the read value of BLKCNT is always 1.</p> <p>0000h Stop count.  0001h 1 block  0002h 2 blocks  ...  FFFFh 65535 blocks</p>
15–13 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
BLKSIZE	<p>Transfer Block Size</p> <p>Specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing, that is, after a transaction has stopped. Read operations during transfers may return an invalid value, and write operations will be ignored.</p>

Table continues on the next page...

**SDHCx\_CMDARG field descriptions**

Field	Description
CMDARG	Command Argument  The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This register is write protected when PRSSTAT[CDIHB0] is set.

**10.4.4.4 Transfer Type register (SDHCx\_XFERTYP)**

This register is used to control the operation of data transfers. The host driver shall set this register before issuing a command followed by a data transfer, or before issuing a resume command. To prevent data loss, the SDHC prevents writing to the bits that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver shall check PRSSTAT[CDIHB] and PRSSTAT[CIHB] before writing to this register. When PRSSTAT[CDIHB] is set, any attempt to send a command with data by writing to this register is ignored; when PRSSTAT[CIHB] bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is nonzero. Besides, block count must also be nonzero, or indicated as single block transfer (bit 5 of this register is 0 when written), or block count is disabled (bit 1 of this register is 0 when written), otherwise SDHC will ignore the sending of this command and do nothing.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, SDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver must issue the command again to retry the transfer. It is also possible that, for some reason, the card responds to the command but SDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The following table shows the summary of how register settings determine the type of data transfer.

**Table 10-67. Transfer Type register setting for various transfer types**

Multi/Single block select	Block count enable	Block count	Function
0	Don't care	Don't care	Single transfer
1	0	Don't care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The following table shows the relationship between XFERTYP[CICEN] and XFERTYP[CCCEN], in regards to XFERTYP[RSPTYP] as well as the name of the response type.

**Table 10-68. Relationship between parameters and the name of the response type**

Response type (RSPTYP)	Index check enable (CICEN)	CRC check enable (CCCEN)	Name of response type
00	0	0	No Response
01	0	1	IR2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

## NOTE

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the

SDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.

- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

### SDHCx\_XFERTYP field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–24 CMDINX	Command Index  These bits shall be set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP	Command Type  There are three types of special commands: suspend, resume, and abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> <li>• Suspend command: If the suspend command succeeds, the SDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DAT line. Because the SDHC does not monitor the content of command response, it does not know if the suspend command succeeded or not. It is the host driver's responsibility to check the status of the suspend command and send another command marked as suspend to inform the SDHC that a suspend command was successfully issued. After the end bit of command is sent, the SDHC deasserts read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the suspend command fails, the SDHC will maintain its current state, and the host driver shall restart the transfer by setting PROCTL[CREQ].</li> <li>• Resume command: The host driver restarts the data transfer by restoring the registers saved before sending the suspend command and then sends the resume command. The SDHC will check for a pending busy state before starting write transfers.</li> <li>• Abort command: If this command is set when executing a read transfer, the SDHC will stop reads to the buffer. If this command is set when executing a write transfer, the SDHC will stop driving the</li> </ul>

Table continues on the next page...

## SDHCx\_XFERTYP field descriptions (continued)

Field	Description
	<p>DAT line. After issuing the abort command, the host driver must issue a software reset (abort transaction).</p> <p>00b Normal other commands.  01b Suspend CMD52 for writing bus suspend in CCCR.  10b Resume CMD52 for writing function select in CCCR.  11b Abort CMD12, CMD52 for writing I/O abort in CCCR.</p>
21 DPSEL	<p>Data Present Select</p> <p>This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following:</p> <ul style="list-style-type: none"> <li>• Commands using only the CMD line, for example: CMD52.</li> <li>• Commands with no data transfer, but using the busy signal on DAT[0] line, R1b or R5b, for example: CMD38.</li> </ul> <p><b>NOTE:</b> In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>0b No data present.  1b Data present.</p>
20 CICEN	<p>Command Index Check Enable</p> <p>If this bit is set to 1, the SDHC will check the index field in the response to see if it has the same value as the command index. If it is not, it is reported as a command index error. If this bit is set to 0, the index field is not checked.</p> <p>0b Disable  1b Enable</p>
19 CCEN	<p>Command CRC Check Enable</p> <p>If this bit is set to 1, the SDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response.</p> <p>0b Disable  1b Enable</p>
18 Reserved	<p>This field is reserved.  This read-only field is reserved and always has the value 0.</p>
17–16 RSPTYP	<p>Response Type Select</p> <p>00b No response.  01b Response length 136.  10b Response length 48.  11b Response length 48, check busy after response.</p>
15–7 Reserved	<p>This field is reserved.  This read-only field is reserved and always has the value 0.</p>
6 NIBBLEPOSIPG	<p>In DDR 4 bit mode nibble position indication.</p> <p>0 The sequence is 'odd high nibble -&gt; even high nibble -&gt; odd low nibble -&gt; even low nibble'.  1 The sequence is 'odd high nibble -&gt; odd low nibble -&gt; even high nibble -&gt; even low nibble'.</p>

Table continues on the next page...

**SDHCx\_XFERTYP field descriptions (continued)**

Field	Description
5 MSBSEL	<p>Multi/Single Block Select</p> <p>Enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the block count register.</p> <p>0b Single block. 1b Multiple blocks.</p>
4 DTDSEL	<p>Data Transfer Direction Select</p> <p>Defines the direction of DAT line data transfers. The bit is set to 1 by the host driver to transfer data from the SD card to the SDHC and is set to 0 for all other commands.</p> <p>0b Write host to card. 1b Read card to host.</p>
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	<p>Auto CMD12 Enable</p> <p>Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the SDHC will issue a CMD12 automatically when the last block transfer has completed. The host driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the SDHC will ignore this bit whether it is set or not.</p> <p>0b Disable 1b Enable</p>
1 BCEN	<p>Block Count Enable</p> <p>Used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.</p> <p>0b Disable 1b Enable</p>
0 DMAEN	<p>DMA Enable</p> <p>Enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the host driver sets the DPSEL bit of this register.</p> <p>0b Disable 1b Enable</p>

### 10.4.4.5 Command Response 0 (SDHCx\_CMDRSP0)

This register is used to store part 0 of the response bits from the card.

Address: Base address + 10h offset

**SDHCx\_CMDRSP0 field descriptions**

Field	Description
CMDRSP0	Command Response 0

### 10.4.4.6 Command Response 1 (SDHCx\_CMDRSP1)

This register is used to store part 1 of the response bits from the card.

Address: Base address + 14h offset

**SDHCx\_CMDRSP1 field descriptions**

Field	Description
CMDRSP1	Command Response 1

### 10.4.4.7 Command Response 2 (SDHCx\_CMDRSP2)

This register is used to store part 2 of the response bits from the card.

Address: Base address + 18h offset

**SDHCx\_CMDRSP2 field descriptions**

Field	Description
CMDRSP2	Command Response 2

**10.4.4.8 Command Response 3 (SDHCx\_CMDRSP3)**

This register is used to store part 3 of the response bits from the card.

The following table describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

**Table 10-69. Response bit definition for each response type**

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bit of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bit of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the SDHC stores only a part of the response data in the command response registers. This enables the host driver to efficiently read 32-bit of response data in one read cycle on a 32-bit bus system. Parts of the response, the index field and the CRC, are checked by the SDHC, as specified by XFERTYP[CICEN] and XFERTYP[CCCEN], and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the SDHC will check R[47:1], and if the response length is 136 the SDHC will check R[119:1].

Because the SDHC may have a multiple block data transfer executing concurrently with a CMD\_wo\_DAT command, the SDHC stores the auto CMD12 response in the CMDRSP3 register. The CMD\_wo\_DAT response is stored in CMDRSP0. This allows the SDHC to

avoid overwriting the Auto CMD12 response with the CMD\_wo\_DAT and vice versa. When the SDHC modifies part of the command response registers, as shown in the table above, it preserves the unmodified bits.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### SDHCx\_DATPORT field descriptions

Field	Description
DATCONT	Data Content  The Buffer Data Port register is for 32-bit data access by the CPU or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

#### 10.4.4.10 Present State register (SDHCx\_PRSTAT)

The host driver can get status of the SDHC from this 32-bit read-only register.

#### NOTE

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CIHB) is set to zero. Other commands shall

be issued when Command Inhibit (CDIHB) is set to zero.  
Possible changes to the SD Physical Specification may add other commands to this list in the future.

SDHCx\_PRSSTAT field descriptions

Field	Description
31–24 DLSL	<p>DAT Line Signal Level</p> <p>Used to check the DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The reset value is effected by the external pullup/pulldown resistors. By default, the read value of this field after reset is 8'b11110111, when DAT[3] is pulled down and the other lines are pulled up.</p> <p>DAT[0] Data 0 line signal level. DAT[1] Data 1 line signal level. DAT[2] Data 2 line signal level. DAT[3] Data 3 line signal level. DAT[4] Data 4 line signal level.</p>

Table continues on the next page...

**SDHCx\_PRSTAT field descriptions (continued)**

Field	Description
	DAT[5] Data 5 line signal level. DAT[6] Data 6 line signal level. DAT[7] Data 7 line signal level.
23 CLSL	CMD Line Signal Level  Used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pullup/pulldown resistor, by default, the read value of this bit after reset is 1b, when the command line is pulled up.
22–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 WPSPL	Write Protect Switch Pin Level  The write protect switch is supported for memory and combo cards. This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it must be tied low, so that the reset value of this bit is high and write is enabled.  0b Write protected (SD_WP=1). 1b Write enabled (SD_WP=0).
18 CDPL	Card Detect Pin Level  This bit reflects the inverse value of the SD_CD# pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SD_CD# pin (that is, when a card is inserted in the socket, it is 0 on the SD_CD# input, and consequently the CDPL reads 1.)  0b No card present (SD_CD#=1). 1b Card present (SD_CD#=0).
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CINS	Card Inserted  Indicates whether a card has been inserted. The SDHC debounces this signal so that the host driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a card insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a card removal interrupt in the Interrupt Status register. A write to the force event register does not effect this bit.  SYSCTL[RSTA] does not effect this bit. A software reset does not effect this bit.  0b Power on reset or no card. 1b Card inserted.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 BREN	Buffer Read Enable  Used for non-DMA read transfers. The SDHC may implement multiple buffers to transfer data efficiently. This read-only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. This read-only flag indicates that valid data exists in the host side buffer.

*Table continues on the next page...*

**SDHCx\_PRSTAT field descriptions (continued)**

Field	Description
	0b Read disable, valid data less than the watermark level exist in the buffer. 1b Read enable, valid data greater than the watermark level exist in the buffer.
10 BWEN	Buffer Write Enable  Used for non-DMA write transfers. The SDHC can implement multiple buffers to transfer data efficiently. This read-only flag indicates whether space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. This read-only flag indicates whether space is available for write data.  0b Write disable, the buffer can hold valid data less than the write watermark level. 1b Write enable, the buffer can hold valid data greater than the write watermark level.
9 RTA	Read Transfer Active Used for detecting completion of a read transfer. This bit is set for either of the following conditions: <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to PROCTL[CREQ] to restart a read transfer.</li> </ul> A transfer complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: <ul style="list-style-type: none"> <li>• When the last data block as specified by block length is transferred to the system, that is, all data are read away from SDHC internal buffer.</li> <li>• When all valid data blocks have been transferred from SDHC internal buffer to the system and no current block transfers are being sent as a result of the stop at block gap request being set to 1.</li> </ul> 0b No valid data. 1b Transferring data.
8 WTA	Write Transfer Active Indicates that a write transfer is active. If this bit is 0, it means no valid write data exists in the SDHC. This bit is set in either of the following cases: <ul style="list-style-type: none"> <li>• After the end bit of the write command.</li> <li>• When writing 1 to PROCTL[CREQ] to restart a write transfer.</li> </ul> This bit is cleared in either of the following cases: <ul style="list-style-type: none"> <li>• After getting the CRC status of the last data block as specified by the transfer count (single and multiple).</li> <li>• After getting the CRC status of any block where data transmission is about to be stopped by a stop at block gap request.</li> </ul> During a write transaction, a block gap event interrupt is generated when this bit is changed to 0, as result of the stop at block gap request being set. This status is useful for the host driver in determining when to issue commands during write busy state.  0b No valid data. 1b Transferring data.
7 SDOFF	SD Clock Gated Off Internally  Indicates that the SD clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion, or the driver has cleared SYSCTL[SDCLKEN] to stop the SD clock. This bit is for the host driver to debug data transaction on the SD bus.  0b SD clock is active. 1b SD clock is gated off.

*Table continues on the next page...*

**SDHCx\_PRSTAT field descriptions (continued)**

Field	Description
6 PEROFF	<p>SDHC clock Gated Off Internally</p> <p>Indicates that the is internally gated off. This bit is for the host driver to debug transaction on the SD bus. When INITA bit is set, SDHC sending 80 clock cycles to the card, SDCLKEN must be 1 to enable the output card clock, otherwise the will never be gate off, so and will be always active. SDHC clockSDHC clockSDHC clockbus clock</p> <p>0b SDHC clock is active.</p> <p>1b SDHC clock is gated off.</p>
5 HCKOFF	<p>System Clock Gated Off Internally</p> <p>Indicates that the system clock is internally gated off. This bit is for the host driver to debug during a data transfer.</p> <p>0b System clock is active.</p> <p>1b System clock is gated off.</p>
4 IPGOFF	<p>Bus Clock Gated Off Internally</p> <p>Indicates that the bus clock is internally gated off. This bit is for the host driver to debug.</p> <p>0b Bus clock is active.</p> <p>1b Bus clock is gated off.</p>
3 SDSTB	<p>SD Clock Stable</p> <p>Indicates that the internal card clock is stable. This bit is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear SYSCTL[SDCLKEN] to remove glitch on the card clock when the frequency is changing.</p> <p>0b Clock is changing frequency and not stable.</p> <p>1b Clock is stable.</p>
2 DLA	<p>Data Line Active Indicates whether one of the DAT lines on the SD bus is in use.</p> <p><b>In the case of read transactions:</b></p> <p>This status indicates whether a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a block gap event interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to PROCTL[CREQ] to restart a read transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ol style="list-style-type: none"> <li>1. When the end bit of the last data block is sent from the SD bus to the SDHC.</li> </ol>

*Table continues on the next page...*

## SDHCx\_PRSTAT field descriptions (continued)

Field	Description
	<p>2. When the read wait state is stopped by a suspend command and the DAT2 line is released.</p> <p>The SDHC will wait at the next block gap by driving read wait at the start of the interrupt cycle. If the read wait signal is already driven (data buffer cannot receive data), the SDHC can wait for a current block gap by continuing to drive the read wait signal. It is necessary to support read wait to use the suspend / resume function. This bit will remain 1 during read wait.</p> <p><b>In the case of write transactions:</b></p> <p>This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a transfer complete interrupt in the interrupt status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the write command.</li> <li>• When writing to 1 to PROCTL[CREQ] to continue a write transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>• When the SD card releases write busy of the last data block, the SDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the SDHC shall assume the card drive "Not busy".</li> <li>• When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request.</li> </ul> <p><b>In the case of command with busy pending:</b></p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released.</p> <p>0b DAT line inactive. 1b DAT line active.</p>
1 CDIHB	<p>Command Inhibit (DAT)</p> <p>This status bit is generated if either the DLA or the RTA is set to 1. If this bit is 0, it indicates that the SDHC can issue the next SD/MMC Command. Commands with a busy signal belong to CDIHB, for example, R1b, R5b type. Except in the case when the command busy is finished, changing from 1 to 0 generates a transfer complete interrupt in the Interrupt Status register.</p> <p><b>NOTE:</b> The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>0b Can issue command which uses the DAT line. 1b Cannot issue command which uses the DAT line.</p>
0 CIHB	<p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the SDHC can issue a SD/MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the CDIHB bit is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a command complete interrupt in the interrupt status register. If the SDHC cannot issue the command because of a command conflict error (see command CRC error) or because of a command not issued by auto CMD12 error, this bit will remain 1 and the command complete is not set. The status of issuing an auto CMD12 does not show on this bit.</p> <p>0b Can issue command using only CMD line. 1b Cannot issue command.</p>

### 10.4.4.11 Protocol Control register (SDHCx\_PROCTL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the SDHC issues a suspend command or the SD card accepts the suspend command:

- If the host driver does not issue a suspend command, the continue request shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card accepts it, a resume command shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card does not accept it, the continue request shall be used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver shall wait for a transfer complete (in the interrupt status register), before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver shall clear the stop at block gap request before or simultaneously.

**SDHCx\_PROCTL field descriptions**

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 WECRM	Wakeup Event Enable On SD Card Removal  Enables a wakeup event, via IRQSTAT[CRM]. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, IRQSTAT[CRM] and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert IRQSTAT[CRM] and the SDHC interrupt.

*Table continues on the next page...*

## SDHCx\_PROCTL field descriptions (continued)

Field	Description
	0b Disabled 1b Enabled
25 WECINS	<p>Wakeup Event Enable On SD Card Insertion</p> <p>Enables a wakeup event, via IRQSTAT[CINS]. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, IRQSTATEN[CINSEN] and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert IRQSTATEN[CINSEN] and the SDHC interrupt.</p> <p>0b Disabled 1b Enabled</p>
24 WECINT	<p>Wakeup Event Enable On Card Interrupt</p> <p>Enables a wakeup event, via IRQSTAT[CINT]. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the card interrupt status and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert the card interrupt status and the SDHC interrupt.</p> <p>0b Disabled 1b Enabled</p>
23–20 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
19 IABG	<p>Interrupt At Block Gap</p> <p>Valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card can't signal an interrupt during a multiple block transfer, this bit must be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>0b Disabled 1b Enabled</p>
18 RWCTL	<p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the SDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the SDHC will stop the SD Clock to pause reading operation.</p> <p>0b Disable read wait control, and stop SD clock at block gap when SABGREQ is set. 1b Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set.</p>
17 CREQ	<p>Continue Request</p> <p>Used to restart a transaction which was stopped using the PROCTL[SABGREQ]. When a suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set PROCTL[SABGREQ] to 0 and set this bit to 1 to restart the transfer.</p> <p>The SDHC automatically clears this bit, therefore it is not necessary for the host driver to set this bit to 0. If both PROCTL[SABGREQ] and this bit are 1, the continue request is ignored.</p>

*Table continues on the next page...*

**SDHCx\_PROCTL field descriptions (continued)**

Field	Description
	0b No effect. 1b Restart
16 SABGREQ	<p>Stop At Block Gap Request</p> <p>Used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the IRQSTATEN[TCSSEN] is set to 1, indicating a transfer completion, the host driver shall leave this bit set to 1. Clearing both PROCTL[SABGREQ] and PROCTL[CREQ] does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The SDHC will honor the PROCTL[SABGREQ] for write transfers, but for read transfers it requires that SDIO card support read wait. Therefore, the host driver shall not set this bit during read transfers unless the SDIO card supports read wait and has set PROCTL[RWCTL] to 1, otherwise the SDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the data port register, the host driver shall set this bit after all block data is written. If this bit is set to 1, the host driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the host driver shall not clear this bit before IRQSTATEN[TCSSEN] is set, otherwise the SDHC's behavior is undefined.</p> <p>This bit effects PRSSTAT[RTA], PRSSTAT[WTa], and PRSSTAT[CDIHB].</p> 0b Transfer 1b Stop
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CDSS	<p>Card Detect Signal Selection</p> <p>Selects the source for the card detection.</p> 0b Card detection level is selected for normal purpose. 1b Card detection test level is selected for test purpose.
6 CDTL	<p>Card Detect Test Level</p> <p>Enabled while the CDSS is set to 1 and it indicates card insertion.</p> 0b Card detect test level is 0, no card inserted. 1b Card detect test level is 1, card inserted.
5–4 EMODE	<p>Endian Mode</p> <p>The SDHC supports all four endian modes in data transfer.</p> 00b Big endian mode 01b Half word big endian mode 10b Little endian mode 11b Reserved
3 D3CD	<p>DAT3 As Card Detection Pin</p> <p>If this bit is set, DAT3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DAT3 is also a chip-select for the SPI mode. A pulldown on this pin and CMD0 may set the card into the SPI mode, which the SDHC does not support. Note: Keep this bit set if SDIO interrupt is used.</p>

*Table continues on the next page...*

**SDHCx\_PROCTL field descriptions (continued)**

Field	Description
	0b DAT3 does not monitor card Insertion. 1b DAT3 as card detection pin.
2–1 DTW	Data Transfer Width  Selects the data width of the SD bus for a data transfer. The host driver shall set it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits.  00b 1-bit mode 01b 4-bit mode 10b 8-bit mode 11b Reserved
0 LCTL	LED Control  This bit, fully controlled by the host driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands.  0b LED off. 1b LED on.

**10.4.4.12 System Control register (SDHCx\_SYSCTL)**

Address: Base address + 2Ch offset

**SDHCx\_SYSCTL field descriptions**

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 INITA	Initialization Active  When this bit is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this bit is self-cleared. This bit is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the PRSSTAT[CIHB] and PRSSTAT[CDIHB] bits are set, writing 1 to this bit is ignored, that is, when command line or data lines are active, write to this bit is not allowed). On the other hand, when this bit is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self-cleared.
26 RSTD	Software Reset For DAT Line Only part of the data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: <ul style="list-style-type: none"> <li>• Data Port register</li> <li>• Buffer Is Cleared And Initialized.Present State register</li> <li>• Buffer Read Enable</li> <li>• Buffer Write Enable</li> <li>• Read Transfer Active</li> <li>• Write Transfer Active</li> <li>• DAT Line Active</li> <li>• Command Inhibit (DAT) Protocol Control register</li> <li>• Continue Request</li> <li>• Stop At Block Gap Request Interrupt Status register</li> <li>• Buffer Read Ready</li> <li>• Buffer Write Ready</li> <li>• DMA Interrupt</li> <li>• Block Gap Event</li> <li>• Transfer Complete</li> </ul> 0b No reset. 1b Reset.
25 RSTC	Software Reset For CMD Line Only part of the command circuit is reset. The following registers and bits are cleared by this bit: <ul style="list-style-type: none"> <li>• PRSSTAT[CIHB]</li> <li>• IRQSTAT[CC]</li> </ul> 0b No Reset. 1b Reset.
24 RSTA	Software Reset For ALL  Effects the entire host controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the host driver shall set this bit to 1 to reset the SDHC. The SDHC shall reset this bit to 0 when the capabilities registers are valid and the host driver can read them. Additional use of SYSCTL[RSTA] does not affect the value of the capabilities registers. After this bit is set, it is recommended that the host driver reset the external card and re-initialize it.  0b No reset. 1b Reset.

*Table continues on the next page...*

## SDHCx\_SYSCTL field descriptions (continued)

Field	Description
23 IPPRSTN	This register's value will be output to CARD from pad directly for hardware reset of the card if card support this feature.
22–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 DTCV	Data Timeout Counter Value  Determines the interval by which DAT line timeouts are detected. See IRQSTAT[DTOE] for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value.  The host driver can clear IRQSTATEN[DTOESEN] to prevent inadvertent time-out events.  0000b SDCLK x 2 <sup>13</sup> When in DDR mode, the corresponding value changes as: SDCLK x 2 <sup>12</sup> . 0001b SDCLK x 2 <sup>14</sup> When in DDR mode, the corresponding value changes as: SDCLK x 2 <sup>13</sup> . ... 1110b SDCLK x 2 <sup>27</sup> When in DDR mode, the corresponding value changes as: SDCLK x 2 <sup>26</sup> . 1111b Reserved When in DDR mode, the corresponding value is also Reserved.
15–8 SDCLKFS	SDCLK Frequency Select  Used to select the frequency of the SDCLK pin. The frequency is not programmed directly. Rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register.  Setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of SDHC clock and the following divisor bits.  <b>NOTE:</b> In SDHCv3 this register field can not be set to 00h(i.e. bypass). The smallest value is 01h, that is divided by 2.  The frequency of SDCLK is set by the following formula: Clock frequency = (Base clock) / (prescaler x divisor)  For example, if the base clock frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input base clock ( SDHC clock ) is about 96 MHz, the default SD Clock after reset is 375 kHz.  According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.  Only the following settings are allowed:  01h Base clock divided by 2. 02h Base clock divided by 4. 04h Base clock divided by 8. 08h Base clock divided by 16. 10h Base clock divided by 32. 20h Base clock divided by 64.

Table continues on the next page...

**SDHCx\_SYSCTL field descriptions (continued)**

Field	Description
	40h Base clock divided by 128. 80h Base clock divided by 256.
7–4 DVS	<p>Divisor</p> <p>Used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisor without deterioration of duty cycle.</p> <p>The setting are as following:</p> <p>0h Divisor by 1.  1h Divisor by 2.  ...  Eh Divisor by 15.  Fh Divisor by 16.</p>
3 SDCLKEN	<p>SD Clock Enable</p> <p>The host controller shall stop SDCLK when writing this bit to 0. SDCLK frequency can be changed when this bit is 0. Then, the host controller shall maintain the same clock frequency until SDCLK is stopped (stop at SDCLK = 0). If PRSSTAT[CINS] is cleared, this bit must be cleared by the host driver to save power.</p>
2 PEREN	<p>Peripheral Clock Enable</p> <p>If this bit is set, SDHC clock will always be active and no automatic gating is applied. Thus the SDCLK is active except for when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the SDHC clock will be automatically off whenever there is no transaction on the SD bus. Because this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The SDHC clock will be internally gated off, if none of the following factors are met:</p> <ul style="list-style-type: none"> <li>• The cmd part is reset, or</li> <li>• Data part is reset, or</li> <li>• A soft reset, or</li> <li>• The cmd is about to send, or</li> <li>• Clock divisor is just updated, or</li> <li>• Continue request is just set, or</li> <li>• This bit is set, or</li> <li>• Card insertion is detected, or</li> <li>• Card removal is detected, or</li> <li>• Card external interrupt is detected, or</li> <li>• 80 clocks for initialization phase is ongoing</li> </ul> <p>0b SDHC clock will be internally gated off.</p> <p>1b SDHC clock will not be automatically gated off.</p>
1 HCKEN	<p>HCLK Enable</p> <p>If this bit is set, system clock will always be active and no automatic gating is applied. When this bit is cleared,  system clock  will be automatically off when no data transfer is on the SD bus.</p> <p>0b System clock</p>

*Table continues on the next page...*

**SDHCx\_SYSCTL field descriptions (continued)**

Field	Description
	will be internally gated off. 1b System clock will not be automatically gated off.
0 IPGEN	<p>IPG Clock Enable</p> <p>If this bit is set, bus clock will always be active and no automatic gating is applied. The bus clock will be internally gated off, if none of the following factors are met:</p> <ul style="list-style-type: none"> <li>• The cmd part is reset, or</li> <li>• Data part is reset, or</li> <li>• Soft reset, or</li> <li>• The cmd is about to send, or</li> <li>• Clock divisor is just updated, or</li> <li>• Continue request is just set, or</li> <li>• This bit is set, or</li> <li>• Card insertion is detected, or</li> <li>• Card removal is detected, or</li> <li>• Card external interrupt is detected, or</li> <li>• The SDHC clock is not gated off</li> </ul> <p><b>NOTE:</b> The bus clock will not be auto gated off if the SDHC clock is not gated off. So clearing only this bit has no effect unless the PEREN bit is also cleared. Also config IPGEN, PEREN and HCKEN to same value, all enable or disable</p> <p>0b Bus clock will be internally gated off. 1b Bus clock will not be automatically gated off.</p>

**10.4.4.13 Interrupt Status register (SDHCx\_IRQSTAT)**

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the CTOE and the CC bits.

**Table 10-70. SDHC status for CTOE/CC bit combinations**

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 10-71. SDHC status for data timeout error/transfer complete bit combinations**

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC Error (CCE) and Command Timeout Error (CTOE).

**Table 10-72. SDHC status for CCE/CTOE Bit Combinations**

Command complete	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Field	Description
28 DMAE	<p>DMA Error</p> <p>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver shall restart the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DSADDR value or from the remaining number of blocks and the block size.</p> <p>0b No error. 1b Error.</p>
27–25 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
24 AC12E	<p>Auto CMD12 Error</p> <p>Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error.</p> <p>0b No error. 1b Error.</p>
23 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
22 DEBE	<p>Data End Bit Error</p> <p>Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC.</p> <p>0b No error. 1b Error.</p>
21 DCE	<p>Data CRC Error</p> <p>Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the Write CRC status having a value other than 010.</p> <p>0b No error. 1b Error.</p>
20 DTOE	<p>Data Timeout Error</p> <p>Occurs when detecting one of following time-out conditions.</p> <ul style="list-style-type: none"> <li>• Busy time-out for R1b,R5b type</li> <li>• Busy time-out after Write CRC status</li> <li>• Read Data time-out</li> </ul> <p>0b No error. 1b Time out.</p>
19 CIE	<p>Command Index Error</p> <p>Occurs if a Command Index error occurs in the command response.</p> <p>0b No error. 1b Error.</p>

Table continues on the next page...

## SDHCx\_IRQSTAT field descriptions (continued)

Field	Description
18 CEBE	<p>Command End Bit Error</p> <p>Occurs when detecting that the end bit of a command response is 0.</p> <p>0b No error. 1b End Bit Error generated.</p>
17 CCE	<p>Command CRC Error</p> <p>Command CRC Error is generated in two cases.</p> <ul style="list-style-type: none"> <li>If a response is returned and the Command Timeout Error is set to 0, indicating no time-out, this bit is set when detecting a CRC error in the command response.</li> <li>The SDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the SDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the SDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict.</li> </ul> <p>0b No error. 1b CRC Error generated.</p>
16 CTOE	<p>Command Timeout Error</p> <p>Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the SDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set, this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the SDHC.</p> <p>0b No error. 1b Time out.</p>
15–9 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
8 CINT	<p>Card Interrupt</p> <p>This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the SDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this bit to 1 can clear this bit, but as the interrupt factor from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt factor from the external card followed by a writing 1 to this bit.</p> <p>When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (it must reset the interrupt factors in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.</p> <p>0b No Card Interrupt. 1b Generate Card Interrupt.</p>
7 CRM	<p>Card Removal</p> <p>This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. To leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register.</p>

*Table continues on the next page...*

## SDHCx\_IRQSTAT field descriptions (continued)

Field	Description
	0b Card state unstable or inserted. 1b Card removed.
6 CINS	<p>Card Insertion</p> <p>This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. To leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.</p> <p>0b Card state unstable or removed.            1b Card inserted.</p>
5 BRR	<p>Buffer Read Ready</p> <p>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. See the Buffer Read Enable bit in the Present State register for additional information.</p> <p>0b Not ready to read buffer.            1b Ready to read buffer.</p>
4 BWR	<p>Buffer Write Ready</p> <p>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. See the Buffer Write Enable bit in the Present State register for additional information.</p> <p>0b Not ready to write buffer.            1b Ready to write buffer.</p>
3 DINT	<p>DMA Interrupt</p> <p>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set.</p> <p>0b No DMA Interrupt.            1b DMA Interrupt is generated.</p>
2 BGE	<p>Block Gap Event</p> <p>If PROCTL[SABGREQ] is set, this bit is set when a read or write transaction is stopped at a block gap. If PROCTL[SABGREQ] is not set to 1, this bit is not set to 1.</p> <p>In the case of a read transaction: This bit is set at the falling edge of the DAT line active status, when the transaction is stopped at SD Bus timing. The read wait must be supported in order to use this function.</p> <p>In the case of write transaction: This bit is set at the falling edge of write transfer active status, after getting CRC status at SD bus timing.</p> <p>0b No block gap event.            1b Transaction stopped at block gap.</p>
1 TC	<p>Transfer Complete</p> <p>This bit is set when a read or write transfer is completed.</p>

*Table continues on the next page...*

**SDHCx\_IRQSTAT field descriptions (continued)**

Field	Description
	<p>In the case of a read transaction: This bit is set at the falling edge of the read transfer active status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length, after the last data has been read to the host system. The second is when data has stopped at the block gap and completed the data transfer by setting PROCTL[SABGREQ], after valid data has been read to the host system.</p> <p>In the case of a write transaction: This bit is set at the falling edge of the DAT line active status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting PROCTL[SABGREQ], and the data transfers are completed, after valid data is written to the SD card and the busy signal released.</p> <p>0b Transfer not complete. 1b Transfer complete.</p>
0 CC	<p>Command Complete</p> <p>This bit is set when you receive the end bit of the command response, except Auto CMD12. See PRSSTAT[CIHB].</p> <p>0b Command not complete. 1b Command complete.</p>

**10.4.4.14 Interrupt Status Enable register (SDHCx\_IRQSTATEN)**

Setting the bits in this register to 1 enables the corresponding interrupt status to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is also cleared, that is, when the bit in this register is cleared, the corresponding bit in interrupt status register is always 0.

**NOTE**

- Depending on PROCTL[IABG] bit setting, SDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the card interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both IRQSTATEN[CTOESN] and IRQSTATEN[CCESEN] to 1.

**10.4.4.16 Auto CMD12 Error Status Register (SDHCx\_AC12ERR)**

When the AC12ESEN bit in the Status register is set, the host driver shall check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

The following table shows the relationship between the Auto CMGD12 CRC error and the Auto CMD12 command timeout error.

**Table 10-73. Relationship between Command CRC Error and Command Timeout Error For Auto CMD12**

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the SDHC is going to issue an Auto CMD12:

- Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command.
  - Set bit 0 to 0 if the auto CMD12 is issued.
2. At the end bit of an auto CMD12 response:
    - Check errors corresponding to bits 1-4.
    - Set bits 1-4 corresponding to detected errors.
    - Clear bits 1-4 corresponding to detected errors.
  3. Before reading the Auto CMD12 error status bit 7:
    - Set bit 7 to 1 if there is a command that can't be issued.
    - Clear bit 7 if there is no command to issue.

The timing for generating the auto CMD12 error and writing to the command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the command register. So it is suggested to read this register only when IRQSTAT[AC12E] is set. An Auto CMD12 error interrupt is generated when one of the error bits (0-4) is set to 1. The command not issued by auto CMD12 error does not generate an interrupt.

### SDHCx\_AC12ERR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error  Setting this bit to 1 means CMD_wo_DAT is not executed due to an auto CMD12 error (D04-D01) in this register.  0b No error. 1b Not issued.
6–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 AC12IE	Auto CMD12 Index Error  Occurs if the command index error occurs in response to a command.  0b No error. 1b Error, the CMD index in response is not CMD12.
3 AC12CE	Auto CMD12 CRC Error  Occurs when detecting a CRC error in the command response.  0b No CRC error. 1b CRC error met in Auto CMD12 response.
2 AC12EBE	Auto CMD12 End Bit Error  Occurs when detecting that the end bit of command response is 0 which must be 1.  0b No error. 1b End bit error generated.
1 AC12TOE	Auto CMD12 Timeout Error

Table continues on the next page...

**SDHCx\_AC12ERR field descriptions (continued)**

Field	Description
	Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, the other error status bits (2-4) have no meaning.  0b No error. 1b Time out.
0 AC12NE	Auto CMD12 Not Executed  If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an auto CMD12. Setting this bit to 1 means the SDHC cannot issue the auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning.  0b Executed. 1b Not executed.

**10.4.4.17 Host Controller Capabilities (SDHCx\_HTCAPBLT)**

This register provides the host driver with information specific to the SDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset. Any write to this register is ignored.

25 VS30	Voltage Support 3.0 V  Depends on the host system ability.  0b 3.0 V not supported. 1b 3.0 V supported.
24 VS33	Voltage Support 3.3 V  Depends on the host system ability.  0b 3.3 V not supported. 1b 3.3 V supported.
23 SRS	Suspend/Resume Support  Indicates whether the SDHC supports suspend / resume functionality. If this bit is 0, the suspend and resume mechanism, as well as the read wait, are not supported, and the host driver shall not issue either suspend or resume commands.  0b Not supported. 1b Supported.
22 DMAS	DMA Support  Indicates whether the SDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly.  0b DMA not supported. 1b DMA supported.
21 HSS	High Speed Support  Indicates whether the SDHC supports high-speed mode and the host system can supply a SD clock frequency from 25 MHz to 50 MHz.  0b High speed not supported. 1b High speed supported.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 MBL	Max Block Length  Indicates the maximum block size that the host driver can read and write to the buffer in the SDHC. The buffer shall transfer block size without wait cycles.  000b 512 bytes

28–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 WRWML	Write Watermark Level  The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RDWML	Read Watermark Level  The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read watermark level is 128.

10.4.4.19 Force Event register (SDHCx\_FEVT)

The Force Event (FEVT) register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding bit of the Interrupt Status Enable register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status register. A read from this register always results in 0's. To change the corresponding status bits in the interrupt status register, make sure to set SYSCTL[IPGEN] so that bus clock is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is selfcleared.

Address: Base address + 50h offset

R	DLLCTRLSLVOVERRIDEVAL								DLLCTRLSLV RRIDE	0	DLLCTRLGATEUP DATE	DLLCTRLSLVDLYTARGET				DLLCTRLSLVFOR CEUPD	DLLCTRLRESET	DLLCTRLENABLE
W																		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		

## SDHCx\_DLLCTRL field descriptions

Field	Description
31–28 DLLCTRLREFUPDATEINT	DLL control loop update interval. The interval cycle is $(2 + \text{REF\_UPDATE\_INT}) \times \text{ref\_clock}$ . By default, the DLL control loop shall update every two ref_clock cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay such as voltage and temperature.
27–20 DLLCTRLSLVUPDATEINT	Slave delay line update interval. If default 0 is used, it means 256 cycles of ref_clock. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state from an un-locked state.

Table continues on the next page...

**SDHCx\_DLLCTRL field descriptions (continued)**

Field	Description
19–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–10 DLLCTRLSLVOVERRIDEVAL	When SLV_OVERRIDE=1 This field is used to select 1 of 64 physical taps manually. A value of 0 selects tap 1, and a value of 0x3f selects tap 64.
9 DLLCTRLSLVOVERRIDE	Set this bit to 1 to enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 DLLCTRLGATEUPDATE	Set this bit to 1 to force dLL not update from now on. Because when clock_in exists, glitches might appear during update. This bit is used by software if we met such kind of condition. Set it to 0 to let dLL update automatically.
6–3 DLLCTRLSLVDLYTARGET	The delay target for the SDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. So the input read-clock can be delayed relative input data from (ref_clock/2)/16 to ref_clock/2.
2 DLLCTRLSLVFORCEUPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when SDHC is idle. This function may not work when SDHC is working on data/cmd/response.
1 DLLCTRLRESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, Reset must be taken low and then asserted again.
0 DLLCTRLENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.4.4.21 DLL Status Register (SDHCx\_DLLSTS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Address: Base address + 64h offset

SDHCx\_DLLSTS field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–8 DLLSTSREFSEL	Reference delay line select taps. Be noted this is encoded by 6 bits for 64 taps.
7–2 DLLSTSSLVSEL	Slave delay line select status. This is the instant value generated from reference chain. Since only when ref_lock is detected can the reference chain get updated, this value should be the right value next be update to the slave line when reference is locked.
1 DLLSTSREFLOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays.
0 DLLSTSSLVLOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

### 10.4.4.22 Vendor Specific register (SDHCx\_VENDOR)

This register contains the vendor-specific control/status register.

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 INTSTVAL	Internal State Value  Internal state value, reflecting the corresponding state value selected by <b>Debug Select</b> field. This field is read-only and write to this field does not have effect.
15–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 EXBLKNU	Exact Block Number Block Read Enable For SDIO CMD53  This bit must be set before S/W issues CMD53 multi-block read with exact block number. This bit must not be set if the CMD53 multi-block read is not exact block number.

*Table continues on the next page...*

**SDHCx\_VENDOR field descriptions (continued)**

Field	Description
	0 None exact block read. 1 Exact block read for SDIO CMD53.
0 EXTDMAEN	External DMA Request Enable  Enables the request to external DMA. When the internal DMA is not in use, and this bit is set, SDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by CPU polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set.  0 In any scenario, SDHC does not send out the external DMA request. 1 When internal DMA is not active, the external DMA request will be sent out.

**10.4.4.23 MMC Boot register (SDHCx\_MMCBOOT)**

This register contains the MMC fast boot control register.

Address: Base address + C4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BOOTBLKCNT

SVN	Specification Version Number  Indicate the host controller specification version.  00h        SD host specification version 1.0. All others   Reserved

## 10.4.5 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA crossbar switch interface, dual-port memory wrapper, data/command controller, clock & reset manager, and clock generator.

### 10.4.5.1 Data buffer

The SDHC uses one configurable data buffer, so that data can be transferred between the system bus and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). The following diagram illustrates the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

**Figure 10-42. SDHC buffer scheme**

There are 3 transfer modes to access the data buffer:

- CPU Polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RDWML watermark value, then by polling IRQSTAT[BRR] the host driver can read the DATPORT register to fetch the amount of words set in the WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RDWML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately deasserted when there is an access on the DATPORT register. If the number of words in the buffer after the current burst meets or exceeds RDWML value, then the DMA request is asserted again. For instance if there are twice as many words in the buffer than the RDWML value, there are two successive DMA requests with only one cycle of deassertion between. The write operation is similar.

Note the accesses CPU Polling mode and External DMA mode both use the IP bus, and if the external DMA is enable, in both modes an external DMA request is sent out whenever the buffer is ready.

- Internal DMA mode:
  - The internal DMA access, either by simple or advanced DMA, is over the crossbar switch bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in WML, the internal DMA starts fetching data over the crossbar switch bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- 1. Burst length configured in the burst length field of WML
- 2. Watermark level boundary
- 3. Block size boundary
- 4. Data boundary configured in the current descriptor if the ADMA is active
- 5. 1 KB address boundary

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software, as illustrated in the following diagrams. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

Figure 10-43. Data swap between system bus and SDHC data buffer in byte little endian mode

Figure 10-44. Data swap between system bus and SDHC data buffer in half word big endian mode

10.4.5.1.1 Write operation sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. Using external DMA through the SDHC DMA request signal.
2. Processor core polling through IRQSTAT[BWR] (interrupt or polling).
3. Using the internal DMA.

When the internal DMA is not used, that is, the XFERTYP[DMAEN] bit is not set when the command is sent, the SDHC asserts a DMA request when the amount of buffer space exceeds the value set in WML, and is ready for receiving new data. At the same time, the SDHC would set IRQSTAT[BWR]. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the contents of the DSADDR to get the starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the write operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

The SDHC will not start data transmission until the number of words set in WML can be held in the buffer. If the buffer is empty and the host system does not write data in time, the SDHC will stop the SD\_CLK to avoid the data buffer underrun situation.

#### 10.4.5.1.2 Read operation sequence

There are three ways to read data from the buffer when the user transfers data to the card:

1. Using the external DMA through the SDHC DMA request signal
2. Processor core polling through IRQSTAT[BRR] (interrupt or polling)
3. Using the internal DMA

When internal DMA is not used, that is, XFERTYP[DMAEN] is not set when the command is sent, the SDHC asserts a DMA request when the amount of data exceeds the value set in WML, that is available and ready for system fetching data. At the same time, the SDHC would set IRQSTAT[BRR]. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the content of the DMA system address register to get the starting address of the abandoned data block. If the current data transfer is in multiblock

mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

For any write transfer mode, the SDHC will not start data transmission until the number of words set in WML are in the buffer. If the buffer is full and the Host System does not read data in time, the SDHC will stop the SDHC\_DCLK to avoid the data buffer overrun situation.

#### 10.4.5.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to use it in the most optimized way. In the SDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length can be from 1 word to the maximum of 31 words. The host driver may configure the value according to the system situation and requirement.

During a multiblock data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive, which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it doesn't support a partial block access, which is not the integer times of 512 bytes.

For block size not times of 4, that is, not word aligned, SDHC requires stuff bytes at the end of each block, because the SDHC treats each block individually. For example, the block size is 7 bytes, there are 12 blocks to write, the system side must write 2 times for each block, and for each block, the ending byte would be abandoned by the SDHC because it sends only 7 bytes to the card and picks data from the following system write, so there would be 24 beats of write access in total.

#### 10.4.5.1.4 Dividing large data transfer

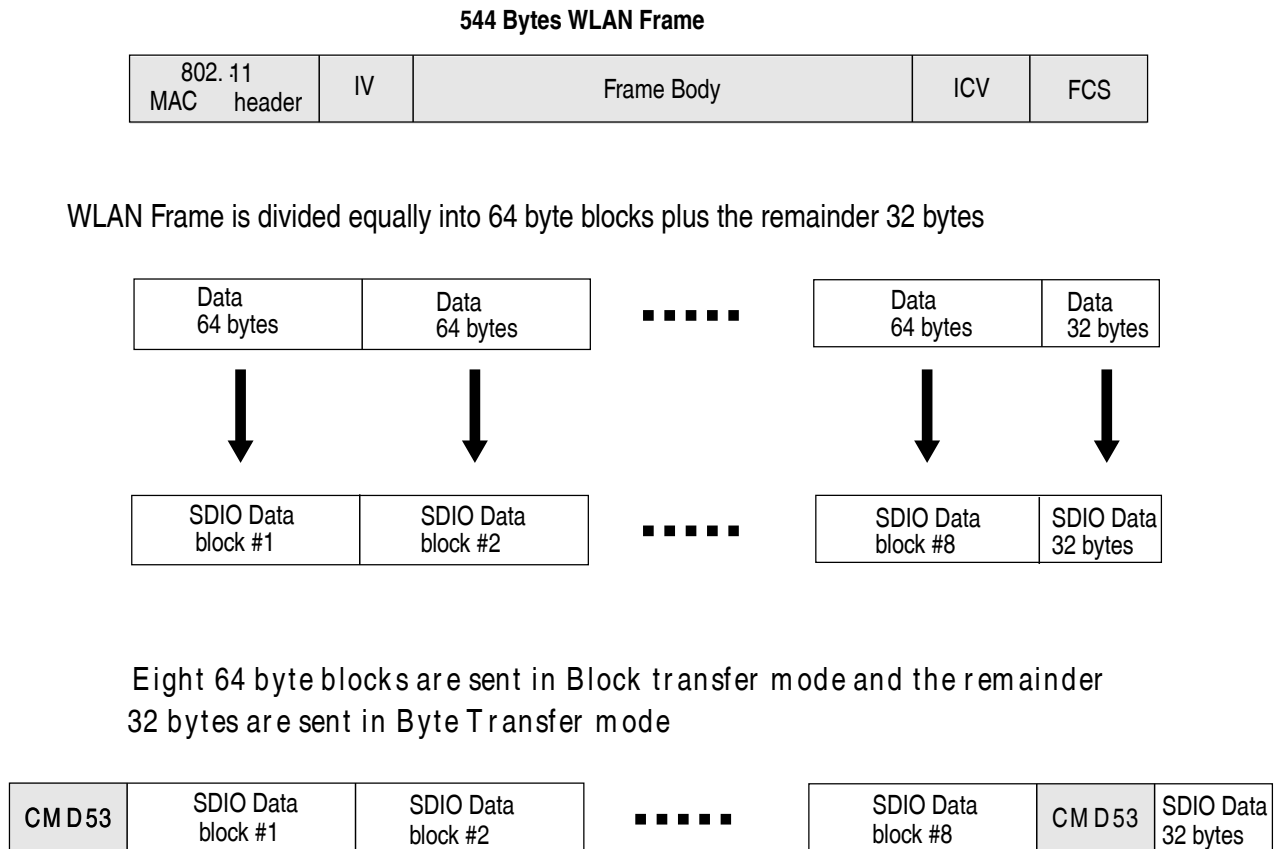

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred

by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

The following diagram illustrates the dividing of large data transfers. Assuming a kind of WLAN SDIO card supports block size only up to 64 bytes. Although the SDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided. See the example below.

**Figure 10-45. Example for dividing large data transfers**

#### 10.4.5.1.5 External DMA request

When the internal DMA is not in use, and external DMA request is enabled, the data buffer will generate a DMA request to the system. During a write operation, when the number of WRWML words can be held in the buffer free space, a DMA request is sent, informing the host system of a DMA write. IRQSTAT[BWR] is also set, as long as IRQSTATEN[BWRSEN] is set. The DMA request is immediately deasserted when an access to the DATPORT register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RDWML words are already in the buffer, a DMA request is sent, informing the host system for a DMA read. IRQSTAT[BRR] is also set, as long as IRQSTATEN[BRRSEN] is set. The DMA request is immediately deasserted when an access to the DATPORT register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer underrun for read operation or overrun for write operation. For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of 2 between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size but not greater than 128 words. This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The SDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level must be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKATTR[BLKSIZE] bits shall be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the SDHC will also set the IRQSTAT[BWR] or IRQSTAT[BRR] bits when the remaining data does not violate data buffer. See [DMA burst length](#) for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred via the DATPORT register, the SDHC will transfer only 31 bytes over the SD bus, as required by the BLKATTR[BLKSIZE] bits. In this data transfer, with non-word aligned block size, the endian mode must be set cautiously, or invalid data will be transferred to/from the card.

### 10.4.5.2 DMA crossbar switch interface

The internal DMA implements a DMA engine and the crossbar switch master. When the internal DMA is enabled (XFERTYP[DMAEN] is set), the interrupt status bits are set if they are enabled. To avoid setting them, clear IRQSTATEN[BWRSEN, BRRSEN]. The following diagram illustrates the DMA crossbar switch interface block.

**Figure 10-46. DMA crossbar switch interface block**

#### 10.4.5.2.1 Internal DMA request

If the watermark level requirement is met in data transfer, and the internal DMA is enabled, the data buffer block sends a DMA request to the crossbar switch interface. Meanwhile, the external DMA request signal is disabled. The delay in response from the internal DMA engine depends on the system bus loading and the priority assigned to the SDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multiblock data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer, which might contain some data of the next block, another DMA request read is sent. This is because the remaining number of words to send for the current block is  $(31 - 6 * 4) / 4 = 2$ . The SDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

#### 10.4.5.2.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in [Internal DMA request](#) again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block

starts, which is 31 bytes, more than 6 words. The host driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

#### 10.4.5.2.3 Crossbar switch master interface

It is possible that the internal DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. `IRQSTAT[DMAE]` is set to inform the driver.

After the DMAE interrupt is received, the software shall send a `CMD12` to abort the current transfer and read `DSADDR[DSADDR]` to get the starting address of the corrupted block. After the DMA error is fixed, the software must apply a data reset and restart the transfer from this address to recover the corrupted block.

#### 10.4.5.3 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into the corresponding registers
- Detects the bus state on the `DAT[0]` line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD transceiver
- SD clock and monitor
- Command agent
- Data agent

### 10.4.5.3.1 SD transceiver

In the SD protocol unit, the transceiver is the main control module. It consists of a FSM and control module, from which the control signals for all other three modules are generated.

### 10.4.5.3.2 SD clock & monitor

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the register bank. The driver can use this for debug purposes.

The module also detects the card detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when PROCTL[D3CD] is set.

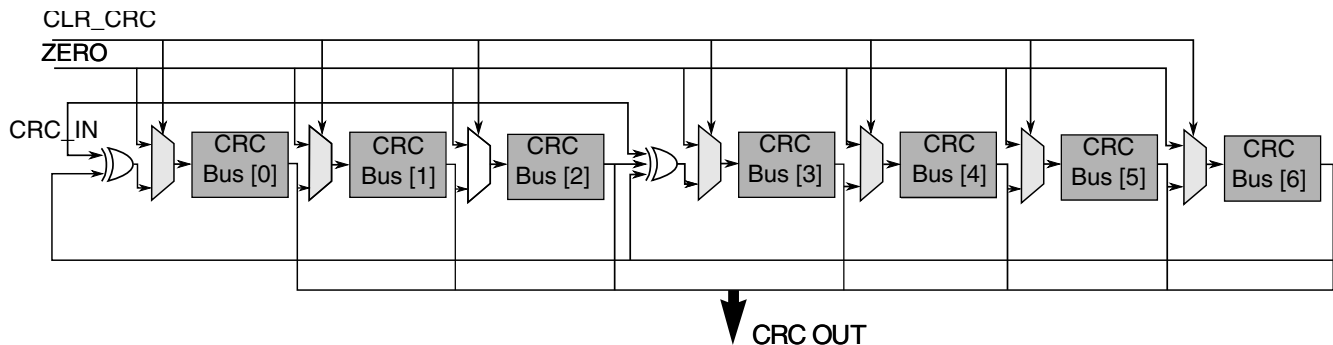

The module detects the write protect (WP) line. With the information of the WP state, the register bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this module will open and the SD clock will be active again.

This module also drives the SDHC\_LCTL output signal when PROCTL[LCTL] is set by the driver.

### 10.4.5.3.3 Command agent

The command agent deals with the transactions on the CMD line. The following diagram illustrates the structure for the command CRC Shift Register.

**Figure 10-47. Command CRC Shift Register**

The CRC polynomials for the CMD line are as follows:

Generator polynomial:  $G(x) = x^7 + x^3 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

#### 10.4.5.3.4 Data agent

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DAT[0] line, and generates the read wait state by the request from the transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial:  $G(x) = x^{16} + x^{12} + x^5 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

#### 10.4.5.4 Clock and reset manager

This module controls all the reset signals within the SDHC.

There are four kinds of reset signals within the SDHC:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

There are three clocks inside the SDHC:

- Bus clock
- SDHC clock
- System clock

The module monitors the activities of all other modules, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

### 10.4.5.5 Clock generator

The clock generator generates the SDHC\_CLK by peripheral source clock in two stages. The following diagram illustrates the structure of the divider. The term "base" represents the frequency of peripheral source clock.

**Figure 10-48. Two stages of the clock divider**

The first stage outputs an intermediate clock (DIV), which can be base, base/2, base/3, ..., or base/16.

The second stage is a prescaler, and outputs the actual clock (SDHC\_CLK). Also it outputs DDR internal processing clock (SDHC\_CLK\_2X). These clocks are the driving clock for all submodules of the SD protocol unit, and the sync FIFOs to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV/2, DIV/4, ..., or DIV/256. Thus, the highest frequency of the SDHC\_CLK is base/2, while the lowest frequency is base/4096. If the base clock is of equal duty ratio (usually true), the duty cycle of SDHC\_CLK/SDHC\_CLK\_2X is also 50%, even when the compound divisor is an odd value.

### 10.4.5.6 SDIO card interrupt

This section discusses SDIO interrupt handling.

#### 10.4.5.6.1 Interrupts in 1-bit mode

In this case, the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

#### 10.4.5.6.2 Interrupt in 4-bit mode

Because the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will be sent by the card and recognized by the host only during a specific time. This is known as the interrupt period. The SDHC will only sample the level on pin 8 during the interrupt period. At all other times, the host will ignore the level on pin 8, and treat it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the interrupt period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the interrupt period. In this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the SDHC\_D1 line will be held low for one clock cycle with the last clock cycle pulling SDHC\_D1 high. On completion of the Interrupt Period, the card releases the SDHC\_D1 line into the high Z state. The SDHC samples the SDHC\_D1] during the interrupt period when PROCTL[IABG] is set.

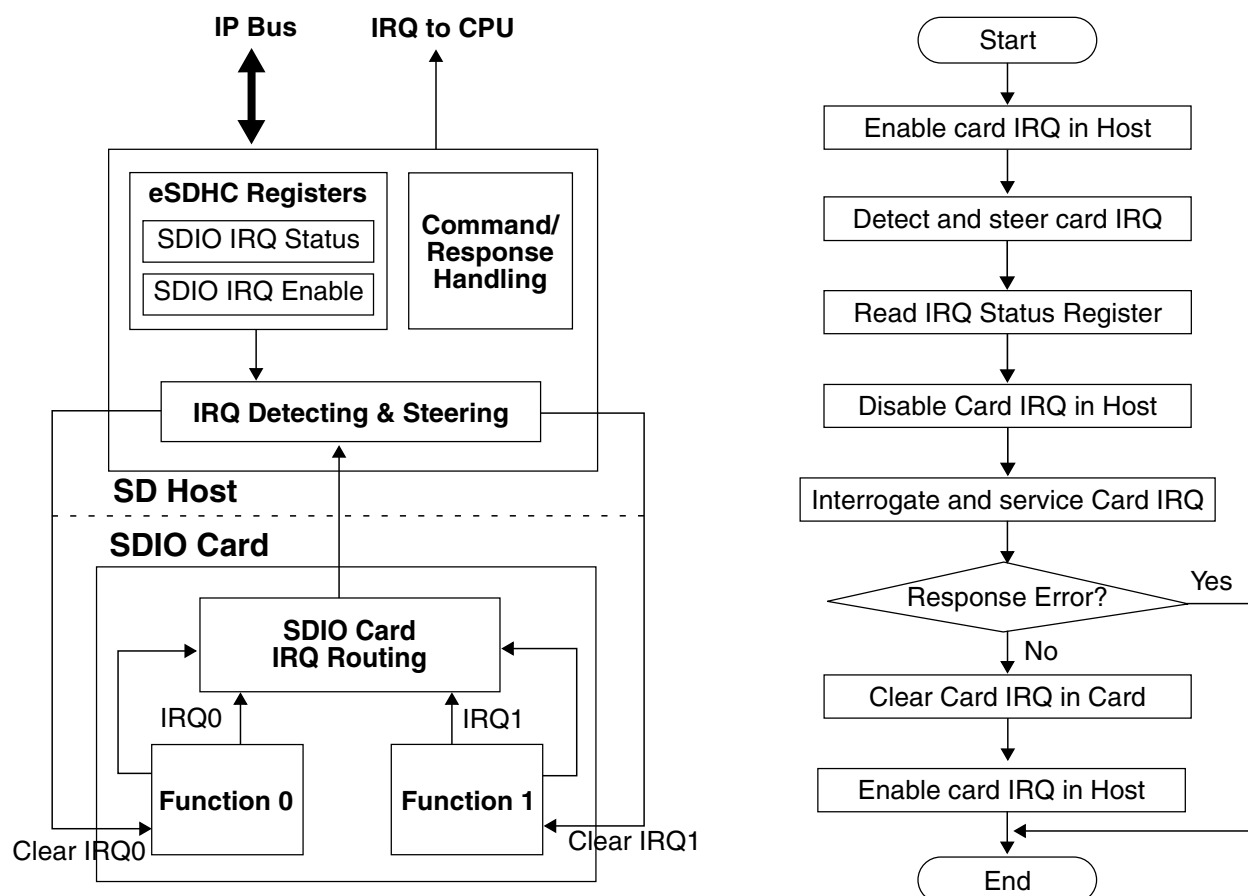

See the SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

#### 10.4.5.6.3 Card interrupt handling

When IRQSIGEN[CINTIEN] is set to 0, the SDHC clears the interrupt request to the host system. The host driver must clear this bit before servicing the SDIO Interrupt and must set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the SDHC will detect the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the host system interrupt controller. When the SDIO status has been set, and the host driver needs to service this interrupt, so the SDIO bit in the interrupt control register of the SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the SDHC and to stop driving the interrupt signal to the system interrupt controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the SDHC starts sampling the interrupt signal again.

The following diagram illustrates the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 10-49. Card interrupt scheme and card interrupt detection and handling procedure**

#### 10.4.5.7 Card insertion and removal detection

The SDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the SDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the SDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

### 10.4.5.8 Power management and wakeup events

When there is no operation between the SDHC and the card through the SD bus, the user can completely disable the bus clock and the SDHC clock in the chip-level clock control module to save power. When the user needs to use the SDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the SDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The SDHC can generate these interrupt even when there are no clocks enabled.

The three interrupts which can be used as wakeup events are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The SDHC offers a power management feature. By clearing the clock enabled bits in the system control register, the clocks are gated in the low position to the SDHC. For maximum power saving, the user can disable all the clocks to the SDHC when there is no operation in progress.

These three wakeup events, or wakeup interrupts, can also be used to wake up the system from low-power modes.

#### Note

To make the interrupt a wakeup event, when all the clocks to the SDHC are disabled or when the whole system is in low-power mode, the corresponding wakeup enabled bit needs to be set. See Protocol Control register for more information.

#### 10.4.5.8.1 Setting wakeup events

For the SDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters Sleep mode. Before the software disables the host clock, it must ensure that all of the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active

- No interrupts are pending
- Internal data buffer is empty

### 10.4.5.9 MMC fast boot

In Embedded MultiMediaCard(eMMC4.3) spec, add fast boot feature needs hardware support.

In Boot Operation mode, the master (multimediacard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

There are two types of Fast Boot mode, boot operation, and Alternative boot operation in eMMC4.3 spec. Each type also has with acknowledge and without acknowledge modes.

#### Note

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

#### 10.4.5.9.1 Boot operation

#### Note

In this block guide, this fast boot is called Normal Fast Boot mode.

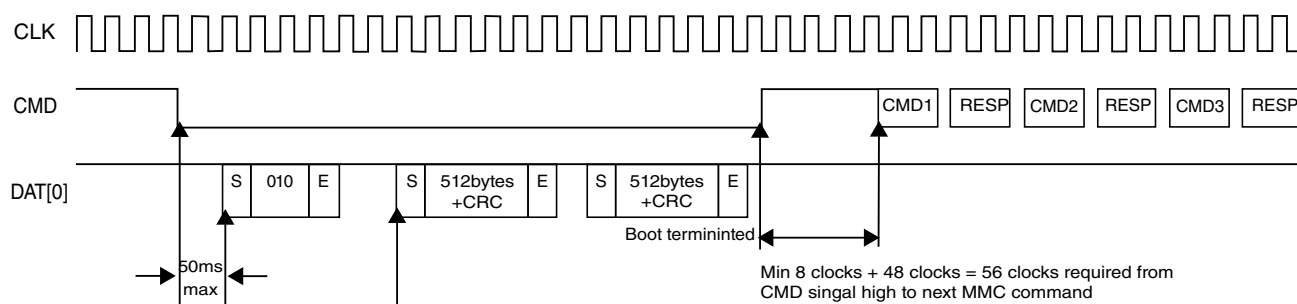

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that Boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes low, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line low to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern 010 to the master within 50 ms after the CMD line goes low. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate Boot mode with the CMD line high.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 10-50. Multimediocard state diagram in Normal Boot mode**

### 10.4.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to 1, the device supports the alternative boot operation.

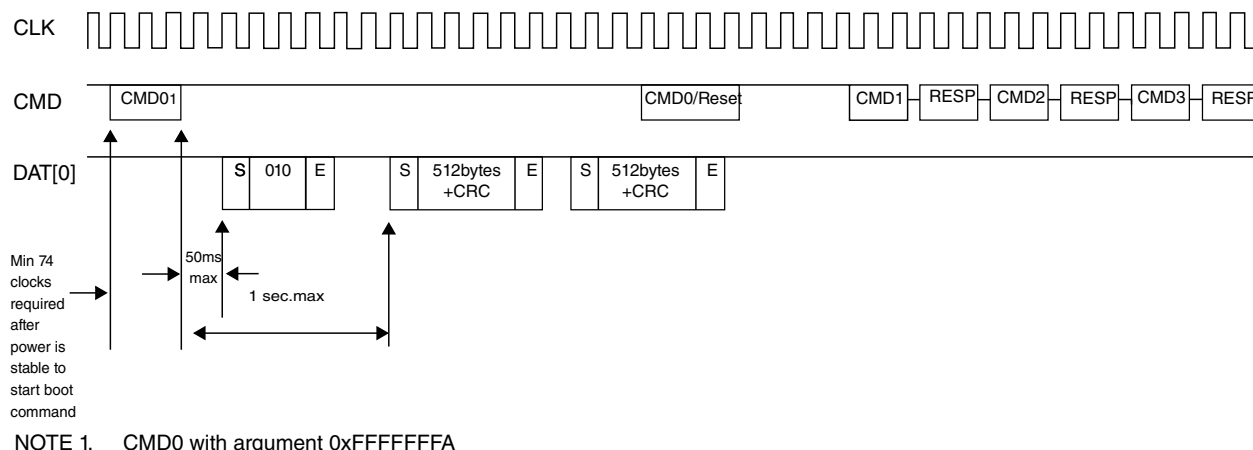

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued, or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 10-51. MultiMediaCard state diagram in Alternative Boot mode**

## 10.4.6 Initialization/application of SDHC

All communication between system and cards are controlled by the host. The host sends commands of two types:

- Broadcast
- Addressed point-to-point

Broadcast commands are intended for all cards, such as GO\_IDLE\_STATE, SEND\_OP\_COND, ALL\_SEND\_CID, and so on. In Broadcast mode, all cards are in the Open-Drain mode to avoid bus contention. See [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter Standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to Push-Pull mode, to have the driving capability for maximum frequency operation. See [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

### 10.4.6.1 Command send and response receive basic operation

Assuming the data type WORD is an unsigned 32-bit integer, the following flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
    recommended to implement in a bit-field manner
    wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
    set CMDTYP, DPSEL, CICCEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
    if (internal DMA is used) wCmd |= 0x1;
    if (multi-block transfer) {
        set MSBSEL bit;
        if (finite block number) {
            set BCEN bit;
            if (auto12 command is to use) set AC12EN bit;
        }
    }
    write_reg(CMDARG, <cmd_arg>); // configure the command argument
    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
    read IRQ Status register and check if any error bits about Command are set
    if (any error bits are set) report error;
    write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the command complete interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

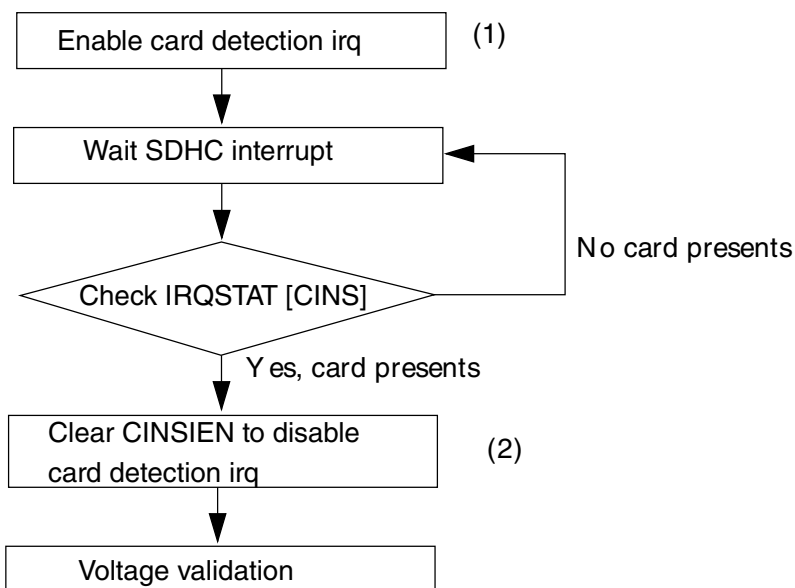

In some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the standby state, no response to the host when CMD2 is sent. The host driver shall deal with 'fake' errors like this with caution.

### 10.4.6.2 Card Identification mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the relative card address (RCA) or to set the RCA for the MMC cards.

#### 10.4.6.2.1 Card detect

The following diagram illustrates the detection of MMC, SD, and SDIO cards using the SDHC.

**Figure 10-52. Flow diagram for card detection**

Here is the card detection sequence:

- Set the CINSIEN bit to enable card detection interrupt

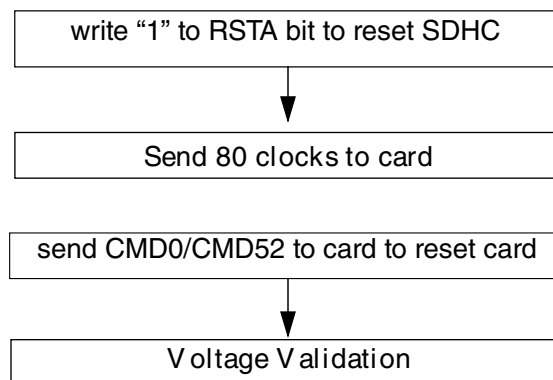

- When an interrupt from the SDHC is received, check IRQSTAT[CINS] in the Interrupt Status register to see whether it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

#### 10.4.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (card and host) which is driven by power on reset (POR)
- Software reset (host only) is initiated by the write operation of the SYSCTL[RSTD], SYSCTL[RSTC], or SYSCTL[RSTA] bits to reset the data part, command part, or all parts of the host controller, respectively
- Card reset (card only). The command, Go\_Idle\_State (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA = 0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. The following diagram illustrates the software flow to reset both the SDHC and the card.

**Figure 10-53. Flow chart for reset of the SDHC and SD I/O card**

```

software_reset()
{
  set_bit(SYSCTRL, RSTA); // software reset the Host
  set DTOCV and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
  configure IO pad to set the power voltage of external card to around 3.0V
  poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
  set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
  send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
}
  
```

```
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

### 10.4.6.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for  $V_{DD}$  are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are able to communicate this information only under data transfer  $V_{DD}$  conditions. This means if the host and card have noncommon  $V_{DD}$  ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send\_Op\_Cont (CMD1 for MMC), SD\_Send\_Op\_Cont (ACMD41 for SD Memory) and IO\_Send\_Op\_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the  $V_{DD}$  range(s) desired by the host. This is accomplished by the host sending the desired  $V_{DD}$  voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the inactive state. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a nonusable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
    operation voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card) Label the card as SDCCombo; // this is an
        SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labelled as SDIO card) return; // card type is identified and voltage range
    is
    set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
    CMD
    prefix
    if (no error calling wait_for_response(APP_CMD, <...>)) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
```

```

for memory part or SD card
wait_for_response(SD_APP_OP_COND); // voltage range is set
if (card_type is UNKNOWN) label the card as SD;
return; //
} // end of if (no error ...)
else if (errors other than time-out occur) { // command/response pair is corrupted
deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card or CE-ATA card
if (card is already labelled as SDCombo) { // change label
re-label the card as SDIO;
ignore the error or report it;
return; // card is identified as SDIO card
} // of if (card is ...
send_command(SEND_OP_COND, <voltage range>, <...>);
if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
label the card as UNKNOWN;
return;
} // of if (RESP_TIMEOUT ...)
if (check for CE-ATA signature succeeded) { // the card is CE-ATA
store CE-ATA specific info from the signature;
label the card as CE-ATA;
} // of if (check for CE-ATA ...)
else label the card as MMC;
} // of else
}

```

#### 10.4.6.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different.

For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V, as defined by the card specification. At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the inactive state. The host then issues the command, All\_Send\_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified, in the ready state, send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send\_Relative\_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send\_Relative\_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in Open-Drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated, the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the wired OR operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state.

The host then issues the broadcast command All\_Send\_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards, the cards in ready state, simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Because the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the Identification state.

Thereafter, the host issues Set\_Relative\_Addr (CMD3) to assign to the card a relative card address (RCA). When the RCA is received the card state changes to the standby state, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
    if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
        send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
        retrieve RCA from response;
    } // end if (card is labelled as SDCombo ...
    else if (card is labelled as SD) { // for SD card
        send_command(ALL_SEND_CID, <...>);
        if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
        send_command(SET_RELATIVE_ADDR, <...>);
        retrieve RCA from response;
    } // else if (card is labelled as SD ...
    else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
        send_command(ALL_SEND_CID, <...>);
        rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also the
relative address to access the CE-ATA card
        send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
    } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

### 10.4.6.3 Card access

This section discusses the various card access methods.

#### 10.4.6.3.1 Block write

This section discusses the block write access methods.

##### 10.4.6.3.1.1 Normal write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the dat line. The transferred data will be discarded and not written, and all further transmitted blocks in Multiple Block Write mode will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS\_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-Data-state for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 to select a different card to place the card into the Standby state and release the DAT line without interrupting the write operation. When reselecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods, by means of external DMA or CPU polling status, with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC cards, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the eSDHC DMA when sending the command with data transfer. AC12EN should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 10.4.6.3.1.2 DDR write

SDHC supports dual data rate mode.

The software flow to write to a card in DDR mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512 byte.
3. Set the SDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).

6. If it is DMA mode, disable the buffer write ready interrupt, configure the DMA settings and enable the SDHC DMA when sending the command with data transfer. If it is CPU Polling mode, Software need to poll the data buffer ready status to write the data to buffer in time. The DDR\_EN\_IPG bit should be set. The XFERTYP[AC12EN] bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 10.4.6.3.1.3 Write with pause

The write operation can be paused during the transfer. Instead of stopping the SD\_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set PROCTL[SABGREQ] to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to deassert to release the busy state, no suspend command is needed.

Like the flow described in [Normal write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the SDHC DMA when sending the command with data transfer. The XFERTYP[AC12EN] bit should also be set.
6. Set PROCTL[SABGREQ].
7. Wait for the transfer complete interrupt.

8. Clear PROCTL[SABGREQ].
9. Check the status bit to see whether a write CRC error occurred.
10. Set PROCTL[CREQ] to continue the write operation.
11. Wait for the transfer complete interrupt.
12. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKATTR[BLKCNT] . As the data transfer and the setting of the PROCTL[SABGREQ] bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The driver shall read the value of BLKATTR[BLKCNT] after the transfer is paused and the transfer complete interrupt is received.

It is also possible that the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the suspend command for the SDIO card. This is because when such a command is sent, the SDHC thinks the system will switch to another function on the SDIO card, and flush the data buffer. The SDHC takes the resume command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, XFERTYP[MSBSEL] and XFERTYP[BCEN] are set as well as XFERTYP[AC12EN]. However, the SDHC will automatically send a CMD12 to mark the end of the multiblock transfer.

#### **10.4.6.3.2 Block read**

This section discusses the block read access methods.

##### **10.4.6.3.2.1 Normal read**

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60,

CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the SDHC DMA when sending the command with data transfer. XFERTYP[AC12EN] must also be set.
6. Wait for the transfer complete interrupt.
7. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

#### 10.4.6.3.2.2 DDR read

SDHC supports dual data rate mode.

The software flow to read from a card in DDR mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512 byte.
3. Set the SDHC number block register (NOB), nob is 5 (for instance).

4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. If it is DMA mode, disable the buffer read ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. If it is CPU Polling mode, Software need to poll the data buffer ready status to read the data from buffer in time. The DDR\_EN\_IPG bit should be set. The XFERTYP[AC12EN] bit should also be set.
7. Wait for the transfer complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 10.4.6.3.2.3 Read with pause

The read operation is not generally able to pause. Only the SDIO card and SDCombo card working under I/O mode supporting the read and wait feature can pause during the read operation. If the SDIO card support read wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the eSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. Set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Like the flow described in [Normal read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set RWCTL.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the SDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. AC12EN must also be set.
8. Set SABGREQ.
9. Wait for the Transfer Complete interrupt.
10. Clear SABGREQ.
11. Check the status bit to see whether read CRC error occurred.
12. Set CREQ to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the SDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. Whether the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the SDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the SDHC will automatically send the CMD12 to mark the end of multi-block transfer.

#### **10.4.6.3.2.4 DLL (delay line) in read path**

The DLL(delay line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT). The reasons why the DLL is needed for SSP are 1.) the path of read data traveling from card

to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided perclk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, the DLL\_enable is no need to set. And another working mode of DLL is target value mode. In this mode, DLL will automatically adjust the number of delay cells according to the target value your set value and PVT changes. Be aware that target value is in the unit of 1/32 clock reference period. If the perclk is 100 MHz, then the reference clock period is 10 ns, setting target value of 16 means 5 ns =  $(16/32) \times 10$  ns. Software can disable automatically update by setting dll\_gate\_update bit.

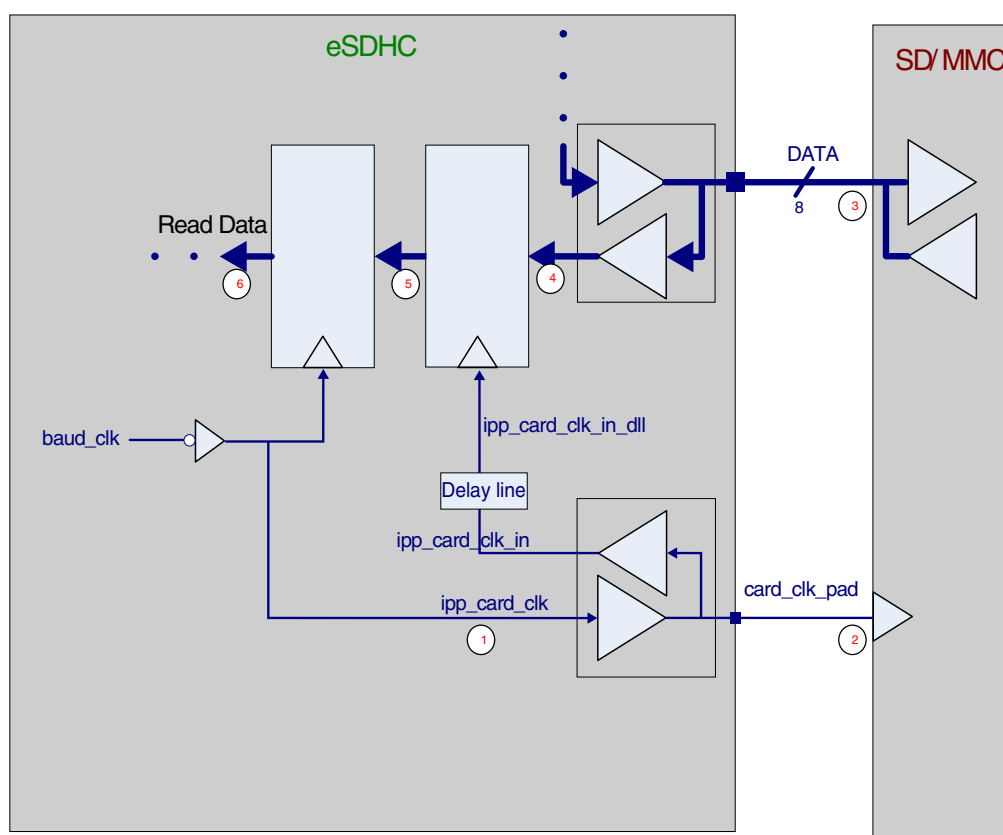

Figure 10-54. DLL(delay line) in read path

#### 10.4.6.3.3 Suspend resume

The SDHC supports the suspend resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

### 10.4.6.3.3.1 Suspend

After setting the PROCTL[SABGREQ] bit, the host driver may send a suspend command to switch to another function of the SDIO card. The SDHC does not monitor the content of the response, therefore it doesn't know whether the suspend command succeeded or not. Accordingly, it doesn't deassert read wait for read pause. To solve this problem, the driver shall not mark the suspend command as a suspend, that is, setting the XFERTYP[CMDTYP] bits to 01. Instead, the driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the driver send another command marked as suspend to inform the SDHC that the current transfer is suspended. As shown in the following sequence for suspend operation:

1. Set PROCTL[SABGREQ] to pause the current data transfer at block gap.
2. After IRQSTAT[BGE] is set, send the suspend command to suspend the active function. XFERTYP[CMDTYP] field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The XFERTYP[CMDTYP] of this command must be 2'b01, so the SDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the SDHC stops driving DAT2 and goes to the Idle state.
5. Save the context registers in the system memory for later use, including the DMA system address register for internal DMA operation, and the block attribute register.
6. Begin operation for another function on the SDIO card.

### 10.4.6.3.3.2 Resume

To resume the data transfer, a resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step 5 of the suspend operation above.
2. Send the resume command. In the transfer type register, all fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume, except the CMDTYP is set to 2'b10.

3. If the resume command has responded, the data transfer will be resumed.

#### 10.4.6.3.4 Transfer error

This section discusses the handling of transfer errors.

##### 10.4.6.3.4.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. Discard the following data blocks and retransfer the block from the corrupted one.

For a multi-block transfer, the host driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the XFERTYP[AC12EN] and BCEND bits are set, the SDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an auto CMD12 will be sent by the SDHC. In this case, the driver shall re-send or re-obtain the last block with a single block transfer.

##### 10.4.6.3.4.2 Internal DMA error

During the data transfer with internal simple DMA, if the DMA engine encounters some error on the system bus, the DMA operation is aborted and DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Reading the DMA system address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Reading the BLKCNT field of the block attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the block attribute register does not change, so this method does not work.

When a DMA error occurs, abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

#### 10.4.6.3.4.3 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and XFERTYP[AC12EN] is set when the data transfer is initiated by the data command, the SDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, the driver can deal with the situations in the following manner:

1. Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The driver should clear the IRQSTAT[AC12E] bits and resend the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error: Because the card responds to the CMD12, the card will abort the transfer. The driver may ignore the error and clear the IRQSTAT[AC12E] bit.
3. Auto CMD12 conflict error or not sent: The command is not sent, so the driver shall send a CMD12 manually.

#### 10.4.6.3.5 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The SDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the SDHC, and the host system is informed by the SDHC asserting the SDHC interrupt line, the interrupt service from the host driver is called.

Because the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before IRQSTAT[CINT] is cleared by written 1. See [Card interrupt handling](#) for the card interrupt handling flow.

#### 10.4.6.4 Switch function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC specifications. The high-speed timing mode for all card devices was also recently defined in various card specifications. To enable these new features, a switch command shall be issued by the host driver.

For SDIO cards, the high-speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6, with the mnemonic symbol as SWITCH\_FUNC. For MMC cards, the high-speed mode is queried by a CMD8 and enabled by a CMD6, with the mnemonic symbol as SWITCH.

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

#### 10.4.6.4.1 Query, enable and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
    send CMD52 to query bit SHS at address 0x13;
    if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
    send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
    change clock divisor value or configure the system clock feeding into eSDHC to generate the
    card_clk of around 50MHz;
    (data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
    send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
    cleared;
    change clock divisor value or configure the system clock feeding into eSDHC to generate the
    card_clk of the desired value below 25MHz;
    (data transactions like normal peers)
}
```

#### 10.4.6.4.2 Query, enable, and disable SD high-speed mode

```
enable_sd_high_speed_mode(void)
{
    set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
    send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
    wait data transfer done bit is set;
    check if the bit 401 of received 512 bit is set;
    if (bit 401 is '0') report the SD card does not support high speed mode and return;
    send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
    check if the bit field 379~376 is 0xF;
    if (the bit field is 0xF) report the function switch failed and return;
    change clock divisor value or configure the system clock feeding into eSDHC to generate the
    card_clk of around 50MHz;
    (data transactions like normal peers)
}
```

```

disable_sd_high_speed_mode(void)
{
    set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
    send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
    check if the bit field 379~376 is 0xF;
    if (the bit field is 0xF) report the function switch failed and return;
    change clock divisor value or configure the system clock feeding into eSDHC to generate the
    card_clk of the desired value below 25MHz;
    (data transactions like normal peers)
}

```

#### 10.4.6.4.3 Query, enable, and disable MMC high-speed mode

```

enable_mmc_high_speed_mode(void)
{
    send CMD9 to get CSD value of MMC;
    check if the value of SPEC_VER field is 4 or above;
    if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
    return;
    set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
    send CMD8 to get EXT_CSD value of MMC;
    extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
    52MHz;
    send CMD6 with argument 0x1B90100;
    send CMD13 to wait card ready (busy line released);
    send CMD8 to get EXT_CSD value of MMC;
    check if HS_TIMING byte (byte number 185) is 1;
    if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
    change clock divisor value or configure the system clock feeding into eSDHC to generate the
    card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
    (data transactions like normal peers)
}

disable_mmc_high_speed_mode(void)
{
    send CMD6 with argument 0x2B90100;
    set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
    send CMD8 to get EXT_CSD value of MMC;
    check if HS_TIMING byte (byte number 185) is 0;
    if (HS_TIMING is not 0) report the function switch failed and return;
    change clock divisor value or configure the system clock feeding into eSDHC to generate the
    card_clk of the desired value below 20MHz;
    (data transactions like normal peers)
}

```

#### 10.4.6.4.4 Set MMC bus width

```

change_mmc_bus_width(void)
{
    send CMD9 to get CSD value of MMC;
    check if the value of SPEC_VER field is 4 or above;
    if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
    return;
    send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
    send CMD13 to wait card ready (busy line released);
    (data transactions like normal peers)
}

```

#### 10.4.6.5 ADMA operation

This section presents code examples for ADMA operation.

### 10.4.6.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
    if (to start data transfer) {
        // Make sure the address is 4KB align.
        Set 'Set' type descriptor;
        {
            Set Act bits to 01;
            Set [31:12] bits data length (byte unit);
        }
        Set 'Tran' type descriptor;
        {
            Set Act bits to 10;
            Set [31:12] bits address (4KB align);
        }
    }
    else if (to fetch descriptor at non-continuous address) {
        Set Act bits to 11;
        Set [31:12] bits the next descriptor address (4KB align);
    }
    else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set End bit to 1;
    }
    if (to generate interrupt for this descriptor) {
        Set Int bit to 1;
    }
    Set Valid bit to 1;
}
```

### 10.4.6.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
    if (to start data transfer) {
        // Make sure the address is 32-bit boundary (lower 2-bit are always '00').
        Set higher 32-bit of descriptor for this data transfer initial address;
        Set [31:16] bits data length (byte unit);
        Set Act bits to '10';
    }
    else if (to fetch descriptor at non-continuous address) {
        Set Act bits to '11';
        // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
        Set higher 32-bit of descriptor for the next descriptor address;
    }
    else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set 'End' bit '1';
    }
    if (to generate interrupt for this descriptor) {
        Set 'Int' bit '1';
    }
    Set the 'Valid' bit to '1';
}
```

### 10.4.6.6 Fast boot operation

This section discusses fast boot operations.

#### 10.4.6.6.1 Normal fast boot flow

1. Software needs to configure SYSCTL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1, MMCBOOT[BOOTMODE] to 0, and MMCBOOT[BOOTACK] to select the ack mode or not. If sending through DMA mode, software needs to configure MMCBOOT[AUTOSABGEN] to enable automatically stop at block gap feature, and MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequency.
3. Software then needs to configure BLKATTR register to set block size/no. If in ddr fast boot mode, block size only can be configure to 512 byte.
4. Software needs to configure PROCTL[DTW]. If in ddr fast boot mode, PROCTL[DTW] only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure CMDARG to set argument if needed (no need in normal fast boot).
6. Software needs to configure XFERTYP register to start the boot process. In Normal Boot mode, XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCN], XFERTYP[AC12EN], XFERTYP[BCEN] and XFERTYP[DMAEN] are kept default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. Note XFERTYP[DMAEN] must be configured as 0 in polling mode. And if XFERTYP[BCEN] is configured as 1, better to configure BLKATTR[BLKSIZE] to the max value. And if in DDR Fast Boot mode, DDR\_EN need to be set to 1.
7. When the step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time-out happened (ack time out or the first data read time out), Interrupt will be triggered, and software need to configure MMCBOOT[BOOTEN] to 0 to disable boot. Thus will make CMD high, and then after at least 56 clocks, it is ready to begin normal initialization process.

8. If no time out, software needs to decide the data read is finished and then configure MMCBOOT[BOOTEN] to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

#### 10.4.6.6.2 Alternative fast boot flow

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT [BOOTEN] to 1, MMCBOOT [BOOTMODE] to 1, and MMCBOOT [BOOTACK] to select the ack mode or not. If sending through DMA mode, it also needs to configure MMCBOOT [AUTOSABGEN] to enable automatically stop at block gap feature. And needs to configure MMCBOOT [DTCVACK] to select the ack timeout value according to the sd clk frequency.
3. Software then needs to configure BLKATTR register to set block size/no. If in ddr fast boot mode, block size only can be configure to 512 byte.
4. Software needs to configure PROCTL[DTW]. If in ddr fast boot mode, DTW can only be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure CMDARG register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure XFERTYP register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICCEN, CCCEN, AC12EN, BCEN, and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in Polling mode, it is better to configure blk no in Block Attributes Register to the max value. And if in DDR Fast Boot mode, DDR\_EN need to be set to 1.
7. When step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time out (ack data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMCBOOT[BOOTEN] to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.

8. If no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after command completed, configure MMCBOOT[BOOTEN] to stop the process. After 8 clocks from command completed, slave(card) is ready for identification step.
9. Reset the host and then begin the normal process.

#### 10.4.6.6.3 Fast boot application case in DMA mode

In the boot application case, because the image destination and the image size are contained in the beginning of the image, switching DMA parameters on the fly during MMC fast boot is required.

In fast boot, host can use ADMA2 (advanced DMA2) with two destinations.

The detail flow:

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1; and MMCBOOT[BOOTMODE] to 0 (normal fast boot), to 1(alternative boot); and MMCBOOT[BOOTACK] to select the ack mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] to set the VAULE1 (value of block count that need to trans first time), so that host will stop at block gap when card block counter is equal to this value. And it needs to configure MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequency.
3. Software then needs to configure BLKATTR register to set block size/no. If in DDR Fast Boot mode, block size only can be configure to 512 byte. In DMA mode, it is better to set block number to the max value(16'hffff).
4. Software needs to configure PROCTL[DTW]. If in DDR Fast Boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enables ADMA2 by configuring PROCTL[DMAS].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (that is, in IRAM, at least 6 words). The first pair descriptor define the start address (IRAM) and data length(512byte\*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writable), data

length is suggest to set 1~2 word (record as VAULE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data\_length data transfer descriptor.

7. Software needs to configure CMDARG register to set argument to 0xFFFFFFFFFA in alternative fast boot, and doesn't need to be set in normal fast boot.
8. Software needs to configure XFERTYP register to start the boot process . XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCEN], XFERTYP[AC12EN], XFERTYP[BCEN], and XFERTYP[DMAEN] are kept at default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. XFERTYP[DMAEN] is configured as 1 in DMA mode. And if XFERTYP[BCEN] is configured as 1, better to configure blk no in BLKATTR register to the max value. And if in DDR Fast Boot mode, DDR\_EN needs to be set to 1.
9. When step 8 is configured, boot process will begin, the first VAULE1 block number data has transfer. Software needs to poll IRQSTAT[TC] bit to determine first transfer is end. Also software needs to poll IRQSTAT[BGE] bit to determine if first transfer stop at block gap.
10. When IRQSTAT[TC] and IRQSTAT[BGE] bits are 1, . SW can analyzes the first code of VAULE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VAULE3 the remain boot code block). Remember set the last descriptor with END.
11. Software needs to configure MMCBOOT register (offset 0xc4) again. Set MMCBOOT[BOOTEN] bit to 1; and MMCBOOT[BOOTMODE] bit to 0 (normal fast boot), to 1 (alternative boot); and MMCBOOT[BOOTACK] bit to select the ack mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] bit to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] bit to set the (VAULE1+1+VAULE3), so that host will stop at block gap when card block counter is equal to this value. And need to configure MMCBOOT[DTOCVACK] bit to select the ack timeout value according to the sd clk frequency.
12. Software needs to clear IRQSTAT[TC] and IRQSTAT[BGE] bit. And software need to clear PROCTL[SABGREQ], and set PROCTL[CREQ] to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software needs to poll IRQSTAT[BGE] bit to determine if the fast boot is over.

**Note**

1. When ADMA boot flow is started, for SDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 words data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

**10.4.6.7 Commands for MMC/SD/SDIO**

The following table lists the commands for the MMC/SD/SDIO cards.

See the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the Multimediacard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DAT
- Addressed (point-to-point) data transfer commands (adtc)

**Table 10-74. Commands for MMC/SD/SDIO cards**

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3 <sup>1</sup>	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.

*Table continues on the next page...*

**Table 10-74. Commands for MMC/SD/SDIO cards (continued)**

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6 <sup>2</sup>	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6 <sup>3</sup>	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.

Table continues on the next page...

**Table 10-74. Commands for MMC/SD/SDIO cards (continued)**

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The

Table continues on the next page...

**Table 10-74. Commands for MMC/SD/SDIO cards (continued)**

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
					properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.

*Table continues on the next page...*

**Table 10-74. Commands for MMC/SD/SDIO cards (continued)**

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62~63	Reserved				
ACMD6 <sup>4</sup>	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.

Table continues on the next page...

**Table 10-74. Commands for MMC/SD/SDIO cards (continued)**

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
ACMD13 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD memory card status.
ACMD22 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23 <sup>4</sup>	ac		R1	SET_WR_BLK_ERASE_COUNT	-
ACMD41 <sup>4</sup>	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42 <sup>4</sup>	ac		R1	SET_CLR_CARD_DETECT	-
ACMD51 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET\_RELATIVE\_ADDR, with a response type of R1. For SD cards, it is referred to as SEND\_RELATIVE\_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH\_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in [Table 2](#).
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in [Table 2](#).
4. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT\_CSD Access Modes are shown in the following table.

**Table 10-75. EXT\_CSD Access Modes**

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

## 10.4.7 Software restrictions

Software for the SDHC must observe the following restrictions.

### 10.4.7.1 Initialization active

The driver cannot set SYSCTL[INITA] when any of the command line or data lines is active, so the driver must ensure both PRSSTAT[CDIHB] and PRSSTAT[CIHB] bits are cleared. To auto clear SYSCTL[INITA], SYSCTL[SDCLKEN] must be 1, otherwise no clocks can go out to the card and SYSCTL[INITA] will never clear.

### 10.4.7.2 Software polling procedure

For polling read or write, when the software begins a buffer read or write, it must access exactly the number of times as the values set in the watermark level register. Moreover, if the block size is not the times of the value in watermark level register, read and write respectively, the software must access exactly the remained number of words at the end of each block.

For example, for read operation, if the WML[RDWML] is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 10.4.7.3 Suspend operation

To suspend the data transfer, the software must inform SDHC that the suspend command is successfully accepted. To achieve this, after the suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (XFERTYP[CMDTYP] bits set as 01) to inform SDHC that the transfer is suspended.

If software needs resume the suspended transfer, it should read the value in BLKATTR[BLKCNT] to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such suspend command, SDHC will regard the current transfer as aborted and change BLKATTR[BLKCNT] to its original value, instead of keeping the remained number of blocks.

### 10.4.7.4 DMA address setting

To configure DMA address register, when TC[IRQSTAT] is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must ensure that TC[IRQSTAT] is cleared prior to configuring DMA address register.

### 10.4.7.5 Data port access

Data port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or external DMA. Otherwise the data would be corrupted inside the SDHC buffer.

### 10.4.7.6 Change clock frequency

SDHC does not automatically gates off the card clock when the host driver changes the clock frequency. To remove possible glitch on the card clock, clear `SYSCTL[SDCLKEN]` when changing clock divisor value and set `SYSCTL[SDCLKEN]` to 1 after `PRSTAT[SDSTB]` is 1 again.

### 10.4.7.7 Multi-block read

For predefined multi-block read operation, that is, the number of blocks to read has been defined by previous `CMD23` for MMC, or predefined number of blocks in `CMD53` for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual `CMD12/CMD52`, is still required by SDHC after the pre-defined number of blocks are done, to drive the internal start response timeout. Manually sending an abort command with `XFERTYP[RSPTYP]` both bits cleared is recommended.

## 10.5 External Bus Interface (FlexBus)

### 10.5.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This chapter describes external bus data transfer operations and error conditions. It describes transfers initiated by the core processor (or any other bus master) and includes detailed timing diagrams showing the interaction of signals in supported bus operations.

### 10.5.1.1 Definition

The FlexBus multifunction external bus interface controller is a hardware module that:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Can be directly connected to the following asynchronous or synchronous slave-only devices with little or no additional circuitry:
  - External ROMs
  - Flash memories
  - Programmable logic devices
  - Other simple target (slave) devices

### 10.5.1.2 Features

FlexBus offers the following features:

- Four independent, user-programmable chip-select signals ( $\overline{\text{FB\_CS3}}$  –  $\overline{\text{FB\_CS0}}$ )
- 8-bit, 16-bit, and 32-bit transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with respect to the assertion of a chip-select
- Programmable address-hold time with respect to the deassertion of a chip-select and transfer direction
- Extended address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

## 10.5.2 Signal descriptions

This table describes the external signals involved in data-transfer operations.

### NOTE

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

**Table 10-76. FlexBus signal descriptions**

Signal	I/O	Function
FB_AD31 - FB_AD0	I/O	<p>This is the address and data bus, FB_AD.</p> <p>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.</p> <p>The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0.</p>
FB_CS3–FB_CS0	O	General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].
FB_BE_31_24 FB_BE_23_16 FB_BE_15_8 FB_BE_7_0	O	<p>Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.</p> <p>For external SRAM or flash devices, the <math>\overline{\text{FB\_BE}}</math> outputs should be connected to individual byte strobe signals.</p>
FB_OE	O	Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.
FB_R/ $\overline{\text{W}}$	O	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/ $\overline{\text{W}}$ high) or a write operation (FB_R/ $\overline{\text{W}}$ low).
FB_TS	O	<p>Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid.</p> <p>An inverted <math>\overline{\text{FB\_TS}}</math> is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus.</p> <p><math>\overline{\text{FB\_TS}}</math>/FB_ALE is asserted for one bus clock cycle.</p> <p>The chip can extend this signal until the first positive clock edge after <math>\overline{\text{FB\_CS}}</math> asserts. See CSCR[EXTS] and <a href="#">Extended Transfer Start/Address Latch Enable</a>.</p>
FB_ALE	O	Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS).
FB_TSIz1–FB_TSIz0	O	<p>Transfer Size—Indicates (along with FB_TBST) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports.</p> <ul style="list-style-type: none"> <li>• 00b = 4 bytes</li> <li>• 01b = 1 byte</li> <li>• 10b = 2 bytes</li> <li>• 11b = 16 bytes (line)</li> </ul> <p>For misaligned transfers, FB_TSIz1–FB_TSIz0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIz1–FB_TSIz0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIz1–FB_TSIz0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIz1–FB_TSIz0 = 01b).</p> <p>For aligned transfers larger than the port size, FB_TSIz1–FB_TSIz0 behave as follows:</p>

*Table continues on the next page...*

Table 10-76. FlexBus signal descriptions (continued)

Signal	I/O	Function
		<ul style="list-style-type: none"> <li>If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size.</li> <li>If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size.</li> </ul> <p>For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each <math>\overline{\text{FB\_TS}}</math> assertion to reflect the next transfer size.</p> <p>For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.</p>
FB_TBST	O	<p>Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size.</p> <p><b>Note:</b> When a burst transfer is in progress (<math>\overline{\text{FB\_TBST}} = 0\text{b}</math>), the transfer size is 16 bytes (<math>\text{FB\_TSIZ1} - \text{FB\_TSIZ0} = 11\text{b}</math>), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.</p>
$\overline{\text{FB\_TA}}$	I	<p>Transfer Acknowledge—Indicates that the external data transfer is complete. When <math>\overline{\text{FB\_TA}}</math> is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When <math>\overline{\text{FB\_TA}}</math> is asserted during a write transfer, the transfer is terminated.</p> <p>If auto-acknowledge is disabled (<math>\text{CSCR}[\text{AA}] = 0</math>), the external memory or peripheral drives <math>\overline{\text{FB\_TA}}</math> to terminate the transfer. If auto-acknowledge is enabled (<math>\text{CSCR}[\text{AA}] = 1</math>), <math>\overline{\text{FB\_TA}}</math> is generated internally after a specified number of wait states, or the external memory or peripheral may assert external <math>\overline{\text{FB\_TA}}</math> before the wait-state countdown to terminate the transfer early. The chip deasserts <math>\overline{\text{FB\_CS}}</math> one cycle after the last <math>\overline{\text{FB\_TA}}</math> is asserted. During read transfers, the external memory or peripheral must continue to drive data until <math>\overline{\text{FB\_TA}}</math> is recognized. For write transfers, the chip continues driving data one clock cycle after <math>\overline{\text{FB\_CS}}</math> is deasserted.</p> <p>The number of wait states is determined by CSCR or the external <math>\overline{\text{FB\_TA}}</math> input. If the external <math>\overline{\text{FB\_TA}}</math> is used, the external memory or peripheral has complete control of the number of wait states.</p> <p><b>Note:</b> External memory or peripherals should assert <math>\overline{\text{FB\_TA}}</math> only while the <math>\overline{\text{FB\_CS}}</math> signal to the external memory or peripheral is asserted.</p> <p>The CSPMCR register controls muxing of <math>\overline{\text{FB\_TA}}</math> with other signals. When the CSPMCR register does not allow fb_ta control, auto-acknowledge must be used (<math>\text{CSCR}[\text{AA}] = 1'b1</math>); otherwise the bus may hang.</p>
FB_CLK	O	FlexBus Clock Output

### 10.5.3 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

### Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations.

### FB memory map

### 10.5.3.1 Chip Select Address Register (FB\_CSAR<sub>n</sub>)

Specifies the associated chip-select's base address.

Address: 4001\_E000h base + 0h offset + (12d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BA																0															
W

#### FB\_CSAR<sub>n</sub> field descriptions

Field	Description
31–16 BA	Base Address  Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed.  <b>NOTE:</b> Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. See the chip memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSAR <sub>n</sub> and CSMR <sub>n</sub> registers appropriately before accessing this region.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 10.5.3.2 Chip Select Mask Register (FB\_CSMR<sub>n</sub>)

Specifies the address mask and allowable access types for the associated chip-select.

Address: 4001\_E000h base + 4h offset + (12d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BAM															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								WP		0					V
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### FB\_CSMR<sub>n</sub> field descriptions

Field	Description
31–16 BAM	Base Address Mask  Defines the associated chip-select's block size by masking address bits.

*Table continues on the next page...*

**FB\_CSMR<sub>n</sub> field descriptions (continued)**

Field	Description
	0 The corresponding address bit in CSAR is used in the chip-select decode. 1 The corresponding address bit in CSAR is a don't care in the chip-select decode.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 WP	Write Protect  Controls write accesses to the address range in the corresponding CSAR.  0 Write accesses are allowed. 1 Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 V	Valid  Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0, which acts as the global chip-select).  <b>NOTE:</b> At reset, $\overline{\text{FB\_CS0}}$ will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.  0 Chip-select is invalid. 1 Chip-select is valid.

**10.5.3.3 Chip Select Control Register (FB\_CSCR<sub>n</sub>)**

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

**NOTE**

To support the global chip-select ( $\overline{\text{FB\_CS0}}$ ), the CSCR0 reset values differ from the other CSCRs. The reset value of CSCR0 is as follows:

- Bits 31–24 are 0b
- Bit 23–3 are chip-dependent
- Bits 3–0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

Address: 4001\_E000h base + 8h offset + (12d × i), where i=0d to 3d

### FB\_CSCRn field descriptions

Field	Description
31–26 SWS	Secondary Wait States  Used only when the SWSEN bit is 1b. Specifies the number of wait states inserted before an internal transfer acknowledge is generated for a burst transfer (except for the first termination, which is controlled by WS).
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SWSEN	Secondary Wait State Enable  0 Disabled. A number of wait states (specified by WS) are inserted before an internal transfer acknowledge is generated for all transfers. 1 Enabled. A number of wait states (specified by SWS) are inserted before an internal transfer acknowledge is generated for burst transfer secondary terminations.
22 EXTS	Extended Transfer Start/Extended Address Latch Enable  Controls how long $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ is asserted.

Table continues on the next page...

**FB\_CSCR<sub>n</sub> field descriptions (continued)**

Field	Description
	0 Disabled. $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ asserts for one bus clock cycle. 1 Enabled. $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ remains asserted until the first positive clock edge after $\overline{\text{FB\_CSn}}$ asserts.
21–20 ASET	Address Setup Controls when the chip-select is asserted with respect to assertion of a valid address and attributes. 00 Assert $\overline{\text{FB\_CSn}}$ on the first rising clock edge after the address is asserted (default for all but $\overline{\text{FB\_CS0}}$ ). 01 Assert $\overline{\text{FB\_CSn}}$ on the second rising clock edge after the address is asserted. 10 Assert $\overline{\text{FB\_CSn}}$ on the third rising clock edge after the address is asserted. 11 Assert $\overline{\text{FB\_CSn}}$ on the fourth rising clock edge after the address is asserted (default for $\overline{\text{FB\_CS0}}$ ).
19–18 RDAH	Read Address Hold or Deselect Controls the address and attribute hold time after the termination during a read cycle that hits in the associated chip-select's address space. <b>NOTE:</b> <ul style="list-style-type: none"> <li>The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.</li> <li>The number of cycles the address and attributes are held after <math>\overline{\text{FB\_CSn}}</math> deassertion depends on the value of the AA bit.</li> </ul> 00 When AA is 1b, 1 cycle. When AA is 0b, 0 cycles. 01 When AA is 1b, 2 cycles. When AA is 0b, 1 cycle. 10 When AA is 1b, 3 cycles. When AA is 0b, 2 cycles. 11 When AA is 1b, 4 cycles. When AA is 0b, 3 cycles.
17–16 WRAH	Write Address Hold or Deselect Controls the address, data, and attribute hold time after the termination of a write cycle that hits in the associated chip-select's address space. <b>NOTE:</b> The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. 00 1 cycle (default for all but $\overline{\text{FB\_CS0}}$ ) 01 2 cycles 10 3 cycles 11 4 cycles (default for $\overline{\text{FB\_CS0}}$ )
15–10 WS	Wait States Specifies the number of wait states inserted after FlexBus asserts the associated chip-select and before an internal transfer acknowledge is generated (WS = 00h inserts 0 wait states, ..., WS = 3Fh inserts 63 wait states).
9 MUX	Multiplexed Mode Selects between a multiplexed and a non-multiplexed address/data bus. 0 Non-multiplexed configuration. Address information is driven on $\overline{\text{FB\_An}}$ and data is read/written on $\overline{\text{FB\_Dn}}$ . 1 Multiplexed configuration. Address information is driven on $\overline{\text{FB\_ADn}}$ , and low-order address lines ( $\overline{\text{FB\_AD}}[7:0]$ for 8-bit port size or $\overline{\text{FB\_AD}}[15:0]$ for 16-bit port size) must be latched using the falling edge of $\overline{\text{FB\_ALE}}$ as the latch enable. Data is read/written on $\overline{\text{FB\_AD}}[7:0]$ for 8-bit port size and $\overline{\text{FB\_AD}}[15:0]$ for 16-bit port size.

Table continues on the next page...

FB\_CSCR<sub>n</sub> field descriptions (continued)

Field	Description
9 BLS	<p>Byte-Lane Shift</p> <p>Specifies if data on FB_AD appears left-aligned or right-aligned during the data phase of a FlexBus access.</p> <p>0 Not shifted. Data is left-aligned on FB_AD. 1 Shifted. Data is right-aligned on FB_AD.</p>
8 AA	<p>Auto-Acknowledge Enable</p> <p>Asserts the internal transfer acknowledge for accesses specified by the chip-select address.</p> <p><b>NOTE:</b> If AA is 1b for a corresponding FB_CS<sub>n</sub> and the external system asserts an external <math>\overline{\text{FB\_TA}}</math> before the wait-state countdown asserts the internal FB_TA, the cycle is terminated. Burst cycles increment the address bus between each internal termination.</p> <p><b>NOTE:</b> This field must be 1b if CSPMCR disables FB_TA.</p> <p>0 Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally. 1 Enabled. Internal transfer acknowledge is asserted as specified by WS.</p>
7–6 PS	<p>Port Size</p> <p>Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles.</p> <p>00 32-bit port size. Valid data is sampled and driven on FB_D[31:0]. 01 8-bit port size. Valid data is sampled and driven on FB_D[31:24] when BLS is 0b, or FB_D[7:0] when BLS is 1b. 1X 16-bit port size. Valid data is sampled and driven on FB_D[31:16] when BLS is 0b, or FB_D[15:0] when BLS is 1b.</p>
5 BEM	<p>Byte-Enable Mode</p> <p>Specifies whether the corresponding <math>\overline{\text{FB\_BE}}</math> is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs.</p> <p>0 <math>\overline{\text{FB\_BE}}</math> is asserted for data write only. 1 <math>\overline{\text{FB\_BE}}</math> is asserted for data read and write accesses.</p>
4 BSTR	<p>Burst-Read Enable</p> <p>Specifies whether burst reads are enabled for memory associated with each chip select.</p> <p>0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads. 1 Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports.</p>
3 BSTW	<p>Burst-Write Enable</p> <p>Specifies whether burst writes are enabled for memory associated with each chip select.</p> <p>0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes. 1 Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.</p>

15–12 GROUP5	FlexBus Signal Group 5 Multiplex control  Controls the multiplexing of the $\overline{\text{FB\_TA}}$ , $\overline{\text{FB\_CS3}}$ , and $\overline{\text{FB\_BE\_7\_0}}$ signals.  <b>NOTE:</b> When GROUP5 is not 0000b, you must write 1b to the CSCR[AA] bit. Otherwise, the bus hangs during a transfer.  0000 $\overline{\text{FB\_TA}}$ 0001 $\overline{\text{FB\_CS3}}$ . You must also write 1b to CSCR[AA]. 0010 $\overline{\text{FB\_BE\_7\_0}}$ . You must also write 1b to CSCR[AA]. Any other value Reserved
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 10.5.4 Functional description

### 10.5.4.1 Use cases

In general, FlexBus supports the following use cases, but note that your device may not support all of these use cases, because of limitations imposed by your specific package's pinouts:

- Multiplexed 32-bit address and 32-bit data
- Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)
- Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)
- Non-multiplexed 32-bit address and 32-bit data busses

**NOTE**

All use cases require signals to actually be available on the pins of your specific device package. Refer to your specific device's signal multiplexing table to verify the availability of specific signals for your device package.

**10.5.4.2 Address comparison**

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

When the transfer address	Then FlexBus
Matches one address register configuration	Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR.  If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle.
Does not match an address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.
Matches more than one address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.

**10.5.4.3 Address driven on address bus**

FlexBus always drives a 32-bit address on the FB\_AD bus regardless of the external memory's or peripheral's address size.

**10.5.4.4 Connecting address/data lines**

The external device must connect its address and data lines as follows:

- Address lines
  - FB\_AD from FB\_AD0 upward
- Data lines
  - If CSCR[BLS] = 0, FB\_AD from FB\_AD31 downward
  - If CSCR[BLS] = 1, FB\_AD from FB\_AD0 upward

### 10.5.4.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB\_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB\_AD16–FB\_AD1 and data15–data0 to FB\_AD31–FB\_AD16. See [Data-byte alignment and physical connections](#) for a graphical connection.

### 10.5.4.6 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB\_AD31–FB\_AD0 )
- Control signals ( $\overline{\text{FB\_TS}}/\overline{\text{FB\_ALE}}$ ,  $\overline{\text{FB\_TA}}$ ,  $\overline{\text{FB\_CS}}_n$ ,  $\overline{\text{FB\_OE}}$ ,  $\overline{\text{FB\_R}}/\overline{\text{W}}$ ,  $\overline{\text{FB\_BE}}_n$ )
- Attribute signals ( $\overline{\text{FB\_TBST}}$ , FB\_TSIZ1–FB\_TSIZ0)

### 10.5.4.7 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB\_CLK):

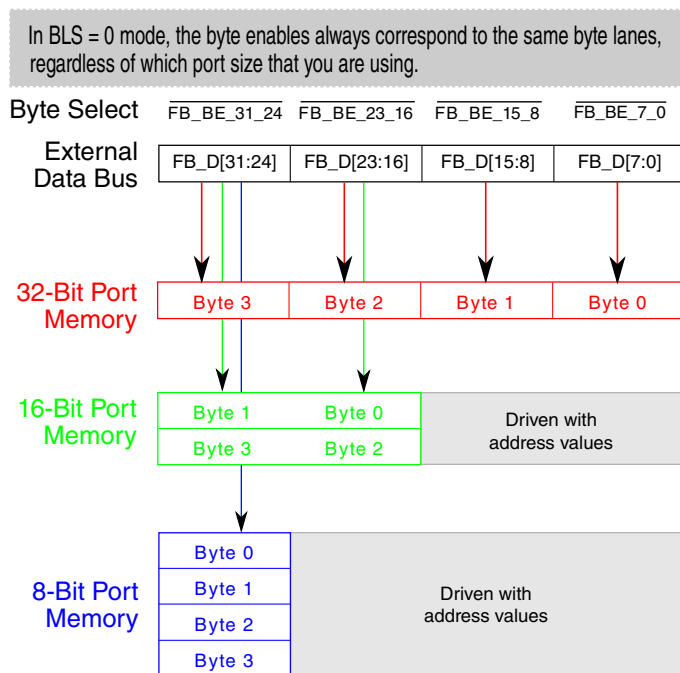

- Address
- Write data
- $\overline{\text{FB\_TS}}/\overline{\text{FB\_ALE}}$
- $\overline{\text{FB\_CS}}_n$
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

### 10.5.4.8 Data-byte alignment and physical connections

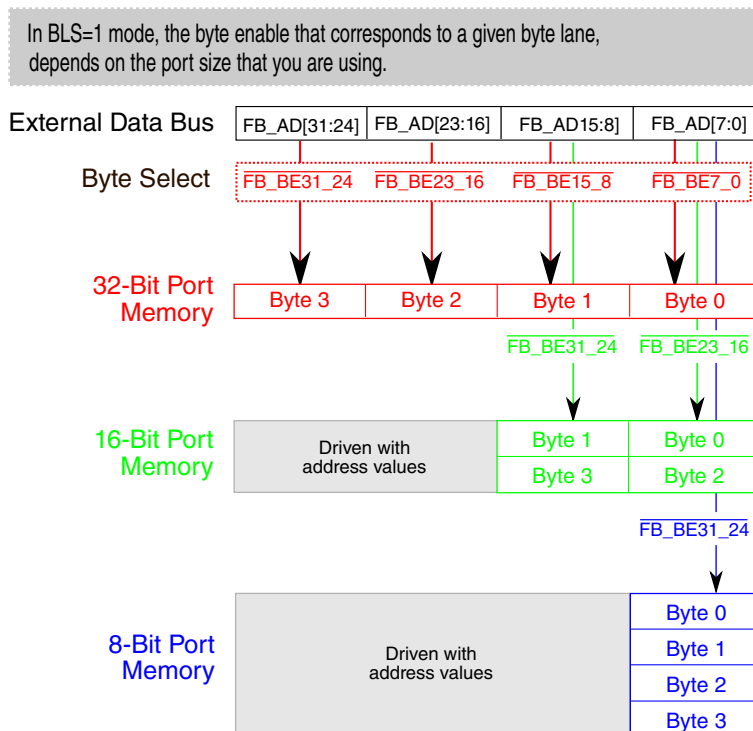

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane FB\_AD31–FB\_AD24 ( $\overline{\text{FB\_BE}}_{31\_24}$ ). A 32-bit transfer through this 8-bit port takes four transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each four-byte lane.

**Figure 10-55. Connections for external memory port sizes (CSCRn[BLS] = 0)**

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

**Figure 10-56. Connections for external memory port sizes (CSCRn[BLS] = 1)**

### 10.5.4.9 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB\_AD31–FB\_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB\_AD31–FB\_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB\_AD31–FB\_AD0 lines not used for data.

#### 10.5.4.9.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
32-bit	Address phase	Address			
	Data phase	Data			
16-bit	Address phase	Address			
	Data phase	Data		Address	
8-bit	Address phase	Address			
	Data phase	Data	Address		

#### 10.5.4.9.2 FlexBus multiplexed operating modes for CSCRn[BLS]=1

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 1b.

Port size and phase		FB_AD			
		31–24	23–16	15–8	7–0
32-bit	Address phase	Address			
	Data phase	Data			
16-bit	Address phase	Address			
	Data phase	Address		Data	
8-bit	Address phase	Address			
	Data phase	Address			Data

### 10.5.4.10 Data transfer states

Basic data transfers occur in four clocks or states. (See [Figure 10-58](#) and [Figure 10-60](#) for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

The states are described in this table.

State	Cycle	Description
S0	All	The read or write cycle is initiated. On the rising clock edge, FlexBus: <ul style="list-style-type: none"> <li>Places a valid address on FB_ADn</li> <li>Asserts <math>\overline{\text{FB\_TS}}/\text{FB\_ALE}</math></li> <li>Drives FB_R/<math>\overline{\text{W}}</math> high for a read and low for a write</li> </ul>
S1	All	FlexBus: <ul style="list-style-type: none"> <li>Negates <math>\overline{\text{FB\_TS}}/\text{FB\_ALE}</math> on the rising edge of FB_CLK</li> <li>Asserts FB_CS<sub>n</sub></li> <li>Drives the data on FB_AD31–FB_ADX for writes</li> <li>Tristates FB_AD31–FB_ADX for reads</li> <li>Continues to drive the address on FB_AD pins that are unused for data</li> </ul> <p>If the external memory or peripheral asserts <math>\overline{\text{FB\_TA}}</math>, then the process moves to S2. If <math>\overline{\text{FB\_TA}}</math> is not asserted internally or externally, then S1 repeats.</p>
	Read	The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with $\overline{\text{FB\_TA}}$ asserted.
S2	All	For internal termination, FlexBus negates $\overline{\text{FB\_CS}}_n$ and the transfer is complete. For external termination, the external memory or peripheral negates $\overline{\text{FB\_TA}}$ , and FlexBus negates $\overline{\text{FB\_CS}}_n$ after the rising edge of FB_CLK at the end of S2.
	Read	FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge or continue to drive the data until the end of S3 or through any additional address hold cycles.
S3	All	FlexBus invalidates the address, data, and FB_R/ $\overline{\text{W}}$ on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.

### 10.5.4.11 FlexBus Timing Examples

#### Note

The timing diagrams throughout this section use signal names that may not be included on your particular device. Ignore these extraneous signals.

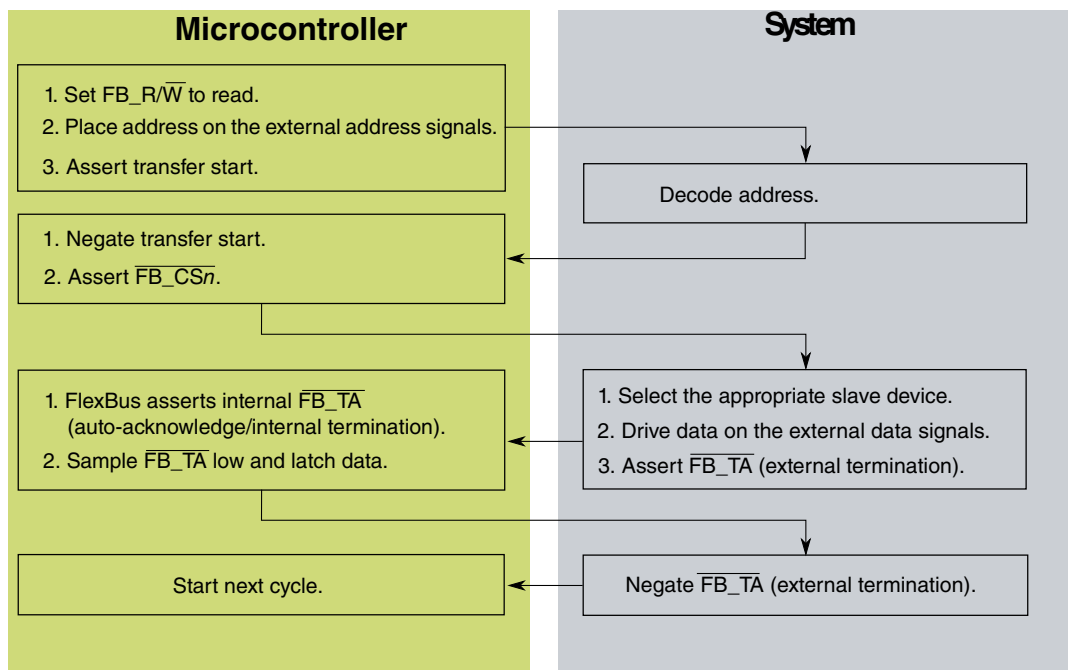

#### Note

Throughout this section:

- FB\_D[X] indicates a 32-, 16-, or 8-bit wide data bus
- FB\_A[Y] indicates an address bus that can be 32, 24, or 16 bits wide.

#### 10.5.4.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device. The following figure shows a read cycle flowchart.

**Figure 10-57. Read Cycle Flowchart**

The read cycle timing diagram is shown in the following figure.

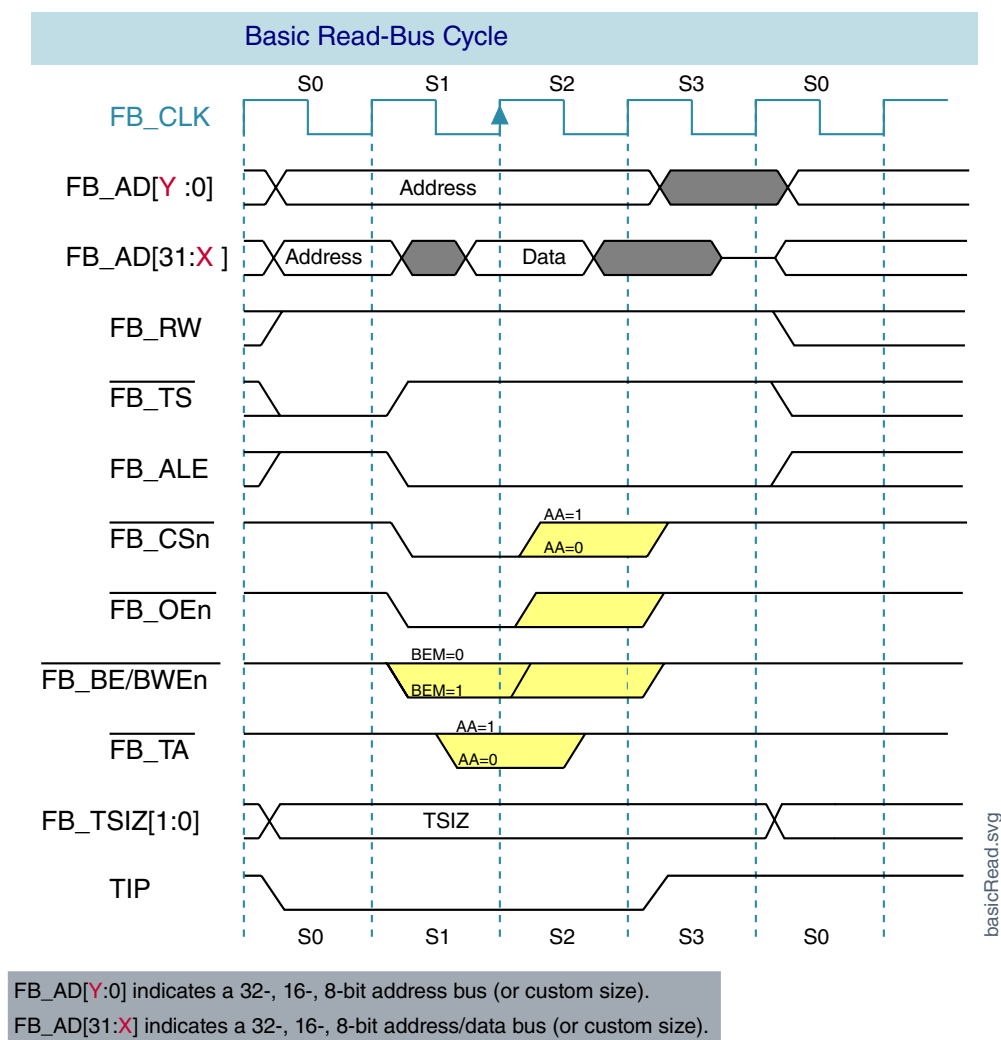

**Note**

$\overline{\text{FB\_TA}}$  does not have to be driven by the external device for internally-terminated bus cycles.

**Note**

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

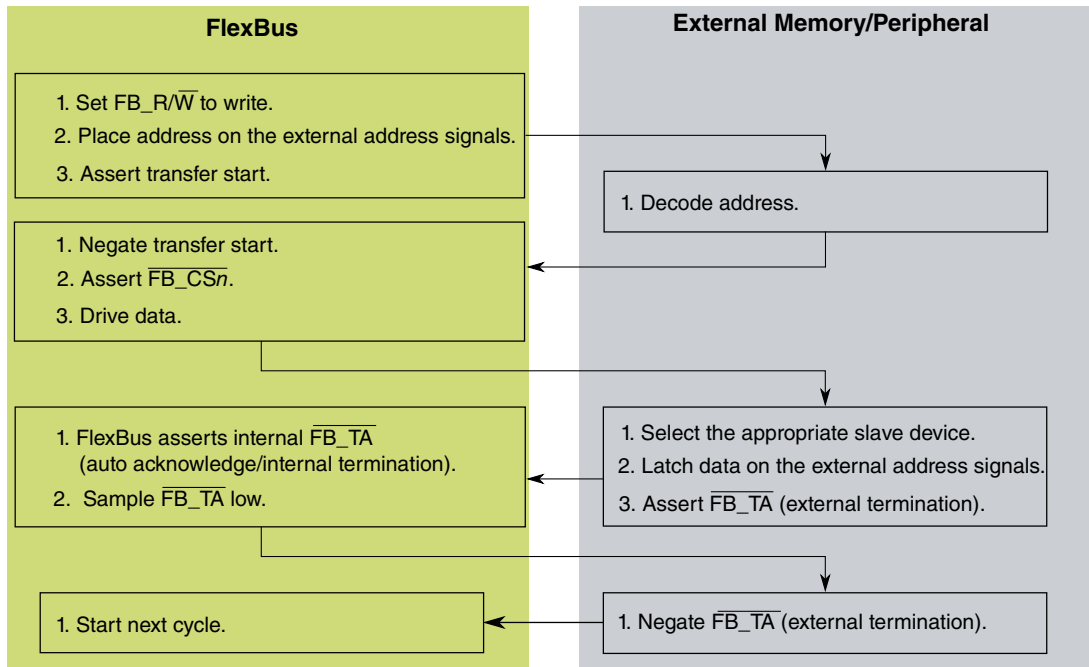

**Figure 10-58. Basic Read-Bus Cycle**

### 10.5.4.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device. The following figure shows the write cycle flowchart.

**Figure 10-59. Write-Cycle Flowchart**

The following figure shows the write cycle timing diagram.

#### Note

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

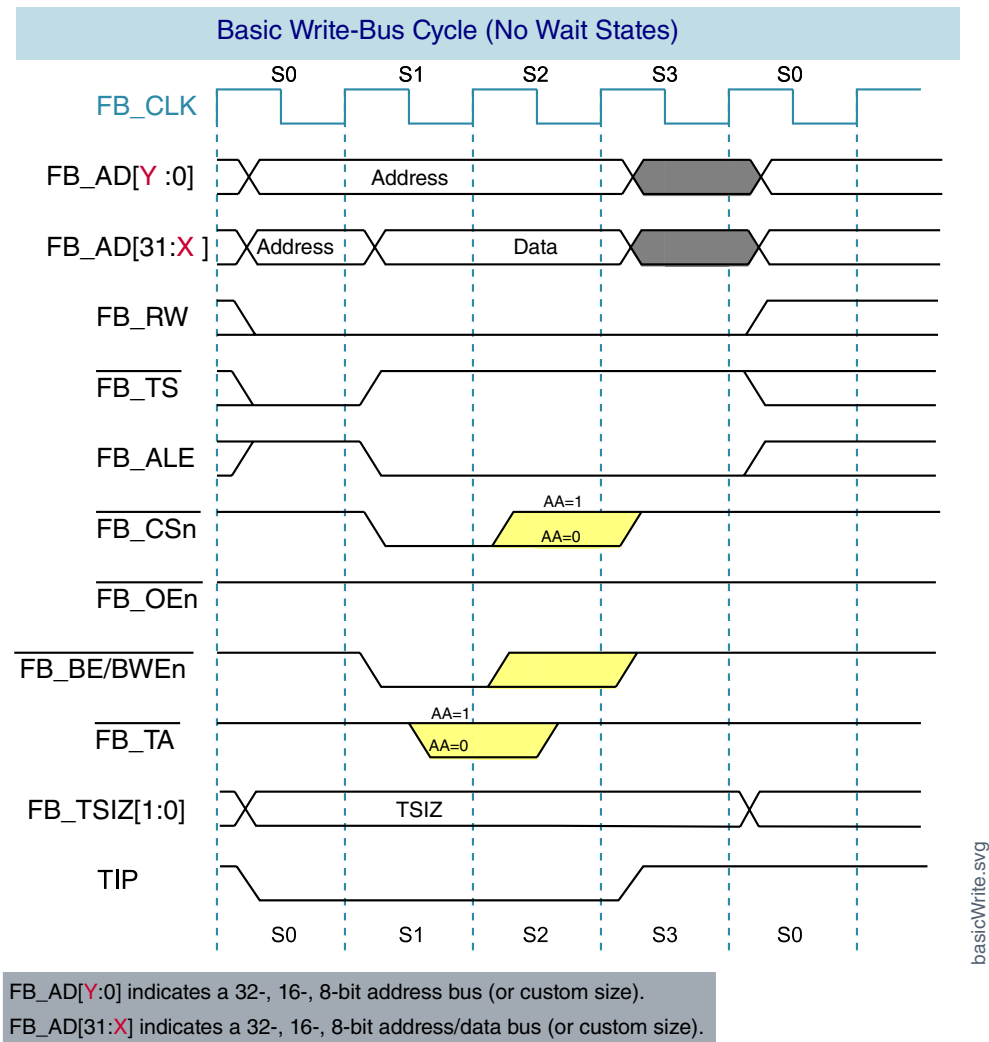

Figure 10-60. Basic Write-Bus Cycle

### 10.5.4.11.3 Bus Cycle Sizing

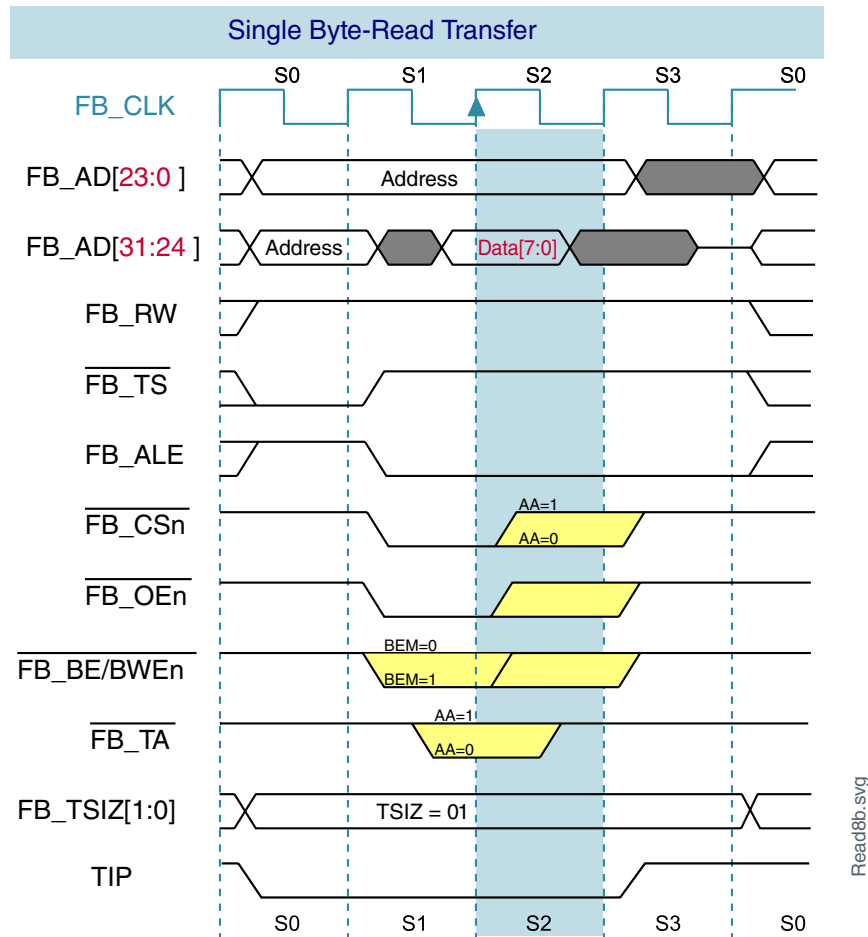

This section shows timing diagrams for various port size scenarios.

#### 10.5.4.11.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The following figure illustrates the basic byte read transfer to an 8-bit device with no wait states:

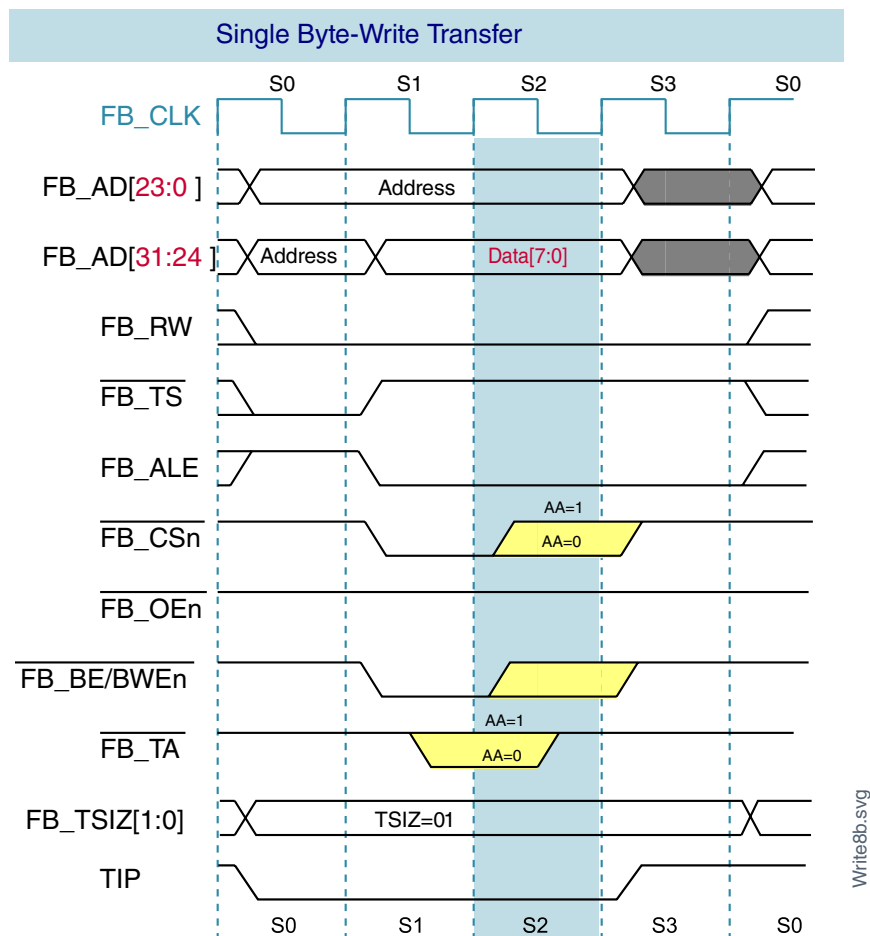

- The address is driven on the full FB\_AD[31:0] bus in the first clock.

- The device tristates FB\_AD[31:24] on the second clock and continues to drive address on FB\_AD[23:0] throughout the bus cycle.
- The external device returns the read data on FB\_AD[31:24] and may tristate the data line or continue driving the data one clock after FB\_TA is sampled asserted.

**Figure 10-61. Single Byte-Read Transfer**

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB\_AD[31:24].

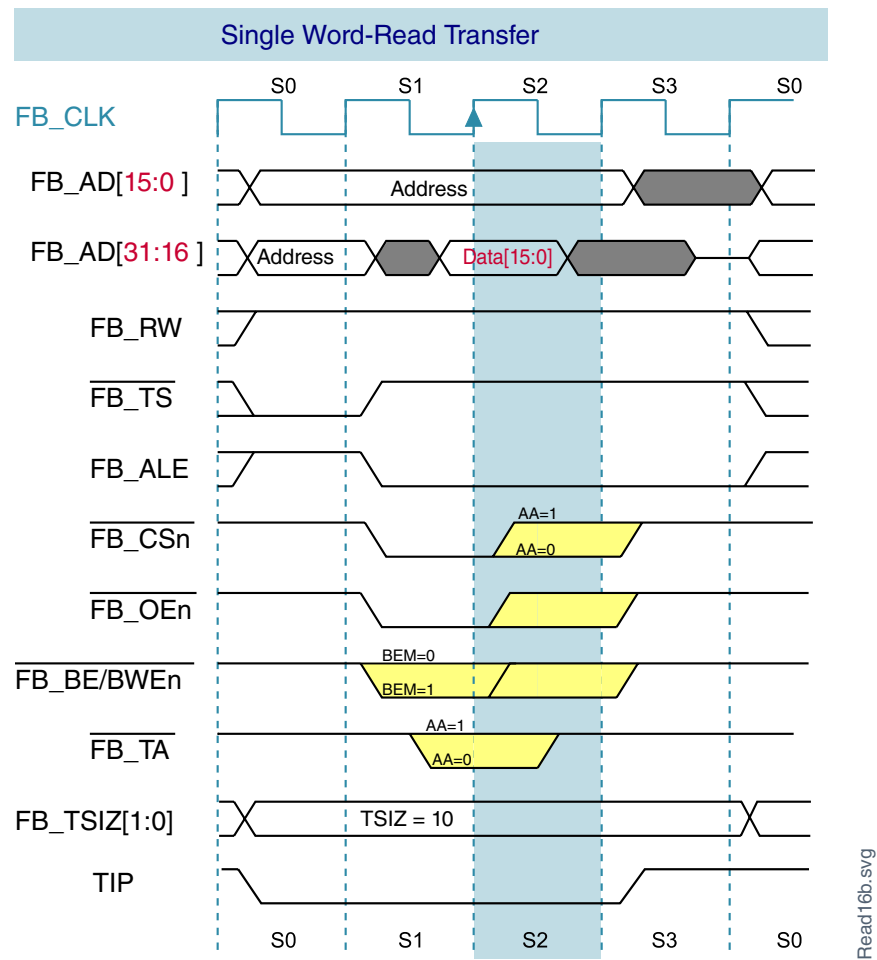

**Figure 10-62. Single Byte-Write Transfer**

#### 10.5.4.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The following figure illustrates the basic word read transfer to a 16-bit device with no wait states.

- The address is driven on the full FB\_AD[31:8] bus in the first clock.
- The device tristates FB\_AD[31:16] on the second clock and continues to drive address on FB\_AD[15:0] throughout the bus cycle.
- The external device returns the read data on FB\_AD[31:16] and may tristate the data line or continue driving the data one clock after  $\overline{\text{FB\_TA}}$  is sampled asserted.

### Figure 10-63. Single Word-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB\_AD[31:16].

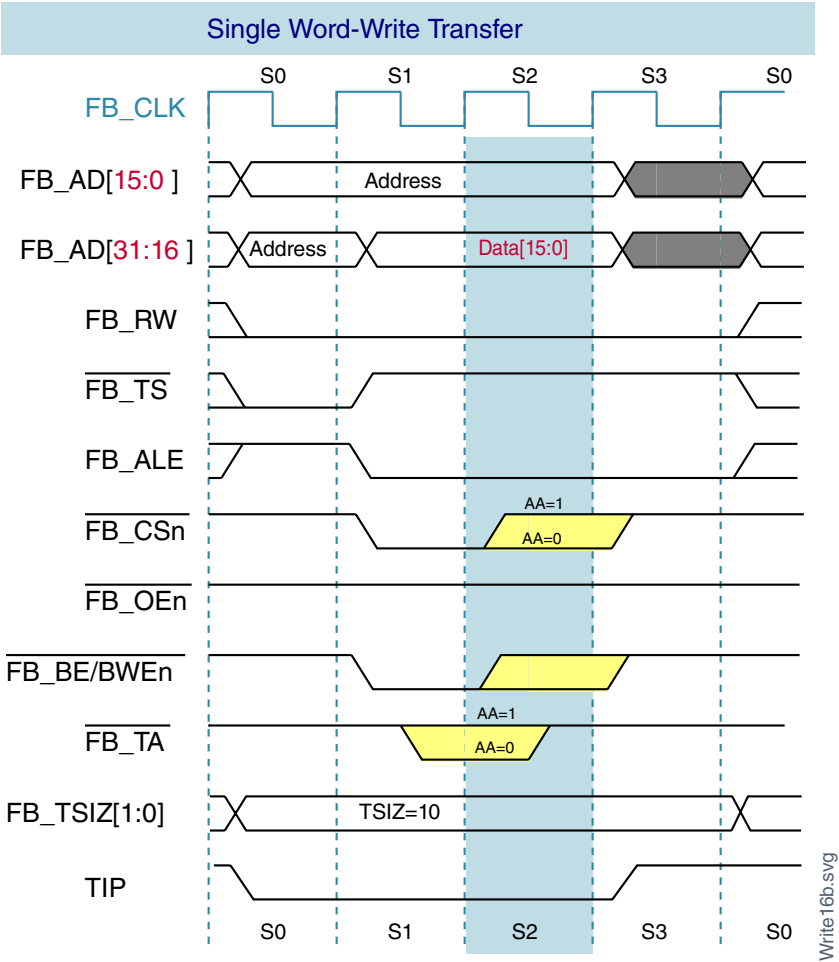

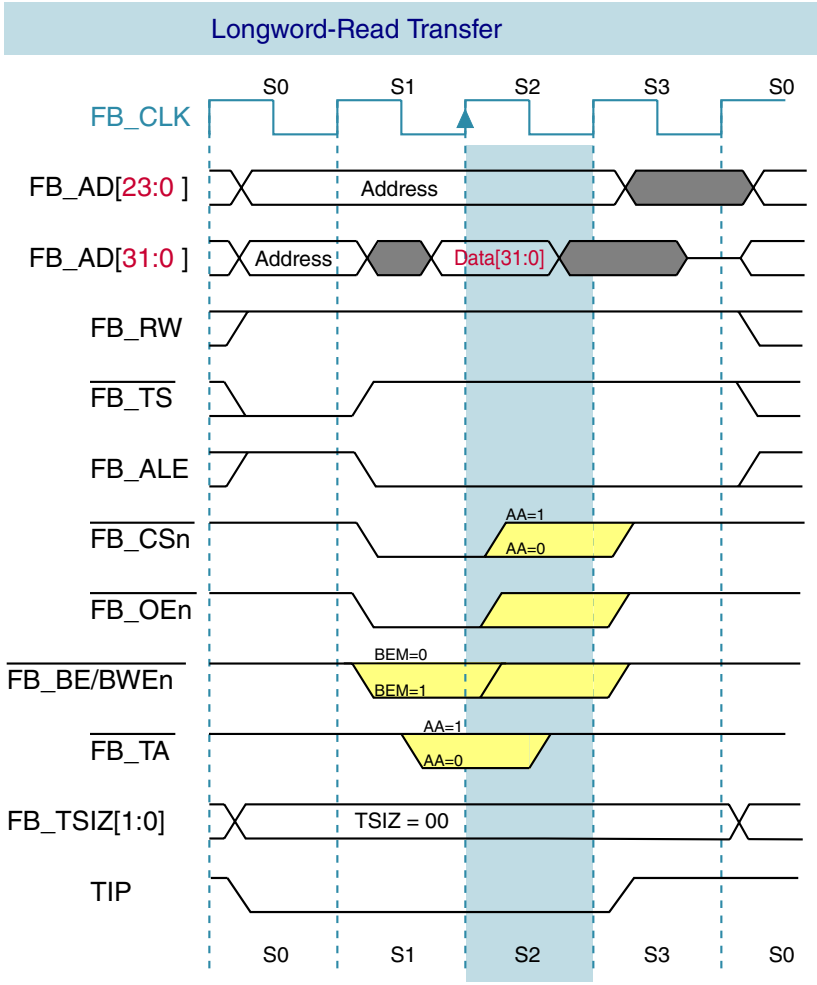

Figure 10-64. Single Word-Write Transfer

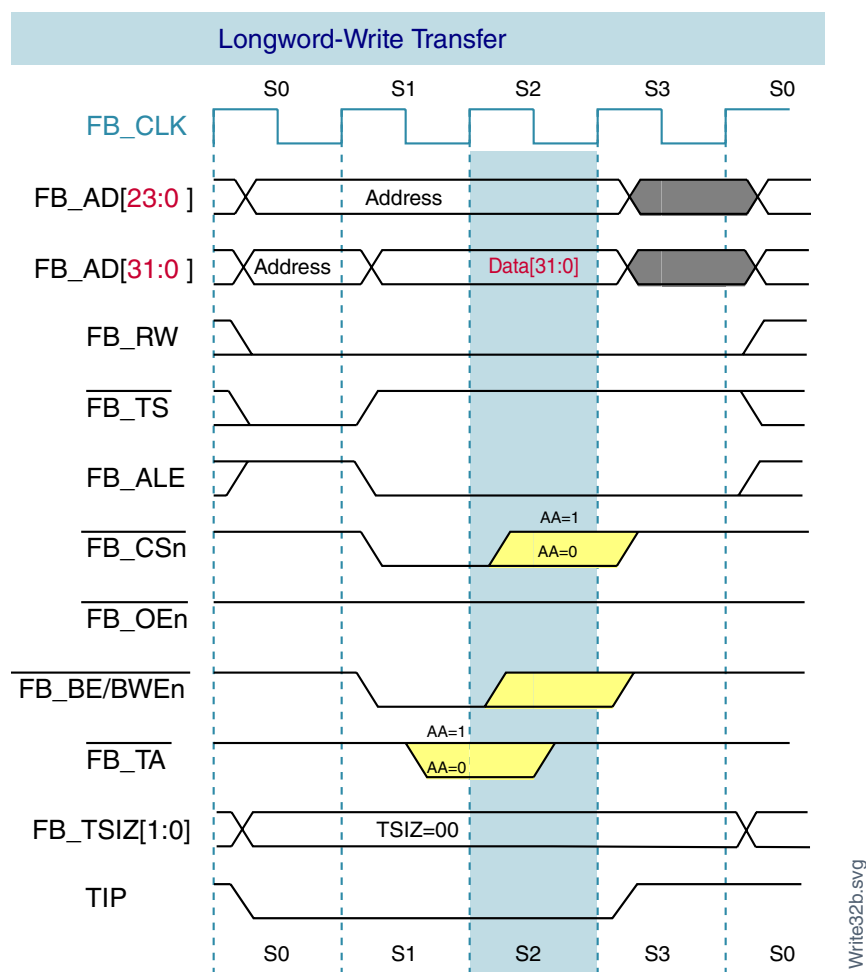

10.5.4.11.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The following figure depicts a longword read from a 32-bit device.

### Figure 10-65. Longword-Read Transfer

The following figure illustrates the longword write to a 32-bit device.

### Figure 10-66. Longword-Write Transfer

#### 10.5.4.11.4 Timing Variations

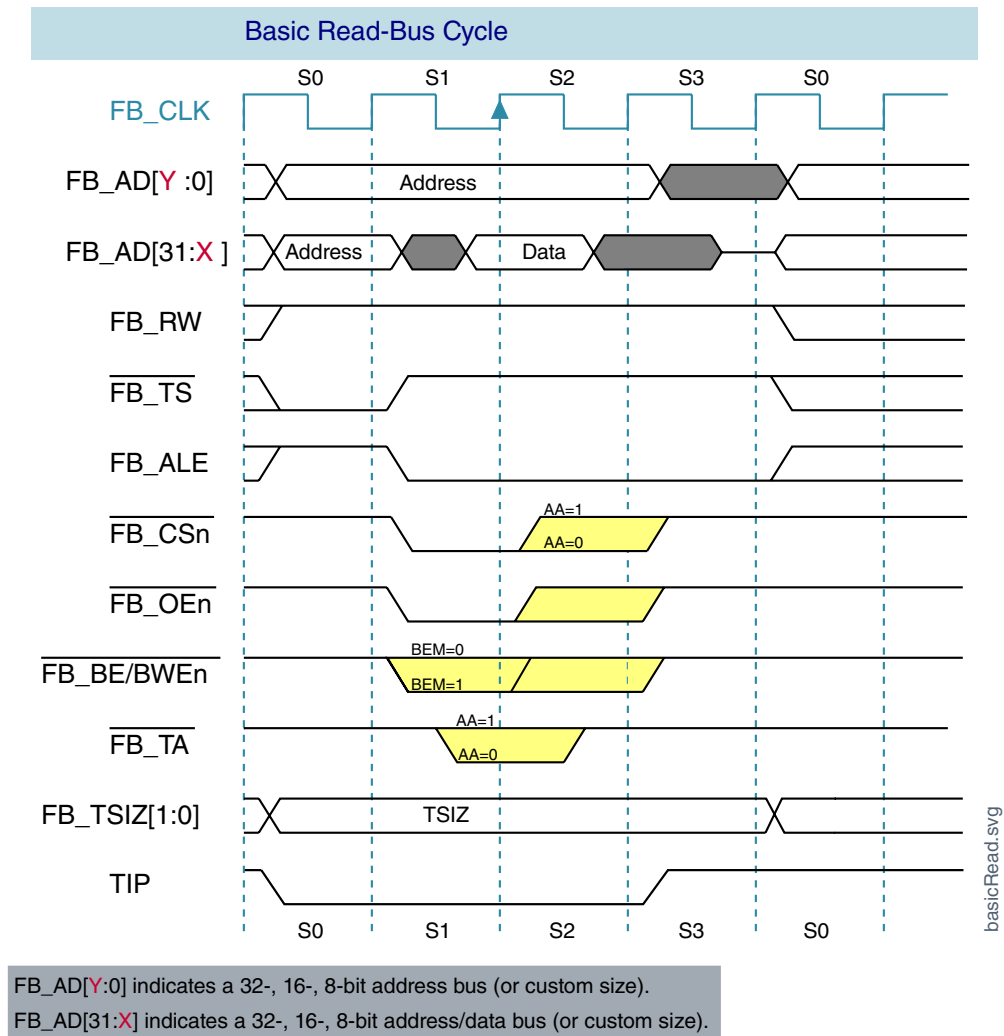

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

#### 10.5.4.11.4.1 Wait States

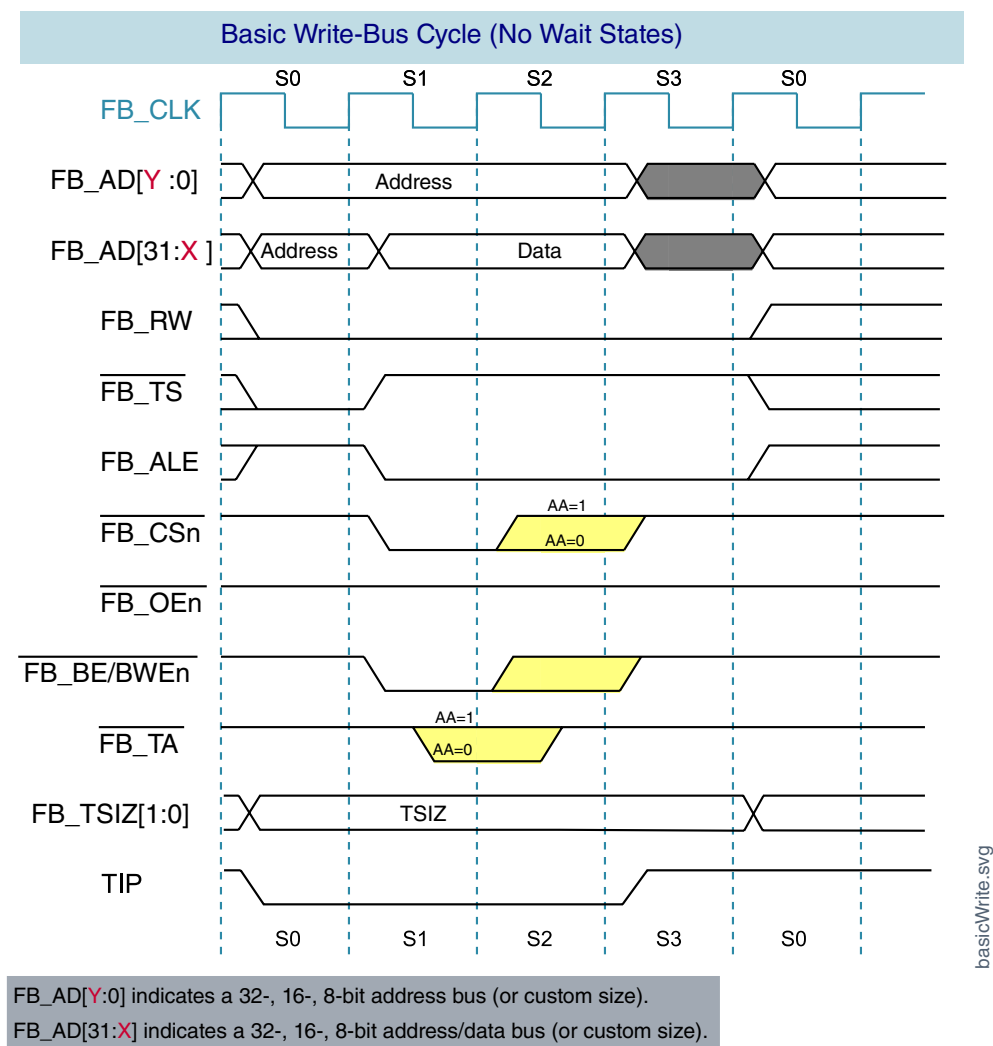

Wait states can be inserted before each beat of a transfer by programming the `CSCRn` registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in [Figure 10-58](#) and [Figure 10-63](#)) with the default of no wait states respectively.

**Figure 10-67. Basic Read-Bus Cycle (No Wait States)**

**Figure 10-68. Basic Write-Bus Cycle (No Wait States)**

If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external  $\overline{\text{FB\_TA}}$  is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.

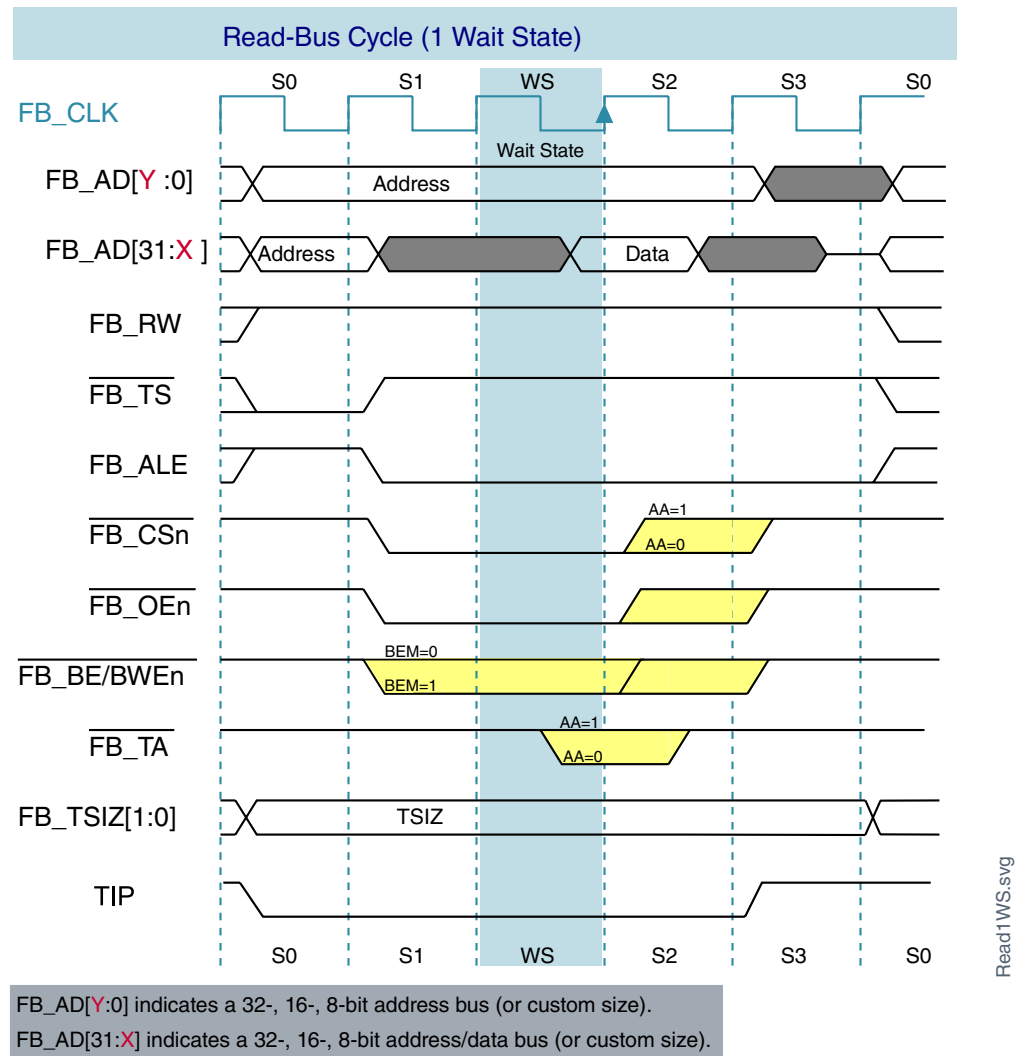

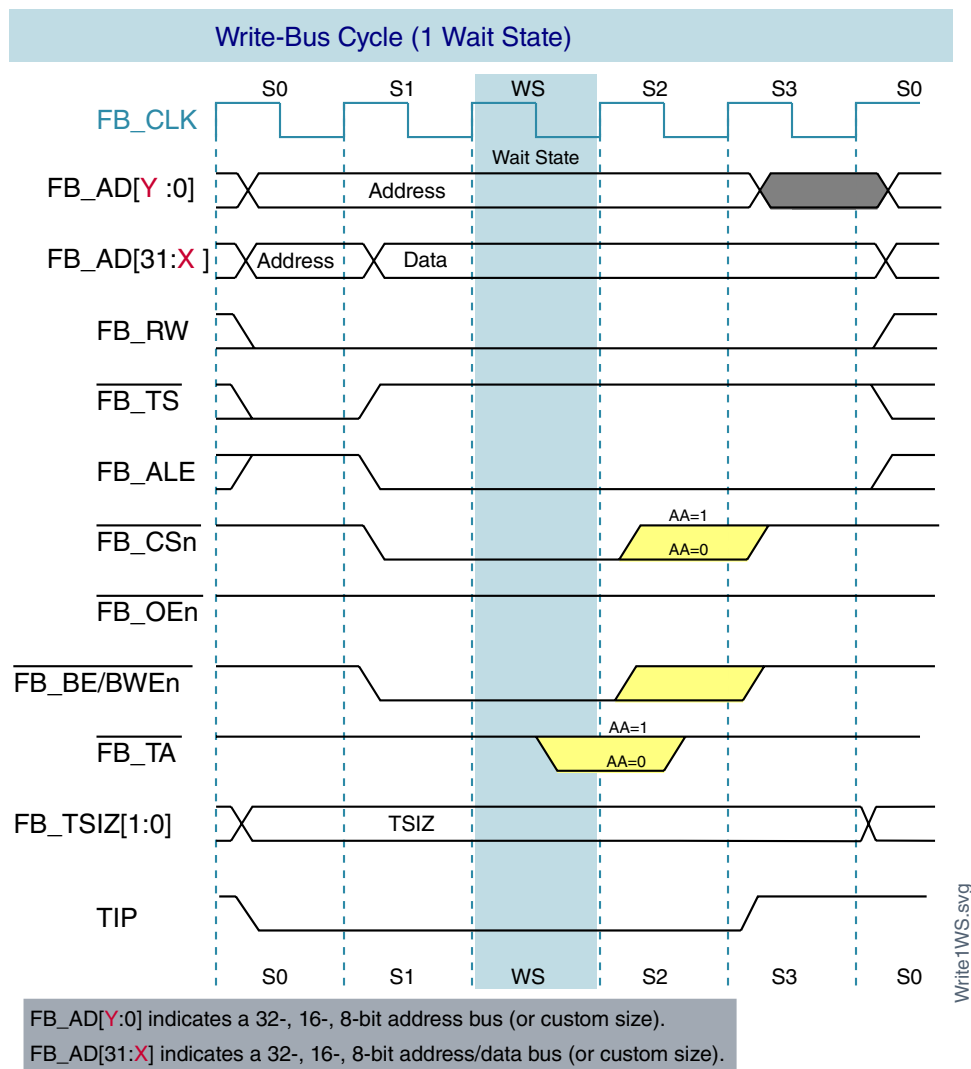

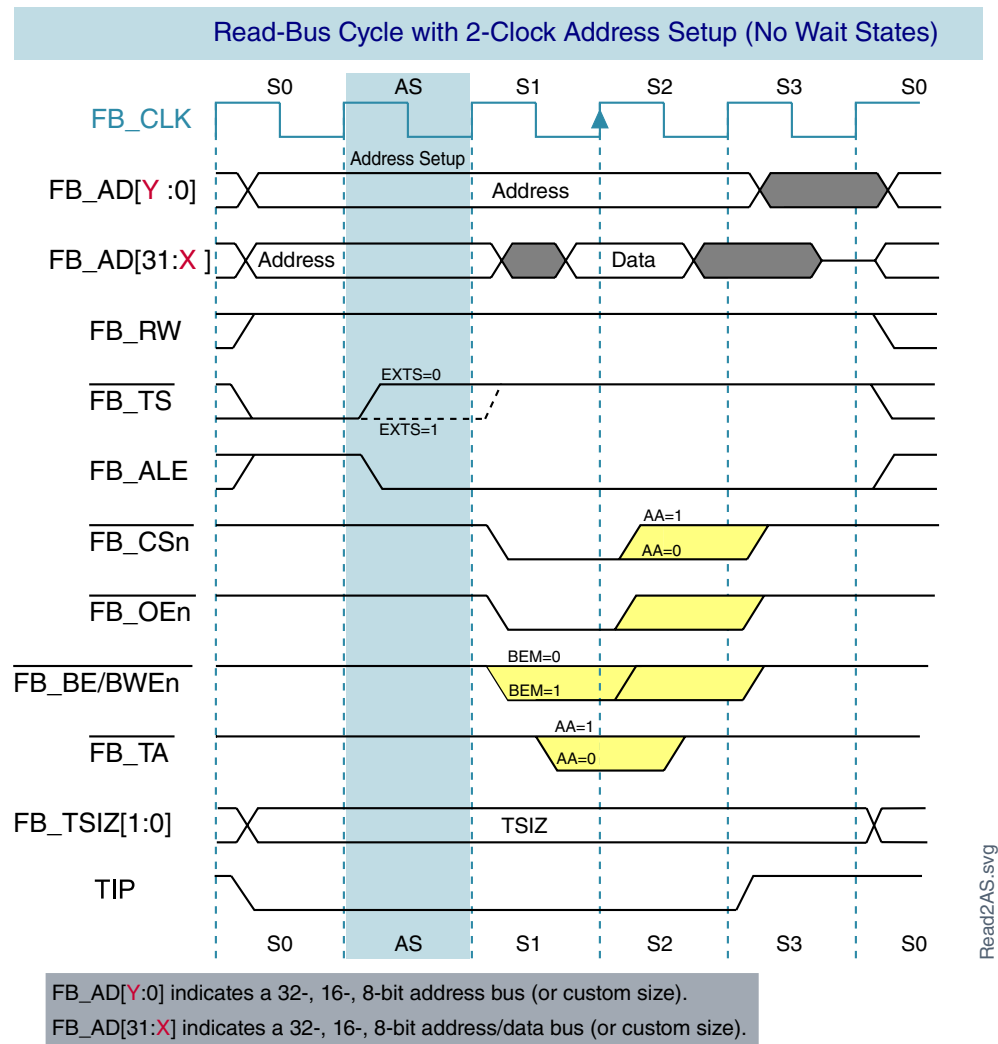

Figure 10-69. Read-Bus Cycle (One Wait State)

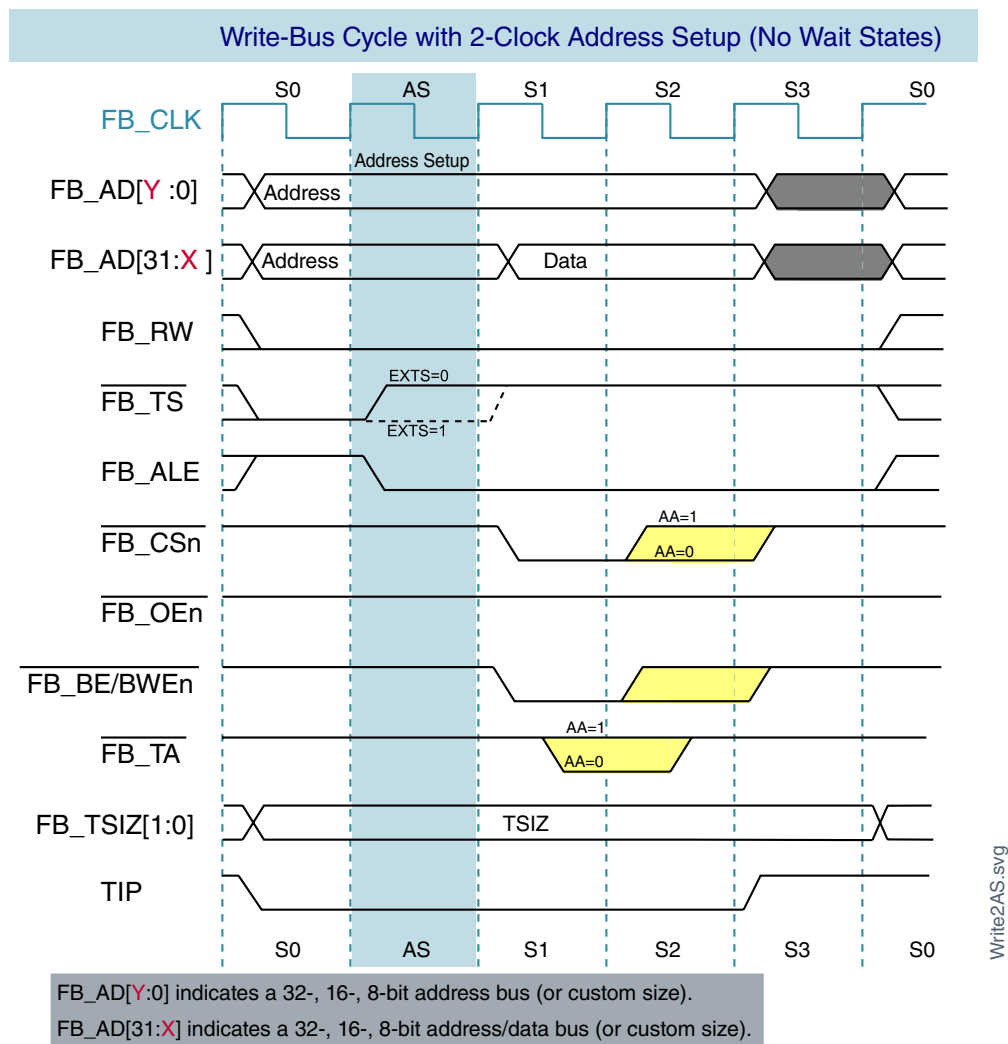

**Figure 10-70. Write-Bus Cycle (One Wait State)**

#### 10.5.4.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable ( $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ ) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

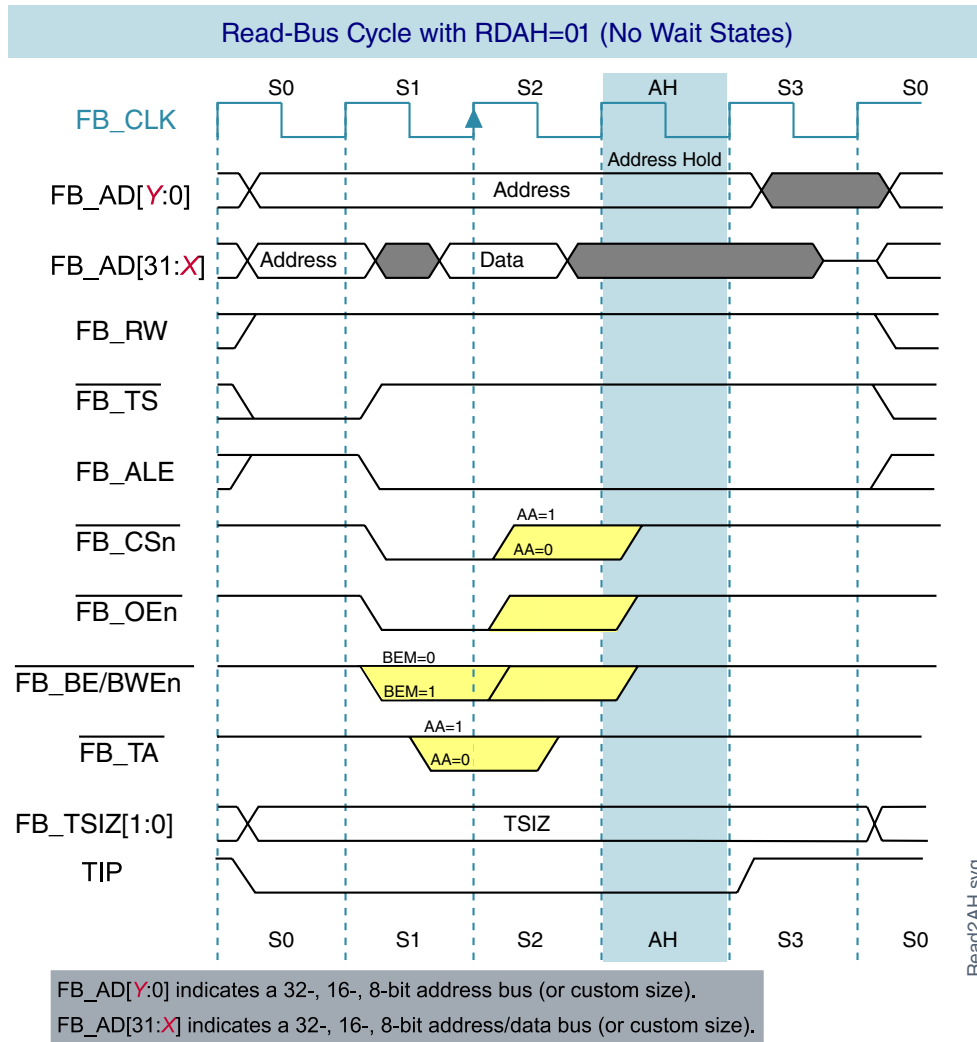

**Figure 10-71. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)**

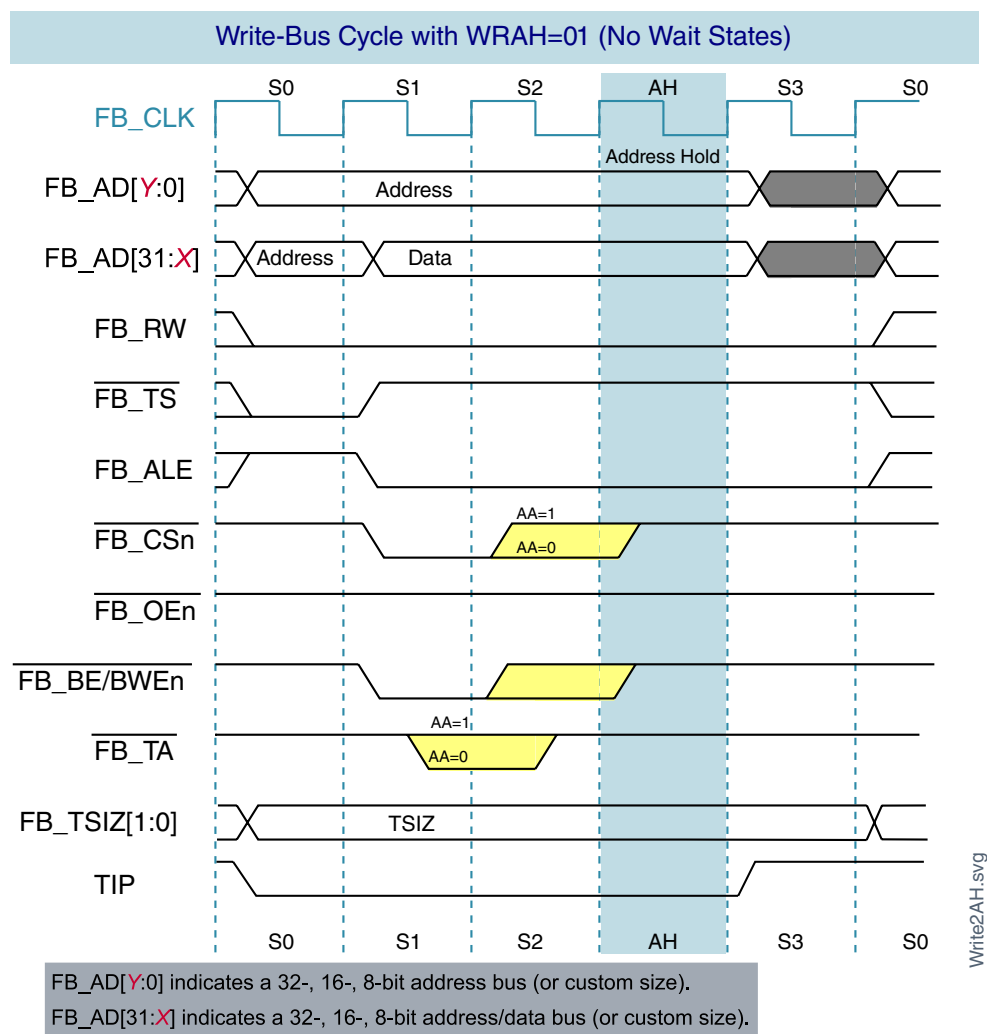

**Figure 10-72. Write-Bus Cycle with Two Clock Address Setup (No Wait States)**

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

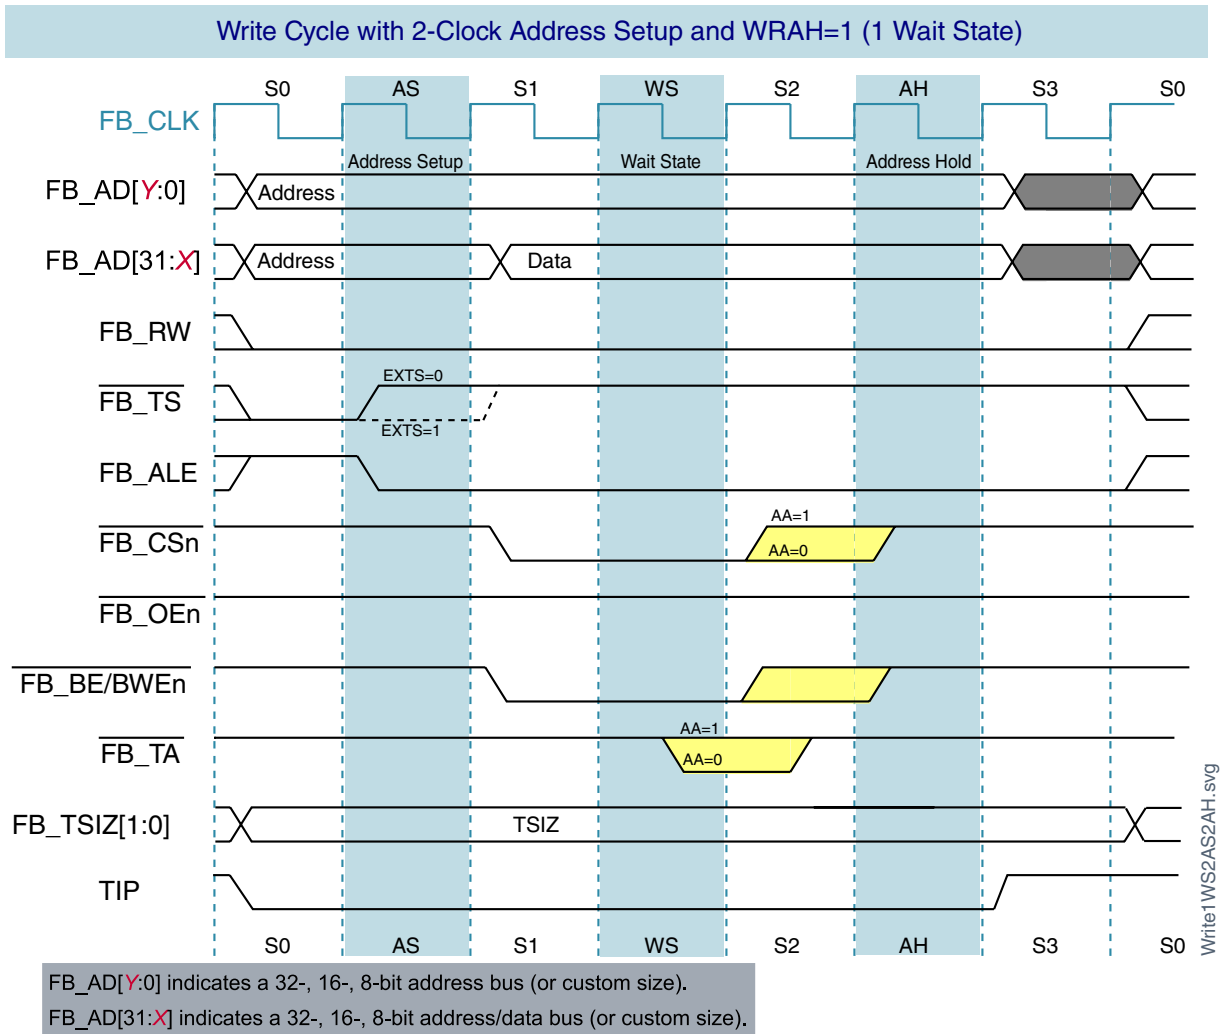

**Figure 10-73. Read Cycle with Two-Clock Address Hold (No Wait States)**

**Figure 10-74. Write Cycle with Two-Clock Address Hold (No Wait States)**

The following figure shows a bus cycle using address setup, wait states, and address hold.

**Figure 10-75. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)**

#### 10.5.4.12 Burst cycles

The chip can be programmed to initiate burst cycles if its transfer size exceeds the port size of the selected destination. The initiation of a burst cycle is encoded on the transfer size pins (FB\_TSI[1:0]). For burst transfers to smaller port sizes, FB\_TSI[1:0] indicates the size of the entire transfer. For example, with bursting enabled, a 16-bit transfer to an 8-bit port takes two beats (two byte-sized transfers), for which FB\_TSI[1:0] equals 10b throughout. A 32-bit transfer to an 8-bit port takes four beats (four byte-sized transfers), for which FB\_TSI[1:0] equals 00b throughout.

### 10.5.4.12.1 Enabling and inhibiting burst

The CSCRn registers enable bursting for reads, writes, or both.

Memory spaces can be declared burst-inhibited for reads and writes by writing 0b to the appropriate CSCRn[BSTR] and CSCRn[BSTW] fields.

### 10.5.4.12.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

Port size PS[1:0]	Transfer size FB_TSIZ[1:0]	Burst-inhibited: Number of transfers Burst enabled: Number of beats
01b (8 bit)	10b (16 bits)	2
	00b (32 bits)	4
1Xb (16 bit)	00b (32 bits)	2
00b (32 bit)	11b (line)	4

The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

### 10.5.4.12.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB\_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

#### Note

- In **non-multiplexed address/data mode**: the address on FB\_A increments only during internally-terminated burst cycles. The first address is driven throughout the entire burst for externally-terminated cycles.
- In **multiplexed address/data mode**: the address is driven on FB\_AD only during the first cycle for all terminated cycles. In other words, the lower address lines only increment during internally-terminated burst cycles

(assuming that the lower address lines are being driven with the address during the data phase).

#### 32-bit Read Burst from 8-bit port 2-1-1-1, with no Wait states

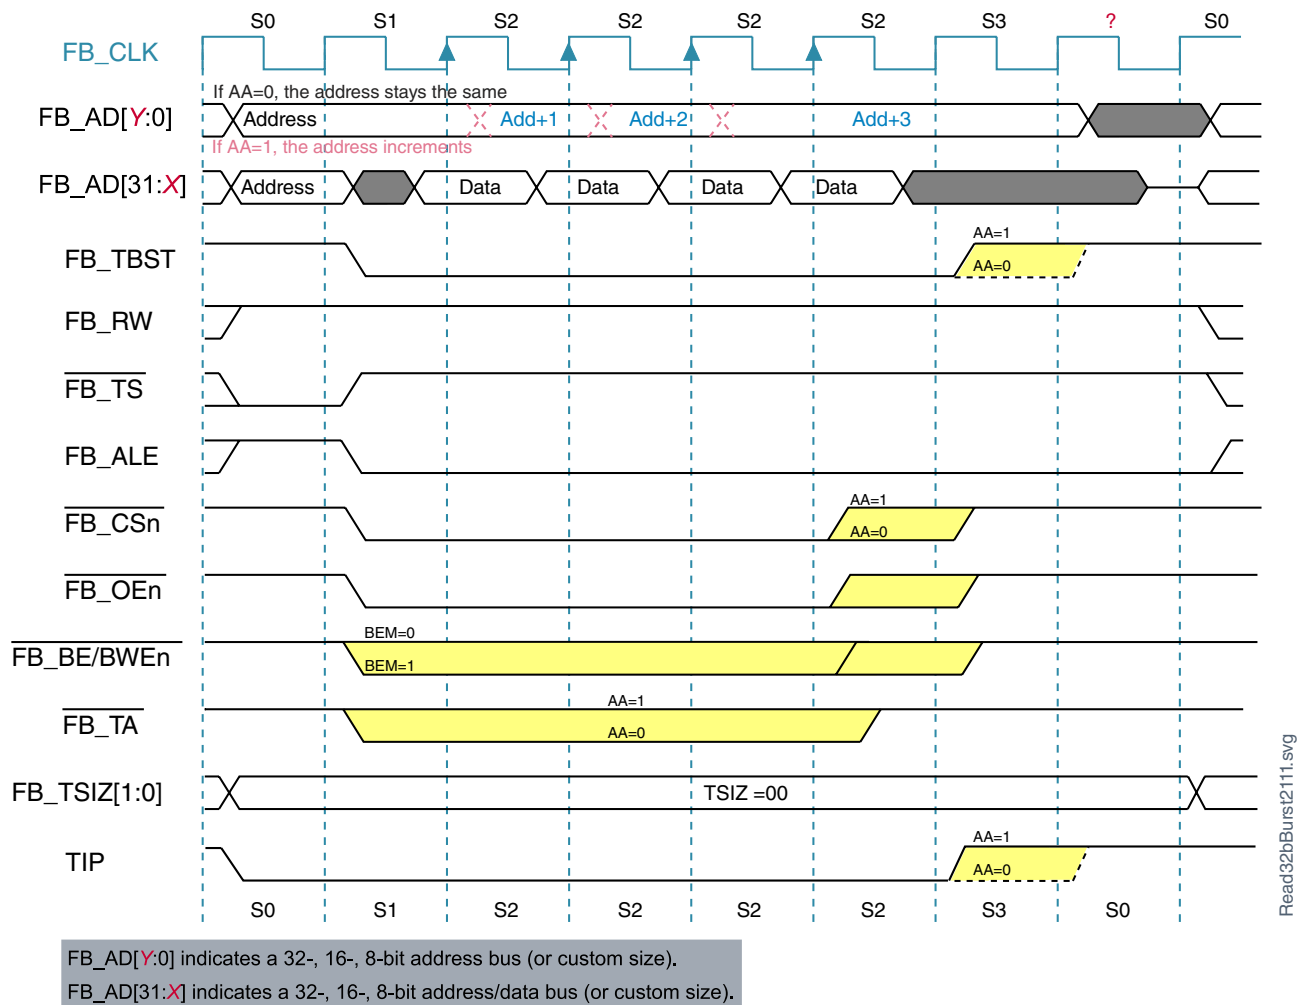

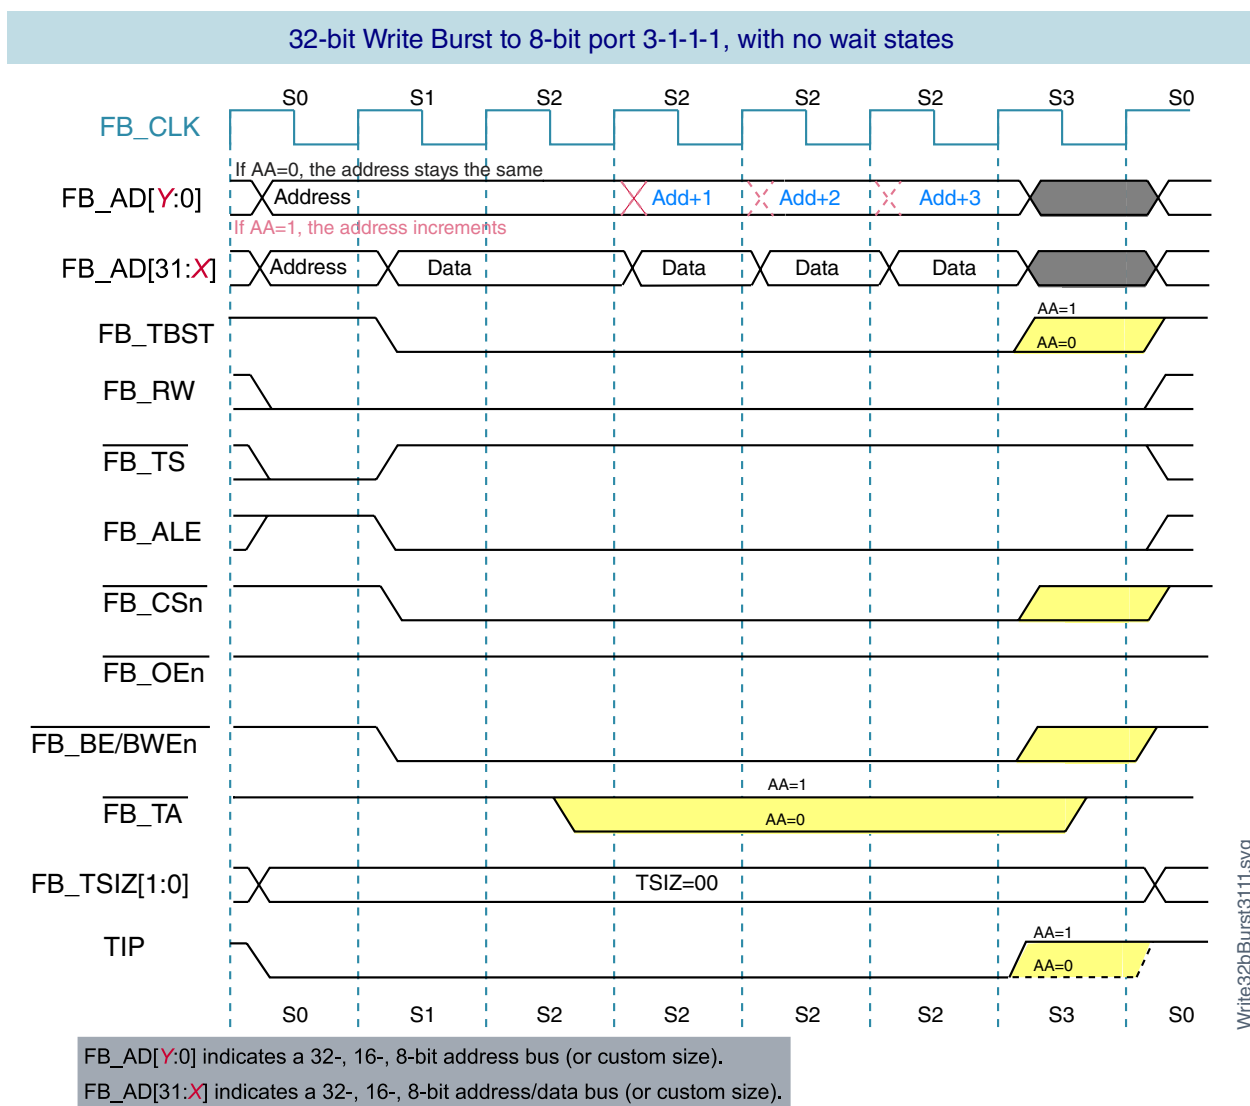

Figure 10-76. 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

#### 10.5.4.12.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB\_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

**Note**

The first beat of any write burst cycle has at least one wait state.  
 If the bus cycle is programmed for zero wait states  
 ( $CSCRn[WS] = 0b$ ), one wait state is added. Otherwise, the  
 programmed number of wait states are used.

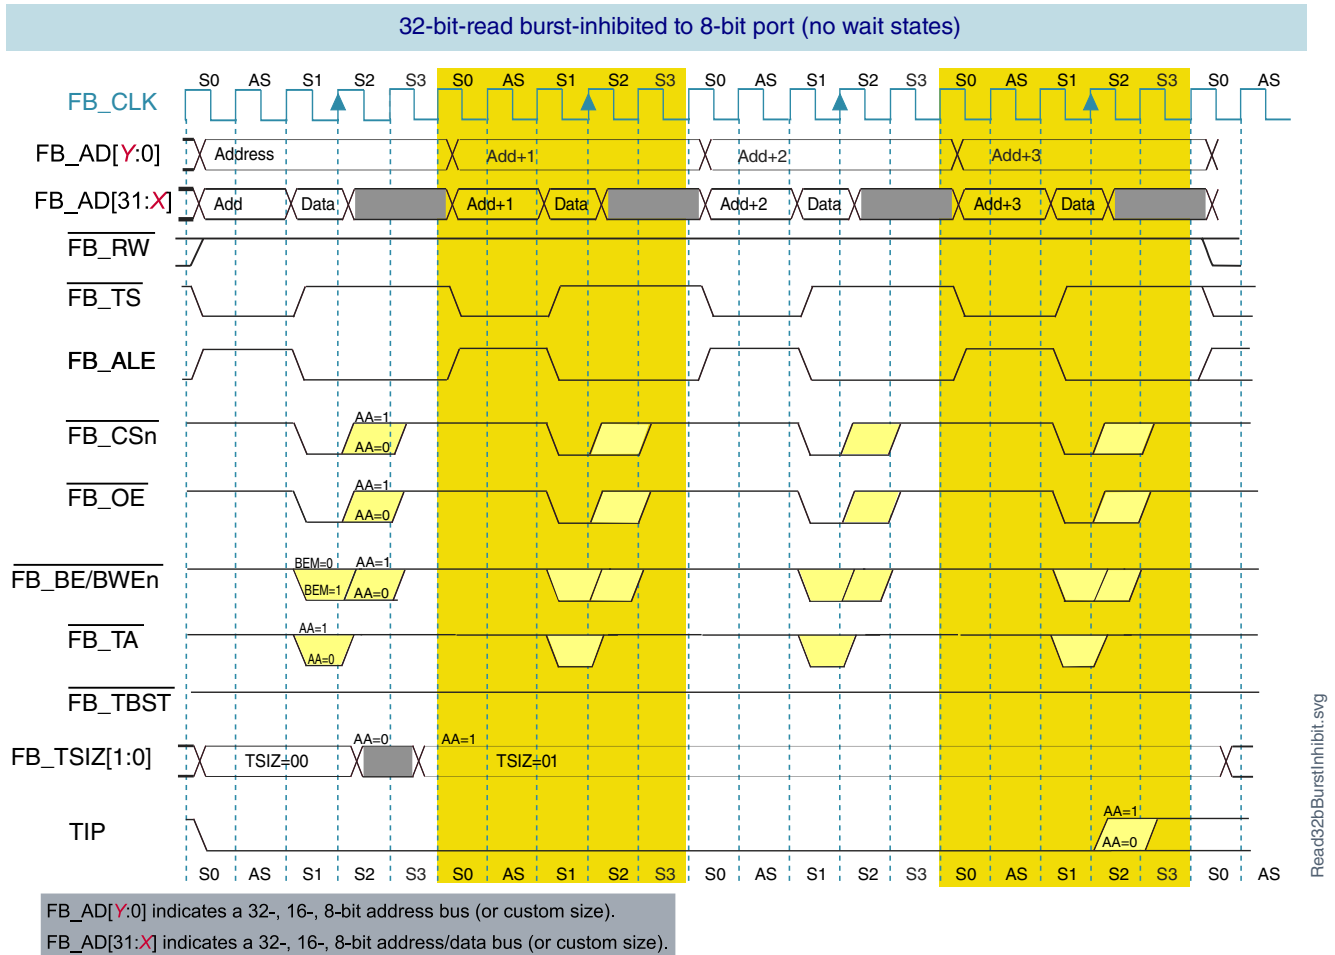

**Figure 10-77. 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)**

#### 10.5.4.12.5 32-bit-read burst-inhibited from 8-bit port (no wait states)

The following figure shows a 32-bit read from an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

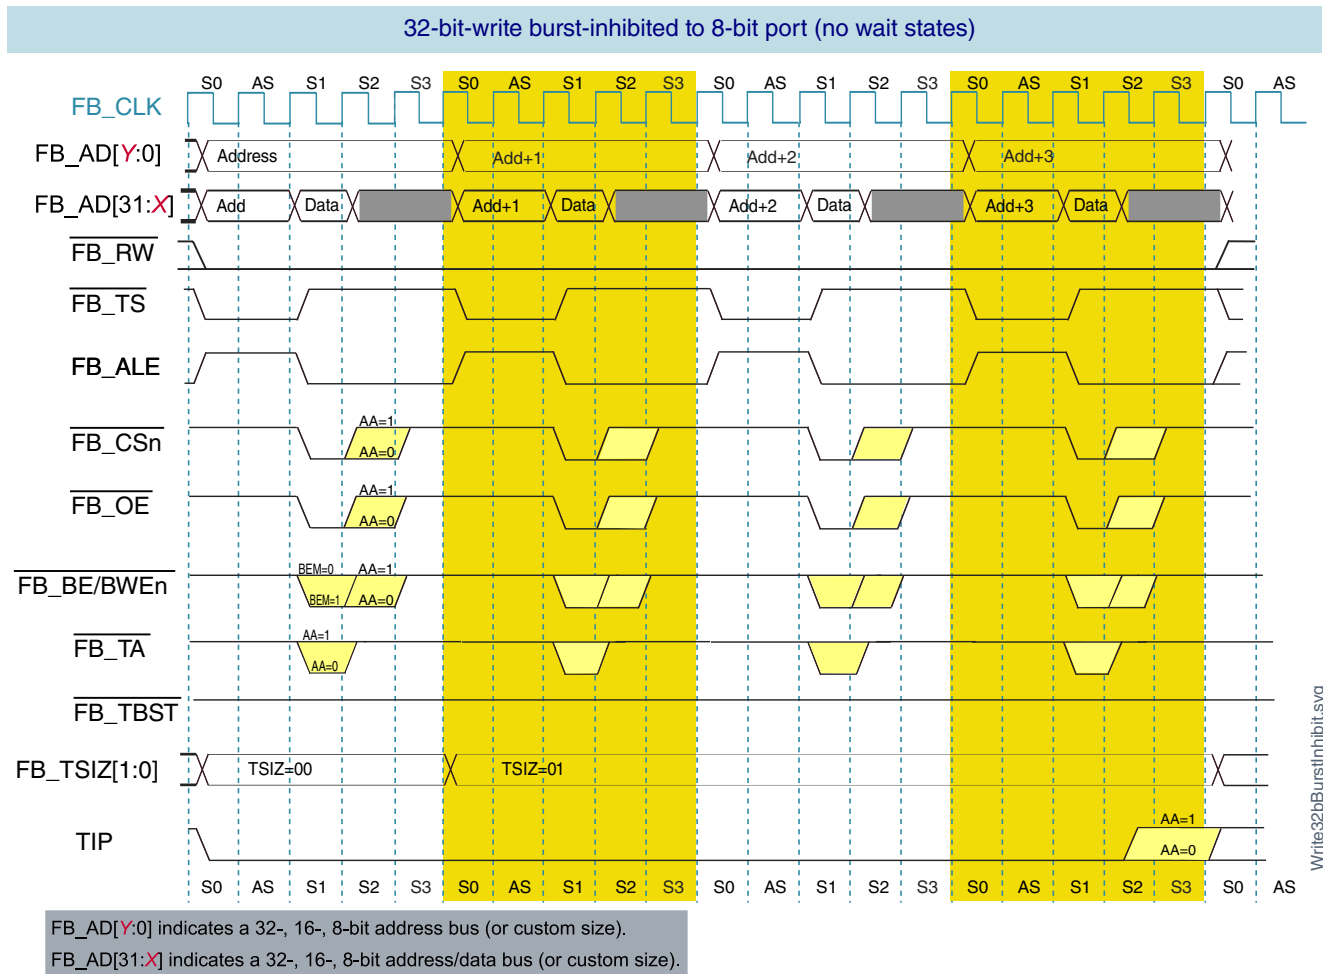

**Note**

There is an extra clock of address setup (AS) for each burst-inhibited transfer between states S0 and S1.

#### 10.5.4.12.6 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

**Figure 10-78. 32-bit-write burst-inhibited to 8-bit port (no wait states)**

#### 10.5.4.12.7 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

#### Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSSEN] = 1b) determines the number of wait states.

## 32-bit Read Burst from 8-bit port 3-2-2-2, with 1 wait state

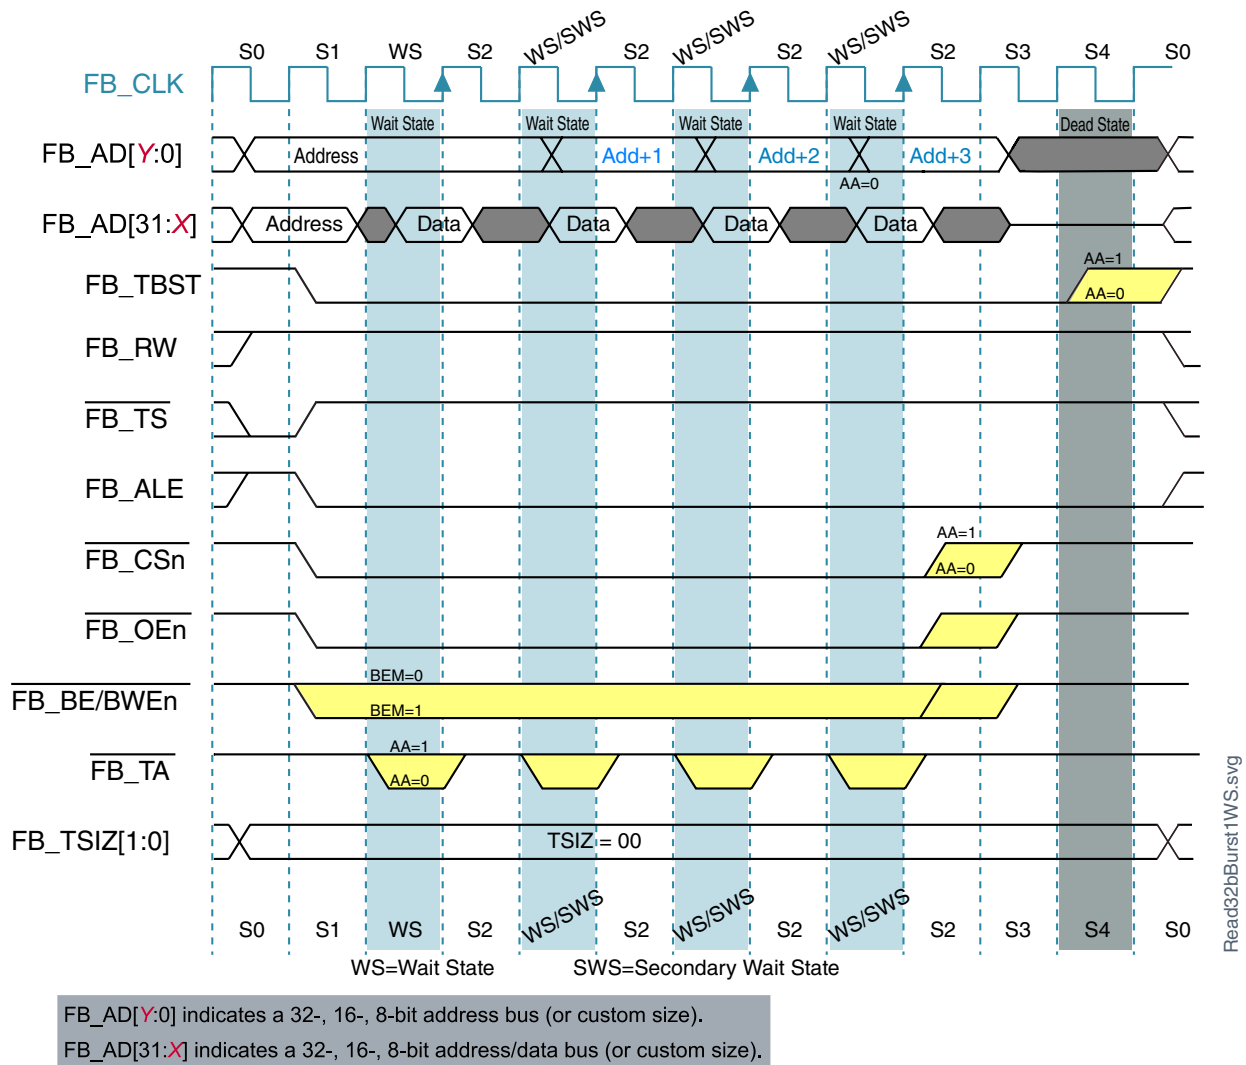

Figure 10-79. 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

## 10.5.4.12.8 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.

**Figure 10-80. 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)**

#### 10.5.4.12.9 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

#### Note

In non-multiplexed address/data mode, the address on FB\_A increments only during internally-terminated burst cycles (CSCRn[AA] = 1b). The attached device must be able to

In multiplexed address/data mode, the address is driven on FB\_AD only during the first cycle for internally- and externally-terminated cycles.

### 32-bit Read Burst from 8-bit port 3-1-1-1, with Address Setup and Hold

**Figure 10-81. 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)**

#### 10.5.4.12.10 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.

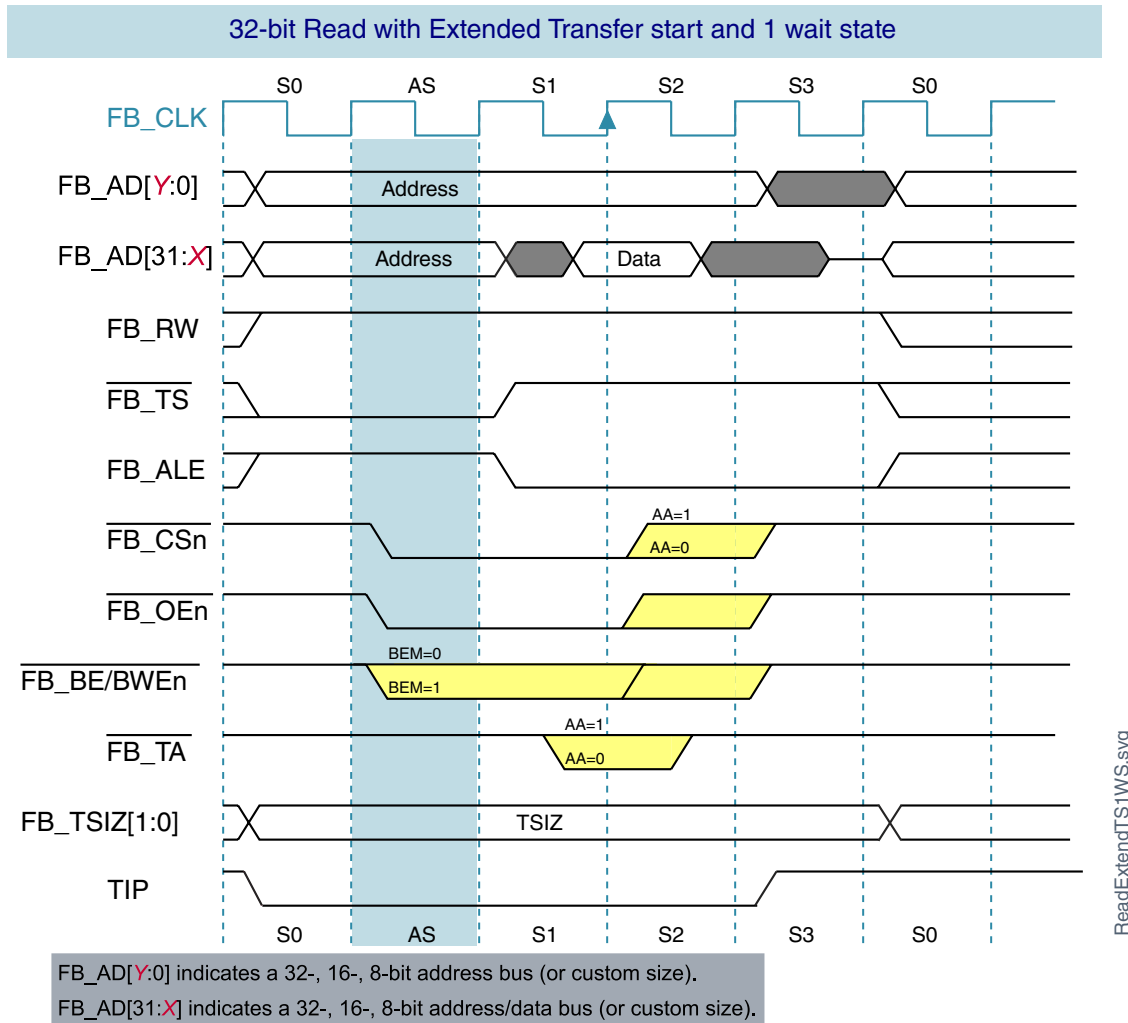

**Figure 10-82. 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)**

### 10.5.4.13 Extended Transfer Start/Address Latch Enable

The  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal asserts for a single bus clock cycle. When  $\text{CSCR}_n[\text{EXTS}]$  is set, the  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal asserts and remain asserted until the first positive clock edge after  $\overline{\text{FB\_CS}}_n$  asserts. See the following figure.

#### NOTE

When  $\text{EXTS}$  is set,  $\text{CSCR}_n[\text{WS}]$  must be programmed to have at least one primary wait state.

**Figure 10-83. Read-Bus Cycle with CSCRn[EXTS] = 1 (One Wait State)**

#### 10.5.4.14 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, then the transfer can be terminated by asserting  $\overline{\text{FB\_TA}}$ . If the processor must manage a bus error differently, then asserting an interrupt to the core along with  $\overline{\text{FB\_TA}}$  when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for  $\overline{\text{FB\_TA}}$ .

## **10.5.5 Initialization/Application Information**

### **10.5.5.1 Initializing a chip-select**

Before using any other chip select to take it out of global chip select mode, you must initialize CS0.

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

### **10.5.5.2 Reconfiguring a chip-select**

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

## 10.6 Cyclic Redundancy Check (CRC)

### 10.6.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

#### 10.6.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

#### 10.6.1.2 Block diagram

The following is a block diagram of the CRC.

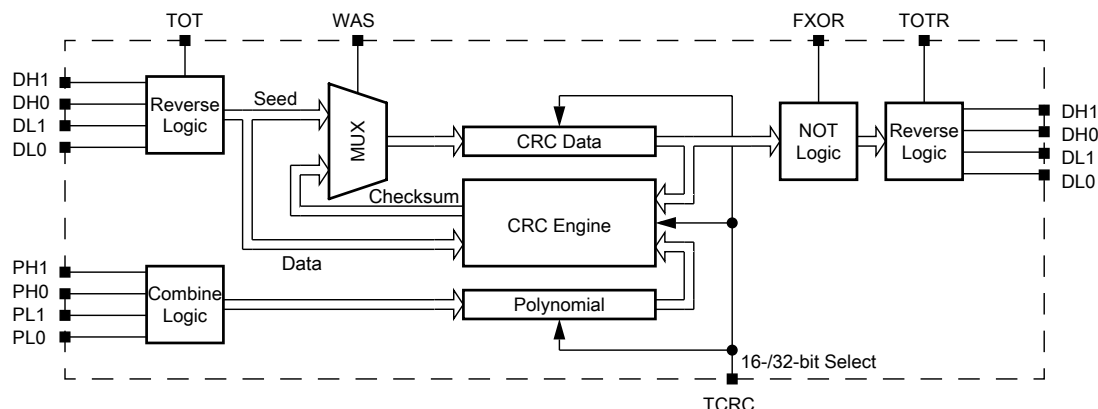

Figure 10-84. Programmable cyclic redundancy check (CRC) block diagram

### 10.6.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

#### 10.6.1.3.1 Run mode

This is the basic mode of operation.

#### 10.6.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

## 10.6.2 Memory map and register descriptions

### CRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
4003_3000	CRC Data register (CRC_DATA)	32	R/W	FFFF_FFFFh	<a href="#">10.6.2.1/1891</a>
4003_3004	CRC Polynomial register (CRC_GPOLY)	32	R/W	0000_1021h	<a href="#">10.6.2.2/1892</a>
4003_3008	CRC Control register (CRC_CTRL)	32	R/W	0000_0000h	<a href="#">10.6.2.3/1893</a>

## CRC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	CRC Data register: High 1 (CRC_DH1)	8	R/W	FFh	<a href="#">10.6.2.1/1894</a>
1	CRC Data register: High 0 (CRC_DH0)	8	R/W	FFh	<a href="#">10.6.2.2/1895</a>
2	CRC Data register: Low 1 (CRC_DL1)	8	R/W	FFh	<a href="#">10.6.2.3/1895</a>
3	CRC Data register: Low 0 (CRC_DL0)	8	R/W	FFh	<a href="#">10.6.2.4/1896</a>
4	CRC Polynomial Register: High 1 (CRC_PH1)	8	R/W	00h	<a href="#">10.6.2.5/1897</a>
5	CRC Polynomial Register: High 0 (CRC_PH0)	8	R/W	00h	<a href="#">10.6.2.6/1897</a>
6	CRC Polynomial Register: Low 1 (CRC_PL1)	8	R/W	10h	<a href="#">10.6.2.7/1898</a>
7	CRC Polynomial Register: Low 0 (CRC_PL0)	8	R/W	21h	<a href="#">10.6.2.8/1898</a>
8	CRC Control register (CRC_CTRL)	8	R/W	00h	<a href="#">10.6.2.9/1899</a>

### 10.6.2.1 CRC Data register (CRC\_DATA)

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: 4003\_3000h base + 0h offset = 4003\_3000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**CRC\_DATA field descriptions**

Field	Description
31–24 HU	CRC High Upper Byte  In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23–16 HL	CRC High Lower Byte  In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15–8 LU	CRC Low Upper Byte  When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
LL	CRC Low Lower Byte  When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

**10.6.2.2 CRC Polynomial register (CRC\_GPOLY)**

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 4003\_3000h base + 4h offset = 4003\_3004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**CRC\_CTRL field descriptions**

Field	Description
31–30 Reserved	Reserved  This field is reserved. This read-only field is reserved and always has the value 0.
29–28 Reserved	Reserved  This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FXOR	Complement Read Of CRC Data Register  Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on the fly complementing of read data.  0 No XOR on reading. 1 Invert or complement the read value of the CRC Data register.
25 WAS	Write CRC Data Register As Seed  When asserted, a value written to the CRC data register is considered a seed value. When deasserted, a value written to the CRC data register is taken as data for CRC computation.  0 Writes to the CRC data register are data values. 1 Writes to the CRC data register are seed values.

*Table continues on the next page...*

**CRC\_CTRL field descriptions (continued)**

Field	Description
24 TCRC	Width of CRC protocol. 0 16-bit CRC protocol. 1 32-bit CRC protocol.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**10.6.2.1 CRC Data register: High 1 (CRC\_DH1)**

This section describes the function of CRC data registers (DH1:DH0:DL1:DL0). The set of CRC data registers contains the value of seed, data, and checksum. When CTRL[WAS] is set, any write to the data registers will be regarded as seed for CRC module. When CTRL[WAS] is de-asserted, any write to the data registers will be regarded as data for CRC module for general CRC computation.

When programming the seed value in 16-bit CRC mode, the DH1:DH0 are not used and reads to these registers returns an indeterminate value. For 32-bit CRC, all registers are used.

When programming data values for CRC calculation, data must be provided in DL0 register only. Writes to other bytes of data registers are ignored.

When final data written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in DL1:DL0. In 32-bit CRC mode, all registers are used. Reads to this register at any time returns the intermediate CRC value, provided CRC module is configured.

Address: 0h base + 0h offset = 0h

Read	DH1							
Write								
Reset	1	1	1	1	1	1	1	1

**CRC\_DH1 field descriptions**

Field	Description
DH1	CRC Data Bits 31:24

### 10.6.2.2 CRC Data register: High 0 (CRC\_DH0)

This section describes the function of CRC data registers (DH1:DH0:DL1:DL0). The set of CRC data registers contains the value of seed, data, and checksum. When CTRL[WAS] is set, any write to the data registers will be regarded as seed for CRC module. When CTRL[WAS] is de-asserted, any write to the data registers will be regarded as data for CRC module for general CRC computation.

When programming the seed value in 16-bit CRC mode, the DH1:DH0 are not used and reads to these registers returns an indeterminate value. For 32-bit CRC, all registers are used.

When programming data values for CRC calculation, data must be provided in DL0 register only. Writes to other bytes of data registers are ignored.

When final data written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in DL1:DL0. In 32-bit CRC mode, all registers are used. Reads to this register at any time returns the intermediate CRC value, provided CRC module is configured.

Address: 0h base + 1h offset = 1h

Bit	7	6	5	4	3	2	1	0
Read	DH0							
Write								
Reset	1	1	1	1	1	1	1	1

**CRC\_DH0 field descriptions**

Field	Description
DH0	CRC Data Bits 23:16

### 10.6.2.3 CRC Data register: Low 1 (CRC\_DL1)

This section describes the function of CRC data registers (DH1:DH0:DL1:DL0). The set of CRC data registers contains the value of seed, data, and checksum. When CTRL[WAS] is set, any write to the data registers will be regarded as seed for CRC module. When CTRL[WAS] is de-asserted, any write to the data registers will be regarded as data for CRC module for general CRC computation.

When programming the seed value in 16-bit CRC mode, the DH1:DH0 are not used and reads to these registers returns an indeterminate value. For 32-bit CRC, all registers are used.

When programming data values for CRC calculation, data must be provided in DL0 register only. Writes to other bytes of data regsiters are ignored.

When final data written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is avaiable in DL1:DL0. In 32-bit CRC mode, all registers are used. Reads to this register at any time returns the intermediate CRC value, provided CRC module is configured.

Address: 0h base + 2h offset = 2h

CRC\_DL1 field descriptions

Field	Description
DL1	CRC Data Bits 15:8

10.6.2.4 CRC Data register: Low 0 (CRC\_DL0)

This section describes the function of CRC data registers (DH1:DH0:DL1:DL0). The set of CRC data registers contains the value of seed, data, and checksum. When CTRL[WAS] is set, any write to the data registers will be regarded as seed for CRC module. When CTRL[WAS] is de-asserted, any write to the data registers will be regarded as data for CRC module for general CRC computation.

When programming the seed value in 16-bit CRC mode, the DH1:DH0 are not used and reads to these registers returns an indeterminate value. For 32-bit CRC, all registers are used.

When programming data values for CRC calculation, data must be provided in DL0 register only. Writes to other bytes of data regsiters are ignored.

When final data written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is avaiable in DL1:DL0. In 32-bit CRC mode, all registers are used. Reads to this register at any time returns the intermediate CRC value, provided CRC module is configured.

### 10.6.2.1 CRC Data register (CRC\_DATA)

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: 4003\_3000h base + 0h offset = 4003\_3000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### CRC\_DATA field descriptions

Field	Description
31–24 HU	CRC High Upper Byte  In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23–16 HL	CRC High Lower Byte  In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15–8 LU	CRC Low Upper Byte  When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
LL	CRC Low Lower Byte  When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

### 10.6.2.2 CRC Polynomial register (CRC\_GPOLY)

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 4003\_3000h base + 4h offset = 4003\_3004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CRC\_PH1 field descriptions

Field	Description
PH1	CRC Polynomial Bits 31:24

10.6.2.6 CRC Polynomial Register: High 0 (CRC\_PH0)

This set of registers contains the value of polynomial for the CRC calculation. The registers of PH1:PH0 contain the upper 16 bits of CRC polynomial, which are only used in 32-bit CRC mode. Writes to PH1:PH0 are ignored in 16-bit CRC mode. The registers of DL1:DL0 contain the lower 16-bits of CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 0h base + 5h offset = 5h

**CRC\_PH0 field descriptions**

Field	Description
PH0	CRC Polynomial Bits 23:16

**10.6.2.7 CRC Polynomial Register: Low 1 (CRC\_PL1)**

This set of registers contains the value of polynomial for the CRC calculation. The registers of PH1:PH0 contain the upper 16 bits of CRC polynomial, which are only used in 32-bit CRC mode. Writes to PH1:PH0 are ignored in 16-bit CRC mode. The registers of DL1:DL0 contain the lower 16-bits of CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 0h base + 6h offset = 6h

Bit	7	6	5	4	3	2	1	0
Read								
Write								
Reset	0	0	0	1	0	0	0	0

**CRC\_PL1 field descriptions**

Field	Description
PH1	CRC Polynomial Bits 15:8

**10.6.2.8 CRC Polynomial Register: Low 0 (CRC\_PL0)**

This set of registers contains the value of polynomial for the CRC calculation. The registers of PH1:PH0 contain the upper 16 bits of CRC polynomial, which are only used in 32-bit CRC mode. Writes to PH1:PH0 are ignored in 16-bit CRC mode. The registers of DL1:DL0 contain the lower 16-bits of CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 0h base + 7h offset = 7h

Bit	7	6	5	4	3	2	1	0
Read								
Write								
Reset	0	0	1	0	0	0	0	1

**CRC\_PL0 field descriptions**

Field	Description
PL0	CRC Polynomial Bits 7:0

10.6.2.9 CRC Control register (CRC\_CTRL)

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

Address: 0h base + 8h offset = 8h

Bit	7	6	5	4	3	2	1	0
Read	0		0		0	FXOR	WAS	TCRC
Write								
Reset	0	0	0	0	0	0	0	0

CRC\_CTRL field descriptions

Field	Description
7–6 Reserved	Reserved  This field is reserved. This read-only field is reserved and always has the value 0.
5–4 Reserved	Reserved  This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 FXOR	Complement Read Of CRC Data Register  Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on the fly complementing of read data.  0 No XOR on reading. 1 Invert or complement the read value of the CRC Data register.
1 WAS	Write CRC Data Register As Seed  When asserted, a value written to the CRC data register is considered a seed value. When deasserted, a value written to the CRC data register is taken as data for CRC computation.  0 Writes to the CRC data register are data values. 1 Writes to the CRC data register are seed values.
0 TCRC	Width of CRC protocol.  0 16-bit CRC protocol. 1 32-bit CRC protocol.

10.6.3 Functional description

### 10.6.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC\_CTRL[WAS], CRC\_PH1, CRC\_PH0, CRC\_PL1 and CRC\_PL0, and CRC result inversion in the applicable registers. Asserting CRC\_CTRL[WAS] enables the programming of the seed value into the CRC\_DH1, CRC\_DH0, CRC\_DL1 and CRC\_DL0 register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC\_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

### 10.6.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

#### 10.6.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CRC\_CTRL[TCRC] to enable 16-bit CRC mode.
2. Write a 16-bit polynomial to the CRC\_PL1 and CRC\_PL0. The CRC\_PH1 and CRC\_PH2 are not usable in 16-bit CRC mode.
3. Set CRC\_CTRL[WAS] to program the seed value.
4. Write a 16-bit seed to CRC\_DL1 and CRC\_DL0. CRC\_DH1 and CRC\_DH0 are not used.
5. Clear CRC\_CTRL[WAS] to start writing data values.
6. Write data values into CRC\_DL0. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC\_DL1 and CRC\_DL0.
7. When all values have been written, read the final CRC result from CRC\_DL1 and CRC\_DL0.

#### 10.6.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC\_CTRL[TCRC] to enable 32-bit CRC mode.
2. Write a 32-bit polynomial to CRC\_PH1, CRC\_PH0, CRC\_PL1 and CRC\_PL0.
3. Set CRC\_CTRL[WAS] to program the seed value.
4. Write a 32-bit seed to CRC\_DH1, CRC\_DH0, CRC\_DL1 and CRC\_DL0.
5. Clear CRC\_CTRL[WAS] to start writing data values.

6. Write data values into CRC\_DL0. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC\_DH1, CRC\_DH0, CRC\_DL1 and CRC\_DL0.
7. When all values have been written, read the final CRC result from CRC\_DH1, CRC\_DH0, CRC\_DL1 and CRC\_DL0. The CRC is calculated byte-wise, and two clocks are required to complete one CRC calculation.

### 10.6.3.3 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

# Chapter 11

## Connectivity

### 11.1 Universal Serial Bus Controller(USB)

#### 11.1.1 Overview

The USB controller block provides high performance USB functionality that complies with the USB 2.0 specification. It is a dual role device which can be configured to act as Host or Device through firmware interface. It is not a true OTG controller.

The USB controller consists of two independent dual role(host/device) USB controller cores. Each controller core has a UTMI interface and is connected to on-chip PHY. For a detailed description about the features, please refer to [Features](#). It is used as both a downstream and upstream port.

The following figure is a block diagram of USB.

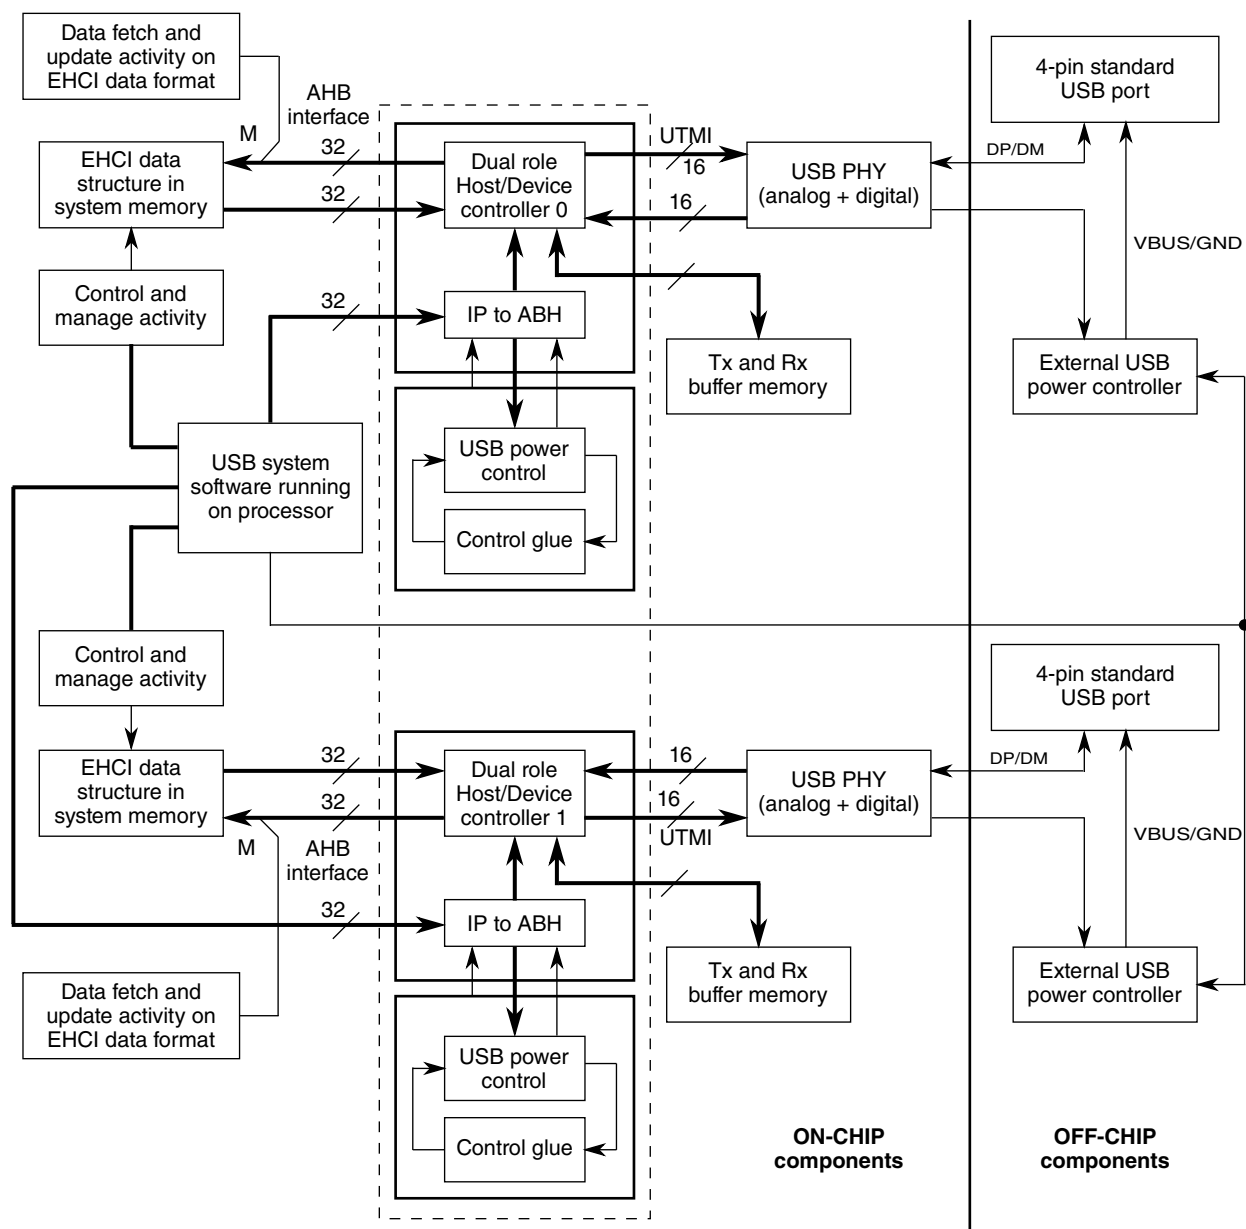

Figure 11-1. USB block diagram

## 11.1.2 Features

The USB includes the following features:

- Low-power mode with local and remote wake-up capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
- Embedded DMA controller.

### 11.1.2.1 Ports

These are detailed list of Ports on each USB devices on VFxxx Controller:

- USB\_DCAP — Common for both of the controller. Connected are two 1.1 pf cap on them.
- USB<sub>x</sub>\_DM — Connect directly to USB four pin connectors DM pin.
- USB<sub>x</sub>\_DP — Connect directly to USB connectors DP pin.
- USB<sub>x</sub>\_GND — Connect directly to USB connectors GND pin also, connect it to ground of board.
- USB<sub>x</sub>\_VBUS — Connect to external power controller.
  - If USB is configured as:
    - Self powered device — The external power controller will drive it with 5 V supply.
    - Bus powered device — Connect it to VBUS of the connector.
    - Host — Connect to VBUS of connector. The external 5V power driver will power the VBUS pin.
- USB<sub>x</sub>\_VBUS\_DETECT — Always connected to connector VBUS.
- USB<sub>x</sub>\_VBUS\_EN — Will be connected to the enable input of the external power controller. This allows to enable the VBUS supply.
- USB<sub>x</sub>\_VBUS\_OC — Over-current indication connects to the flag output of the external power controller or switch. This is used in host mode to indicate a VBUS over-current condition.
- USB<sub>x</sub>\_SOF\_PULSE — Can be used to configure sample rate to any of external audio/video sampler to match rate with current USB bus speed.

#### 11.1.2.1.1 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode. Each USB controller core can be configured for High Speed operation (480 Mbps), Full Speed operation (12Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

#### 11.1.2.1.2 Normal Mode

The USB controller can be configured to work in either Host mode or Device (Peripheral mode).

The USB is not a true OTG. It can be configured by software to function either as peripheral or as host. The ID pin, which is unique for OTG operation, is not present in this implementation. There are no five pin interface. The user will get four pin host/device interface.

### **11.1.2.1.3 Low Power Mode**

Each USB PHY has a low power mode (Low power Suspend Mode) to reduce power consumption. It can be entered by setting bit "PHCD" in USB\_PORTSC1 register. This bit must only be set after the bus is in suspend state. When operating as host, software can set the SUSP bit in the PORTC1 register to suspend the bus. When operating in peripheral mode, the controller will automatically enter suspend mode when the bus has been idle for 3 ms. At that time, software can enable the low-power suspend feature in the PHY.

Either the local ARM platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For detail about Suspend/Resume, please see [USB Power Control Block](#).

## **11.1.3 Non-core Registers**

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers. These registers are implementation specific. The registers and the bit mapping may vary across different devices.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to [Register Interface](#).

### **NOTE**

For reserved bits, please preserve the value when writing (read its reset value, then write this value back).

"USB" prefix in register name indicates it is a core register for USB controller core.

"USBC" prefix in register name indicates it is a USB non-core register.

### USBC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_4800	USB Control Register (USBC0_CTRL)	32	R/W	0000_3000h	<a href="#">11.1.3.1/1916</a>
4003_4818	UTMI PHY Control Register (USBC0_PHY)	32	R/W	0000_0000h	<a href="#">11.1.3.2/1919</a>
400B_4800	USB Control Register (USBC1_CTRL)	32	R/W	0000_3000h	<a href="#">11.1.3.1/1916</a>
400B_4818	UTMI PHY Control Register (USBC1_PHY)	32	R/W	0000_0000h	<a href="#">11.1.3.2/1919</a>

11.1.3.1 USB Control Register (USBCx\_CTRL)

The USB control register controls features that are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: Base address + 800h offset

USBCx\_CTRL field descriptions

Field	Description
31 WIR	USB Wake-up Interrupt Request  This bit indicates that a wake-up interrupt request is received on the USB port. This bit is cleared by disabling the wake-up interrupt (clearing bit "WIE").  1 Wake-up Interrupt Request received 0 No wake-up interrupt request received

Table continues on the next page...

**USBCx\_CTRL field descriptions (continued)**

Field	Description
30–26 Reserved	This field is reserved.
25 VBUS_CH_INT_MASK	When this bit is set, generation of VBUS_EN_INTR is masked. 0 VBUS_EN_INTR not masked 1 VBUS_EN_INTR masked
24 VBUS_CH_STAT	This bit is set by host controller whenever Port Power Enable/Disable event occurs. 0 No Change in Port Power 1 Change in Port Power Control
23–18 Reserved	This field is reserved.
17 WKUP_VBUS_EN	Wake-up on VBUS change enable 1 Enable 0 Disable
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 WKUP_SW	USB Core Software Wake-up 1 Force wake-up 0 Inactive
14 WKUP_SW_EN	USB Core Software Wake-up Enable 1 Enable 0 Disable
13 UTMI_ON_CLOCK	Force USB Core UTMI PHY clock output on even if suspend mode. 1 Force clock output on 0 Inactive
12 SUSPENDM	Force OTG UTMI PHY Suspend This bit is used to force PHY into low-power mode. During normal operation, software should set bit PHCD, after the bus is suspended, in USB core register PORTSC1 to put PHY into low-power mode. For Freescale test only. 1 Inactive 0 Force OTG UTMI PHY Suspend
11 RESET	Force USB UTMI PHY Reset Not for use in normal operation. During normal operation, software should set USBCMD. RST bit to reset the UTMI PHY 1 Reset the PHY 0 Inactive
10 WIE	Wake-up Interrupt Enable This bit enables or disables the wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode

*Table continues on the next page...*

**USBCx\_CTRL field descriptions (continued)**

Field	Description
	1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	USB Power Polarity  This bit should be set according to power switch's enable polarity.  1 Power switch has an active-high enable input 0 Power switch has an active-low enable input
8 OVER_CUR_POL	USB Polarity of Overcurrent  1 Low active 0 High active
7 OVER_CUR_DIS	Disable USB Overcurrent Detection  1 Disables overcurrent detection 0 Enables overcurrent detection
Reserved	This field is reserved. Reserved

### 11.1.3.2 UTMI PHY Control Register (USBCx\_PHY)

Address: Base address + 818h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	UTMI_CLK_VLD	0														
W	w1c

\* Notes:

- The reset value depends on the implementation.

## USBx\_HWGENERAL field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10–9 SM	Serial interface mode capability  00 No Serial Engine, always use parallel signaling. 01 Serial Engine present, always use serial signaling for FS/LS. 10 Software programmable - Reset to use parallel signaling for FS/LS 11 Software programmable - Reset to use serial signaling for FS/LS
8–6 PHYM	Transceiver type  000 UTMI/UMTI+

Table continues on the next page...

**USBx\_HWGENERAL field descriptions (continued)**

Field	Description
	001 ULPI DDR 010 ULPI 011 Serial
5–4 PHYW	Data width of the transceiver connected to the controller core.  00 Reserved 01 16-bit wide data bus [30MHZ clock from the transciever] 10 Reserved 11 Reserved
-	This field is reserved. Reserved

**11.1.4.3 Host Hardware Parameters (USBx\_HWHOST)**

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												NPORT		HC	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

**USBx\_HWHOST field descriptions**

Field	Description
31–4 -	This field is reserved. Reserved
3–1 NPORT	The Number of downstream ports supported by the host controller is NPORT+1. As all two controller cores are single port, these bits are set to '000b'.
0 HC	Host Capable. Both controller cores support host operation mode.  1 Support host operation mode 0 Not support

### 11.1.4.4 Device Hardware Parameters (USBx\_HWDEVICE)

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved										DEVEP				DC	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

**USBx\_HWDEVICE field descriptions**

Field	Description
31–6 -	This field is reserved. Reserved
5–1 DEVEP	Device Endpoint Number OTG controller core has six Endpoints.
0 DC	Device Capable. 1 support device operation mode 0 not support

### 11.1.4.5 TX Buffer Hardware Parameters (USBx\_HWTXBUF)

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TXCHANADD								Reserved								TXBURST							
W																																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	0	1	1	0	0	0	0	0	1	0	0

**USBx\_HWTXBUF field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
23–16 TXCHANADD	TX Buffer size is: $(2^{\text{TXCHANADD}}) * 4$ Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For OTG controller core, there is one TX Buffer for each endpoint, so 6 TX buffers in total.
15–8 -	This field is reserved. Reserved

Table continues on the next page...

## USBx\_HWTXBUF field descriptions (continued)

Field	Description
TXBURST	Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST bits in USB core regisiter UOG_BURSTSIZE. Please see <a href="#">Programmable Burst Size (USB_BURSTSIZE)</a> .

## 11.1.4.6 RX Buffer Hardware Parameters (USBx\_HWRXBUF)

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																RXADD				RXBURST											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0	0	0	1	0	0

## USBx\_HWRXBUF field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 RXADD	Buffer total size for all receive endpoints is (2 <sup>RXADD</sup> ). RX Buffer size is: (2 <sup>RXADD</sup> ) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For OTG controller core, there is one RX Buffer, shared by 6 Endpoints.
RXBURST	Default burst size for memory to RX buffer transfer. This is reset value of RXPBURST bits in USB core regisiter UOG_BURSTSIZE. Please see <a href="#">Programmable Burst Size (USB_BURSTSIZE)</a> .

## 11.1.4.7 General Purpose Timer #0 Load (USBx\_GPTIMER0LD)

This register controls load value of the count timer in register n\_GPTIMER0CTRL.  
Please see [General Purpose Timer #0 Controller \(USB\\_GPTIMER0CTRL\)](#) .

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																GPTLD															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### USBx\_GPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value  These fields are loaded to GPTCNT bits when GPTRST bit is set '1b'.  This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7.  <b>NOTE:</b> Max value is 0xFFFFF or 16.777215 seconds.

#### 11.1.4.8 General Purpose Timer #0 Controller (USBx\_GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n\_USBSTS register (See [USB Status Register \(USB\\_USBSTS\)](#) ), interrupt enable bit is TIE0 bit in n\_USBINTR register. (See [Interrupt Enable Register \(USB\\_USBINTR\)](#) .)

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	GPTRUN	GPTRST	Reserved						GPTCNT							
W	GPTRUN	GPTRST

**USBx\_SBUSCFG field descriptions**

Field	Description
31–3 -	This field is reserved. Reserved
AHBBRST	AHB master interface Burst configuration These bits controls AHB master transfer type sequence (or priority). <b>NOTE:</b> This register overrides n_BURSTSIZE register when its value is not zero.  000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

11.1.4.12 Capability Register Length (USBx\_CAPLENGTH)

The following figure shows Capability Register Length (CAPLENGTH) which indicates the offset that should be added to the register base address at the beginning of the Operational Register.

USBx\_CAPLENGTH field descriptions

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

11.1.4.13 Host Controller Interface Version (USBx\_HCIVERSION)

The following figure shows the Host Interface version number (HCIVERSION), which is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

USBx\_HCIVERSION field descriptions

Field	Description
HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

### 11.1.4.14 Host Controller Structural Parameters (USBx\_HCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (HCSPARAMS).

Address: Base address + 104h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				N_TT				N_PTT				Reserved			PI
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	N_CC				N_PCC				Reserved			PPC	N_PORTS			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

#### USBx\_HCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR)
15–12 N_CC	Number of Companion Controller (N_CC). These bits are '0000b' in both the controller cores. 0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.
11–8 N_PCC	Number of Ports per Companion Controller

Table continues on the next page...

### USBx\_HCSPARAMS field descriptions (continued)

Field	Description
	For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC.
7–5 -	This field is reserved. Reserved
4 PPC	Port Power Control  This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register.  Valid values are in the range of 1h to Fh. A zero in this field is undefined.  These bits are always set to '0001b' because both the controller cores are Single-Port Host.

#### 11.1.4.15 Host Controller Capability Parameters (USBx\_HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: Base address + 108h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### USBx\_HCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer. These bits are set '00h' in both the controller cores.

*Table continues on the next page...*

USBx\_HCCPARAMS field descriptions (continued)

Field	Description
7–4 IST	Isochronous Scheduling Threshold. These bits are set '00h' in both the controller cores.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 ASP	Asynchronous Schedule Park Capability This bit is set '1b' in both the controller cores.
1 PFL	Programmable Frame List Flag If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.
0 ADC	64-bit Addressing Capability

11.1.4.16 Device Controller Interface Version (USBx\_DCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: Base address + 120h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	DCIVERSION															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

USBx\_DCIVERSION field descriptions

Field	Description
DCIVERSION	Device Controller Interface Version Number Default value is '01h', which means rev0.1.

11.1.4.17 Device Controller Capability Parameters (USBx\_DCCPARAMS)

These fields describe the overall device capability of the controller.

Address: Base address + 124h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved

## USBx\_USBCMD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	<p>Interrupt Threshold Control -Read/Write.</p> <p>The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below.</p> <p>Value Maximum Interrupt Interval</p> <p>0x00 Immediate (no threshold)</p> <p>0x01 1 micro-frame</p> <p>0x02 2 micro-frames</p> <p>0x04 4 micro-frames</p> <p>0x08 8 micro-frames</p> <p>0x10 16 micro-frames</p> <p>0x20 32 micro-frames</p> <p>0x40 64 micro-frames</p>
15 FS2	<p>See also bits 3-2</p> <p>Frame List Size - (Read/Write or Read Only). [host mode only]</p> <p>This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one.</p> <p>This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index.</p> <p><b>NOTE:</b> This field is made up from USBCMD bits 15, 3 and 2.</p>

Table continues on the next page...

## USBx\_USBCMD field descriptions (continued)

Field	Description
	<p>Value Meaning</p> <p>000 1024 elements (4096 bytes) Default value</p> <p>001 512 elements (2048 bytes)</p> <p>010 256 elements (1024 bytes)</p> <p>011 128 elements (512 bytes)</p> <p>100 64 elements (256 bytes)</p> <p>101 32 elements (128 bytes)</p> <p>110 16 elements (64 bytes)</p> <p>111 8 elements (32 bytes)</p>
14 ATDTW	<p>Add dTD TripWire - Read/Write. [device mode only]</p> <p>This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software.</p> <p>This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.</p>
13 SUTW	<p>Setup TripWire - Read/Write. [device mode only]</p> <p>This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see <a href="#">USB Device Mode (USB_USBMODE)</a> ) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software.</p> <p>This bit would also be cleared by hardware when a hazard detected.</p>
12 -	<p>This field is reserved.</p> <p>Reserved</p>
11 ASPE	<p>Asynchronous Schedule Park Mode Enable - Read/Write.</p> <p>If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled.</p> <p>This field is set to '1b' in this implementation.</p>
10 -	<p>This field is reserved.</p> <p>Reserved</p>
9–8 ASP	<p>Asynchronous Schedule Park Mode Count - Read/Write.</p> <p>If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when <i>Park Mode Enable</i> is a one as this will result in undefined behavior.</p> <p>This field is set to 3h in all 4 controller core.</p>
7 -	<p>This field is reserved.</p> <p>Reserved</p>
6 IAA	<p>Interrupt on Async Advance Doorbell - Read/Write.</p> <p>This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell.</p>

Table continues on the next page...

## USBx\_USBCMD field descriptions (continued)

Field	Description
	<p>When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold.</p> <p>The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results.</p> <p>This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.</p>
5 ASE	<p>Asynchronous Schedule Enable - Read/Write. Default 0b.</p> <p>This bit controls whether the host controller skips processing the Asynchronous Schedule.</p> <p>Only the host controller uses this bit.</p> <p>Values Meaning</p> <p>0 Do not process the Asynchronous Schedule.</p> <p>1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.</p>
4 PSE	<p>Periodic Schedule Enable- Read/Write. Default 0b.</p> <p>This bit controls whether the host controller skips processing the Periodic Schedule.</p> <p>Only the host controller uses this bit.</p> <p>Values Meaning</p> <p>0 Do not process the Periodic Schedule</p> <p>1 Use the PERIODICLISTBASE register to access the Periodic Schedule.</p>
3-2 FS1	See description at bit 15
1 RST	<p>Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register.</p> <p>Host operation mode:</p> <p>When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior.</p> <p>Device operation mode:</p> <p>When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.</p>
0 RS	<p>Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop.</p> <p>Host operation mode:</p> <p>When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one).</p>

*Table continues on the next page...*

**USBx\_USBCMD field descriptions (continued)**

Field	Description
	<p>Device operation mode:</p> <p>Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.</p>

11.1.4.19 USB Status Register (USBx\_USBSTS)

This register indicates various states of the Host/Device controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: Base address + 144h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBx\_USBSTS field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–20 -	This field is reserved. Reserved
19 UPI	USB Host Periodic Interrupt This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero.
18 UAI	USB Host Asynchronous Interrupt This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the asynchronous schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes.

*Table continues on the next page...*

## USBx\_USBSTS field descriptions (continued)

Field	Description
	This bit is not used by the device controller and will always be zero.
17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO.  This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only.  This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0).  Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.  This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).  Only used in the host operation mode.
13 RCL	Reclamation - Read Only.  This is a read-only status bit used to detect an empty asynchronous schedule.  Only used in the host operation mode.
12 HCH	HCHalted - Read Only.  This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error).  Only used in the host operation mode.  Default value is '0b' for OTG core.  This is because OTG core is not operating as host in default. Please see CM bit in UOG_USBMODE register.
11 -	This field is reserved. Reserved
10 ULPII	ULPI Interrupt - R/WC.  This bit will be set '1b' by hardware when there is an event completion in ULPI viewport.  This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLI	DCSuspend - R/WC.  When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state.  Only used in device operation mode.

*Table continues on the next page...*

## USBx\_USBSTS field descriptions (continued)

Field	Description
7 SRI	<p>SOF Received - R/WC.</p> <p>When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received.</p> <p>Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.</p> <p>In host mode, this bit will be set every 125us and can be used by host controller driver as a time base.</p> <p>Software writes a 1 to this bit to clear it.</p>
6 URI	<p>USB Reset Received - R/WC.</p> <p>When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit.</p> <p>Only used in device operation mode.</p>
5 AAI	<p>Interrupt on Async Advance - R/WC.</p> <p>System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source.</p> <p>Only used in host operation mode.</p>
4 SEI	<p>System Error- R/WC.</p> <p>This bit is will be set to '1b' when an Error response is seen on the system interface. In general, this will happen when pointers to data structures or pointers to data are pointing to invalid memory.</p> <p>This bit is only used in host mode.</p>
3 FRI	<p>Frame List Rollover - R/WC.</p> <p>The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the UOG_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles.</p> <p>Only used in host operation mode.</p>
2 PCI	<p>Port Change Detect - R/WC.</p> <p>The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.</p> <p>The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.</p>
1 UEI	<p>USB Error Interrupt (USBERRINT) - R/WC.</p> <p>When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set</p> <p>The device controller detects resume signaling only.</p>
0 UI	<p>USB Interrupt (USBINT) - R/WC.</p>

Table continues on the next page...

**USBx\_USBSTS field descriptions (continued)**

Field	Description
	<p>This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.</p> <p>This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.</p>

**11.1.4.20 Interrupt Enable Register (USBx\_USBINTR)**

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n\_USBSTS) still shows interrupt sources even if they are disabled by the n\_USBINTR register, allowing polling of interrupt events by the software.

Table continues on the next page...

**USBx\_USBINTR field descriptions (continued)**

Field	Description
25 TIE1	General Purpose Timer #1 Interrupt Enable When this bit is one and the TI1 bit in n_USBSTS register is a one the controller will issue an interrupt.
24 TIE0	General Purpose Timer #0 Interrupt Enable When this bit is one and the TI0 bit in n_USBSTS register is a one the controller will issue an interrupt.
23–20 -	This field is reserved. Reserved
19 UPIE	USB Host Periodic Interrupt Enable When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable This bit is usable only if the controller supports UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_UOG_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.

*Table continues on the next page...*

**USBx\_USBINTR field descriptions (continued)**

Field	Description
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enalbe When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

**11.1.4.21 USB Frame Index (USBx\_FRINDEX)**

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n\_USBCMD register.

This register must be written as a DWord. Byte writes produce-undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### USBx\_DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0.  When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register.  Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0).  <b>NOTE:</b> After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

### 11.1.4.24 Next Asynch. Address (USBx\_ASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: Base address + 158h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### USBx\_BURSTSIZE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

### 11.1.4.27 TX FIFO Fill Tuning (USBx\_TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

$T_0$  = Standard packet overhead

$T_1$  = Time to send data payload

$T_{ff}$  = Time to fetch packet into TX FIFO up to specified level.

$T_s$  = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

$T_p$  = Total Packet Time (fetch and send) packet

$$T_p = T_{ff} + T_0 + T_1$$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure  $T_p$  remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is  $< T_s$  then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the  $n\_TSCHEALTH$  ( $T_{ff}$ ) described below.

Address: Base address + 164h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USBx\_TXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write)  This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in UOG_USBMODE register is set.  Default value is '00h' for OTG controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear)  This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.  Default value is '08h' for OTG controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0]  This register adds an additional fixed offset to the schedule time estimator described above as $T_{ff}$ . As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for

Field	Description
21–16 EPTNE[5:0]	TX Endpoint NAK Enable - R/W.  Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set.  Bit [N] - Endpoint #[N], N is 0-5
15–6 -	This field is reserved. Reserved
EPRNE[5:0]	RX Endpoint NAK Enable - R/W.  Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set.  Bit [N] - Endpoint #[N], N is 0-5

**11.1.4.30 Port Status & Control (USBx\_PORTSC1)****Host Controller**

A host controller could implement one to eight port status and control registers. The number is determined by N\_PORTS bits in HWSPARAMs register (please see [Host Controller Structural Parameters \(USB\\_HCSPARAMS\)](#) ). Software could read this parameter register to determine how many ports need service.

Both the controller cores are Single-Port Host, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

**Device Controller**

A device controller has only port register one (PORTSC1) and it does not support power control. Port control in device mode is only used for status port reset, suspend, resume, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

## Core Registers

Table continues on the next page...

## USBx\_PORTSC1 field descriptions (continued)

Field	Description
	00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Always = 0.  This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port.  Port owner handoff is not supported, therefore this bit will always be 0.
12 PP	Port Power (PP)-Read/Write or Read Only.  The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows:  PPC PP Operation  0 1b Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.  1 1b/0b - Read/Write. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.  When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port).  This feature is implemented in both the controller cores (PPC = 1).
11–10 LS[1:0]	Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines.  In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS.  In device mode, the use of linestate by the device controller driver is not necessary.  The encoding of the bits are:  Bits [11:10] Meaning  00 SE0 10 J-state 01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b.  When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode.  <b>NOTE:</b> HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b.  In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0.

Table continues on the next page...

## USBx\_PORTSC1 field descriptions (continued)

Field	Description
	<p>When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. <i>This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.</i></p> <p>In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero.</p>
7 SUSP	<p>Suspend - Read/Write or Read Only. Default = 0b.</p> <p>1=Port in suspend state. 0=Port not in suspend state.</p> <p>In Host Mode: Read/Write.</p> <p>Port Enabled Bit and Suspend bit of this register define the port states as follows:</p> <p>Bits [Port Enabled, Suspend] Port State</p> <p>0x Disable</p> <p>10 Enable</p> <p>11 Suspend</p> <p>When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress.</p> <p>The host controller will unconditionally set this bit to zero when software sets the <i>Force Port Resume</i> bit to zero. The host controller ignores a write of zero to this bit.</p> <p>If host software sets this bit to a one when the port is not enabled (that is, <i>Port enabled</i> bit is a zero) the results are undefined.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode: Read Only.</p> <p>In device mode this bit is a read only status bit.</p>
6 FPR	<p>Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0.</p> <p>In Host Mode:</p> <p>Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one. <i>This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.</i></p> <p>Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation and clear the bit when the port control state switches to HS or FS idle.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>This bit is not-EHCI compatible.</p> <p>In Device mode:</p>

Table continues on the next page...

## USBx\_PORTSC1 field descriptions (continued)

Field	Description
	After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0.  This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0.  This bit will automatically transition from one to zero when the over current condition is removed.  1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0.  In Host Mode:  For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it.  This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_PORTSC1)</a> ) is zero.  In Device mode:  The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0.  In Host Mode:  Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events.  When the port is disabled, (0b) downstream propagation of data is blocked except for reset.  This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_PORTSC1)</a> ) is zero in host mode.  In Device Mode:  The device port is always enabled, so this bit is always '1b'.
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0.  In Host Mode:  Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it.  This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_PORTSC1)</a> ) is zero in host mode.  In Device Mode:  This bit is undefined in device controller mode.

Table continues on the next page...

## USBx\_PORTSC1 field descriptions (continued)

Field	Description
0 CCS	<p>Current Connect Status-Read Only.</p> <p>In Host Mode:</p> <p>1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the <i>Connect Status Change</i> bit (Bit 1) to be set.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode:</p> <p>1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.</p>

## 11.1.4.31 On-The-Go Status &amp; control (USBx\_OTGSC)

It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status input register, or cause an OTG interrupt.

See also [USB Device Mode \(USB\\_USBMODE\)](#) register.

### USBx\_OTGSC field descriptions

Field	Description
31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 1MSSE	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 1MSS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC).

Table continues on the next page...

**USBx\_OTGSC field descriptions (continued)**

Field	Description
	Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 1msT	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7-6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## USBx\_OTGSC field descriptions (continued)

Field	Description
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

## 11.1.4.32 USB Device Mode (USBx\_USBMODE)

Address: Base address + 1A8h offset

15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active)  Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.

Table continues on the next page...

## USBx\_USBMODE field descriptions (continued)

Field	Description
	<p>Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB.</p> <p><b>NOTE:</b> Time duration to pre-fill the FIFO becomes significant when stream disable is active. See <a href="#">TX FIFO Fill Tuning (USB_TXFILLTUNING)</a> and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.</p> <p><b>NOTE:</b> The use of this feature substantially limits of the overall USB performance that can be achieved.</p>
3 SLOM	<p>Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See <a href="#">Control Endpoint Operation Model</a> .</p> <p>0 Setup Lockouts On (default);</p> <p>1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in <a href="#">USB Command Register (USB_USBCMD)</a> .</p>
2 ES	<p>Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The field in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word.</p> <p>Bit Meaning</p> <p>0 Little Endian [Default]</p> <p>1 Big Endian</p>
CM	<p>Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host &amp; device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the <i>RESET</i> bit in the USBCMD register before reprogramming this register.</p> <p>For OTG controller core, reset value is '10b'.</p> <p>Bit Meaning</p> <p>00 Idle [Default for combination host/device]</p> <p>01 Reserved</p> <p>10 Device Controller [Default for device only controller]</p> <p>11 Host Controller [Default for host only controller]</p>

## 11.1.4.33 Endpoint Setup Status (USBx\_ENDPTSETUPSTAT)

Address: Base address + 1ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

19–18 TXT	TX Endpoint Type - Read/Write 00 - Control Endpoint0 is fixed as a Control End Point.
17 -	This field is reserved. Reserved
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK [Default] 1 End Point Stalled  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
6–4 -	This field is reserved. Reserved
3–2 RXT	RX Endpoint Type - Read/Write 00 Control Endpoint0 is fixed as a Control End Point.
1 -	This field is reserved. Reserved
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.

**11.1.4.39 Endpoint Controln (USBx\_ENDPTCTRLn)**

There is a UOG\_ENDPTCTRLx register for each endpoint in a device.

**NOTE**

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is bulk, isochronous, or interrupt-types). Leaving an

unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: Base address + 1C4h offset + (4d × i), where i=0d to 4d

### USBx\_ENDPTCTRLn field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23 TXE	TX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
22 TXR	TX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
21 TXI	TX Data Toggle Inhibit 0 PID Sequencing Enabled. [Default] 1 PID Sequencing Disabled. This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.
20 -	This field is reserved. Reserved

Table continues on the next page...

## USBx\_ENDPTCTRLn field descriptions (continued)

Field	Description
19–18 TXT	TX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX Endpoint Data Source - Read/Write 0 Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK 1 End Point Stalled  This bit is set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It is cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint.  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues to returning STALL until this bit is either cleared by software or automatically cleared as above.  <b>NOTE:</b> For CONTROL type endpoint, there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. Take care that the STALL bit is not set immediately after writing a '1' to it. Please follow this procedure: continually write this STALL bit until it is set or until a new setup has been received by checking the associated ENDPTSETUPSTAT bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled  An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence  Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled  This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 -	This field is reserved. Reserved.
3–2 RXT	RX Endpoint Type - Read/Write 00 Control

*Table continues on the next page...*

**USBx\_ENDPTCTRLn field descriptions (continued)**

Field	Description
	01 Isochronous 10 Bulk 11 Reserved
1 RXD	RX Endpoint Data Sink - Read/Write - TBD 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled  This bit is set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It is cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint,  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues to returning STALL until this bit is either cleared by software or automatically cleared as above.

### 11.1.5 Functional description

These sections describe the functionality of the various building blocks of the USB.

#### 11.1.5.1 USB dual role device/host controller

The USB Dual Role controller is an EHCI-compatible USB core which supports High Speed / Full Speed / Low Speed operation.

The USB controller core supports HS/FS/LS operation in Host mode and HS/FS operation in device mode.

##### 11.1.5.1.1 Host mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

##### 11.1.5.1.2 Peripheral (Device) Mode

- Up to 6 bidirectional endpoints

- High/Full speed operation
- Remote wake-up capable

### 11.1.5.2 USB Power Control Block

The USB controller supports low-power suspend and wake-up functionality. The power control block allows for placing the transceiver in low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of low power mode when needed. Additionally, the power control block can wake-up the ARM platform from sleep mode by generating an interrupt.

#### 11.1.5.2.1 Entering Low Power Suspend mode

Low Power Suspend mode is always entered under the control of the driver software by setting the appropriate bit in USB core register PORTSC1. Once the controller is suspended, the clocks to the USB can be stopped.

#### NOTE

For Suspend-Resume, USB PLL must be kept on for the respective USB controllers.

#### 11.1.5.2.2 Wake-up events

The power control block monitors the USB bus when the USB core is in the suspend state. Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) can be generated to ARM platform if related wake-up interrupt enable bit is set. This interrupt also re-activates the ARM platform clocks if they were stopped during the suspend.

##### 11.1.5.2.2.1 Host mode events

The Host controller wakes-up on the following events:

- Remote wake-up request

A peripheral can request the host to re-activate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when J-K transition on DM/DP line is detected.

- Wake-up on overcurrent

If wake-up on overcurrent is enabled (WKOC bit in USB core register PORTSC1 is set to 1), the power control block sends a wake-up request to the USB core when over-current event is detected.

- Wake-up on disconnect

If wake-up on disconnection is enabled (WKDC bit in USB core register PORTSC1 is set to 1), the power control block sends a wake-up request to the USB core when disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-up on connect

If wake-up on connection is enabled (WKCEN bit in USB core register PORTSC1 is set to 1), the power control sub-block sends a wake-up request to the USB core when connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, and WKCEN, please see [Port Status & Control \(USB\\_PORTSC1\)](#).

#### 11.1.5.2.2.2 Device mode events

When the OTG controller is configured for peripheral operation, the power control block sends a wake-up request to the USB core when any non-IDLE state is detected on the USB bus.

#### NOTE

Wake Up from USB needs following configuration:

1. REFTOP inside ANADIG must be ON in stop mode (required for Device Mode).
  - If ANATOP\_STOP\_MODE is used for stop mode (ANATOP\_STOP\_MODE bit is set in CCM Low Power Control Register), then 'stop\_mode\_config bit' in "ANADIG\_ANA\_MISC0" register inside ANADIG must be set to '1'.
  - If ANATOP\_STOP\_MODE is NOT used for stop mode, then keep "reftop\_pwd" bit to '0' in "anadig\_anamisc0" register inside ANADIG.
2. Either Main Regulator OR Weak Regulator (1P1 & 2P5) must be ON in stop mode.

- If ANATOP\_STOP\_MODE is used for stop mode (ANATOP\_STOP\_MODE bit is set in CCM Low Power Control Register), then “enable\_weak\_linreg” bit in “anadig\_reg2p5” register inside ANADIG must be set to ‘1’.
- If ANATOP\_STOP\_MODE is NOT used for stop mode, then either enable Weak Regulators 1P1 & 2P5 (set “enable\_weaklinreg” bit in “anadig\_reg2p5” register inside ANADIG) or enable Main regulators 1P1 & 2P5 (set “enable\_linreg” bit in “anadig\_reg1p1” & “anadig\_reg1p1” registers inside ANADIG). To reduce power consumption in stop mode, main regulators are turned off, and weak regulators are turned on to support wake-up from USB.

### 11.1.5.3 Interrupts

#### 11.1.5.3.1 USB core interrupts

Each USB core uses one dedicated vector in the interrupt table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB cores. Refer to the [Interrupt Enable Register \(USB\\_USBINTR\)](#) for details.

#### 11.1.5.3.2 USB wake-up interrupts

Each USB core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but use the same vector as the corresponding USB controller cores' interrupt. These interrupts are generated by the Power Control blocks, which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and ARM platform clocks are disabled, such that a wake-up condition on the USB bus can reactivate the ARM platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the ARM platform clock. The software should then wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow

sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

## 11.1.6 USB operation model

This section describes the detailed application knowledge for OTG ports. It can be generally divided in two parts, one for Host and the other for Device. The Host part applies to the OTG ports when operating in Host mode. The Device part applies to the OTG ports when operating in Device mode.

### 11.1.6.1 Register interface

Slave accesses from the controlling processor enables access to the configuration, control, and status registers. One function of the system address map is the registers base address, which must begin on a 32-bit boundary. Register offset definitions are listed in the table below.

Configuration, control and status registers are divided into three categories: identification, capability, and operational registers.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read-only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are comprised of dynamic control or status registers that may be read only, read/write, or read/write to clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

[Table 11-1](#) describes the interface register sets.

**Table 11-1. Interface register sets**

Offset	Register Set	Explanation
000h-07Ch	Identification registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation.  These values are used as parameters to the host/device controller driver.

*Table continues on the next page...*

**Table 11-1. Interface register sets (continued)**

080h-0FCh 140h-1FCh	Operational registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.
------------------------	-----------------------	---

### 11.1.6.1.1 Configuration, Control and Status Register Set

Table 11-2 describes the Device/Host capability registers.

**Table 11-2. Device/Host capability registers**

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_ID	Identification Register	O	O
004h	4	USB_HWGENERAL	General Hardware Parameters	O	O

### 11.1.6.1.2 Identification registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

### 11.1.6.2 Host data structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware). The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) support for the host controller interface. The asynchronous list is the root for all the bulk and control transfer type support. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

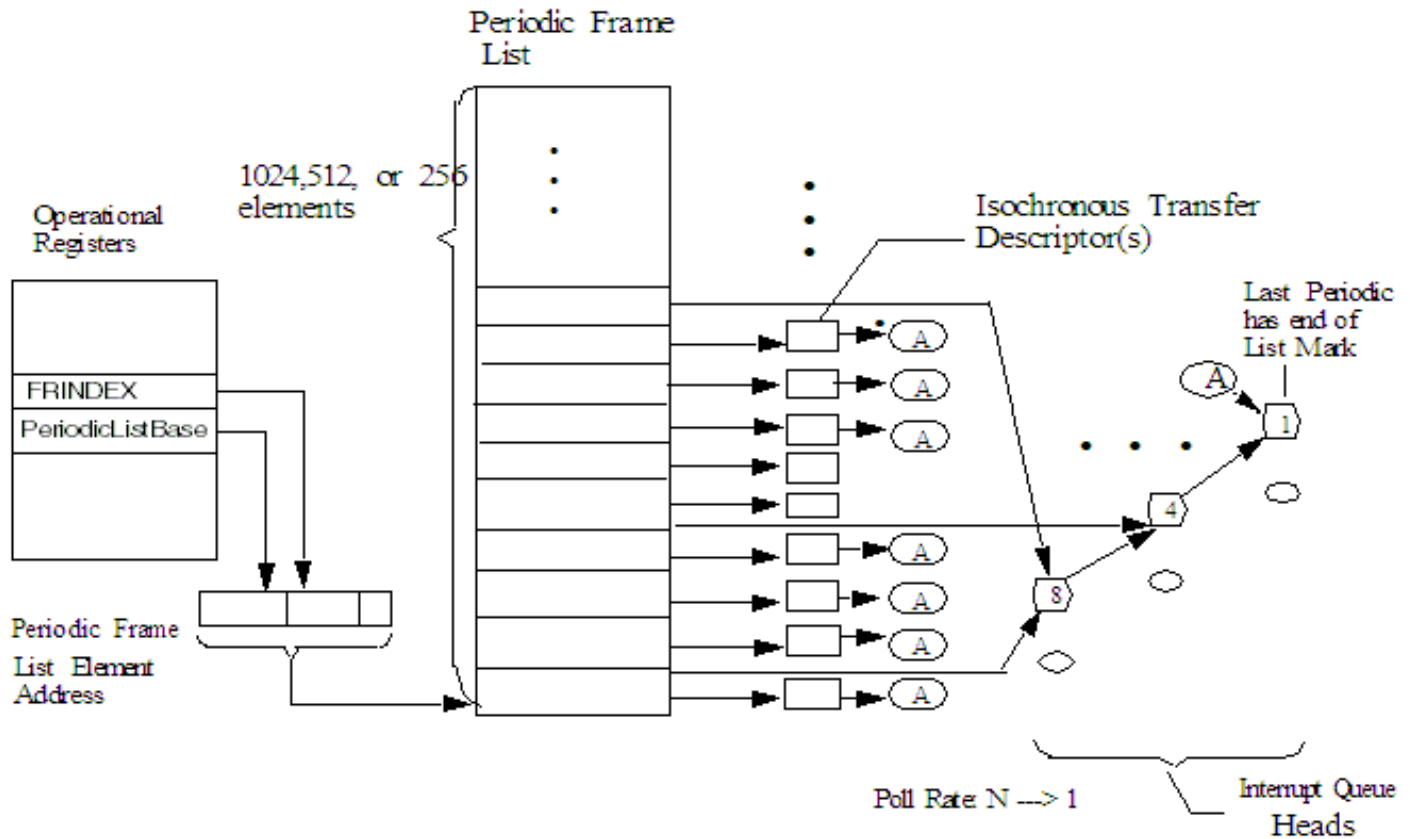

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

#### 11.1.6.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB\_PERIODICLISTBASE address register and the USB\_FRINDEX register. The periodic schedule is based on an array of pointers called the Periodic Frame List. The USB\_PERIODICLISTBASE address register is combined with the USB\_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

[Figure 11-2](#) shows the organization of periodic schedule.

**Figure 11-2. Periodic schedule organization**

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 KB page-aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB\_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB\_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

[Table 11-3](#) illustrates the format of the Frame list element pointer.

Table 11-3. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																												0	Typ			03-00H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 11-4. Typ field value definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor
11b	Frame Span Traversal Node

11.1.6.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB\_ASYNC\_LIST\_ADDR register) is where all the control and bulk transfers are managed. Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

**Figure 11-3. Asynchronous schedule organization**

The Asynchronous list is a simple circular list of queue heads. The USB\_ASYNC\_LIST\_ADDR register is simply pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

### 11.1.6.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in Table 11-5. This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

**Table 11-5. Isochronous Transaction Descriptor (iTD)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

--	----------------------------	--	----------------------------

These fields may be modified by the host controller if the I/O field indicates an OUT.

#### 11.1.6.2.3.1 Next Link Pointer-Host Data Structures

The first DWord of an iTD is a pointer to the next schedule data structure. [Table 11-6](#) describes the Next Schedule Element pointer field.

**Table 11-6. Next Schedule Element pointer**

Bit	Description
31-5	Link Pointer (LP). These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTd/siTd) or Queue Head (QH).
4-3	Reserved. These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1= Link Pointer field is not valid. 0= Link Pointer field is valid.

### 11.1.6.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status. Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the

Table 11-7 describes iTD Transaction Status and Control fields.

**Table 11-7. iTD Transaction Status and Control**

Bit	Description										
31-28	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:										
	<table> <tr> <th>Bit</th><th>Definition</th></tr> <tr> <td>31</td><td>Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.</td></tr> <tr> <td>30</td><td>Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, no action is necessary.</td></tr> <tr> <td>29</td><td>Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.</td></tr> <tr> <td>28</td><td>Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.</td></tr> </table>	Bit	Definition	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, no action is necessary.	29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
Bit	Definition										
31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.										
30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, no action is necessary.										
29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.										
28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.										
27-16	Transaction X Length. For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0±zero length data, 1±one byte, 2±two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).										
15	Interrupt On Complete (IOC). If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.										
14-12	Page Select (PG). These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.										
11-0	Transaction X Offset. This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.										

### 11.1.6.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous. Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) \* 1024 (maximum packet size) \* 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

Tables below illustrate the field descriptions.

**Table 11-8. iTD Buffer Pointer Page 0 (Plus)**

Bit	Description
31-12	Buffer Pointer (Page 0). This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit reserved for future use and should be initialized by software to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

**Table 11-9. iTD Buffer Pointer Page 1 (Plus)**

Bit	Description
31-12	Buffer Pointer (Page 1). This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0	Maximum Packet Size. This directly corresponds to the maximum packet size of the associated endpoint ( <i>wMaxPacketSize</i> ). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the <i>Multi</i> field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

**Table 11-10. iTD Buffer Pointer Page 2 (Plus)**

Bit	Description
31-12	Buffer Pointer. This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2	Reserved. This bit reserved for future use and should be set to zero.

*Table continues on the next page...*

**Table 11-10. iTD Buffer Pointer Page 2 (Plus) (continued)**

1-0	Multi. This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are:  Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame 10b Two transactions to be issued for this endpoint per micro- frame 11b Three transactions to be issued for this endpoint per micro- frame
-----	--

**Table 11-11. iTD Buffer Pointer Page 3-6**

Bit	Description
31-12	Buffer Pointer. This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0	Reserved. These bits reserved for future use and should be set to zero.

#### 11.1.6.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

Figure below shows the Split Transaction Isochronous Transfer Descriptor (siTD).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Host Controller Read/Write		Host Controller Read Only.
--	----------------------------	--	----------------------------

#### 11.1.6.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

Table 11-13 describes the Next Link Pointer fields.

**Table 11-13. Next Link Pointer**

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Link Pointer field is not valid. 0=Link Pointer is valid.

#### 11.1.6.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

Tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

**Table 11-14. Endpoint and Transaction Translator Characteristics**

Bit	Description
31	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

**Table 11-15. Micro-frame Schedule Control**

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the mFrame C-Mask field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the mFrame S-mask field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

#### 11.1.6.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer. [Table 11-16](#) describes siTD transfer state fields.

**Table 11-16. siTD Transfer Status and Control**

Bit	Description								
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.								
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the <i>CurrentOffset</i> field to construct a data buffer pointer (0 selects <i>Page 0</i> pointer and 1 selects <i>Page 1</i> ). The host controller is not required to write this field back when the siTD is retired ( <i>Active</i> bit transitioned from a one to a zero).								
29-26	Reserved. This field reserved for future use and should be set to zero.								
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)								
15-8	μFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.								
7-0	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:								
	<table> <tr> <th>Bit</th><th>Definition</th></tr> <tr> <td>7</td><td>Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.</td></tr> <tr> <td>6</td><td>ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.</td></tr> <tr> <td>5</td><td>Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overflow condition occurs, no action is necessary.</td></tr> </table>	Bit	Definition	7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.	6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overflow condition occurs, no action is necessary.
Bit	Definition								
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.								
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.								
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overflow condition occurs, no action is necessary.								

Table continues on the next page...

**Table 11-16. siTD Transfer Status and Control (continued)**

Bit	Description	
4		Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.
3		Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2		Missed Micro-Frame. The host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction.
1		Split Transaction State (SplitXstate). The bit encodings are:  Value Meaning  00b Do Start Split.  This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask.  01b Do Complete Split.  This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0		Reserved. Bit reserved for future use and should be set to zero.

#### 11.1.6.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. [Table 11-17](#) describes the siTD buffer pointer fields.

**Table 11-17. Buffer Page Pointer List (plus)**

Bit	Description	
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K paged aligned, physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field <i>P</i> specifies the <i>current</i> active pointer	
11-0	Page 0:  Current Offset. The 12 least significant bits of the Page 0 pointer is the current byte offset for the current page pointer (as selected with the page indicator bit ( <i>P</i> field)). The host controller is not required to write this field back when the siTD is retired ( <i>Active</i> bit transitioned from a one to a zero). The least significant bits of Page 1 pointer is split into three sub-fields  Page 1:	
	Bits	Description
	11-5	Reserved

*Table continues on the next page...*

**Table 11-17. Buffer Page Pointer List (plus) (continued)**

Bit	Description	
4-3		Transaction position (TP). This field is used with T-count to determine whether to send <i>all</i> , <i>first</i> , <i>middle</i> , or <i>last</i> with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are:  Value Meaning  00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full-speed that is greater than 188 bytes. 10b Mid. This is the <i>middle</i> payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the <i>last</i> payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0		Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

#### 11.1.6.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD. This pointer cannot reference any other schedule data structure.

[Table 11-18](#) describes the siTD back link pointer fields

**Table 11-18. siTD Back Link Pointer**

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

#### 11.1.6.2.5 Queue Element Transfer Descriptor (qTD)

This data structure is only used with a queue head. This data structure is used for one or more USB transactions. This data structure is used to transfer up to 20480 (5\*4096) bytes. The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. This structure is 32 bytes (or one 32-byte cache line). This data structure must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following field definitions of updates to the qTD are to the qTD portion of a queue head.

Table 11-19 shows the Queue head data structure.

**Table 11-19. Queue Head Data Structure**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Next qTD Pointer																												0				T	03-00H
Alternate Next qTD Pointer																												0				T	07-04H
dt	Total Bytes to Transfer														io c	C_Page	Cerr	PID Code	Status								0B-08H						
Buffer Pointer (page 0)																	Current Offset											0F-0CH					
Buffer Pointer (page 0)																	-											13-10H					
Buffer Pointer (page 0)																	-											17-14H					
Buffer Pointer (page 0)																	-											1B-18H					
Buffer Pointer (page 0)																	-											1F-1CH					

	Host Controller Read/Write		Host Controller Read Only.
--	----------------------------	--	----------------------------

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

### 11.1.6.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor. [Table 11-20](#) describes Next qTD pointer fields.

**Table 11-20. qTD Next Element Transfer Pointer (DWord 0)**

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

### 11.1.6.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next client buffer on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet. [Table 11-21](#) describes the TD Alternate Next Element Transfer Pointer field descriptions.

**Table 11-21. TD Alternate Next Element Transfer Pointer (DWord 1)**

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

### 11.1.6.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

#### NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

[Table 11-22](#) describes the TD Token fields.

Table 11-22. TD Token (DWord 2)

Bit	Description	
31	Data Toggle. This is the data toggle sequence bit. The use of this bit depends on the setting of the <i>Data Toggle Control</i> bit in the queue head.	
30-16	<p>Total Bytes to Transfer. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that <i>Total Bytes To Transfer</i> be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.</p> <p>Although it is possible to create a transfer up to 20K this assumes the 1<sup>st</sup> offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</p>	
15	Interrupt On Complete (IOC). If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12	Current Page (C_Page). This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.	
11-10	<p>Error Counter (CERR). This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the <i>Halted</i> bit to a one, and error status bit for the error that caused <i>CERR</i> to decrement to zero. An interrupt is generated if the <i>USB Error Interrupt Enable</i> bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.</p> <p>Error Decrement Counter Transaction Error Yes Data Buffer Error No<sup>3</sup> Stalled No<sup>1</sup> Babble Detected No<sup>1</sup> No Error No<sup>2</sup></p>	
	Error	Decrement Counter Error Decrement Counter
	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented
	2	<p>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</p> <p>See <a href="#">Split Transaction Interrupt</a> for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See <a href="#">Asynchronous - Do Complete Split</a> for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.</p>
	3	Data buffer errors are host problems. They don't count against the device's retries.
	<b>NOTE:</b> Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9-8	PID Code. This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)

Table continues on the next page...

Table 11-22. TD Token (DWord 2) (continued)

Bit	Description	
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, $\mu$ Frame S-mask field in
	11b	Reserved
7-0	Status. This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the <i>Halted</i> bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split- transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are:  Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
	0	Ping State (P)/ERR. If the <i>QH.EPS</i> field indicates a High-speed device and the <i>PID_Code</i> indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are:  Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint.

**Table 11-22. TD Token (DWord 2)**

Bit	Description
	If the <i>QH.EPS</i> field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

#### 11.1.6.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the *C\_Page* field.

[Table 11-23](#) describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

**Table 11-23. qTD Buffer Pointer(s) (DWords 3-7)**

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field <i>C_Page</i> specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using <i>C_Page</i> (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment <i>C_Page</i> and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by <i>C_Page</i> ). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

#### 11.1.6.2.6 Queue Head

[Table 11-24](#) shows the Queue head structure layout.

**Table 11-24. Queue Head Structure Layout**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## Transfer Overlay Transfer Results

## Static Endpoint State

These fields are used exclusively to support split transactions to USB 2.0 Hubs

	Host Controller Read/Write		Host Controller Read Only.
--	----------------------------	--	----------------------------

### 11.1.6.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

[Table 11-25](#) describes the Queue head DWord 0 fields.

**Table 11-25. Queue Head DWord 0**

Bit	Description
-----	-------------

*Table continues on the next page...*

**Table 11-25. Queue Head DWord 0 (continued)**

31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

#### 11.1.6.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint. There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

[Table 11-26](#) describes the Endpoint characteristics: Queue head DWord 1 fields.

**Table 11-26. Endpoint Characteristics: Queue Head DWord 1**

Bit	Description
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.
27	Control Endpoint Flag (C). If the <i>QH.EPS</i> field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint ( <i>wMaxPacketSize</i> ). The maximum value this field may contain is 0x400 (1024).
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.

*Table continues on the next page...*

**Table 11-26. Endpoint Characteristics: Queue Head DWord 1 (continued)**

14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition.  0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head.  1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See <a href="#">Rebalancing the Periodic Schedule</a> , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the <i>EPS</i> field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the <i>EPS</i> field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

[Table 11-27](#) describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

**Table 11-27. Endpoint Capabilities: Queue Head DWord 2**

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are:  Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame 10b Two transactions to be issued for this endpoint per micro-frame 11b Three transactions to be issued for this endpoint per micro-frame
29-23	Port Number. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address <i>Hub Addr</i> below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask ( $\mu$ Frame C-Mask). This field is ignored by the host controller unless the <i>EPS</i> field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the <i>Active</i> and <i>SplitX-state</i> fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the $\mu$ Frame C- Mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.

*Table continues on the next page...*

**Table 11-27. Endpoint Capabilities: Queue Head DWord 2 (continued)**

7-0	Interrupt Schedule Mask ( $\mu$ Frame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the $\mu$ Frame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the EPS field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the PID_Code field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the EPS field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.
-----	---

### 11.1.6.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

[Table 11-28](#) describes the current qTD link pointer field descriptions.

**Table 11-28. Current qTD Link Pointer**

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves an execution cache for the transfer.

Table 11-29 describes the Host-controller rules for bits in overlay.

**Table 11-29. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)**

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt) $\mu$ RW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from <i>RL</i> before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from <i>RL</i> during an overlay.
6	31	Data Toggle. The <i>Data Toggle Control</i> controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This 2-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the <i>EPS</i> field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the <i>S-bytes</i> field in a <i>qTD</i> is zero before activating the <i>qTD</i> . This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

### 11.1.6.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary. See [Host Controller Operational Model for FSTNs](#) for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB\_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
	Normal Path Link Pointer																												0	Typ		T	03-00H			
	Back Path Link Pointer																												0	Typ		T	07-04H			

**Table 11-30. Frame Span Traversal Node Structure Layout**

	Host Controller Read/Write		Host Controller Read Only.
--	----------------------------	--	----------------------------

#### 11.1.6.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

[Table 11-31](#) describes the FSTN normal path pointer fields.

**Table 11-31. FSTN Normal Path Pointer Field Descriptions**

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/ siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1=Link Pointer field is not valid. 0=Link Pointer is valid.

#### 11.1.6.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head. If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

[Table 11-32](#) describes the FSTN back path link pointer fields.

**Table 11-32. FSTN Back Path Link Pointer Field Descriptions**

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator.

**Table 11-32. FSTN Back Path Link Pointer Field Descriptions**

	0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.
--	---

### 11.1.6.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software). Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

#### 11.1.6.3.1 Host Controller Initialization

When the system boots, the host controller is enumerated, assigned a base address for the register space and BIOS sets the USB\_FLADJ register to a system-specific value. After initial power-on or HCRreset (hardware or through HCRreset bit in the USB\_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

[Table 11-33](#) describes the default values of operational registers.

**Table 11-33. Default Values of Operational Register Space**

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if <i>Asynchronous Schedule Park Capability</i> is one)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNC_LISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/PPC set to one); 00003000h (w/PPC set to zero)

To initialize the host controller, software should perform the following steps:

- Reset the controller by setting the USBCMD:RST bit and wait for it to clear. Configure the controller for HOST operation by setting USBMODE.CMD to 3.
- Program the USB\_CTRLDSSEGMENT register with 4-Gbyte segment where all of the interface data structures are allocated.
- Write the appropriate value to the USB\_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB\_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB\_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled port enabled High-speed ports, but the schedules have not enabled. The EHCI Host controller do not transmit SOFs to enabled Full- or Low-speed ports. To communicate with devices through the asynchronous schedule, system software must write the USB\_ASYNDLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB\_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB\_USBCMD register.

#### NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB\_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

#### 11.1.6.3.2 Port Routing and Control

A USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers. Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

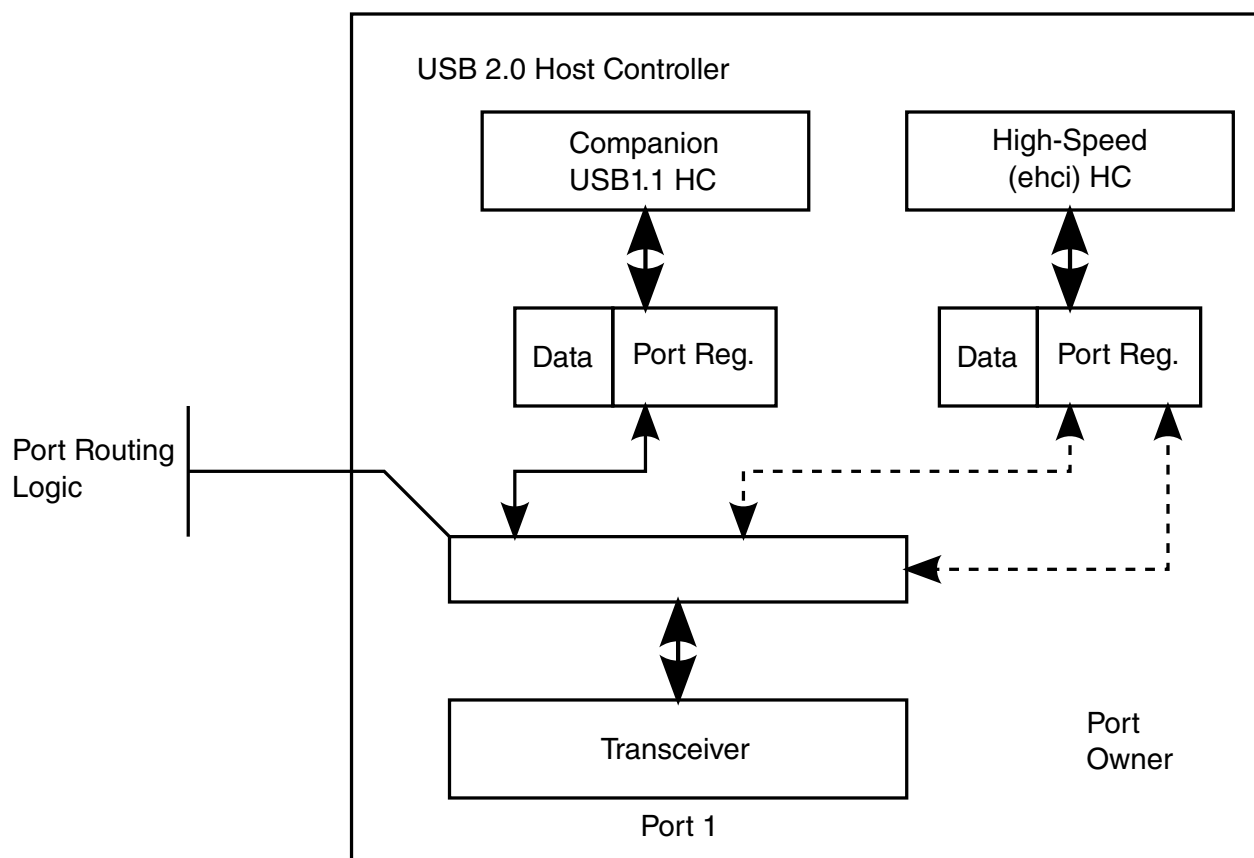

#### NOTE

The USB controller on this part does not require nor support companion controllers to support Full Speed/Low Speed

devices. Therefore, no port routing is present in the controller. Please refer to [Embedded Transaction Translator Function](#) for detail!

Figure 11-4 illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

**Figure 11-4. Example USB 2.0 Host Controller Port Routing Block Diagram**

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.<sup>4</sup>

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At

4. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N\_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N\_CC has a non-zero value there exists companion host controllers. If N\_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See [Host Controller Structural Parameters \(USB\\_HCSPARAMS\)](#).

#### 11.1.6.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller. The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power

application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

[Table 11-34](#) summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

**Table 11-34. Default Port Routing Depending on EHCI HC CF Bit**

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see <a href="#">Port Status &amp; Control (USB_PORTSC1)</a> ). The EHCI HC can temporarily release control of the port to a companion HC by setting the <i>PortOwner</i> bit in the PORTSC1 register to one.

#### 11.1.6.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation. The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB\_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

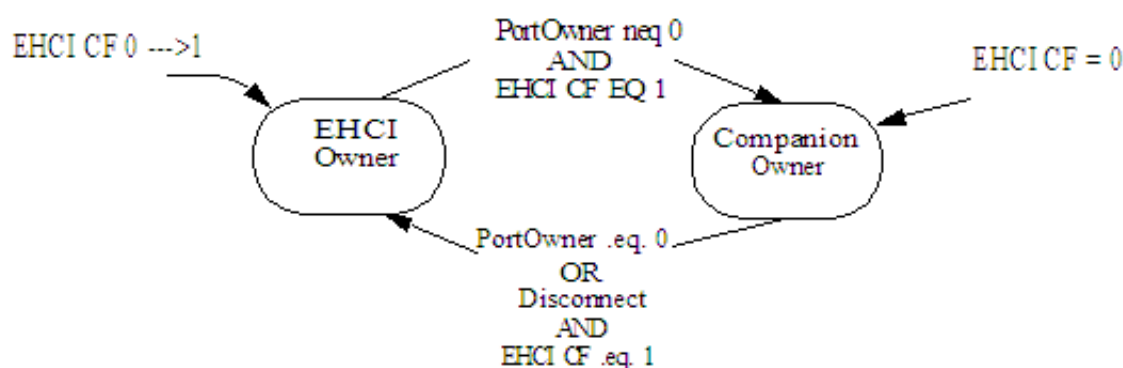

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB\_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB\_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB\_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB\_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from 1b to 0b). When a disconnect occurs, the disconnect

event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

### 11.1.6.3.2.3 Example Port Routing State Machine

Figure 11-5 illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

**Figure 11-5. Port Owner Handoff State Machine**

#### 11.1.6.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB\_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB\_PORTSC1 register. This allows software to take ownership of a port from a companion host

controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

#### 11.1.6.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occurs:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

#### 11.1.6.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB\_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see [Host Controller Structural Parameters \(USB\\_HCSPARAMS\)](#)). When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

[Table 11-35](#) describes the summary behavioral model.

**Table 11-35. Port Power Enable Control Rules**

CF	CHC <sup>1</sup> (PP)	EHC <sup>2</sup> (PP)	Owner	PPE <sup>3</sup>	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.

*Table continues on the next page...*

**Table 11-35. Port Power Enable Control Rules (continued)**

1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

### 11.1.6.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB\_PORTSC1 register has an over-current status and over-current change bit. The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB\_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB\_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB\_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB\_USBINTR register is one, then the host controller issues an interrupt

to the system. Refer to [Table 11-36](#) for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

### 11.1.6.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub. Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB\_PORTSC1 registers.

Selective suspend is a feature supported by every USB\_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB\_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the ARM platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB\_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

### 11.1.6.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB\_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see [Port Status & Control \(USB\\_PORTSC1\)](#)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB\_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB\_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB\_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB\_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB\_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB\_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

[Table 11-36](#) summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB\_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB\_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB\_USBSTS register.

**Table 11-36. Behavior During Wake-up Events**

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, the USB_PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB\_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

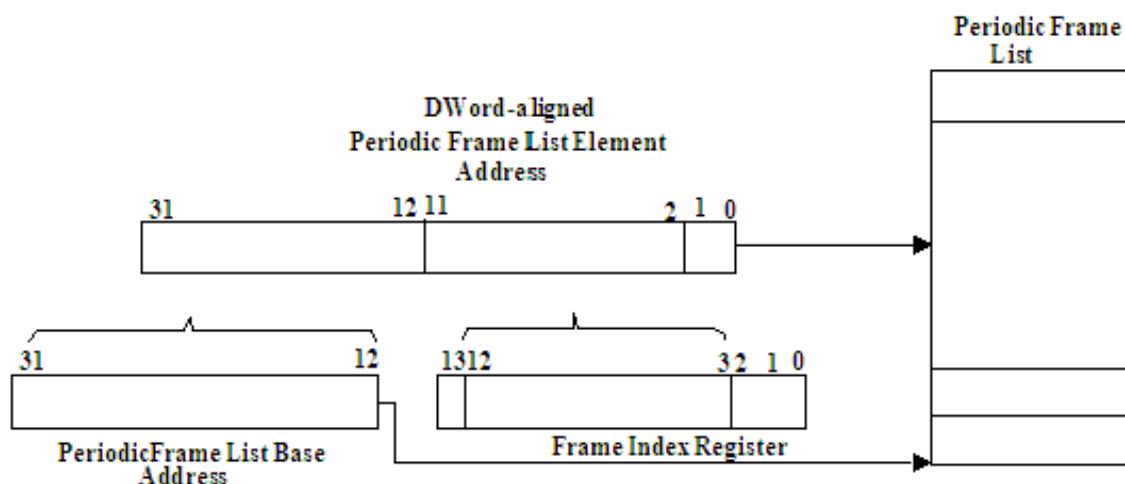

#### 11.1.6.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule. The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB\_PERIODICLISTBASE register (see [Frame List Base Address \(USB\\_PERIODICLISTBASE\)\)](#)/Device Address (USB\_DEVICEADDR). The USB\_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in [Host data structures](#). In each micro-frame, if the periodic schedule is enabled (see [Periodic Scheduling Threshold](#)) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB\_PERIODICLISTBASE and the USB\_FRINDEX registers (see [Figure 11-6](#)). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

[Figure 11-6](#) illustrates the derivation of pointer into frame list array.

**Figure 11-6. Derivation of Pointer into Frame List Array**

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB\_ASYNC\_LIST\_ADDR to access the asynchronous schedule, see [Figure 11-7](#).

**Figure 11-7. General Format of Asynchronous Schedule List**

The USB\_ASYNC\_LIST\_ADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB\_ASYNC\_LIST\_ADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See [Asynchronous Schedule](#) for complete operational details.

#### 11.1.6.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries. For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

##### 11.1.6.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction. This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each

packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 11-8. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ( $f(x)$ ) between the 80% and Last Start curves. The function  $f(x)$  adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

Figure 11-8 illustrates the Best-Fit Approximation.

**Figure 11-8. Best Fit Approximation**

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in Table 11-37. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

**Table 11-37. Example Worse-case Transaction Timing Components**

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function ( $f(x)$ ) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The  $f(x)$  in [Figure 11-8](#) was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```

Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
  Local Temp = MaximumPacketSize + 192
  Local rvalue = TRUE
  If MaximumPacketSize >= 128 then
    Temp += 128
  End If
  If Temp > HC_BytesLeftInFrame then
    Rvalue = FALSE
  End If
  Return rvalue
End

```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the  $f(x)$  plot was getting close to the LastStart line.

### 11.1.6.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned. Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in [Figure 11-9](#)). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

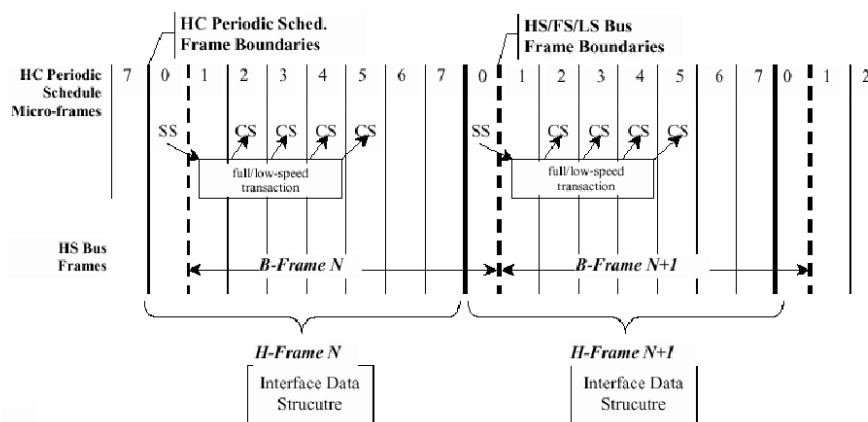

**Figure 11-9. Frame Boundary Relationship between HS bus and FS/LS Bus**

The simple projection, as [Figure 11-9](#) illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB\_FRINDEX) documented in [USB Frame Index \(USB\\_FRINDEX\)](#) and initially illustrated in [Schedule Traversal Rules](#). Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in [Figure 11-10](#). This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

Figure 11-10 illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

**Figure 11-10. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries**

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in Figure 11-10. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in [USB Frame Index \(USB\\_FRINDEX\)](#), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. [USB Frame Index \(USB\\_FRINDEX\)](#) provides the requirements that software should adhere when writing a new value in FRINDEX.

[Table 11-38](#) illustrates the required relationship between the value of FRINDEX and the value of SOFV.

**Table 11-38. Operation of FRINDEX and SOFV (SOF Value Register)**

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b
N+1	N	000b	N+1	N+1	001b
N+1	N+1	001b	N+1	N+1	010b
N+1	N+1	010b	N+1	N+1	011b
N+1	N+1	011b	N+1	N+1	100b
N+1	N+1	100b	N+1	N+1	101b
N+1	N+1	101b	N+1	N+1	110b
N+1	N+1	110b	N+1	N+1	111b

**NOTE**

Where [F] = [13:3]; [μF] = [2:0]

**11.1.6.3.6 Periodic Schedule**

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB\_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB\_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB\_PERIODICLISTBASE register to traverse the periodic schedule. The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero. The Periodic Schedule Status bit in the USB\_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB\_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the

Figure 11-11 illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

**Figure 11-11. Example Periodic Schedule**

### 11.1.6.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in [Isochronous \(High-Speed\) Transfer Descriptor \(iTD\)](#). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

### 11.1.6.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Each iTD can span 8 micro-frames worth of transactions. When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array. If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB\_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

#### 11.1.6.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

Figure 11-12 illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

**Figure 11-12. Example Association of iTDs to Client Request Buffer**

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page

(for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

#### 11.1.6.3.7.2.1 Periodic Scheduling Threshold

The Isochronous Scheduling Threshold field in the USB\_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures. It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB\_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software

can use the value of the USB\_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB\_FRINDEX register (plus the constant 1 uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame  $N$ , if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame  $N + 1$ . If the current micro-frame is 7, then software can add isochronous transactions to Frame  $N + 2$ .

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

#### 11.1.6.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB\_USBCMD register. If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB\_ASYNC\_LISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB\_ASYNC\_LISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB\_ASYNC\_LISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB\_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB\_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB\_ASYNC\_LIST\_ADDR register. The default value of the USB\_ASYNC\_LIST\_ADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB\_USBCMD and the Asynchronous Schedule Status bit in the USB\_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit is set to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB\_ASYNC\_LIST\_ADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB\_ASYNC\_LIST\_ADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see [Empty Asynchronous Schedule Detection](#) )
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB\_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in [Figure 11-7](#). Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTID or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

### 11.1.6.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section. There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB\_ASYNC\_LIST\_ADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB\_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadCurrent is a pointer to a queue head that is
-- already in the active list
-- pQHeadNew is a pointer to the queue head to be added
--
-- This algorithm links a new queue head into a existing
-- list
--
pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer
pQueueHeadCurrent.HorizontalPointer = physicalAddressOf (pQueueHeadNew)
End InsertQueueHead
```

### 11.1.6.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section. There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list. Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB\_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB\_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list.

Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```

UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
    --
    -- Requirement: all inputs must be properly initialized.
    --
    -- pQHeadPrevious is a pointer to a queue head that
    -- references the queue head to remove
    -- pQHeadToUnlink is a pointer to the queue head to be
    -- removed
    -- pQHeadNext is a pointer to a queue head still in the
    -- schedule. Software provides this pointer with the
    -- following strict rules:
    --     if the host software is one queue head, then
    --     pQHeadNext must be the same as
    --     QueueheadToUnlink.HorizontalPointer. If the host
    --     software is unlinking a consecutive series of
    --     queue heads, QHeadNext must be set by software to
    --     the queue head remaining in the schedule.
    --
    -- This algorithm unlinks a queue head from a circular list
    --
    pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
    pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead

```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB\_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB\_USBSTS register) that the host controller sets after it has released all on-chip

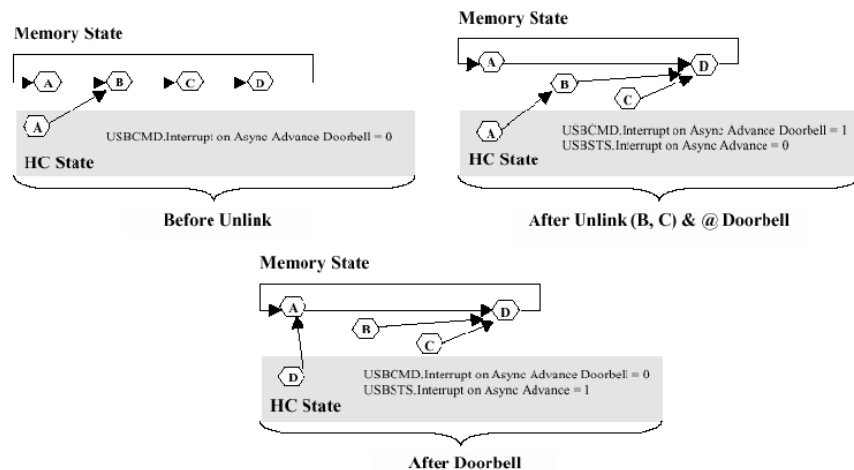

state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB\_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

Figure 11-13 illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A & B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example).

Figure 11-13 illustrates the generic queue head unlink scenario.

**Figure 11-13. Generic Queue Head Unlink Scenario**

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

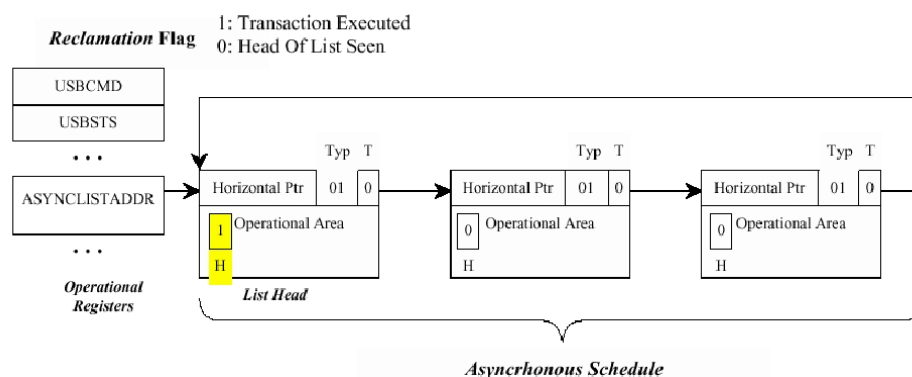

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB\_USBSTS register, before using the doorbell handshake again.

### 11.1.6.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty. The queue head data structure (see [Table 11-24](#)) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB\_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see [Asynchronous Schedule Traversal: Start Event](#)).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in [Figure 11-14](#)

**Figure 11-14. Asynchronous Schedule List w/Annotation to Mark Head of List**

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

### 11.1.6.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame. It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the

host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

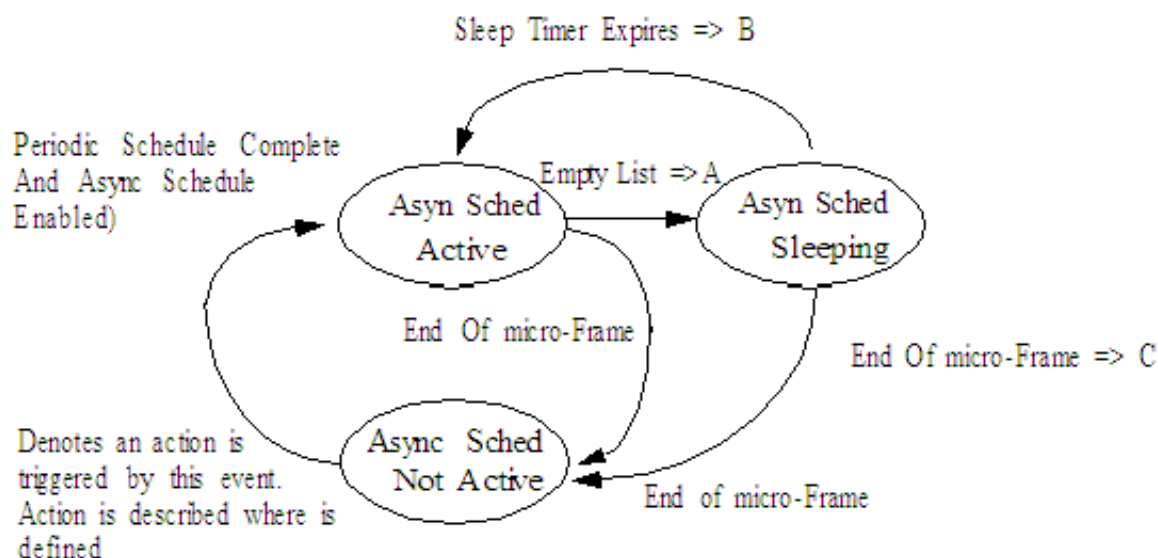

#### 11.1.6.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting?*

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10  $\mu$ sec. The value is derived based on the analysis in [Example Derivation for AsyncSchedSleepTime](#). The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. [Figure 11-15](#) illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

**Figure 11-15. Example State Machine for Managing Asynchronous Schedule Traversal**

The actions referred to in [Figure 11-15](#) are defined in [Table 11-39](#).

**Table 11-39. Asynchronous Schedule SM Transition Actions**

Action	Action Description Label
A	On detection of the empty list, the host controller sets the <i>AsynchronousTraversalSleepTimer</i> to <i>AsyncSchedSleepTime</i> .
B	When the <i>AsynchronousTraversalSleepTimer</i> expires, the host controller sets the <i>Reclamation</i> bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see <a href="#">Nak Count Reload Control</a> ).
C	The host controller cancels the sleep timer ( <i>AsynchronousTraversalSleepTimer</i> ).

#### 11.1.6.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB\_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

#### 11.1.6.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsynchronousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB\_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

#### 11.1.6.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

#### 11.1.6.3.8.4.5 Example Derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next. It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

[Table 11-40](#) summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

**Table 11-40. Typical Low-/Full-speed Transaction Times**

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10  $\mu$ s provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10  $\mu$ s sleep period would allow the host controller to get the NAK results on the first complete-split.

#### 11.1.6.3.8.5 Asynchronous Schedule Traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame. In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in [Restarting Asynchronous Schedule Before EOF](#). Asynchronous schedule *Start Events* are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see [Restarting Asynchronous Schedule Before EOF](#)).

#### 11.1.6.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see [Empty Asynchronous Schedule Detection](#)) depends on the proper management of the *Reclamation* bit in the USB\_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see [Fetch Queue Head](#)).

It is required that the host controller sets the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in [Asynchronous Schedule Traversal: Start Event](#), occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see [Execute Transaction](#)). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

#### 11.1.6.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head (see [Queue Head Initialization](#)). Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in [Table 11-41](#). The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

[Table 11-41](#) describes the *NakCnt* field adjustment rules.

**Table 11-41. NakCnt Field Adjustment Rules**

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement <i>NakCnt</i>	N/A (protocol error)
OUT	decrement <i>NakCnt</i>	No Action <sup>1, 1</sup> Start
Split	decrement <i>NakCnt</i>	N/A (protocol error)
Complete Split	No Action	Decrement <i>NakCnt</i>

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in [Nak Count Reload Control](#).

**NOTE**

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all *NakCnt*'s go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see [Empty Asynchronous Schedule Detection](#) ).

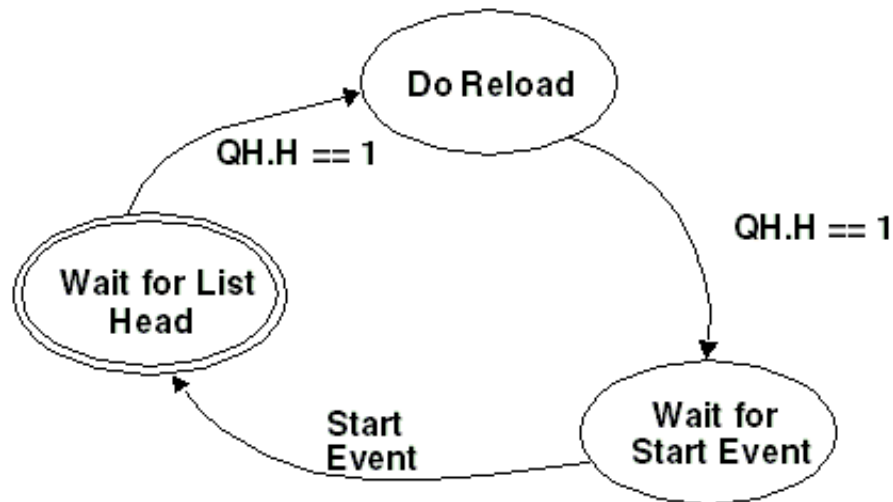

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see [Asynchronous Schedule Traversal: Start Event](#). Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

**11.1.6.3.9.1 Nak Count Reload Control**

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see [Execute Transaction](#) ). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see [Table 11-24](#)) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see [Asynchronous Schedule Traversal: Start Event](#) for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see [Figure 11-14](#)).

[Figure 11-16](#) illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction ([Figure 11-16](#)). The host controller does not perform the nak counter reload operation if the *RL* field (see [Table 11-24](#)) is set to zero.

**Figure 11-16. Example HC State Machine for Controlling Nak Counter Reloads**

#### 11.1.6.3.9.1.1 Wait for List Head

This is the initial state. The state machine enters this state from Wait for Start Event when a start event as defined in [Asynchronous Schedule Traversal: Start Event](#) occurs. The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule. This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

#### 11.1.6.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

#### 11.1.6.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

### 11.1.6.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

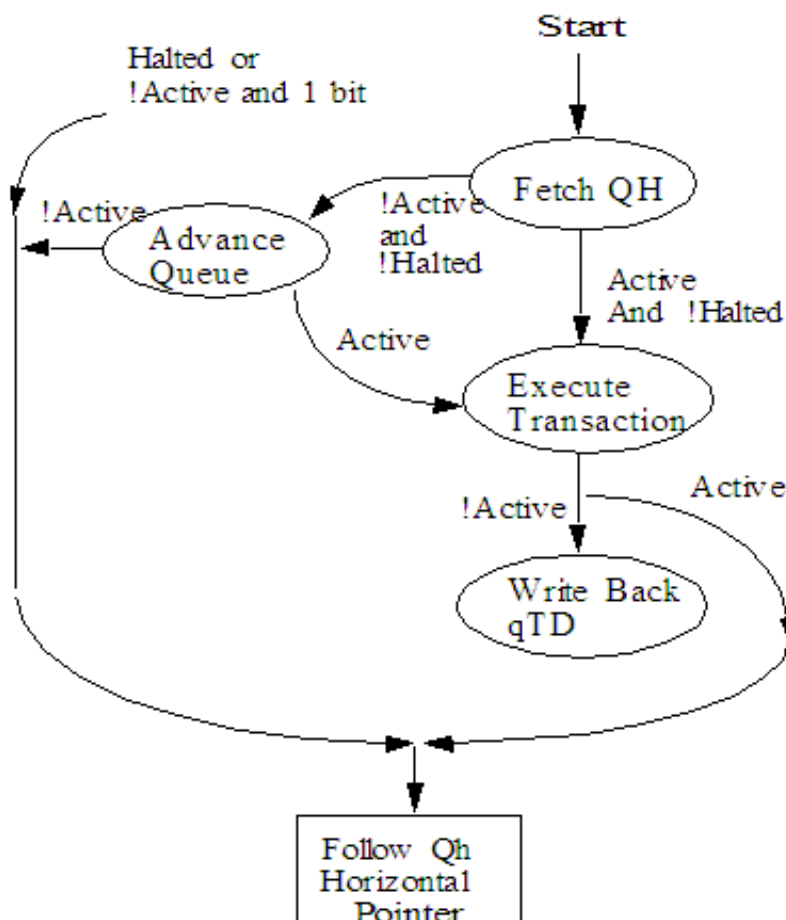

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in [Table 11-24](#)). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in [Figure 11-17](#). This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. [Figure 11-17](#) illustrates the Host Controller Queue Head Traversal State Machine.

**Figure 11-17. Host Controller Queue Head Traversal State Machine**

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see [Execute Transaction](#)) describes the basic requirements for all endpoints. [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

### NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

### 11.1.6.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see [Next Asynch. Address \(USB\\_ASYNCLISTADDR\)](#))/[Endpoint List Address \(USB\\_ENDPTLISTADDR\)](#) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in [Table 11-24](#).

While in this state, the host controller performs operations to implement empty schedule detection (see [Empty Asynchronous Schedule Detection](#) ) and Nak Counter reloads (see [Operational Model for Nak Counter](#)). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in [Empty Asynchronous Schedule Detection](#) ). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in [Operational Model for Nak Counter](#).

This state is complete when the queue head has been read on-chip.

### 11.1.6.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

#### NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host

controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control (dte)* bit (see [Table 11-26](#)).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

### 11.1.6.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#).

#### 11.1.6.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it. For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

#### 11.1.6.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria:

The pre-operation is:

Checks the Nak counter reload state ([Operational Model for Nak Counter](#)). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

#### 11.1.6.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#))

for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.

- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,<sup>4</sup> or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#) for example method for implementing the frame boundary test).

#### NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example, advanced by the number of bytes successfully moved), and the *C\_Page* field is updated to the appropriate value (if necessary). See [Buffer Pointer List Use for Data Streaming with qTDs](#).

#### NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID\_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in [Transaction Error](#).

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and

a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to [Split Transactions](#) for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C\_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

#### 11.1.6.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt). The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB.USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C\_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB.USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB.USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

#### 11.1.6.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule. This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in [Execute Transaction](#) apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB.HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB.USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB.USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB.USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in [Execute Transaction](#) . It only effects

how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

Table 11-42 summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

**Table 11-42. Actions for Park Mode, based on Endpoint Response and Residual Transfer State**

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. <sup>1,2</sup>
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. <sup>2</sup>
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. <sup>2</sup>
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

#### 11.1.6.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero. The source data for the write-back is the transfer results area of the queue head overlay area (see Table 11-42). The host controller uses the *Current qTD Pointer* field as the target address for the qTD. The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

#### NOTE

If the retired qTD is the last one on the linked list (Terminate bit set on link pointers), then the host controller will read it one more time to check if the driver software updated the link pointers. If the memory holding the last qTD is re-used by software before the controller has read the qTD, the host controller may incorrectly use that data as a valid qTD and perform incorrect actions or even crash. For this reason, driver software should not remove the last qTD from the linked list.

#### 11.1.6.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

### 11.1.6.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*. This means: if the buffer spans more than one physical page, it must obey the following rules (Figure 11-18 illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C\_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C\_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

Figure 11-18 illustrates a nominal example of how System software would initialize the buffer pointers list and the *C\_Page* field for a transfer size of 16383 bytes. *C\_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

**Figure 11-18. Example Mapping of qTD Buffer Pointers to Buffer Pages**

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C\_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4<sup>th</sup> transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C\_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4<sup>th</sup> transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C\_Page*) when necessary. The three conditions for how the host controller handles *C\_Page*:

- The current transaction does not span a page boundary. The value of *C\_Page* is not adjusted by the host controller.
- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C\_Page* before writing back status for the transaction.

**NOTE**

The only valid adjustment the host controller may make to *C\_Page* is to increment by one.

**11.1.6.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule**

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate. System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame with-in 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in [Table 11-43](#).

**Table 11-43. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate**

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 01h	A queue head for the <i>bInterval</i> of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the <i>S-Mask</i> field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 02h	Another example of a queue head with a <i>bInterval</i> of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the <i>S-Mask</i> is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

**11.1.6.3.10.8 Managing Transfer Complete Interrupts from Queue Heads**

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete (IOC)* bit set to one, or whenever a transfer (qTD) completes with a short packet. If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

### 11.1.6.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints. Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see [Table 11-45](#)).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

[Table 11-44](#) illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

**Table 11-44. Ping Control State Transition Table**

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr <sup>1</sup>	Do Ping
Do Ping	PING	Stall	N/C <sup>2</sup> Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr <sup>1</sup>	Do Ping
Do OUT	OUT	Stall	N/C <sup>2</sup>

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

**Table 11-45. Ping State bit Encoding**

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

#### 11.1.6.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs. This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol. Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

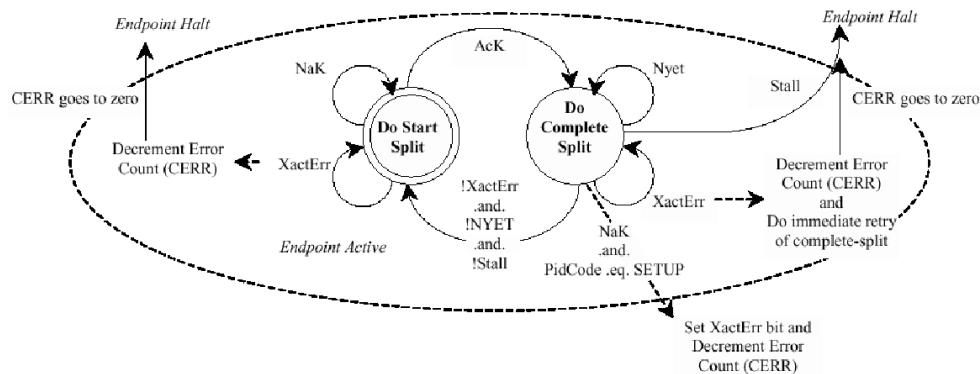

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see [Split Transaction Isochronous Transfer Descriptor \(siTD\)](#)). Control, Bulk and Interrupt are managed using the queuing data structures (see [Queue Head](#)). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

##### 11.1.6.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head. All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type (C)* bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be

zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

**Figure 11-19. Host Controller Asynchronous Schedule Split-Transaction State Machine**

#### 11.1.6.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CERR*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

#### 11.1.6.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (*XactErr*). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- **ACK.** The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).

### 11.1.6.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule. Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#), but only occurs on the completion of a split transaction.

#### 11.1.6.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field. The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

Figure 11-20 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and <sup>C</sup>X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

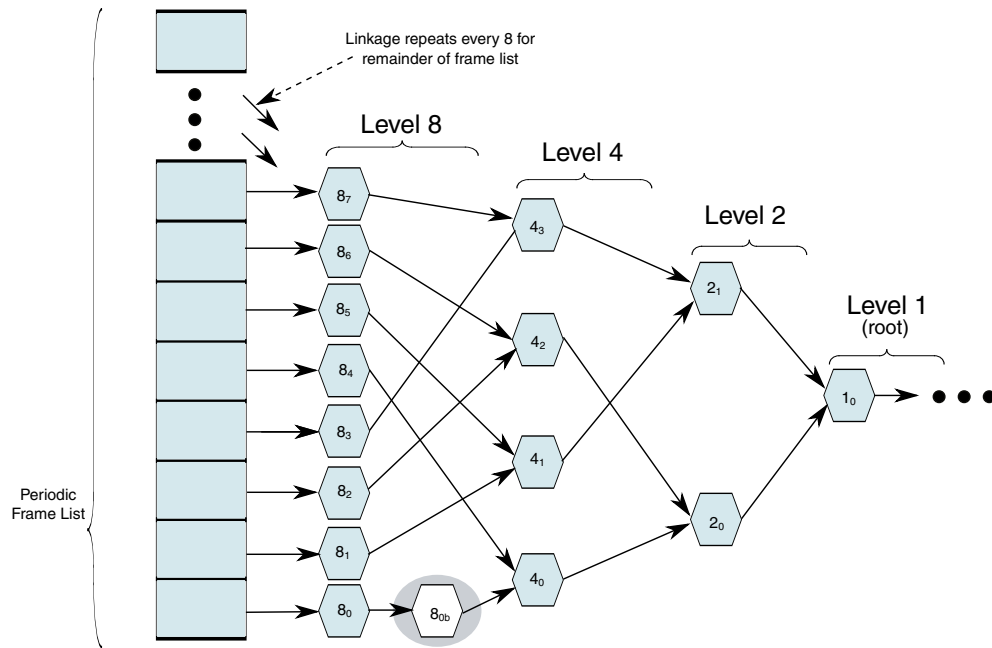

**Figure 11-20. Split Transaction, Interrupt Scheduling Boundary Conditions**

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

Figure 11-21 illustrates the general layout of the periodic schedule.

**Figure 11-21. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading**

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a  $2^N$  poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if  $8_{0b}$  where such an endpoint. Without additional support on the interface, to get  $8_{0b}$  reachable at the correct time, software would have to link  $8_1$  to  $8_{0b}$ . It would then have to move  $4_1$  and everything linked after into the same path as  $4_0$ . This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. [Host Controller Operational Model for FSTNs](#) defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see [Table 11-22](#)). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-

split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 11-20](#), case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do\_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.

- *Frame C-mask*. This is a field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 11-20](#), case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do\_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

#### 11.1.6.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c). An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see [siTD Back Link Pointer](#)).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.
- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

### NOTE

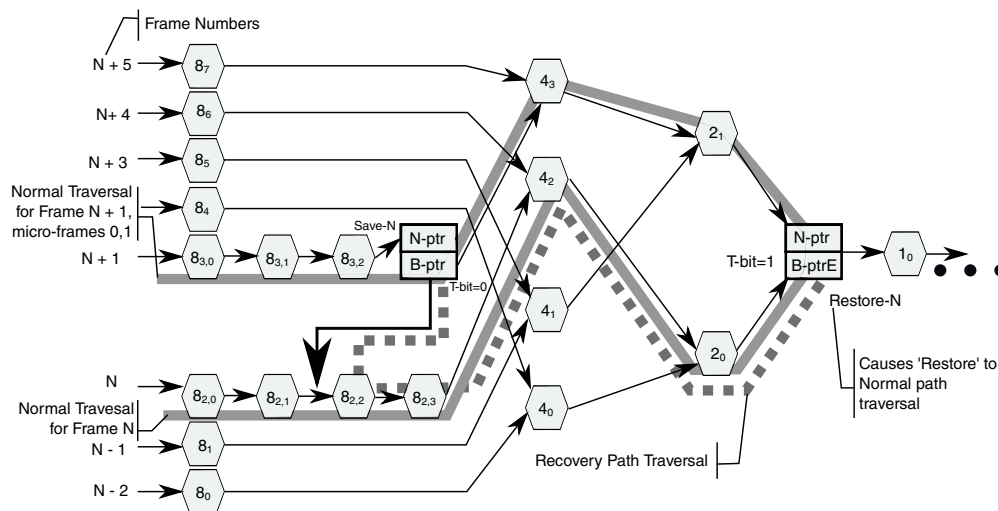

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See [Execute Transaction](#) and [Tracking Split Transaction Progress for Interrupt Transfers](#) for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See [Periodic Isochronous - Do Complete Split](#) for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.
- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in [Figure 11-22](#).

**Figure 11-22. Example Host Controller Traversal of Recovery Path via FSTNs**

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in Figure 11-22 with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {83,0, 83,1, 83,2, Save-A, 82,2, 82,3, 42, 20, Restore-N, 43, 21, Restore-N, 10}. The nodes on the recovery-path are bolded. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {82,0, 82,1, 82,2, 82,3, 42, 20, Restore-N, 10}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {83,0, 83,1, 83,2, Save-A, 43, 21, Restore-N, 10}.

### 11.1.6.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse. When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer* and *T-bit* equal to zero.
    - *Back Path Link Pointer.Type* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer's T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth rebalance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

#### 11.1.6.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost. For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline. When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog-mask* bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

#### 11.1.6.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

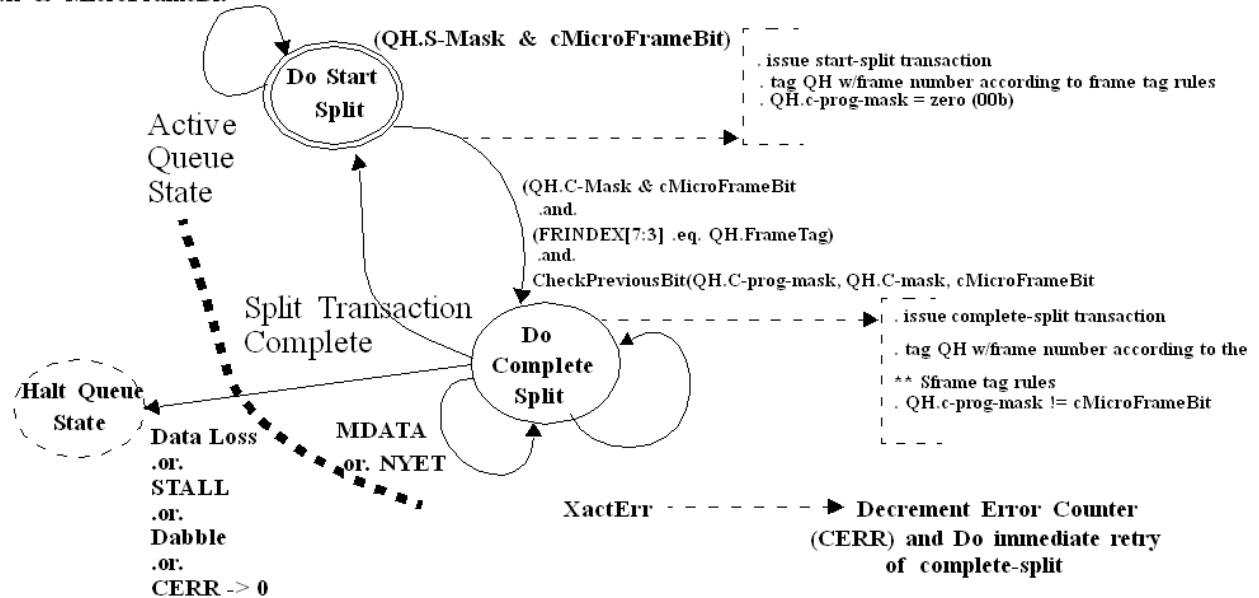

- *cMicroFrameBit*. This is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is,  $cMicroFrameBit = (1 \text{ shifted-left}(FRINDEX[2:0]))$ ). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

Figure 11-23 illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at *Do\_Start* and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to *Do\_Complete*. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the *Do\_Complete* state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the *Do\_Complete* state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

!(QH.S-Mask &amp; MicroFrameBit

**Figure 11-23. Split Transaction State Machine for Interrupt**

See Previous Section for the frame tag management rules.

#### Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the *Do\_Complete Split* state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- **NAK.** A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- **ACK.** An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- **DATA 0/1.** Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- **ERR.** The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- **NYET (and Last).** The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section [Periodic Isochronous - Do Complete Split](#) for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section ), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

### Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX[7:3]*. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

Algorithm Boolean CheckPreviousBit(*QH.C-prog-mask*, *QH.C-mask*, *cMicroFrameBit*)  
Begin

```
-- Return values:
-- TRUE - no error
-- FALSE - error
--
```

```
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask) then
    If not(previousBit bitAND QH.C-prog-mask) then
        rvalue = FALSE;
    End if
End If
```

```
-- If the C-prog-mask already has a one in this bit position,
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
```

## Core Registers

```
If (cMicroFrameBit bitAND QH.C-prog-mask) then
    rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section [Periodic Isochronous - Do Start Split](#)). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section ). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.
- Transaction Error (*XactErr*). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in

the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.

- **ACK.** This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- **MDATA.** This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- **DATA0/1.** This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- **NAK.** The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.
- **ERR.** There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- **STALL.** The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or

response was lost. [Table 11-46](#) lists the possible combinations and the appropriate action.

**Table 11-46. Interrupt IN/OUT Do Complete Split State Execution Criteria**

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame. Host controller should continue walking the schedule.
A not(C)	If $PIDCode = IN$ Halt QHD If $PIDCode = OUT$ Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If $PIDCode$ is an IN, then the Queue head must be halted.  If $PIDCode$ is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A not(B) C	If $PIDCode = IN$ Halt QHD If $PIDCode = OUT$ Retry start-split	<i>QH.FrameTag</i> test failed. This means that exactly one or more <i>H-Frames</i> have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If $PIDCode$ is an IN, then the Queue head must be halted.  If $PIDCode$ is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If $PIDCode = IN$ Halt QHD If $PIDCode = OUT$ Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If $PIDCode$ is an IN, then the Queue head must be halted.  If $PIDCode$ is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one. Note: When executing in the context of a <i>Recovery Path</i> mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a <i>Recovery Path</i> mode.

## Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This

accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see [Figure 11-20](#)).

- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c ([Figure 11-20](#)).
- Rule 3: If transitioning from Do\_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases ([Figure 11-20](#)).

#### 11.1.6.3.12.2.6 Rebalancing the Periodic Schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation. This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction (I)* bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

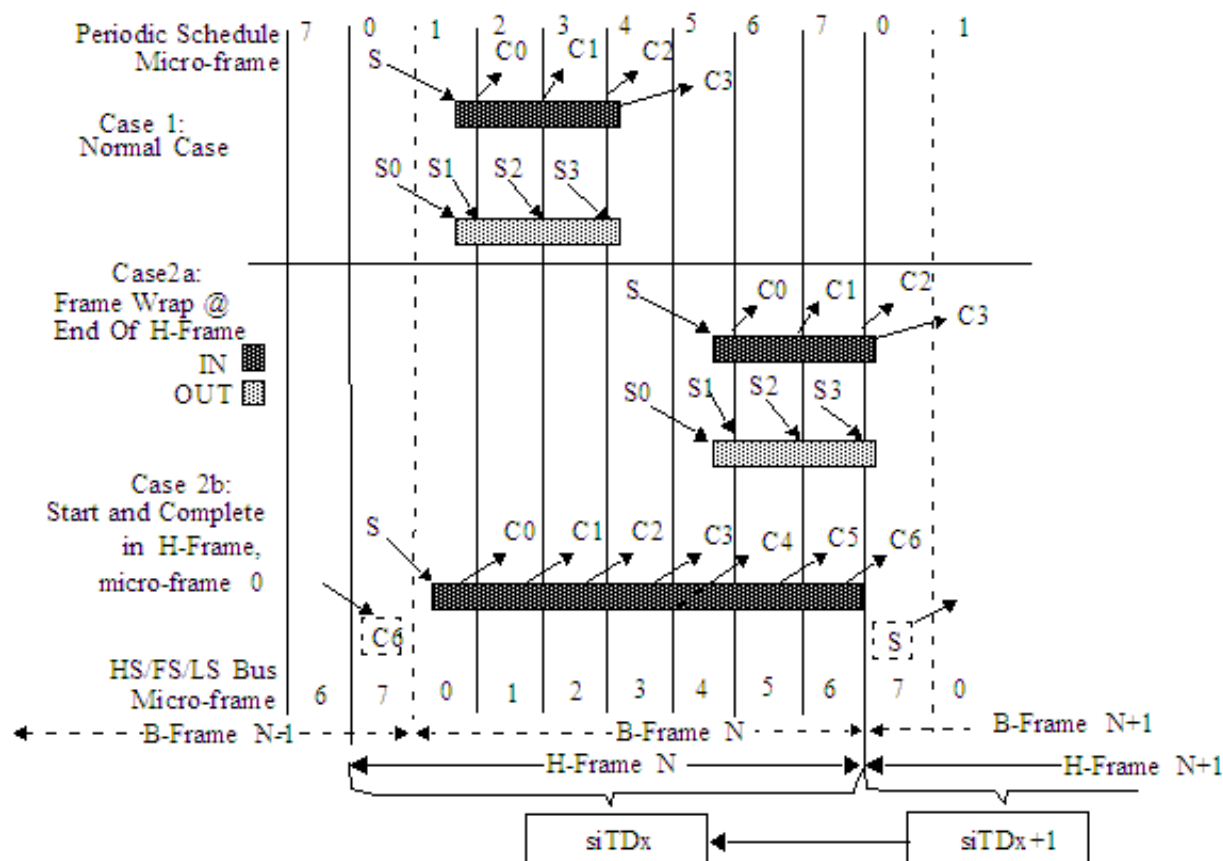

### 11.1.6.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions. This data structure uses the scheduling model of isochronous TDs (iT<sub>D</sub>, Section [Isochronous \(High-Speed\) Transfer Descriptor \(iT<sub>D</sub>\)](#)) (see Section [Managing Isochronous Transfers Using iT<sub>D</sub>s](#) for the operational model of iT<sub>D</sub>s) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

#### 11.1.6.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur. The requirements described in Section [Split Transaction Scheduling Mechanisms for Interrupt](#) apply. [Figure 11-24](#) illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The <sup>S</sup>X and <sup>C</sup>X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

**Figure 11-24. Split Transaction, Isochronous Scheduling Boundary Conditions**

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to  $N$  complete-splits. The scheduling boundary cases are:

- *Case 1:* The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.
- *Case 2a:* This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.

- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see [Figure 11-25](#)). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in [Section Split Transaction Execution State Machine for Interrupt](#).
- *Frame S-mask*. This is a field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-24](#), case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by *USB.FRINDEX[2:0]* is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-24](#), case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Complete Split, and the current micro-frame as indicated by *USB.FRINDEX[2:0]* is 2, 3, 4, or 5, then execute a complete-split transaction.
- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data

buffer must be used. This rule applies to both IN and OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. Figure 11-25 illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

**Figure 11-25. siTD Scheduling Boundary Examples**

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction siTD<sub>X</sub> is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of *H-Frame*<sub>Y+1</sub>, or micro-frame 0 of *H-Frame*<sub>Y+2</sub>. The complete splits are scheduled using siTD<sub>X+2</sub> (not shown). The complete-splits to extract this data

must use the buffer pointer from  $siTD_{X+1}$ . The only way for the host controller to reach  $siTD_{X+1}$  from  $H-Frame_{Y+2}$  is to use  $siTD_{X+2}$ 's back pointer. The host controller rules for when to use the back pointer are described in Section [Periodic Isochronous - Do Complete Split](#).

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame N* and the last complete-split would need to occur in micro-frame 1 of *H-Frame N+1*. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

#### 11.1.6.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use  $siTD$ s, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for  $siTD$ s). Software has the option of reusing  $siTD$  several times in the complete periodic schedule. However, it must ensure that the results of split transaction  $N$  are consumed and the  $siTD$  reinitialized (activated) before the host controller gets back to the  $siTD$  (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an  $siTD$  via the fields *Transaction Position (TP)* and *Transaction Count (T-count)*. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper

annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section [Periodic Isochronous - Do Start Split](#) for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB.FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section [Asynchronous - Do Complete Split](#) for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue

heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

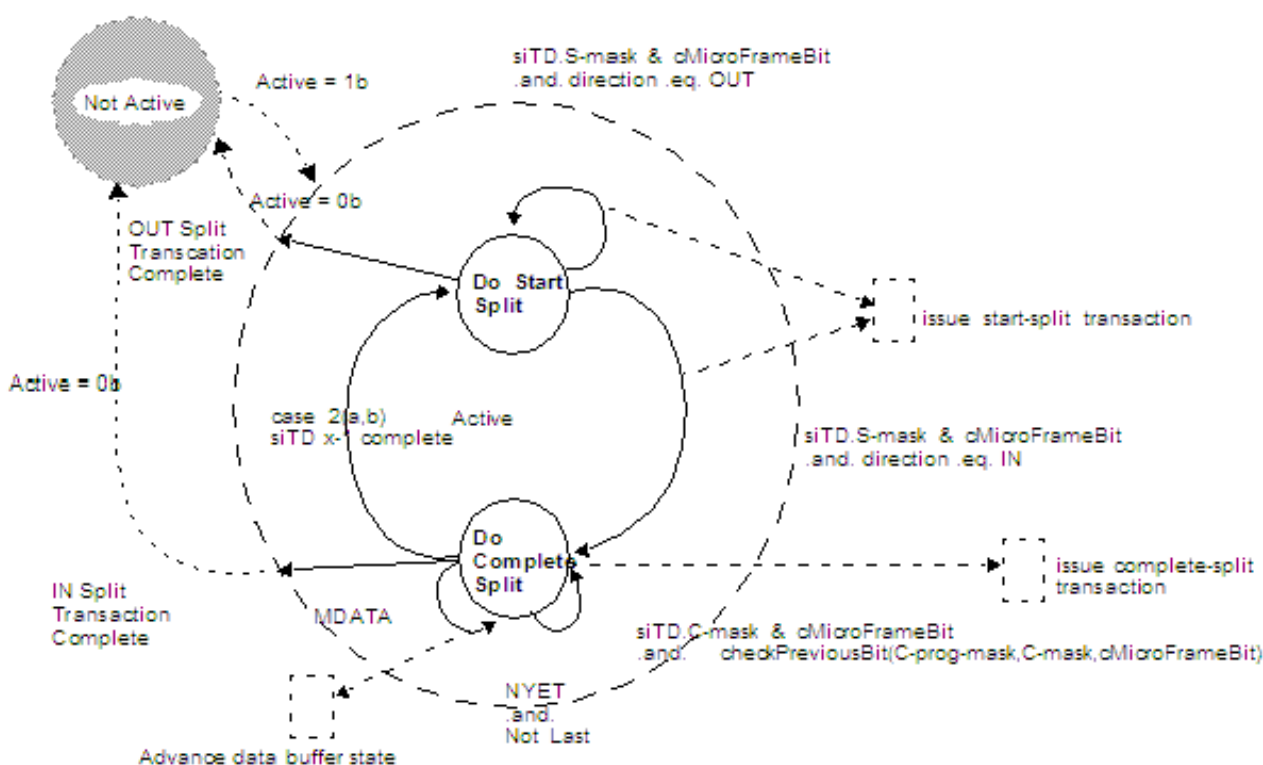

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

#### 11.1.6.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section [Tracking Split Transaction Progress for Interrupt Transfers](#), plus the variable *cMicroFrameBit* defined in Section [Split Transaction Execution State Machine for Interrupt](#) to track the progress of an isochronous split transaction. [Figure 11-26](#) illustrates

the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

**Figure 11-26. Split Transaction State Machine for Isochronous**

#### 11.1.6.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state. An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total*

*Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

*T-Count* is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see [Figure 11-25](#)) is used to determine the initial value of *TP*. The initial cases are summarized in [Table 11-47](#).

**Table 11-47. Initial Conditions for OUT siTD's TP and T-count Fields**

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

[Table 11-48](#) illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

**Table 11-48. Transaction Position (TP)/Transaction Count (T-Count) Transition Table**

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when <i>T-count</i> starts at 2.

*Table continues on the next page...*

**Table 11-48. Transaction Position (TP)/Transaction Count (T-Count) Transition Table (continued)**

BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when <i>T-count</i> starts at greater than 2.
MID	!=1	MID	<i>TP</i> stays at MID while <i>T-count</i> is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in [Table 11-48](#).

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section [Split Transaction for Isochronous - Processing Examples](#).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit()* algorithm defined in Section [Periodic Isochronous - Do Complete Split](#) can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

#### 11.1.6.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section [Periodic Isochronous - Do Complete Split](#)). The sequence in which this test is applied depends on the current value of *USB.FRINDEX[2:0]*. If *USB.FRINDEX[2:0]* is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(*siTD.C-prog-mask*, *siTD.C-mask*, *cMicroFrameBit*)  
Begin

```

Boolean rvalue = TRUE;
previousBit = cMicroFrameBit rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates whether there was an intent
-- to send a complete split in the previous micro-frame. So, if the
-- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
-- happened.
if previousBit bitAND siTD.C-mask then
    if not (previousBit bitAND siTD.C-prog-mask) then
        rvalue = FALSE
    End if
End if
Return rvalue

```

End Algorithm

If Test A is true and *USB.FRINDEX[2:0]* is zero or one, then this is a case 2a or 2b scheduling boundary (see [Figure 11-24](#)). See Section [Periodic Isochronous - Do Complete Split](#) for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,
- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- **ERR.** The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- **Transaction Error (XactErr).** The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- **DATAx (0 or 1).** This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT

status bit in the USBSTS register to a one. The host controller will not detect this condition.

- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section [Periodic Isochronous - Do Complete Split](#) . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.
- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-masks* incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

#### 11.1.6.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see [Figure 11-24](#)) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. [Table 11-49](#) enumerates the transaction state fields.

**Table 11-49. Summary siTD Split Transaction State**

Buffer State	Status	Execution Progress
--------------	--------	--------------------

Table continues on the next page...

**Table 11-49. Summary siTD Split Transaction State (continued)**

Total Bytes To Transfer	All bits in the status field	C-prog-mask
P (page select)		
Current Offset		
TP (transaction position)		
T-count (transaction count)		

**NOTE**

*TP* and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from *siTD<sub>X-1</sub>*.

In order to access *siTD<sub>X-1</sub>*, the host controller reads on-chip the siTD referenced from *siTD<sub>X</sub>.Back Pointer*.

The host controller must save the entire state from *siTD<sub>X</sub>* while processing *siTD<sub>X-1</sub>*. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If *siTD<sub>X-1</sub>* is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see [Table 11-49](#)) of *siTD<sub>X-1</sub>* is appropriately advanced based on the results and written back to memory. If the resultant state of *siTD<sub>X-1</sub>*'s *Active* bit is a one, then the host controller returns to the context of *siTD<sub>X</sub>*, and follows its next pointer to the next schedule item. No updates to *siTD<sub>X</sub>* are necessary.

If *siTD<sub>X-1</sub>* is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If  $siTD_{X-1}$ 's *Active* bit is a zero, (because it was zero when the host controller first visited  $siTD_{X-1}$  via  $siTD_X$ 's back pointer, it transitioned to zero as a result of a detected error, or the results of  $siTD_{X-1}$ 's complete-split transaction transitioned it to zero), then the host controller returns to the context of  $siTD_X$  and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and  $siTD_X.S\text{-}mask[0]$  is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of  $siTD_X$ , then follows  $siTD_X.Next\ Pointer$  to the next schedule item. If the criterion is not met, the host controller simply follows  $siTD_X.Next\ Pointer$  to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of  $siTD_{X-1}$  will have its *Active* bit set to zero when the host controller returns to the context of  $siTD_X$ . Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

#### 11.1.6.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines. The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see [Figure 11-17](#)).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, [Table 11-50](#) illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

**Table 11-50. Example Case 2a - Software Scheduling siTDs for an IN Endpoint**

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	

Table continues on the next page...

**Table 11-50. Example Case 2a - Software Scheduling siTDs for an IN Endpoint (continued)**

X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that siTD<sub>X+1</sub>'s *Back Pointer.T-bit* is a zero, saves the state of siTD<sub>X+1</sub> and fetches siTD<sub>X</sub>. It executes the complete split transaction using the transaction state of siTD<sub>X</sub>. If the siTD<sub>X</sub> split transaction is complete, siTD's *Active* bit is set to zero and results written back to siTD<sub>X</sub>. The host controller retains the fact that siTD<sub>X</sub> is retired and transitions the *SplitXState* in the siTD<sub>X+1</sub> to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD<sub>X+1</sub> when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section [Periodic Isochronous - Do Complete Split](#)), that is, before all the scheduled complete-splits have been executed, the host controller will transition siTD<sub>X</sub>.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, siTD<sub>X+1</sub> does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame* X+2, micro-frame 0, the host controller detects that siTD<sub>X+2</sub>'s *Back Pointer.T-bit* is a zero, saves the state of siTD<sub>X+2</sub> and fetches siTD<sub>X+1</sub>. As described above, it executes another split transaction, receives an MDATA response, updates the

transfer state, but does not modify the *Active* bit. The host controller returns to the context of  $\text{siTD}_{X+2}$ , and traverses its next pointer without any state change updates to  $\text{siTD}_{X+2}$ . S

During *H-Frame*  $X+2$ , micro-frame 1, the host controller detects  $\text{siTD}_{X+2}$ 's *S-mask*[0] is a zero, saves the state of  $\text{siTD}_{X+2}$  and fetches  $\text{siTD}_{X+1}$ . It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of  $\text{siTD}_{X+2}$  and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for  $\text{siTD}_{X+2}$  when it reaches micro-frame 4. <TBD describe how software detects that there was missing micro-frames (don't think we care about missing out micro-frames. There is enough residual state to identify than not all transactions were executed.).

### 11.1.6.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports. When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create ARM platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the ARM platform, based on recent history usage. In the more aggressive power saving modes, the ARM platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the ARM platform power management software can detect this activity over time and inhibit the transition of the ARM platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the ARM platform power management software from placing the ARM platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the ARM platform power management to get the ARM platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very

specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the ARM platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the ARM platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

#### 11.1.6.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J\_State, Test K\_State, Test\_Packet, Test Force\_Enable, and Test SE0\_NAK as described in the USB Specification Revision 2.0. The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB.CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB.PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test\_Force\_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCRreset* to a one.

### 11.1.6.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources. There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section [Interrupt Enable Register \(USB\\_USBINTR\)](#)).

Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section [Host System Error](#) details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, ARM platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section [Interrupt Enable Register \(USB\\_USBINTR\)](#)) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section [USB Status Register \(USB\\_USBSTS\)](#)) from a one to a zero.

### 11.1.6.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

#### 11.1.6.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully. [Table 11-51](#) lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

**Table 11-51. Summary of Transaction Errors**

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1 <sup>1</sup>
Timeout	-1	XactErr set to a one.	1 <sup>1</sup>
Bad PID. <sup>2</sup>	-1	XactErr set to a one.	1 <sup>1</sup>
Babble	N/A	Section <a href="#">Serial Bus Babble</a>	1
Buffer Error	N/A	Section <a href="#">Data Buffer Error</a>	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see [Halting a Queue Head](#).
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

#### 11.1.6.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*. When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](#)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB.USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB.USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

### NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

#### 11.1.6.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction. This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

#### 11.1.6.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB.USBSTS register to be set to a one. In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB.USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB.USBSTS register is also set to a one.

#### 11.1.6.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB.USBSTS register is set to a one. If the *USB Interrupt Enable* bit is set in the USB.USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

### 11.1.6.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section [Interrupt on Async Advance](#) ).

#### 11.1.6.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one. If the *Port Change Interrupt Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

#### 11.1.6.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs. If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

#### 11.1.6.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register. If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section [Removing Queue Heads from Asynchronous Schedule](#) .

#### 11.1.6.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors. The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to

continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. Table 11-52 summarizes the required actions taken on the various host errors.

**Table 11-52. Summary Behavior of EHCI Host Controller on Host System Errors**

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

### NOTE

After a *Host System Error*, Software must reset the host controller through *HCRreset* in the USB.USBCMD register before re-initializing and restarting the host controller.

## 11.1.6.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>. Device operation & On-The-Go operation

is not specified in the EHCI and thus the implementation supported in this core is proprietary. The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

#### **11.1.6.4.1 Embedded Transaction Translator Function**

The USB-HS OTG High-Speed USB On-The-Go OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

##### **11.1.6.4.1.1 Capability Registers**

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N\_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N\_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

##### **11.1.6.4.1.2 Operational Registers**

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the [Port Status & Control \(USB\\_PORTSC1\)](#) register.

### 11.1.6.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in [Table 11-53](#).

**Table 11-53. Summary of EHCI**

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub) ]

### 11.1.6.4.1.4 Data Structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the Root Hub with an embedded Transaction Translator. Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
  - Hub Address = 0
  - Transactions to direct attached device/hub.
    - QH.EPS = Port Speed
  - Transactions to a device downstream from direct attached FS hub.

- QH.EPS = Downstream Device Speed

**NOTE**

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

## 2. siTD (for direct attach FS) - Periodic (ISO Endpoint)

- All FS ISO transactions:
  - Hub Address = 0
  - siTD.EPS = 00 (full speed)
    - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

### 11.1.6.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. <http://www.usb.org>) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

#### 11.1.6.4.1.5.1 Micro-frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

#### 11.1.6.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. [Table 11-54](#) summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

**Table 11-54. Summary of the Conditions of Handshakes<sup>1</sup>**

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

#### 11.1.6.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

##### 11.1.6.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

#### 11.1.6.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

#### 11.1.6.4.1.5.3.3 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

#### 11.1.6.4.1.5.3.4 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

#### 11.1.6.4.1.5.3.5 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

### NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

#### 11.1.6.4.1.5.3.6 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N\_TT field in the [Host Controller Structural Parameters \(USB\\_HCSPARAMS\)](#) register.

### 11.1.6.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

### 11.1.6.4.3 USB.USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the [USB Device Mode \(USB\\_USBMODE\)](#) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

#### 11.1.6.4.3.1 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

#### 11.1.6.4.3.2 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode. EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See [USB Status Register \(USB\\_USBSTS\)](#) and [Interrupt Enable Register \(USB\\_USBINTR\)](#) registers.

### 11.1.6.4.4 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

#### 11.1.6.4.4.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

### 11.1.6.4.5 Miscellaneous variations from EHCI

#### 11.1.6.4.5.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the [Port Status & Control \(USB\\_PORTSC1\)](#) register providing a capability that is not defined by EHCI.

#### 11.1.6.4.5.2 Discovery

##### 11.1.6.4.5.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the [Port Status & Control \(USB\\_PORTSC1\)](#) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to the reset the controller.
- After 10 ms, software shall write a '0' to the reset the controller.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

##### 11.1.6.4.5.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.

- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

#### 11.1.6.4.5.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI since the release of revision 3.2.1. In earlier product revisions, the test packet mode was not EHCI compatible. An alternate host controller driver procedure is no longer necessary or supported.

#### 11.1.6.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller. The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

#### NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writeable fields. The device controller must preserve the read-only fields on all data structure writes.

The USB-HS OTG High-Speed USB On-The-Go core includes DCD Software called the USB 2.0 Device API. The Device API provides an easy to use Application Program Interface for developing device (peripheral) applications using the USB-HS OTG High-Speed USB On-The-Go core. The Device API incorporates and abstracts for the application developer all of the elements of the program interface.

[Figure 11-27](#) shows the organization of the End Point Queue Head.

**Figure 11-27. End Point Queue Head Organization**

Device queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

#### NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

#### 11.1.6.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

**Table 11-55. Endpoint Queue Head (dQH)**

3	3	29		28		2	2	2	2	2	2	2	1	1	1	1	15		1	1	1	1	1	9	8	7	6	5	4	3	2	1	0

--	------------------------------	--	------------------------------

### 11.1.6.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 11-56 describes the endpoint capabilities.

**Table 11-56. Endpoint Capabilities/Characteristics**

Bit	Description
31-30	<p>Mult. This field is used to indicate the number of packets executed per transaction description as given by the following:</p> <p>00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD)</p> <p>01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions.</p> <p><b>NOTE:</b> Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.</p>

Table continues on the next page...

**Table 11-56. Endpoint Capabilities/Characteristics (continued)**

29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where total transfer length is a multiple . This bit is not relevant for Isochronous  0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default).  1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

#### 11.1.6.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

#### 11.1.6.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

[Table 11-57](#) describes the dTD Pointer.

**Table 11-57. Next dTD Pointer**

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

### 11.1.6.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

#### NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

[Table 11-58](#) describes the Multiple Mode Control.

**Table 11-58. Multiple Mode Control (HCCPARAMS)**

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

### 11.1.6.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for given transfer. The DCD should not attempt to modify any field in an active dTD except the Next Link Pointer, which should only be modified as described in section [Managing Transfers with Transfer Descriptors](#).

Table below shows the Endpoint Transfer Descriptor (dTD).

**Table 11-59. Endpoint Transfer Descriptor (dTD)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

--	------------------------------	--	------------------------------

Table 11-60 describes the dTD Pointer.

**Table 11-60. Next dTD Pointer**

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

Table 11-61 describes the dTD Token.

**Table 11-61. dTD Token**

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	<p>Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.</p> <p>The maximum value software may store in the field is 5*4K(5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1<sup>st</sup> offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K(4000H).</p> <p>If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</p> <p>It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of <i>Maximum Packet Length</i>. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less than <i>Maximum Packet Length</i>.</p>
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	<p>Multiplier Override (MultiO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO.</p> <p>Example:</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default]</p> <p>Three packets are sent: {Data2(8); Data1(7); Data0(0)}</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2</p> <p>Two packets are sent: {Data1(8); Data0(7)}</p> <p>For maximal efficiency, software should compute MultiO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultiO should be 1.</p> <p>Note: Non-ISO and Non-TX endpoints must set MultiO="00".</p>
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	<p>Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are:</p> <p>Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4,2,0 Reserved.</p>

Table 11-62 describes the dTD Buffer Page Pointer List.

**Table 11-62. dTD Buffer Page Pointer List**

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

### 11.1.6.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus. Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

#### 11.1.6.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

1. Set Controller Mode in the USBx\_USBMODE register to device mode.
2. Allocate and Initialize device queue heads in system memory.

#### NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USBx\_USBMODE.

- Minimum: Initialize device queue heads 0 Tx & 0 Rx.
- For information on device queue heads, refer to section [Device Data Structures](#).

**NOTE**

All device queue heads associated with control endpoints must be initialized before the control endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

3. Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
4. Enable the microprocessor interrupt associated with the USB-HS OTG High-Speed USB On-The-Go core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the [Interrupt Enable Register \(USB\\_USBINTR\)](#) and the [USB Status Register \(USB\\_USBSTS\)](#) register tables.
5. Set Run/Stop bit to Run Mode.
  - After the Run bit is set, a device reset will occur. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the following Port State and Control section below.

**NOTE**

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

### 11.1.6.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'. After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0. The following state diagram depicts the state of a USB 2.0 device.

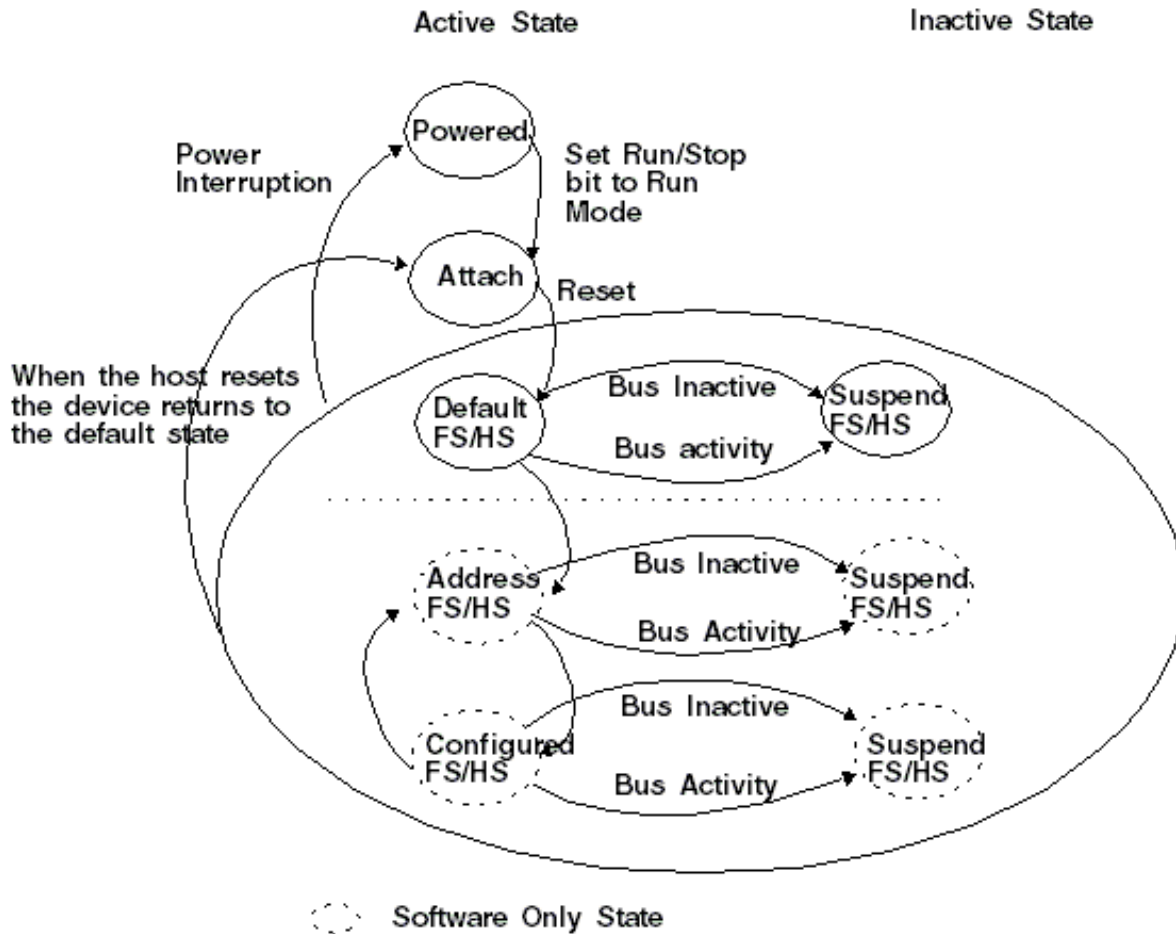

Figure 11-28. Device State Diagram

States *powered*, *attach*, *defaultFS/HS*, *suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

Table 11-63 describes the Device Controller State Information Bits.

Table 11-63. Device Controller State Information Bits

Bit	Register
DCSuspend	USB Status Register (USB_USBSTS)
USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	Port Status & Control (USB_PORTSC1)

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRLx registers and initializing the associated queue heads.

#### 11.1.6.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices. When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the [Endpoint Status \(USB\\_ENDPTSTAT\)](#) register and writing the same value back to the [Endpoint Status \(USB\\_ENDPTSTAT\)](#) register.

Clear all the endpoint complete status bits by reading the [Endpoint Complete \(USB\\_ENDPTCOMPLETE\)](#) register and writing the same value back to the [Endpoint Complete \(USB\\_ENDPTCOMPLETE\)](#) register.

Cancel all primed status by waiting until all bits in the [Endpoint Initialization \(USB\\_ENDPTPRIME\)](#) are 0 and then writing 0xFFFFFFFF to [Endpoint De-Initialize \(USB\\_ENDPTFLUSH\)](#).

Read the reset bit in the [Port Status & Control \(USB\\_PORTSC1\)](#) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the [Port Status & Control \(USB\\_PORTSC1\)](#) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

### NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

## 11.1.6.6.2.2 Suspend/Resume

### 11.1.6.6.2.2.1 Suspend

#### Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

#### Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the [Port Status & Control \(USB\\_PORTSC1\)](#) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

### **NOTE**

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

#### **11.1.6.6.2.2.2 Resume**

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port. Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the [Port Status & Control \(USB\\_PORTSC1\)](#) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

### **NOTE**

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

#### **11.1.6.6.2.3 Managing Endpoints**

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk*, *interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. If the maximum of 16 endpoint numbers, one for each endpoint direction are being used by the device controller, then 32 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

#### 11.1.6.6.2.4 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRLx register. Each 32-bit ENDPTCTRLx is split into an upper and lower half. The lower half of ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. [Table 11-64](#) shows the fields and values for the Device Controller Endpoint initialization.

**Table 11-64. Device Controller Endpoint Initialization**

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

#### 11.1.6.6.2.5 Stalling

There are two occasions where the device controller may need to return to the host a STALL

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the `ENDPTCTRLx` register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the `ENDPTCTRLx` register can ensure that both stall bits are set at the same instant.

### NOTE

Any write to the `ENDPTCTRLx` register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

Table 11-65 shows the response matrix for the Device Controller Stall.

**Table 11-65. Device Controller Stall Response Matrix**

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

#### 11.1.6.6.2.6 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe. For more information on data toggle, refer to the USB 2.0 specification.

#### 11.1.6.6.2.6.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the `ENDPTCTRLx` register. This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

#### 11.1.6.6.2.6.2 Data Toggle Inhibit

### NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the `DATA0/DATA1` bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

#### 11.1.6.6.2.6.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the `USB.ENDPTSTATUS` register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

#### 11.1.6.6.2.6.4 *Priming Receive Endpoints*

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

### 11.1.6.6.3 **Operational Model For Packet Transfers**

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification. At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

### 11.1.6.6.3.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$

With Zero Length Termination (ZLT) = 1

$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$

**Table 11-66. Variable Length Transfer Protocol Example (ZLT = 0)**

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

**Table 11-67. Variable Length Transfer Protocol Example (ZLT = 1)**

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

#### NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. \*\*\* Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. \*\*\* Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. \*\*\* This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). \*\*\* This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

### NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

#### 11.1.6.6.3.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

Table 11-68 shows the response matrix for Interrupt/Bulk Endpoint Bus.

**Table 11-68. Interrupt/Bulk Endpoint Bus Response Matrix**

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

### NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

### 11.1.6.6.3.2 Control Endpoint Operation Model

#### 11.1.6.6.3.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

In hardware versions 2.3 and later, the setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

#### Setup Packet Handling (Pre-2.3 hardware)

- After receiving an interrupt and inspecting [USB Device Mode \(USB\\_USBMODE\)](#) to determine that a setup packet was received on a particular pipe:
  1. Duplicate contents of dQH.SsetupBuffer into local software byte array.
  2. Write '1' to clear corresponding [Endpoint Setup Status \(USB\\_ENDPTSETUPSTAT\)](#) bit and thereby disabling Setup Lockout. (That is, the Setup Lockout activates as soon as a setup arrives. By writing to the [Endpoint Setup Status \(USB\\_ENDPTSETUPSTAT\)](#), the device controller will accept new setup packets.)
  3. Process setup packet using local software byte array copy and execute status/handshake phases.

#### NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

**NOTE**

To limit the exposure of setup packets to the setup lockout mechanism (if used), the DCD should designate the priority of responding to setup packets above responding to other packet completions.

## Setup Packet Handling (2.3 hardware and later)

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in [USB Device Mode \(USB\\_USBMODE\)](#). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

**NOTE**

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting [Endpoint Setup Status \(USB\\_ENDPTSETUPSTAT\)](#) to determine that a setup packet was received on a particular pipe:
  - a. Write 1 to clear corresponding bit [Endpoint Setup Status \(USB\\_ENDPTSETUPSTAT\)](#).
  - b. Write 1 to Setup Tripwire (SUTW) in [USB Command Register \(USB\\_USBCMD\)](#) register.
  - c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  - d. Read Setup TripWire (SUTW) in [USB Command Register \(USB\\_USBCMD\)](#) register. (if set - continue; if cleared - goto 2)
  - e. Write 0 to clear Setup Tripwire (SUTW) in [USB Command Register \(USB\\_USBCMD\)](#) register.
  - f. Process setup packet using local software byte array copy and execute status/handshake phases.

**NOTE**

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

**11.1.6.6.3.2.2 Data Phase**

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the [Endpoint Initialization \(USB\\_ENDPTPRIME\)](#) register is zero and the associated bit in the [Endpoint Status \(USB\\_ENDPTSTAT\)](#) register is a one. If a prime fails, ie. The [Endpoint Initialization \(USB\\_ENDPTPRIME\)](#) bit goes to zero and the [Endpoint Status \(USB\\_ENDPTSTAT\)](#) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status ([Endpoint Status \(USB\\_ENDPTSTAT\)](#)) to enforce data coherency with the setup packet.

### NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

#### 11.1.6.6.3.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

### NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

#### 11.1.6.6.3.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

[Table 11-69](#) shows the response matrix for the Control Endpoint Bus.

**Table 11-69. Control Endpoint Bus Response Matrix**

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	

*Table continues on the next page...*

**Table 11-69. Control Endpoint Bus Response Matrix (continued)**

Setup	ACK	ACK	ACK	N/A	SYSEERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSEERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

#### 11.1.6.6.3.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes. Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro)Frame are transmitted/received. Note: MULT is a 2-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoint. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to

the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

#### NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received\*\*
    - \*\* Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]

- Fulfillment Error [*Transaction Error* bit is set]
  - # Packets Occurred > 0 AND # Packets Occurred < MULT
- CRC Error [*Transaction Error* bit is set]

### NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

#### 11.1.6.6.3.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochroous data pipe to the host, the (micro)frame number (USB.FRINDEX register) can be used as a marker. To cause a packet transfer to occur at a specific (micro)frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB.FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro)frame N-1 so that the device controller will execute delivery during (micro)frame N.

### NOTE

Priming an endpoint towards the end of (micro)frame N-1 will not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

#### 11.1.6.6.3.3.2 Isochronous Endpoint Bus Response Matrix

Table 11-70 shows the response matrix for the Isochronous Endpoint Bus.

**Table 11-70. Isochronous Endpoint Bus Response Matrix**

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

#### 11.1.6.6.4 Managing Queue Heads

Figure 11-29 shows the End Point Queue Head.

**Figure 11-29. End Point Queue Head Diagram**

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by `USB.ENDPOINTLISTADDR` contains a group of all dQH's in a sequential list as shown in Figure 11-29. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section [Software Link Pointers](#)).

In addition to the current and next pointers and the dTD overlay examined in section [Operational Model For Packet Transfers](#), the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

##### 11.1.6.6.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required bandwidth an in conjunction with the USB Chapter 9 protocol.

**NOTE**

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

**NOTE**

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

**11.1.6.6.4.2 Operational Model For Setup Transfers**

As discussed in section [Control Endpoint Operation Model](#), setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

**NOTE**

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

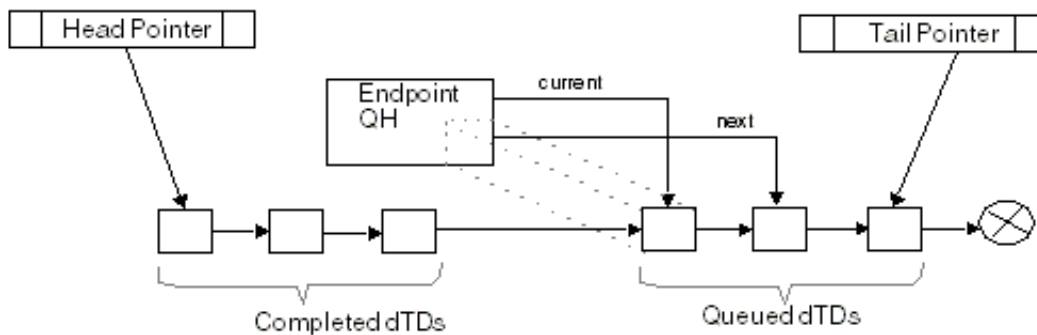

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section [Flushing/De-priming an Endpoint](#).
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

**NOTE**

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

**11.1.6.6.5 Managing Transfers with Transfer Descriptors****11.1.6.6.5.1 Software Link Pointers**

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. Figure 11-30 shows the Software Link Pointers.

**Figure 11-30. Software Link Pointers**

**NOTE**

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

**11.1.6.6.5.2 Building a Transfer Descriptor**

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

### 11.1.6.6.5.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty:

- Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding)
- Case 1: Link list is empty
  - 1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  - 2. Clear active & halt bit in dQH (in case set from a previous error).
  - 3. Prime endpoint by writing 1 to correct bit position in [Endpoint Initialization \(USB\\_ENDPTPRIME\)](#).
- Case 2: Link list is not empty
  - 1. Add dTD to end of linked list.
  - 2. Read correct prime bit in [Endpoint Initialization \(USB\\_ENDPTPRIME\)](#)- if 1 DONE.
  - 3. Set ATDTW bit in USBCMD register to 1.
  - 4. Read correct status bit in [Endpoint Status \(USB\\_ENDPTSTAT\)](#). (store in tmp. variable for later)
  - 5. Read ATDTW bit in USBCMD register.
  - If 0 goto 3.
  - If 1 continue to 6.
  - 6. Write ATDTW bit in USBCMD register to 0.
  - 7. If status bit read in (3) is 1 DONE.
  - 8. If status bit read in (3) is 0 then Goto Case 1: Step 1.

#### 11.1.6.6.5.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

#### NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the [Device Error Matrix](#).

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

#### 11.1.6.6.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in [Endpoint De-Initialize \(USB\\_ENDPTFLUSH\)](#).
2. Wait until all bits in [Endpoint De-Initialize \(USB\\_ENDPTFLUSH\)](#) are '0'.

- Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read [Endpoint Status \(USB\\_ENDPTSTAT\)](#) to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
    - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using [Endpoint De-Initialize \(USB\\_ENDPTFLUSH\)](#). A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

#### 11.1.6.6.5.6 Device Error Matrix

[Table 11-71](#) summarizes packet errors that are not automatically handled by the Device Controller.

**Table 11-71. Device Error Matrix**

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. [Table 11-72](#) describes the errors.

**Table 11-72. Error Descriptions**

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length.
	** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Hst failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

### 11.1.6.6.6 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

#### 11.1.6.6.6.1 High-Frequency Interrupts

High frequency interrupts in particular should be handed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

[Table 11-73](#) describes the High frequency interrupt events.

**Table 11-73. High Frequency Interrupt Events**

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in <a href="#">Figure 11-29</a> shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt <sup>1</sup> - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in <a href="#">Figure 11-29</a> shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

#### 11.1.6.6.6.2 Low-Frequency Interrupts

The low frequency events include the following interrupts. These interrupt can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

[Table 11-74](#) shows the Low frequency interrupt events.

**Table 11-74. Low Frequency Interrupt Events**

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

### 11.1.6.6.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

Table 11-75 shows the error interrupt events

**Table 11-75. Error Interrupt Events**

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

## 11.1.7 Glossary of Terms and Abbreviations

This chapter lists and defines terms and abbreviations used throughout this specification.

**Table 11-76. Glossary**

ACK	Handshake packet indicating a positive acknowledgment.
Active Device	A device that is powered and is not in the Suspend state.
Asynchronous Data	Data transferred at irregular intervals with relaxed latency requirements.
Asynchronous RA	The incoming data rate, $F^{si}$ , and the outgoing data rate, $F^{so}$ , of the RA process are independent (i.e., there is no shared master clock). See also rate adaptation.
Asynchronous SRC	The incoming sample rate, $F^{si}$ , and outgoing sample rate, $F^{so}$ , of the SRC process are independent (i.e., there is no shared master clock). See also sample rate conversion.
Audio Device	A device that sources or sinks sampled analog data.
AWG#	The measurement of a wire's cross-section, as defined by the American Wire Gauge standard.
b/s	Transmission rate expressed in bits per second.
B/s	Transmission rate expressed in bytes per second.
Babble	Unexpected bus activity that persists beyond a specified point in a (micro) frame.
Bandwidth	The amount of data transmitted per unit of time, typically bits per second (b/s) or bytes per second (B/s).
Big Endian	A method of storing data that places the most significant byte of multiple-byte values at a lower storage address. For example, a 16-bit integer stored in big endian format places the least significant byte at the higher address and the most significant byte at the lower address. See also little endian.
Bit	A unit of information used by digital computers. Represents the smallest piece of addressable memory within a computer. A bit expresses the choice between two possibilities and is typically represented by a logical one (1) or zero (0).
Bit Stuffing	Insertion of a "0" bit into a data stream to cause an electrical transition on the data wires, allowing a PLL to remain locked.

*Table continues on the next page...*

**Table 11-76. Glossary (continued)**

Buffer	Storage used to compensate for a difference in data rates or time of occurrence of events, when transmitting data from one device to another.
Bulk Transfer	One of the four USB transfer types. Bulk transfers are non-periodic, large burst communication typically used for a transfer that can use any available bandwidth and can be delayed until bandwidth is available. See also transfer type.
Bus Enumeration	Detecting and identifying USB devices.
Byte	A data element that is eight bits in size.
Capabilities	Those attributes of a USB device that are administrated by the host.
Characteristics	Those qualities of a USB device that are unchangeable; for example, the device class is a device characteristic.
Client	Software resident on the host that interacts with the USB System Software to arrange data transfer between a function and the host. The client is often the data provider and consumer for transferred data.
Configuring Software	Software resident on the host software that is responsible for configuring a USB device. This may be a system configurator or software specific to the device.
Control Endpoint	A pair of device endpoints with the same endpoint number that are used by a control pipe. Control endpoints transfer data in both directions and, therefore, use both endpoint directions of a device address and endpoint number combination. Thus, each control endpoint consumes two endpoint addresses.
Control Pipe	Same as a message pipe.
Control Transfer	One of the four USB transfer types. Control transfers support configuration/command/status type communications between client and function. See also transfer type.
CRC	See Cyclic Redundancy Check.
CTI	Computer Telephony Integration.
Cyclic Redundancy Check (CRC)	A check performed on data to see if an error has occurred in transmitting, reading, or writing the data. The result of a CRC is typically stored or transmitted with the checked data. The stored or transmitted result is compared to a CRC calculated for the data to determine if an error has occurred.
Default Address	An address defined by the USB Specification and used by a USB device when it is first powered or reset. The default address is 00H.
Default Pipe	The message pipe created by the USB System Software to pass control and status information between the host and a USB device's endpoint zero.
Device	A logical or physical entity that performs a function. The actual entity described depends on the context of the reference. At the lowest level, device may refer to a single hardware component, as in a memory device. At a higher level, it may refer to a collection of hardware components that perform a particular function, such as a USB interface device. At an even higher level, device may refer to the function performed by an entity attached to the USB; for example, a data/FAX modem device. Devices may be physical, electrical, addressable, and logical. When used as a non-specific reference, a USB device is either a hub or a function.
Device Address	A seven-bit value representing the address of a device on the USB. The device address is the default address (00H) when the USB device is first powered or the device is reset. Devices are assigned a unique device address by the USB System Software.
Device Endpoint	A uniquely addressable portion of a USB device that is the source or sink of information in a communication flow between the host and device. See also endpoint address.
Device Resources	Resources provided by USB devices, such as buffer space and endpoints. See also Host Resources and Universal Serial Bus Resources.
Device Software	Software that is responsible for using a USB device. This software may or may not also be responsible for configuring the device for use.

*Table continues on the next page...*

**Table 11-76. Glossary (continued)**

Downstream	The direction of data flow from the host or away from the host. A downstream port is the port on a hub electrically farthest from the host that generates downstream data traffic from the hub. Downstream ports receive upstream data traffic.
Driver	When referring to hardware, an I/O pad that drives an external load. When referring to software, a program responsible for interfacing to a hardware device, that is, a device driver.
DWord	Double word. A data element that is two words (i.e., four bytes or 32 bits) in size.
Dynamic Insertion and Removal	The ability to attach and remove devices while the host is in operation.
E <sup>2</sup> PROM	See Electrically Erasable Programmable Read Only Memory.
EEPROM	See Electrically Erasable Programmable Read Only Memory.
Electrically Erasable Programmable Read Only Memory (EEPROM)	Non-volatile rewriteable memory storage technology.
End User	The user of a host.
Endpoint	See device endpoint.
Endpoint Address	The combination of an endpoint number and an endpoint direction on a USB device. Each endpoint address supports data transfer in one direction.
Endpoint Direction	The direction of data transfer on the USB. The direction can be either IN or OUT. IN refers to transfers to the host; OUT refers to transfers from the host.
Endpoint Number	A four-bit value between 0H and FH, inclusive, associated with an endpoint on a USB device.
Envelope detector	An electronic circuit inside a USB device that monitors the USB data lines and detects certain voltage related signal characteristics.
EOF	End-of- (micro) Frame.
EOP	End-of-Packet.
External Port	See port.
Eye pattern	A representation of USB signaling that provides minimum and maximum voltage levels as well as signal jitter.
False EOP	A spurious, usually noise-induced event that is interpreted by a packet receiver as an EOP.
Flush (Endpoint)	A term used in this device controller implementation to describe the action of clearing an endpoint ready status.
Frame	A 1-millisecond time base established on full-/low-speed buses.
Frame Pattern	A sequence of frames that exhibit a repeating pattern in the number of samples transmitted per frame. For a 44.1 kHz audio transfer, the frame pattern could be nine frames containing 44 samples followed by one-frame containing 45 samples.
Fs	See sample rate.
Full-duplex	Computer data transmission occurring in both directions simultaneously.
Full-speed	USB operation at 12 Mb/s. See also low-speed and high-speed
Function	A USB device that provides a capability to the host, such as an ISDN connection, a digital microphone, or speakers.
Handshake Packet	A packet that acknowledges or rejects a specific condition. For examples, see ACK and NAK.
High-bandwidth endpoint	A high-speed device endpoint that transfers more than 1024 bytes and less than 3073 bytes per microframe.
High-speed	USB operation at 480 Mb/s. See also low-speed and full-speed
Host	The host computer system where the USB Host Controller is installed. This includes the host hardware platform (CPU, bus, etc.) and the operating system in use.

*Table continues on the next page...*

**Table 11-76. Glossary (continued)**

Host Controller	The host's USB interface.
Host Controller Driver (HCD)	The USB software layer that abstracts the Host Controller hardware. The Host Controller Driver provides an SPI for interaction with a Host Controller. The Host Controller Driver hides the specifics of the Host Controller hardware implementation.
Host Resources	Resources provided by the host, such as buffer space and interrupts. See also Device Resources and Universal Serial Bus Resources.
Hub	A USB device that provides additional connections to the USB.
Hub Tier	One plus the number of USB links in a communication path between the host and a function.
I/O Request Packet	An identifiable request by a software client to move data between itself (on the host) and an endpoint of a device in an appropriate direction.
Interrupt Request (IRQ)	A hardware signal that allows a device to request attention from a host. The host typically invokes an interrupt service routine to handle the condition that caused the request.
Interrupt Transfer	One of the four USB transfer types. Interrupt transfer characteristics are small data, non-periodic, low frequency, and bounded-latency. Interrupt transfers are typically used to handle service needs. See also transfer type.
IRP	See I/O Request Packet.
IRQ	See Interrupt Request.
Isochronous Data	A stream of data whose timing is implied by its delivery rate
Isochronous Device	An entity with isochronous endpoints, as defined in the USB Specification, that sources or sinks sampled analog streams or synchronous data streams.
Isochronous Sink Endpoint	An endpoint that is capable of consuming an isochronous data stream that is sent by the host.
Isochronous Source Endpoint	An endpoint that is capable of producing an isochronous data stream and sending it to the host.
Isochronous Transfer	One of the four USB transfer types. Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device. See also transfer type.
Jitter	A tendency toward lack of synchronization caused by mechanical or electrical changes. More specifically, the phase shift of digital pulses over a transmission medium.
kb/s	Transmission rate expressed in kilobits per second.
kB/s	Transmission rate expressed in kilobytes per second.
Little Endian	Method of storing data that places the least significant byte of multiple-byte values at lower storage addresses. For example, a 16-bit integer stored in little endian format places the least significant byte at the lower address and the most significant byte at the next address. See also big endian.
LOA	Loss of bus activity characterized by an SOP without a corresponding EOP.
Low-speed	USB operation at 1.5 Mb/s. See also full-speed and high-speed.
LSb	Least significant bit.
LSB	Least significant byte.
Mb/s	Transmission rate expressed in megabits per second.
MB/s	Transmission rate expressed in megabytes per second.
Message Pipe	A bi-directional pipe that transfers data using a request/data/status paradigm. The data has an imposed structure that allows requests to be reliably identified and communicated.
Microframe	A 125-microsecond time base established on high-speed buses.
MSb	Most significant bit.

*Table continues on the next page...*

**Table 11-76. Glossary (continued)**

MSB	Most significant byte.
NAK	Handshake packet indicating a negative acknowledgment.
Non Return to Zero Invert (NRZI)	A method of encoding serial data in which ones and zeroes are represented by opposite and alternating high and low voltages where there is no return to zero (reference) voltage between encoded bits. Eliminates the need for clock pulses.
NRZI	See Non Return to Zero Invert.
Object	Host software or data structure representing a USB entity.
Packet	A bundle of data organized in a group for transmission. Packets typically contain three elements: control information (e.g., source, destination, and length), the data to be transferred, and error detection and correction bits.
Packet Buffer	The logical buffer used by a USB device for sending or receiving a single packet. This determines the maximum packet size the device can send or receive.
Packet ID (PID)	A field in a USB packet that indicates the type of packet and by inference, the format of the packet and the type of error detection applied to the packet.
PCI	Programming and control interface
Phase	A token, data, or handshake packet. A transaction has three phases
Phase Locked Loop (PLL)	A circuit that acts as a phase detector to keep an oscillator in phase with an incoming frequency.
Physical Device	A device that has a physical implementation; e.g., speakers, microphones, and CD players.
PID	See Packet ID.
Pipe	A logical abstraction representing the association between an endpoint on a device and software on the host. A pipe has several attributes; for example, a pipe may transfer data as streams (stream pipe) or messages (message pipe) See also stream pipe and message pipe.
PLL	See Phase Locked Loop.
Polling	Asking multiple devices, one at a time, if they have any data to transmit.
POR	See Power On Reset.
Port	Point of access to or from a system or circuit. For the USB, the point where a USB device is attached.
Power On Reset (POR)	Restoring a storage device, register, or memory to a predetermined state when power is applied.
Prime (Endpoint)	A term used in this device controller implementation to describe the action of readying an endpoint to transmit or receive data.
Programmable Data Rate	A fixed data rate (single-frequency endpoints), a limited number of data rates (32 kHz, 44.1 kHz, 48 kHz, ...), or a continuously programmable data rate. The exact programming capabilities of an endpoint must be reported in the appropriate class-specific endpoint descriptors.
Protocol	A specific set of rules, procedures, or conventions relating to format and timing of data transmission between two devices.
RA	See rate adaptation.
Rate Adaptation	The process by which an incoming data stream, sampled at $F^s_i$ , is converted to an outgoing data stream, sampled at $F^s_o$ , with a certain loss of quality, determined by the rate adaptation algorithm. Error control mechanisms are required for the process. $F^s_i$ and $F^s_o$ can be different and asynchronous. $F^s_i$ is the input data rate of the RA; $F^s_o$ is the output data rate of the RA.
Request	A request made to a USB device contained within the data portion of a SETUP packet.
Retire	The action of completing service for a transfer and notifying the appropriate software client of the completion.
Root Hub	A USB hub directly attached to the Host Controller. This hub (tier 1) is attached to the host.
Root Port	The downstream port on a Root Hub.

*Table continues on the next page...*

**Table 11-76. Glossary (continued)**

Sample	The smallest unit of data on which an endpoint operates; a property of an endpoint.
Sample Rate (Fs)	The number of samples per second, expressed in Hertz (Hz).
Sample Rate Conversion (SRC)	A dedicated implementation of the RA process for use on sampled analog data streams. The error control mechanism is replaced by interpolating techniques.
Service	A procedure provided by a System Programming Interface (SPI).
Service Interval	The period between consecutive requests to a USB endpoint to send or receive data.
Service Jitter	The deviation of service delivery from its scheduled delivery time.
Service Rate	The number of services to a given endpoint per unit time.
SOF	See Start-of-Frame.
SOP	Start-of-Packet.
SPI	See System Programming Interface.
Split transaction	A transaction type supported by host controllers and hubs. This transaction type allows full- and low-speed devices to be attached to hubs operating at high-speed.
SRC	See Sample Rate Conversion.
Stage	One part of the sequence composing a control transfer; stages include the Setup stage, the Data stage, and the Status stage.
Start-of-Frame (SOF)	The first transaction in each (micro) frame. An SOF allows endpoints to identify the start of the (micro) frame and synchronize internal endpoint clocks to the host.
Stream Pipe	A pipe that transfers data as a stream of samples with no defined USB structure.
Synchronization Type	A classification that characterizes an isochronous endpoint's capability to connect to other isochronous endpoints.
Synchronous RA	The incoming data rate, $F^{si}$ , and the outgoing data rate, $F^{so}$ , of the RA process, are derived from the same master clock. There is a fixed relation between $F^{si}$ and $F^{so}$ .
Synchronous SRC	The incoming sample rate, $F^{si}$ , and outgoing sample rate, $F^{so}$ , of the SRC process are derived from the same master clock. There is a fixed relation between $F^{si}$ and $F^{so}$ .
System Programming Interface (SPI)	A defined interface to services provided by system software.
TDM	See Time Division Multiplexing.
TDR	See Time Domain Reflectometer.
Termination	Passive components attached at the end of cables to prevent signals from being reflected or echoed.
Time Division Multiplexing (TDM)	A method of transmitting multiple signals (data, voice, and/or video) simultaneously over one communications medium by interleaving a piece of each signal one after another.
Time Domain Reflectometer (TDR)	An instrument capable of measuring impedance characteristics of the USB signal lines.
Timeout	The detection of a lack of bus activity for some predetermined interval.
Token Packet	A type of packet that identifies what transaction is to be performed on the bus.
Transaction	The delivery of service to an endpoint; consists of a token packet, optional data packet, and optional handshake packet. Specific packets are allowed/required based on the transaction type.
Companion Controller	A functional component of a USB hub. The Companion Controller responds to special high-speed transactions and translates them to full/low-speed transactions with full/low-speed devices attached on downstream facing ports.
Transfer	One or more bus transactions to move information between a software client and its function.
Transfer Type	Determines the characteristics of the data flow between a software client and its function. Four standard transfer types are defined: control, interrupt, bulk, and isochronous.

*Table continues on the next page...*

**Table 11-76. Glossary (continued)**

Turn-around Time	The time a device needs to wait to begin transmitting a packet after a packet has been received to prevent collisions on the USB. This time is based on the length and propagation delay characteristics of the cable and the location of the transmitting device in relation to other devices on the USB.
Universal Serial Bus Driver (USBD)	The host resident software entity responsible for providing common services to clients that are manipulating one or more functions on one or more Host Controllers.
Universal Serial Bus Resources	Resources provided by the USB, such as bandwidth and power. See also Device Resources and Host Resources.
Upstream	The direction of data flow towards the host. An upstream port is the port on a device electrically closest to the host that generates upstream data traffic from the hub. Upstream ports receive downstream data traffic.
USBD	See Universal Serial Bus Driver.
USB-IF	USB Implementers Forum, Inc. is a nonprofit corporation formed to facilitate the development of USB compliant products and promote the technology.
Virtual Device	A device that is represented by a software interface layer. An example of a virtual device is a hard disk with its associated device driver and client software that makes it able to reproduce an audio .WAV file.
Word	A data element that is two bytes (16 bits) in size.

## 11.2 Universal Serial Bus 2.0 Integrated PHY (USBPHY)

### 11.2.1 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s. See the following figure for a block diagram of the PHY.

The integrated PHY provides a standard UTM interface. The USB\_DP and USB\_DM pins connect directly to a USB connector. USBPHY0 is the PHY interface for USB OTG 0 controller; USBPHY1 is the PHY interface for USB OTG 1 controller.

**Figure 11-31. USB 2.0 PHY Block Diagram**

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.

## 11.2.2 USB PHY Memory Map/Register Definition

### USBPHY Hardware Register Format Summary

Each of the PHY registers is accessible through 4 addresses:

- A generic R/W address for regular read/write access
- A "\_SET" address (generic + 0x4) for bit-set operation
- A "\_CLR" address (generic + 0x8) for bit-clear operation
- A "\_TOG" address (generic + 0xC) for bit-toggle operation

The generic register address is used to read or write the register. The \_SET, \_CLR, and \_TOG accesses provide atomic (single instruction) bit manipulation on the register. To perform bit operation on a register, simply write a data word with all affected bits set to "1" to the desired register. For example, setting bits 2 and 5 in registers REG looks like this: REG\_SET = 0x24; // write binary 100100 sets bits 2 and 5.

### USBPHY memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_0800	USB PHY Power-Down Register (USBPHY0_PWD)	32	R/W	001E_1C00h	<a href="#">11.2.2.1/ 2147</a>
4005_0804	USB PHY Power-Down Register (USBPHY0_PWD_SET)	32	R/W	001E_1C00h	<a href="#">11.2.2.1/ 2147</a>
4005_0808	USB PHY Power-Down Register (USBPHY0_PWD_CLR)	32	R/W	001E_1C00h	<a href="#">11.2.2.1/ 2147</a>
4005_080C	USB PHY Power-Down Register (USBPHY0_PWD_TOG)	32	R/W	001E_1C00h	<a href="#">11.2.2.1/ 2147</a>
4005_0810	USB PHY Transmitter Control Register (USBPHY0_TX)	32	R/W	1006_0607h	<a href="#">11.2.2.2/ 2148</a>
4005_0814	USB PHY Transmitter Control Register (USBPHY0_TX_SET)	32	R/W	1006_0607h	<a href="#">11.2.2.2/ 2148</a>
4005_0818	USB PHY Transmitter Control Register (USBPHY0_TX_CLR)	32	R/W	1006_0607h	<a href="#">11.2.2.2/ 2148</a>
4005_081C	USB PHY Transmitter Control Register (USBPHY0_TX_TOG)	32	R/W	1006_0607h	<a href="#">11.2.2.2/ 2148</a>
4005_0820	USB PHY Receiver Control Register (USBPHY0_RX)	32	R/W	0000_0000h	<a href="#">11.2.2.3/ 2150</a>
4005_0824	USB PHY Receiver Control Register (USBPHY0_RX_SET)	32	R/W	0000_0000h	<a href="#">11.2.2.3/ 2150</a>
4005_0828	USB PHY Receiver Control Register (USBPHY0_RX_CLR)	32	R/W	0000_0000h	<a href="#">11.2.2.3/ 2150</a>
4005_082C	USB PHY Receiver Control Register (USBPHY0_RX_TOG)	32	R/W	0000_0000h	<a href="#">11.2.2.3/ 2150</a>
4005_0830	USB PHY General Control Register (USBPHY0_CTRL)	32	R/W	C020_0040h	<a href="#">11.2.2.4/ 2152</a>
4005_0834	USB PHY General Control Register (USBPHY0_CTRL_SET)	32	R/W	C020_0040h	<a href="#">11.2.2.4/ 2152</a>

### 11.2.2.1 USB PHY Power-Down Register (USBPHYx\_PWDn)

The USB PHY Power-Down Register provides overall control of the PHY power state.

Address: Base address + 0h offset + (4d × i), where i=0d to 3d

**USBPHYx\_PWDn field descriptions**

Field	Description
31–21 RSVD2	Reserved
20 RXPWDRX	0 = Normal operation. 1 = Power-down the entire USB PHY receiver block except for the full-speed differential receiver.  <b>NOTE:</b> This bit will be auto-cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
19 RXPWDDIFF	0 = Normal operation. 1 = Power-down the USB high-speed differential receiver.  <b>NOTE:</b> This bit will be auto-cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.

*Table continues on the next page...*

## USBPHYx\_PWDn field descriptions (continued)

Field	Description
18 RXPWD1PT1	0 = Normal operation. 1 = Power-down the USB full-speed differential receiver.  <b>NOTE:</b> This bit will be auto-cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
17 RXPWDENV	0 = Normal operation. 1 = Power-down the USB high-speed receiver envelope detector (squelch signal).  <b>NOTE:</b> This bit will be auto-cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
16–13 RSVD1	Reserved
12 TXPWDV2I	This bit is used to powerdown the USB PHY transmit V-to-I converter and the current mirror.  <b>NOTE:</b> This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.  0 Normal operation. 1 Powerdown the USB PHY transmit V-to-I converter and the current mirror.
11 TXPWDIBIAS	This bit can power-down the USB PHY current bias block for the transmitter.  <b>NOTE:</b> This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.  0 Normal operation 1 Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path.
10 TXPWDFS	0 = Normal operation. 1 = Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output.  <b>NOTE:</b> This bit will be auto-cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
RSVD0	Reserved

## 11.2.2.2 USB PHY Transmitter Control Register (USBPHYx\_TXn)

The USB PHY Transmitter Control Register handles the transmit controls.

Address: Base address + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD2												TXCAL45DP			RSVD1			TXCAL45DN			RSVD0			D_CAL							
W																																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	1

## USBPHYx\_TXn field descriptions

Field	Description
31–20 RSVD2	Reserved
19–16 TXCAL45DP	Decode to trim the nominal 45-Ohm resistance to the USB_DP output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.  <b>NOTE:</b> Trimming this resistance will impact both the overshoot/undershoot of the Full Speed TX output and the amplitude of the High Speed TX output.
15–12 RSVD1	Reserved  <b>Note:</b> This bit should remain clear.
11–8 TXCAL45DN	Decode to trim the nominal 45-Ohm resistance to the USB_DN output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
7–4 RSVD0	Reserved  <b>Note:</b> This bit should remain clear.
D_CAL	Decode to trim the nominal 17.78ma current source for the High Speed TX drivers on USB_DP and USB_DM. This current is directly proportional to the amplitude of the High Speed TX eye diagram.>  0000    Maximum current, approximately 19% above nominal. 0111    Nominal. 1111    Minimum current, approximately 19% below nominal

11.2.2.3 USB PHY Receiver Control Register (USBPHYx\_RXn)

The USB PHY Receiver Control Register handles receive path controls.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

USBPHYx\_RXn field descriptions

Field	Description
31–23 RSVD2	Reserved
22 RXDBYPASS	0 = Normal operation. 1 = Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver. This test mode is intended for lab use only.
21–7 RSVD1	Reserved

Table continues on the next page...

**USBPHYx\_RXn field descriptions (continued)**

Field	Description
6–4 DISCONADJ	<p>The DISCONADJ field adjusts the trip point for the disconnect detector:</p> <p>0000 = Trip-Level Voltage is 0.57500 V</p> <p>0001 = Trip-Level Voltage is 0.56875 V</p> <p>0010 = Trip-Level Voltage is 0.58125 V</p> <p>0011 = Trip-Level Voltage is 0.58750 V</p> <p>01XX = Reserved</p> <p>1XXX = Reserved</p>
3 RSVD0	Reserved
ENVADJ	<p>The ENVADJ field adjusts the trip point for the envelope detector.</p> <p>000 = Trip-Level Voltage is 0.11250 V</p> <p>001 = Trip-Level Voltage is 0.10000 V</p> <p>010 = Trip-Level Voltage is 0.13750 V</p> <p>011 = Trip-Level Voltage is 0.10625 V</p> <p>1XX = Reserved</p>

### 11.2.2.4 USB PHY General Control Register (USBPHYx\_CTRLn)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

Address: Base address + 30h offset + (4d × i), where i=0d to 3d

## USBPHYx\_CTRLn field descriptions

Field	Description
31 SFTRST	Writing a 1 to this bit will soft-reset the USBPHY_PWD, USBPHY_TX, USBPHY_RX, and USBPHY_CTRL registers.
30 CLKGATE	Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.  Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHY_CTRL is enabled.
29 UTMI_SUSPENDM	Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHY_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	Forces the next FS packet that is transmitted to have a EOP with LS timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHY_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHY_DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	Almost same as OTGID_STATUS in USBPHY_STATUS Register. The only difference is that OTG_ID_VALUE has debounce logic to filter the glitches on ID Pad.
26–25 RSVD1	Reserved
24 FSDLL_RST_EN	Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 ENVBUSCHG_WKUP	Enables the feature to wakeup USB if VBUS is toggled when USB is suspended.
22 ENIDCHG_WKUP	Enables the feature to wakeup USB if ID is toggled when USB is suspended.
21 ENDPDMCHG_WKUP	Enables the feature to wakeup USB if DP/DM is toggled when USB is suspended. This bit is enabled by default.
20 ENAUTOCLR_PHY_PWD	Enables the feature to auto-clear the PWD register bits in USBPHY_PWD if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
19 ENAUTOCLR_CLKGATE	Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
18 RSVD0	Reserved
17 WAKEUP_IRQ	Indicates that there is a wakeup event. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
16 ENIRQWAKEUP	Enables interrupt for the wakeup events.
15 ENUTMILEVEL3	Enables UTMI+ Level3. This should be enabled if needs to support external FS Hub with LS device connected
14 ENUTMILEVEL2	Enables UTMI+ Level2. This should be enabled if needs to support LS device
13 DATA_ON_LRADC	Enables the LRADC to monitor USB_DP and USB_DM. This is for use in non-USB modes only.
12 DEVPLUGIN_IRQ	Indicates that the device is connected. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
11 ENIRQDEVPLUGIN	Enables interrupt for the detection of connectivity to the USB line.

Table continues on the next page...

**USBPHYx\_CTRLn field descriptions (continued)**

Field	Description
10 RESUME_IRQ	Indicates that the host is sending a wake-up after suspend. This bit is also set on a reset during suspend. Use this bit to wake up from suspend for either the resume or the reset case. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
9 ENIRQRESUMEDetect	Enables interrupt for detection of a non-J state on the USB line. This should only be enabled after the device has entered suspend mode.
8 RESUMEIRQSTICKY	Set to 1 will make RESUME_IRQ bit a sticky bit until software clear it. Set to 0, RESUME_IRQ only set during the wake-up period.
7 ENOTGIDDETECT	Enables circuit to detect resistance of MiniAB ID pin.
6 OTG_ID_CHG_IRQ	OTG ID change interrupt. Indicates the value of ID pin changed.
5 DEVPLUGIN_POLARITY	For device mode, if this bit is cleared to 0, then it trips the interrupt if the device is plugged in. If set to 1, then it trips the interrupt if the device is unplugged.
4 ENDEVPLUGINDETECT	For device mode, enables 200-KOhm pullups for detecting connectivity to the host.
3 HOSTDISCONDETECT_IRQ	Indicates that the device has disconnected in high-speed mode. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
2 ENIRQHOSTDISCON	Enables interrupt for detection of disconnection to Device when in high-speed host mode. This should be enabled after ENDEVPLUGINDETECT is enabled.
1 ENHOSTDISCONDETECT	For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. After a disconnection has been detected, this bit must be toggled Off/On in order to clear the detect status. In general, software sets this bit when high-speed operation is detected after the bus reset and the bit is cleared when a disconnection is detected.
0 ENOTG_ID_CHG_IRQ	Enable OTG_ID_CHG_IRQ.

### 11.2.2.5 USB PHY Status Register (USBPHYx\_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: Base address + 40h offset

### USBPHYx\_STATUS field descriptions

Field	Description
31–11 RSVD4	Reserved
10 RESUME_STATUS	Indicates that the host is sending a wake-up after suspend and has triggered an interrupt.
9 RSVD3	Reserved
8 OTGID_STATUS	Indicates the results of ID pin on MiniAB plug. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 RSVD2	Reserved
6 DEVPLUGIN_STATUS	Indicates that the device has been connected on the USB_DP and USB_DM lines.
5–4 RSVD1	Reserved
3 HOSTDISCONDETECT_STATUS	Indicates that the device has disconnected while in high-speed host mode.
RSVD0	Reserved

### 11.2.2.6 USB PHY Debug Register (USBPHYx\_DEBUGn)

This register is used to debug the USB PHY.

Address: Base address + 50h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	RSVD3		CLKGATE	HOST_RESUME_DEBUG	SQUELCHRESETLENGTH					ENSQUELCHRESET	RSVD2			SQUELCHRESETCOUNT			
W																	
Reset	0	1	1	1	1	1	1	1	0	0	0	1	1	0	0	0	
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	RSVD1			ENTX2RXCOUNT	TX2RXCOUNT				RSVD0		ENHSTPULLDOWN	HSTPULLDOWN	DEBUG_INTERFACE_HOLD	OTGIDPIOLOCK			
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## USBPHYx\_DEBUGn field descriptions

Field	Description
31 RSVD3	Reserved
30 CLKGATE	Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28–25 SQUELCHRESETLENGTH	Duration of RESET in terms of the number of 480-MHz cycles.
24 ENSQUELCHRESET	Set bit to allow squelch to reset high-speed receive.
23–21 RSVD2	Reserved
20–16 SQUELCHRESETCOUNT	Delay in between the detection of squelch to the reset of high-speed RX.
15–13 RSVD1	Reserved
12 ENTX2RXCOUNT	Set this bit to allow a countdown to transition in between TX and RX.
11–8 TX2RXCOUNT	Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7–6 RSVD0	Reserved
5–4 ENHSTPULLDOWN	Set bit 5 to 1 to override the control of the USB_DP 15-KOhm pulldown. Set bit 4 to 1 to override the control of the USB_DM 15-KOhm pulldown. Clear to 0 to disable.
3–2 HSTPULLDOWN	Set bit 3 to 1 to pull down 15-KOhm on USB_DP line. Set bit 2 to 1 to pull down 15-KOhm on USB_DM line. Clear to 0 to disable.
1 DEBUG_INTERFACE_HOLD	Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	Once OTG ID from USBPHY_STATUS_OTGID_STATUS is sampled, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

11.2.2.7 UTMI Debug Status Register 0  
(USBPHYx\_DEBUG0\_STATUS)

The UTMI Debug Status Register 0 holds multiple views for counters and status of state machines. This is used in conjunction with the USBPHY\_DEBUG1.DBG\_ADDRESS field to choose which function to view. The default is described in the bit fields below and is used to count errors.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SQUELCH_COUNT						UTMI_RXERROR_FAIL_COUNT										LOOP_BACK_FAIL_COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx\_DEBUG0\_STATUS field descriptions

Field	Description
31–26 SQUELCH_COUNT	Running count of the squelch reset instead of normal end for HS RX.
25–16 UTMI_RXERROR_FAIL_COUNT	Running count of the UTMI_RXERROR.
LOOP_BACK_FAIL_COUNT	Running count of the failed pseudo-random generator loopback. Each time entering testmode, counter goes to 900D and will count up for every detected packet failure in digital/analog loopback tests.

11.2.2.8 UTMI Debug Status Register 1 (USBPHYx\_DEBUG1n)

Chooses the muxing of the debug register to be shown in USBPHY\_DEBUG0\_STATUS.

Address: Base address + 70h offset + (4d × i), where i=0d to 3d

USBPHYx\_DEBUG1n field descriptions

Field	Description
31–15 RSVD1	Reserved
14–13 ENTAILADJVD	Delay increment of the rise of squelch: 00 = Delay is nominal 01 = Delay is +20% 10 = Delay is -20% 11 = Delay is -40%
RSVD0	Reserved <b>Note:</b> This bit should remain clear.

11.2.2.9 UTMI RTL Version (USBPHYx\_VERSION)

Fields for RTL Version.

Address: Base address + 80h offset

## USBPHYx\_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

## 11.2.2.10 USB PHY IP Block Register (USBPHYx\_IPn)

Address: Base address + 90h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved													DELAY_SOF	EN_LS_EOP_SE0	VERSION_ID
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved													EN_USB_CLKS	PLL_LOCKED	PLL_POWER
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## USBPHYx\_IPn field descriptions

Field	Description
31–19 -	This field is reserved. Reserved
18 DELAY_SOF	Delays the transmission of SOF after resume to provide more time for devices to reactive HS terminations. <b>NOTE:</b> Software must set this bit when the controller operates in host mode, to prevent false HS-disconnect detection. This bit has no effect for device mode operation.
17 EN_LS_EOP_SE0	Enables LS_EOP/SE0 to be sent after resume or wakeup per USB specification. <b>NOTE:</b> Software must set this bit to 1 when the controller operates in host mode. This bit has no effect for device mode operation.

Table continues on the next page...

## USBPHYx\_IPn field descriptions (continued)

Field	Description
	<b>NOTE:</b> When this bit is not set, some devices may not wake up properly when the host controller sends resume.
16 VERSION_ID	USB PHY version identifier. This bit is always set.
15–3 1	This field is reserved. Reserved
2 EN_USB_CLKS	If set to 0, 9-phase PLL outputs for USB PHY are powered down. If set to 1, 9-phase PLL outputs for USB PHY are powered up. Additionally, the UTMICLK120_GATE and UTMICLK30_GATE must be deasserted in the UTMI phy to enable USB operation. This bit came from the clkctrl PIO control block (clkctrl_pllctrl0_en_usb_clks).
1 PLL_LOCKED	Software controlled bit to indicate when the USB PLL has locked. Software needs to wait 10 us after enabling the PLL POWER bit (0) before asserting this bit. If set to 0, tells the UTMI module that the USB PLL has not locked. If set to 1, tells the UTMI module that the USB PLL has locked. Software should clear this bit prior to turning off the USB PLL. This bit came from the clkctrl module.
0 PLL_POWER	USB PLL Power On (0 = PLL off; 1 = PLL On). Allow 10 us after turning the PLL on before using the PLL as a clock source. This is the time the PLL takes to lock to 480 MHz. This bit came from the clkctrl PIO control block (clkctrl_pllctrl0_power).

## 11.2.3 USB Analog Memory Map/Register Definition

## USB\_ANALOG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

#### USB\_ANALOG\_USB0\_VBUS\_DETECT<sub>n</sub> field descriptions

Field	Description
31 EN_CHARGER_RESISTOR	Enable 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB. This functionality is a legacy feature held over from USB Battery Charging Specification Revision 1.0 and is incompatible with either the plugged-in detector or Battery Charging Specification Revision 1.2.

Table continues on the next page...

**USB\_ANALOG\_USB0\_VBUS\_DETECT $n$  field descriptions (continued)**

Field	Description
	0 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB is not enabled 1 Enable 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB
30–28 Reserved	This read-only field is reserved and always has the value 0.
27 CHARGE_VBUS	USB OTG charge $V_{BUS}$ . 0 Charging of the $V_{BUS}$ is not enabled 1 Enable charging of the $V_{BUS}$
26 DISCHARGE_VBUS	USB OTG discharge $V_{BUS}$ . 0 Discharging of the $V_{BUS}$ is not enabled 1 Enable discharging of the $V_{BUS}$
25–21 Reserved	This read-only field is reserved and always has the value 0.
20 VBUSVALID_PWRUP_CMPS	Powers up comparators for $V_{BUS\_valid}$ detector. 0 Powering up comparators for $V_{BUS\_valid}$ detector is not enabled 1 Enable powering up comparators for $V_{BUS\_valid}$ detector.
19 Reserved	This read-only field is reserved and always has the value 0.
18 VBUSVALID_TO_B	This bit muxes the Bvalid comparator to the VBUSVALID comparator and is used for test purposes only. 0 Multiplexing of the Bvalid comparator to the VBUSVALID comparator is not enabled 1 Enable multiplexing of the Bvalid comparator to the VBUSVALID comparator
17–8 Reserved	This read-only field is reserved and always has the value 0.
7 VBUSVALID_OVERRIDE	Override value for the VBUSVALID hardware signal. 0 Value for the VBUSVALID hardware signal is not overridden 1 Override value for the VBUSVALID hardware signal.
6 AVALID_OVERRIDE	Override value for the AVALID hardware signal. 0 AVALID hardware signal is not overridden 1 Override value for the AVALID hardware signal
5 BVALID_OVERRIDE	Override value for the BVALID hardware signal. 0 BVALID hardware signal is not overridden 1 Override value for the BVALID hardware signal
4 SESSEND_OVERRIDE	Override value for the SESSEND hardware signal. 0 SESSEND hardware signal is not overridden 1 Override value for the SESSEND hardware signal
3 VBUS_OVERRIDE_EN	Enable the override of the VBUSVALID, AVALID, BVALID, and SESSEND signals from the USB OTG PHY with override register bit values. 0 Use hardware generated values 1 Use the software controlled values.

R	0								FORCE_DETECT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**USB\_ANALOG\_USB0\_CHRG\_DETECT<sub>n</sub> field descriptions**

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 Reserved	This read-only field is reserved and always has the value 0.
22 CHRG_DET_CTRL	Forces internal USB charging circuitry to enable basic USB battery charging v1.1 device charger detection functionality. 0 USB battery charging v1.1 device charger detection functionality is not enabled 1 Enable basic USB battery charging v1.1 device charger detection functionality
21 CHRG_DET_STATUS	Status of internal charge detection. 0 Charger not detected. 1 Charger detected.
20 EN_B	This bit enables the charger detector. 0 Enable the charger detector. 1 Disable the charger detector.
19 CHK_CHRG_B	This bit checks whether a charger (either a dedicated charger or a host charger) is connected to USB port. 0 Check whether a charger (either a dedicated charger or a host charger) is connected to USB port. 1 Do not check whether a charger is connected to the USB port.
18 CHK_CONTACT	This bit checks whether the USB plug has been in contact with each other. 0 Do not check the contact of USB plug. 1 Check whether the USB plug has been in contact with each other.
17–1 Reserved	This read-only field is reserved and always has the value 0.
0 FORCE_DETECT	Set this bit to 1 to force the charger detector circuit to signal the presence of a charger. 0 The charger detector circuit is not forced to signal the presence of a charger. 1 Force the charger detector circuit to signal the presence of a charger.

11.2.3.3 USB0 V<sub>BUS</sub> Detect Status definition register  
(USB\_ANALOG\_USB0\_VBUS\_DETECT\_STATUS)

This register defines the status bits of the V<sub>BUS</sub> detectors of USB1.

Address: 4005\_0000h base + 1C0h offset = 4005\_01C0h

USB\_ANALOG\_USB0\_VBUS\_DETECT\_STATUS field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

**USB\_ANALOG\_USB0\_VBUS\_DETECT\_STATUS field descriptions (continued)**

Field	Description
3 VBUS_VALID	<p>V<sub>BUS</sub> valid for USB OTG. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software.</p> <p>0 V<sub>BUS</sub> not valid for USB OTG 1 V<sub>BUS</sub> valid for USB OTG</p>
2 AVALID	<p>Indicates V<sub>BUS</sub> is valid for a A-peripheral. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software.</p> <p>0 V<sub>BUS</sub> is not valid for a A-peripheral 1 V<sub>BUS</sub> is valid for a A-peripheral</p>
1 BVALID	<p>V<sub>BUS</sub> valid for USB B-session. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software.</p> <p>0 V<sub>BUS</sub> is not valid for USB B-session 1 V<sub>BUS</sub> valid for USB B-session</p>
0 SESSEND	<p>Session end for USB OTG. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software like the SESSEND bit below. Note: This bit's default value depends on whether VDD5V is present.</p> <p>0 VDD5V is present. 1 VDD5V is not present.</p>

### 11.2.3.4 USB0 Charger Detect Status definition register (USB\_ANALOG\_USB0\_CHRG\_DETECT\_STATUS)

This register defines the status bits for the USB charger detector of USB1.

Address: 4005\_0000h base + 1D0h offset = 4005\_01D0h

This functionality is a legacy feature held over from USB Battery Charging Specification Revision 1.0 and is incompatible with either the plugged-in detector or Battery Charging Specification Revision 1.2.  0 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB is not enabled 1 Enable 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB

Table continues on the next page...

**USB\_ANALOG\_USB1\_VBUS\_DETECT $n$  field descriptions (continued)**

Field	Description
30–28 Reserved	This read-only field is reserved and always has the value 0.
27 CHARGE_VBUS	USB OTG charge $V_{BUS}$ . 0 Charging of the $V_{BUS}$ is not enabled 1 Enable charging of the $V_{BUS}$
26 DISCHARGE_VBUS	USB OTG discharge $V_{BUS}$ . 0 Discharging of the $V_{BUS}$ is not enabled 1 Enable discharging of the $V_{BUS}$
25–21 Reserved	This read-only field is reserved and always has the value 0.
20 VBUSVALID_PWRUP_CMPS	Powers up comparators for $V_{BUS\_valid}$ detector. 0 Powering up comparators for $V_{BUS\_valid}$ detector is not enabled 1 Enable powering up comparators for $V_{BUS\_valid}$ detector.
19 Reserved	This read-only field is reserved and always has the value 0.
18 VBUSVALID_TO_B	This bit muxes the Bvalid comparator to the VBUSVALID comparator and is used for test purposes only. 0 Multiplexing of the Bvalid comparator to the VBUSVALID comparator is not enabled 1 Enable multiplexing of the Bvalid comparator to the VBUSVALID comparator
17–8 Reserved	This read-only field is reserved and always has the value 0.
7 VBUSVALID_OVERRIDE	Override value for the VBUSVALID hardware signal. 0 Value for the VBUSVALID hardware signal is not overridden 1 Override value for the VBUSVALID hardware signal.
6 AVALID_OVERRIDE	Override value for the AVALID hardware signal. 0 AVALID hardware signal is not overridden 1 Override value for the AVALID hardware signal
5 BVALID_OVERRIDE	Override value for the BVALID hardware signal. 0 BVALID hardware signal is not overridden 1 Override value for the BVALID hardware signal
4 SESSEND_OVERRIDE	Override value for the SESSEND hardware signal. 0 SESSEND hardware signal is not overridden 1 Override value for the SESSEND hardware signal
3 VBUS_OVERRIDE_EN	Enable the override of the VBUSVALID, AVALID, BVALID, and SESSEND signals from the USB OTG PHY with override register bit values. 0 Use hardware generated values 1 Use the software controlled values.
VBUSVALID_THRESH	Set the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50mV of hysteresis to prevent chattering at the comparator trip point.

1 EN_DEGLITCH	Enables the deglitching circuit of the USB PLL output.
0 -	This field is reserved. Reserved

## 11.2.4 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in [Figure 11-32](#).

### 11.2.4.1 UTMI

The UTMI block handles the line\_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL supplies a 120 MHz signal to all of the digital logic. The UTMI block does a final divide-by-four to develop the 30 MHz clock used in the interface.

### 11.2.4.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx\_valid, tx\_validh and tx\_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

### 11.2.4.3 Digital Receiver

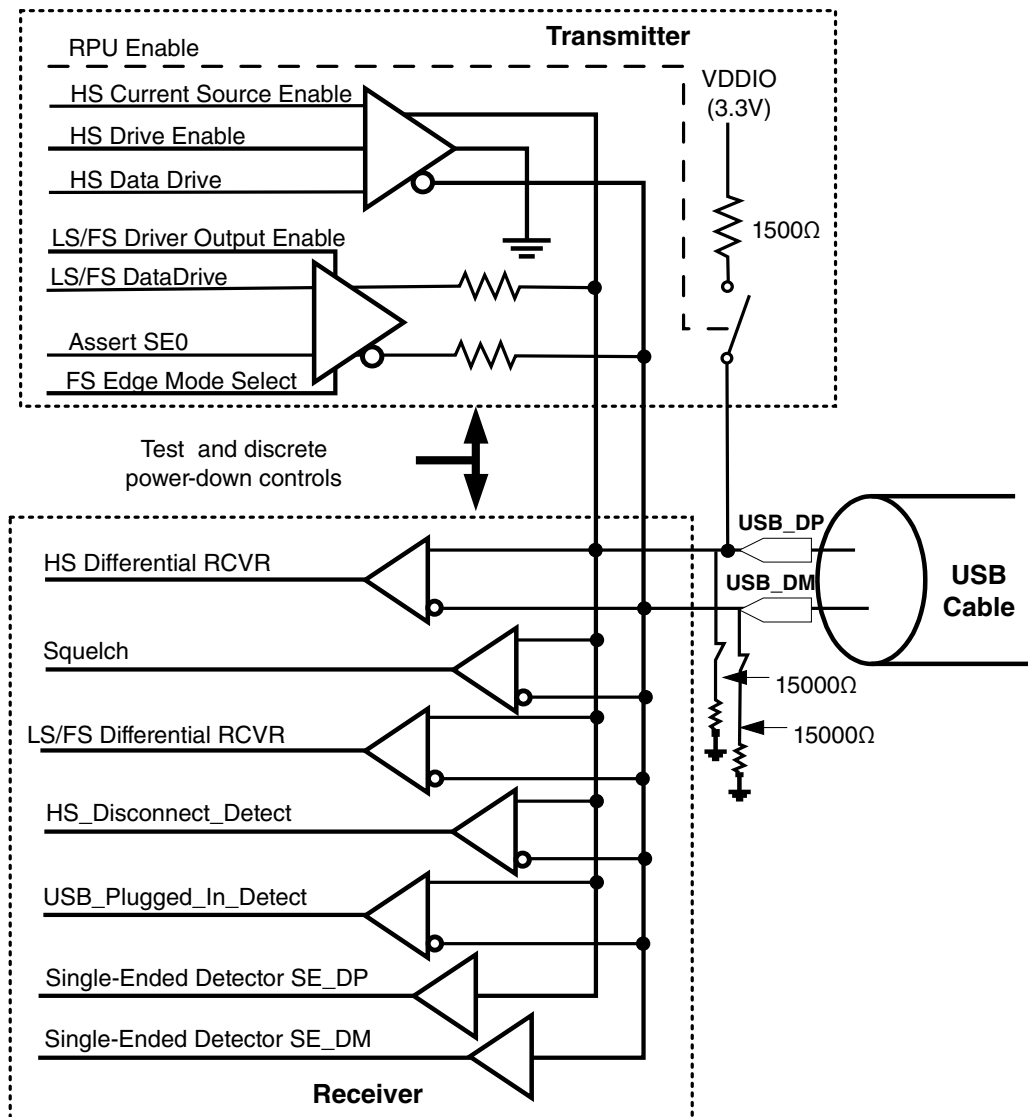

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and a 9X, 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffers restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx\_valid, rx\_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx\_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx\_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

### 11.2.4.4 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module

, as shown in the figure below and described further in this section.

**Figure 11-32. USB 2.0 PHY Analog Transceiver Block Diagram**

#### 11.2.4.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.

Otherwise, its output is 0. Its purpose is to discriminate the  $\pm 400$ -mV differential voltage resulting from the high-speed drivers current flow into the dual  $45\Omega$  terminations found on each leg of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

#### 11.2.4.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

#### 11.2.4.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB\_DP line is above the crossover point and the USB\_DM line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

#### 11.2.4.4.4 HS Disconnect Detector

This host-side function is not used in applications, but is included to make a complete UTMI macrocell. It is a differential analog receiver and threshold comparator.

It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

#### 11.2.4.4.5 USB Plugged-In Detector

The USB plugged-in detector looks for both USB\_DP and USB\_DM to be high. There is a pair of large on-chip pullup resistors (200 K $\Omega$ ) that hold both USB\_DP and USB\_DM high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case.

When operating in device mode, the upstream port in host/hub interface contains a 15 K $\Omega$  pulldown resistor which could easily override the 200 K $\Omega$  pullup resistor. When plugged in, at least one signal in the pair will be low, which will force the plugged-in detector's output high.

#### 11.2.4.4.6 Single-Ended USB\_DP Receiver

The single-ended USB\_DP receiver output is high whenever the USB\_DP input is above its nominal 1.8 V threshold.

#### 11.2.4.4.7 Single-Ended USB\_DM Receiver

The single-ended USB\_DM receiver output is high whenever the USB\_DM input is above its nominal 1.8 V threshold.

#### 11.2.4.4.8 9X Oversample Module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

### 11.2.4.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 K $\Omega$  pullup resistor.

See [Figure 1](#).

#### 11.2.4.5.1 Switchable High-Speed 45 $\Omega$ Termination Resistors

High-speed current mode differential signaling requires good 90  $\Omega$  differential termination at each end of the USB cable. This results from switching in 45  $\Omega$  terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45  $\Omega$  at each end, each driver sees a 22.5  $\Omega$  load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in [Figure 1](#). The USBPHY\_TX\_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45 $\Omega$  terminator on the USB\_DP signal.

#### 11.2.4.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially "open drain" low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

The tx\_ls\_en signal is used to select the USB\_DP/USB\_DM edge for low-speed or full-speed. Setting this bit to 1 selects the low-speed driver; otherwise the full-speed driver is selected. These drivers are both turned on, simultaneously, for high-speed signaling. This has the effect of switching in both 45  $\Omega$  terminating resistors. The tx\_fs\_hiz signal originates in the digital transmitter section. The hs\_term signal that also controls these drivers comes from the UTMI.

#### 11.2.4.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB\_DP signal or the USB\_DM signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5  $\Omega$  termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit. The Iref, Ibias, and V to I circuits are shared with the integrated battery charger.

#### 11.2.4.5.4 Switchable 1.5K $\Omega$ USB\_DP Pullup Resistor

This product contains a switchable 1.5 K $\Omega$  pullup resistor on the USB DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

#### 11.2.4.5.5 Switchable 15K $\Omega$ USB\_DP Pulldown Resistor

This product contains a switchable 15 K $\Omega$  pulldown resistor on both USB\_DP and USB\_DM signals. This is used in host mode to indicate to the device controller that a host is present.

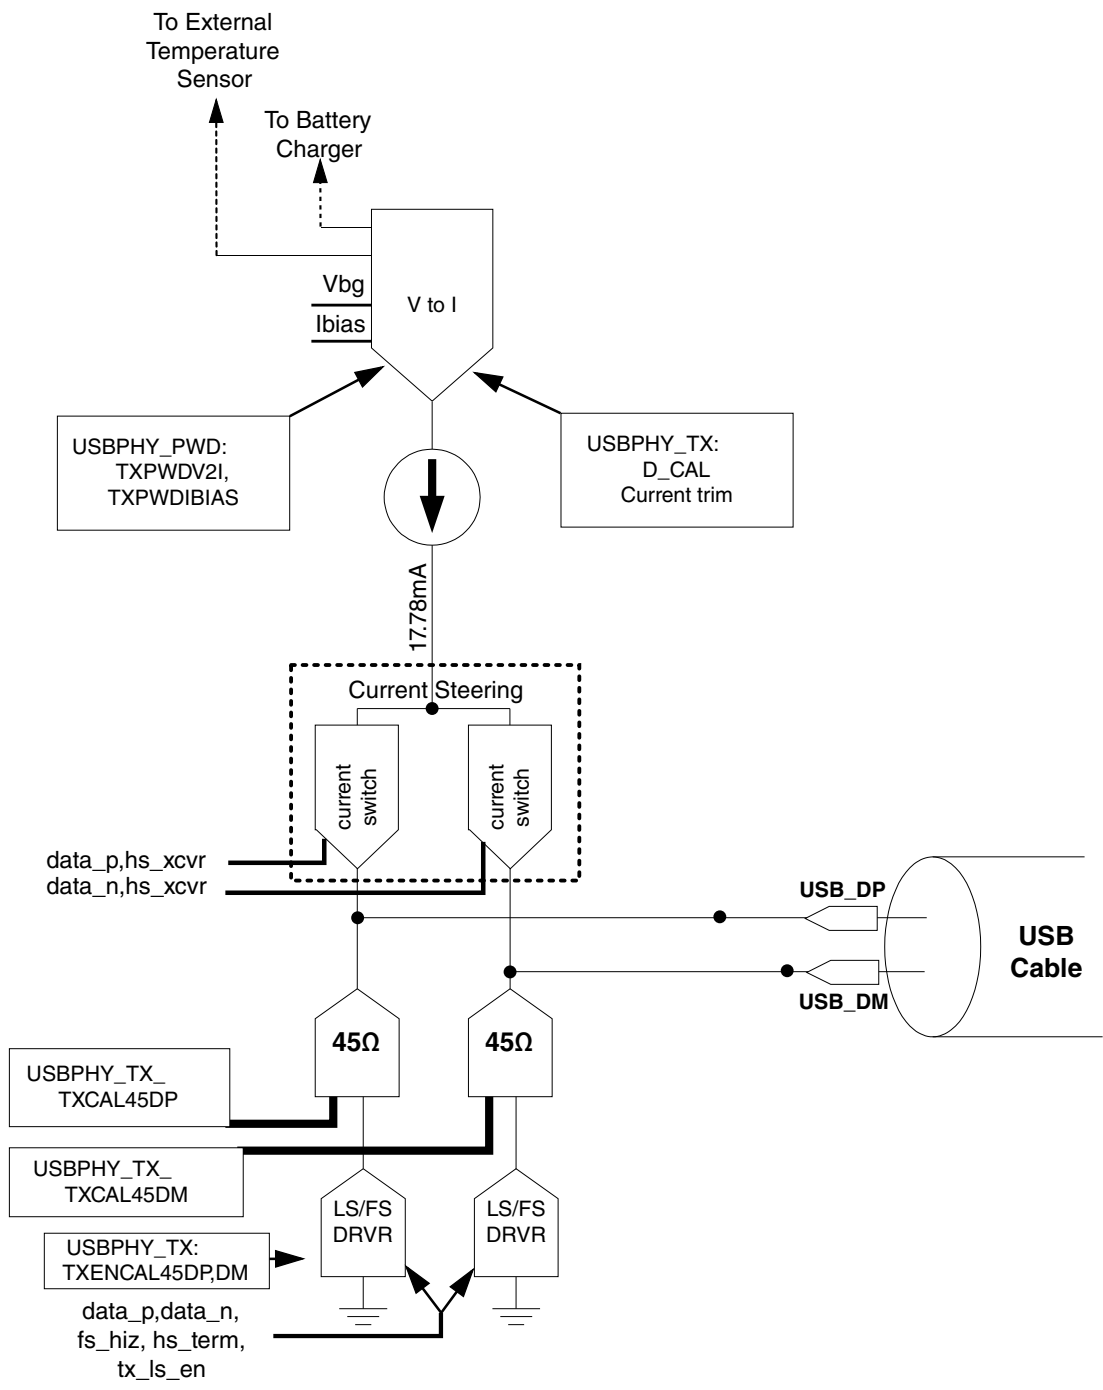

Figure 11-33. USB 2.0 PHY Transmitter Block Diagram

The table below summarizes the response of the PHY analog transmitter to various states of UTMI input and key transmit/receive state machine states.

Table 11-77. USB PHY Terminator States

UTMI OPMODE	UTM TERM	UTM XCVR	T/R	Function	45 $\Omega$ HI-Z	1500 $\Omega$ HI-Z

### 11.2.4.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

```

HW_USBPHY_TX_TXCAL45DP = 0x0
HW_USBPHY_TX_TXCAL45DM = 0x0
HW_USBPHY_TX_D_CAL = 0x7

```

## 11.3 MediaLB (MLB) (R-Series only)

### 11.3.1 Introduction

A block diagram of the MLB is available at [Figure 11-34](#).

#### 11.3.1.1 Overview

The Media Local Bus (MLB) block implements the Physical Layer and Link Layer of the MediaLB specification, interfacing to an MLB controller. The MLB implements the 3-pin MLB mode and can run at speeds up to 1024Fs. It does not implement MLB controller functionality.

All MLB devices support a set of physical channels for sending data over the MLB. Each physical channel is 4 bytes in length (quadlet) and grouped into logical channels with one or more physical channels allocated to each logical channel. These logical channels can be in any combination of channel type (synchronous, asynchronous, control, or isochronous) and direction (transmit or receive).

The MLB provides support for up to 16 logical channels and up to 31 physical channels with a maximum of 124 bytes of data per frame. Each logical channel is referenced using an unique channel address and represents a unidirectional data path between the MLB device transmitting the data and the MLB device(s) receiving the data.

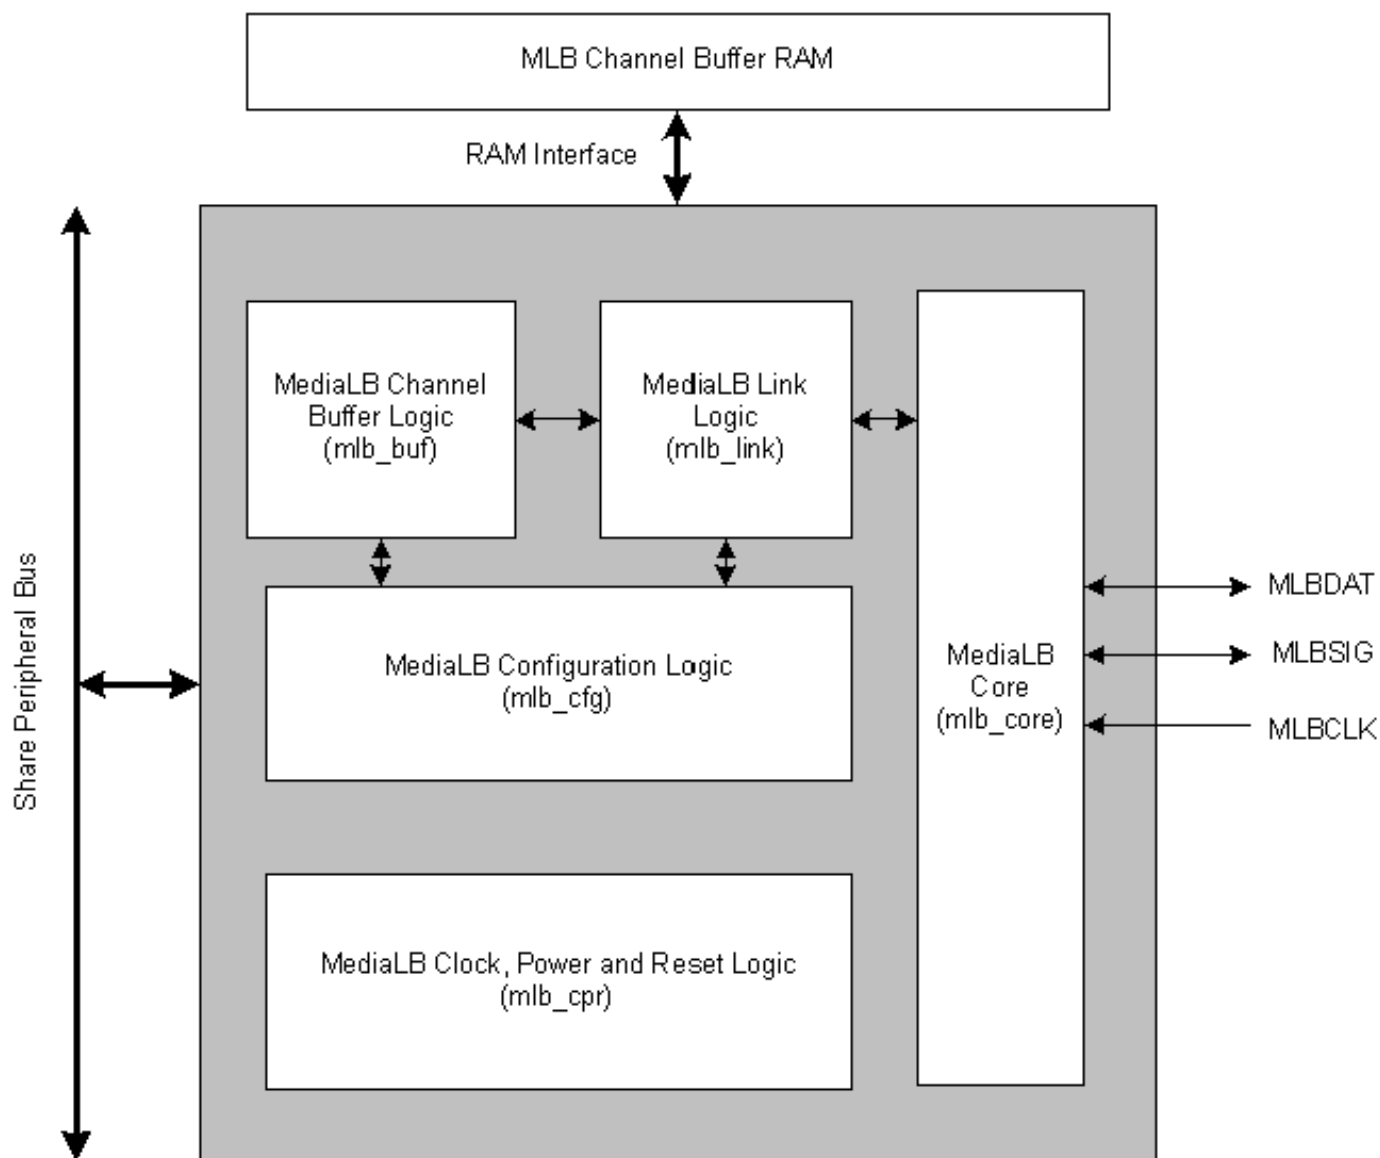

The MLB controller generates a unique frame sync pattern once per MOST network frame. This pattern defines the frame and channel boundaries of the signal information and data lines.

The MLB Controller initiates all communication over the MLB by sending out the logical channel address on the signal information line for each physical channel. This logical address indicates to the appropriate MLB device that it can transmit data for that logical channel during the next physical channel slot. One quadlet later, the transmitting MLB device sends out a MLB command byte on the signal information line and the corresponding data on the data line. All other MLB devices (including the controller) have already compared the logical channel address with their internal table of addresses to determine if they are the intended recipient of the data on this logical channel.

The receiving MLB device responds with a receive status response on the signal information line one byte after the transmitting device sends the MLB command byte. Note that synchronous data transmissions (which are the only data formats to support multiple receivers) are not acknowledged, but asynchronous, control and isochronous data transmissions are acknowledged.

For more information about the MediaLB protocol, please refer to the MediaLB Specification.

**Figure 11-34. MLB Block Diagram**

### 11.3.1.2 Features

- Support for up to 16 logical channels and 31 physical channels running at a maximum speed of 1024Fs
- Transmission of commands and data, and reception of receive status when functioning as the transmitting device associated with a logical channel address
- Reception of commands and data, and transmission as receive status responses when functioning as the receiving device associated with a logical channel address
- MLB lock detection
- System channel command handling
- Local buffer memory of 2k quadlets shared between all logical channels

### 11.3.1.3 Logic Blocks

The MediaLB design is split into five major components:

**MediaLB Core-** The MediaLB Core implements the physical layer of the MediaLB interface. This physical layer performs serial-to-parallel and parallel-to-serial data transformations and MLB frame synchronization.

**MediaLB CPR Logic-** The MLB Clocks, Power, and Reset (CPR) Logic implements clock and reset control.

**MediaLB Link Logic-** The MediaLB Link Logic implements the link layer functionality of the MediaLB interface, including:

- checking of synchronous, asynchronous, control, and isochronous channel protocol,
- handling of both RX and TX initiated breaks,
- generating RX responses to the MediaLB Core,
- generating TX commands for the MediaLB Core,
- processing of and responding to the system channel commands,
- detection of MLB bus lock/unlock, and
- recognition and pipe-lining of logical Channel Addresses.

**MediaLB Configuration Logic-** The MediaLB Configuration Logic implements the memory space for the Configuration Control Registers and Channel Configuration Registers. These configuration and control registers are used to define various parameters and control the operation of the MediaLB Device.

**MediaLB Channel Buffer Logic-** The function of the MediaLB Channel Buffer logic block includes:

- buffering of logical channel data for bus latency issues,
- multiplexing of logical channel data in Big- and Little-Endian mode, and
- implementation of hardware loop-back mode between logical channels.

### 11.3.1.4 Modes of Operation

The MediaLB uses DMA mode to transfer data between hardware channels and system memory. The byte order in which data is transferred is determined by enabling either Big-Endian or Little-Endian mode through the DCCR.MLE bit.

The MediaLB also provides customers with a single test mode, called Loop-Back Test Mode. This mode provides basic testing capabilities for the MLB pads, physical layer, link layer, channel protocol, and local channel buffer, by enabling a single RX channel and a single TX channel. The RX channel is used to transfer data directly to the enabled TX channel.

#### NOTE

MediaLB transmits quadlet-aligned isochronous data packets (data transferred in full quadlet chunks, with the exception of the last quadlet). Given an isochronous data packet size of 7 bytes, a quadlet-aligned transmission has 4 bytes in the first physical channel (IsoSync4Bytes) and 3 bytes in the next physical channel (Iso3Bytes). An example of a non-quadlet-aligned transmission is 3 bytes in the first physical channel (IsoSync3Bytes), 1 byte in the second physical channel (Iso1Byte), and 3 bytes in the third physical channel (Iso3Bytes). Isochronous receive channels are designed to support data that is either quadlet-aligned or non-quadlet-aligned. However, incoming non-quadlet-aligned data may be corrupted when the Little-Endian bit (DCCR.MLE) is set.

### 11.3.2 External Signal Description

The MediaLB has three external signals which are summarized in [Table 11-78](#).

**Table 11-78. Signal Properties**

Name	Function	I/O	Reset	Pull
MLBCLK	MLB Clock	I	In	Down
MLBDAT	MLB Data	I/O	In	Down
MLBSIG	MLB Signal	I/O	In	Down

## 11.3.2.1 Detailed Signal Descriptions

**Table 11-79. MediaLB Interface**

Signal	I/O	Description	
MLBCLK	I	MLB Clock	
		<b>State Meaning</b>	Asserted/Negated-Supports a 256Fs, 512Fs or 1024Fs clock input from the MediaLB controller.
		<b>Timing</b>	Assertion/Negation-Supports maximum frequency of 49.2 MHz for a 48 kHz sample rate. <b>NOTE:</b> System clock should be faster than MLBCLK.
MLBDAT	I/O	MLB Data	
		<b>State Meaning</b>	Asserted/Negated-MediaLB data for serial receive/transmit channel data.
		<b>Timing</b>	Assertion/Negation-Registered on the falling edge of MLBCLK.
MLBSIG	I/O	MLB Signal	
		<b>State Meaning</b>	Asserted/Negated-MediaLB signal information for serial transmit channel commands, serial receive channel responses, and logical channel address information.
		<b>Timing</b>	Assertion/Negation-Registered on the falling edge of MLBCLK.

## 11.3.3 Memory Map and Register Definition

**MLB memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 11.3.3.1 Device Control Configuration Register (MLB\_DCCR)

The Device Control Configuration Register (DCCR) is used to control basic features of the MediaLB, such as clock rate, lock status, enable, and reset behavior.

Address: 4004\_3000h base + 0h offset = 4004\_3000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R						MLK										
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**MLB\_DCCR field descriptions**

Field	Description
31 MDE	MediaLB Device Enable. When set, enables the MediaLB Interface based on the other bits in the register. 0 MediaLB Device Disabled 1 MediaLB Device Enabled
30 LBM	Loop-Back Mode Enable. When set, enables the loop-back testing of the MediaLB bus between logical channel N (RX) and logical channel N+1 (TX). {N=0, 2, 4, 6,...,14} 0 Loop-Back Mode Disabled
29–28 MCS	MediaLB Clock Select. These field must be programmed by system software to reflect the MLBCLK_IN speed.

*Table continues on the next page...*

**MLB\_DCCR field descriptions (continued)**

Field	Description
	00 256Fs: supports 8 quadlets per frame 01 512Fs: supports 16 quadlets per frame 10 1024Fs: supports 32 quadlets per frame 11 Reserved
27 M5PS	MediaLB 5-Pin Select.
26 MLK	MLB Lock. When set, indicates that the MLB Port is synchronized to the incoming MLB frame. The MediaLB port may not lock to the incoming MediaLB frame until FRAMESYNC is detected at the same position for up to five consecutive frames. If MLK is set (locked), MLK is cleared after not receiving FRAMESYNC at the expected time for two consecutive frames. While MLK is set, FRAMESYNC patterns occurring at locations other than the expected one are ignored.
25 MLE	MLB Little Endian. This field determines how MLB quadlet based data is stored in system memory.  0 Big Endian mode 1 Little Endian mode
24 MHRE	MLB Hardware Reset Enable. When set, enables hardware to automatically reset the MediaLB physical and link layer logic upon the reception of either a global (SDCR.MDS = 8'h0000) or device specific (SDCR.MDS = DA) MlbReset (FEh) System Command.  0 MediaLB device does not reset on reception of system reset command. 1 MediaLB device is reset on reception of system reset command.
23 MRS	MLB Software Reset. When set, resets the MLB physical and link layer logic. Hardware clears this bit automatically.  0 MediaLB device is not reset by software. 1 MediaLB device is reset by software.
22–8 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
MDA	MLB Device Address. Determines the unique DeviceAddress (DA) for the MLB Device. DeviceAddresses are used by the system channel MlbScan command.  DA[15:0] = {7'h00, MDA[8:1], 1'b0}

### 11.3.3.2 System Status Configuration Register (MLB\_SSCR)

The System Status Configuration register (SSCR) allows system software to monitor and control the status of the MLB network. The register is updated once per frame by hardware during the MLB System Channel. Except for the bits associated with MLB lock and unlock (SSCR.SDMU and SSCR.SDML), the bits of the SSCR register are not valid until the MLB is locked to the MLB interface. System software must service status events before the start of the next MLB frame to prevent the current frame status from being lost.

Address: 4004\_3000h base + 4h offset = 4004\_3004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W

W										w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MLB\_SSCR field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
7 SSRE	System Service Request Enable. System software can set this bit to indicate that this MLB Device is present and needs service. An RxStatus DeviceServiceRequest (82h) will be sent in response to a MlbScan System Command from the MLB Controller. Hardware clears this bit after the RxStatus is sent.  0 MLB device responds to System Scan Command with Device Present (80h). 1 MLB device responds to System Scan Command with Device Service Request (82h).
6 SDMU	System Detects MLB Unlock. This bit is set to indicate that the MLB Device has unlocked from the MLB frame. Detecting a MLB unlock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.

Table continues on the next page...

**MLB\_SSCR field descriptions (continued)**

Field	Description
	0 MLB device has not unlocked from MediaLB frame. 1 MLB device has unlocked from MediaLB frame.
5 SDML	System Detects MLB Lock. This bit is set to indicate that the MLB Device has locked to the MLB frame. Detecting a MLB lock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.  0 MLB device has not locked to MediaLB frame. 1 MLB device has locked to MediaLB frame.
4 SDSC	System Detects SubCommand. This bit is set to indicate that the MLB Device has received the MlbSubCmd (E6h) System Command. The user-defined software command is stored in the SDCR register. The decoding of this command is left up to software. Detecting MlbSubCmd generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.  0 MLB device has not detected a Sub-command System Command. 1 MLB device has detected a Sub-command System Command.
3 SDCS	System Detects Channel Scan. This bit is set to indicate that the MLB Device has received the MlbScan (E4h) System Command. The target DeviceAddress is stored in the SDCR register. Detecting MlbScan generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.  0 MLB device has not detected a System Scan Command. 1 MLB device has detected a System Scan Command.
2 SDNU	System Detects Network Unlock. This bit is set to indicate that the MLB Device has received the MOST_Unlock (E2h) System Command. Detecting MOST_Unlock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.  0 MLB device has not detected an Unlock Command. 1 MLB device has detected an Unlock Command.
1 SDNL	System Detects Network Lock. This bit is set to indicate that the MLB Device has received the MOST_Lock (E0h) System Command. Detecting MOST_Lock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.  0 MLB device has not detected a Lock Command. 1 MLB device has detected a Lock Command.
0 SDR	System Detects Reset. This bit is set to indicate that the MLB Device has received the MlbReset (FEh) System Command. The target DeviceAddress is stored in the SDCR register. Detecting MLBReset generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software.  0 MLB device has not detected a Reset Command. 1 MLB device has detected a Reset Command.

### 11.3.3.3 System Data Configuration Register (MLB\_SDCR)

The System Data Configuration Register (SDCR) allows system software to receive control information from the MLB Controller. The register is updated once per frame by hardware during the MLB System Channel. System software must read SDCR before the start of the next MLB frame to prevent the current frame data from being lost.

Address: 4004\_3000h base + 8h offset = 4004\_3008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**MLB\_SDCR field descriptions**

Field	Description
MSD	MLB System Data. This register is loaded with the data from MLBDAT during the System Channel quadlet.

### 11.3.3.4 System Mask Configuration Register (MLB\_SMCR)

The System Mask Configuration register (SMCR) allows system software to mask system status interrupts.

Address: 4004\_3000h base + Ch offset = 4004\_300Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								SMMU	SMML	SMSC	SMCS	SMNU	SMNL	SMR	
W																
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0

**MLB\_SMCR field descriptions**

Field	Description
31–7 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
6 SMMU	System Masks MLB Unlock. When set, this bit masks system interrupts generated when a MLB unlock is detected. At reset, MediaLB unlock events are masked (SMMU = 1)  0 MLB unlock system interrupt is enabled. 1 MLB unlock system interrupt is disabled.
5 SMML	System Masks MLB Lock. When set, this bit masks system interrupts generated when MLB lock is detected. At reset, MediaLB lock events are masked (SMML = 1).  0 MLB lock system interrupt is enabled. 1 MLB lock system interrupt is disabled.
4 SMSC	System Masks SubCommand. When set, this bit masks system interrupts for the MlbSubCmd (E6h) System Command.  0 MLB SubCommand system interrupt is enabled. 1 MLB SubCommand system interrupt is disabled.
3 SMCS	System Masks Channel Scan. When set, this bit masks system interrupts for the MlbScan (E4h) System Command.  0 MLB Channel Scan system interrupt is enabled. 1 MLB Channel Scan system interrupt is disabled.
2 SMNU	System Masks Network Unlock. When set, this bit masks system interrupts for the MOST_Unlock (E2h) System Command  0 MLB Network Unlock system interrupt is enabled. 1 MLB Network Unlock system interrupt is disabled.
1 SMNL	System Masks Network Lock. When set, this bit masks system interrupts for the MOST_Lock (E0h) System Command.  0 MLB Network Lock system interrupt is enabled. 1 MLB Network Lock system interrupt is disabled.
0 SMR	System Masks Reset. When set, this bit masks system interrupts for the MlbReset (FEh) System Command.  0 MLB Reset system interrupt is enabled. 1 MLB Reset system interrupt is disabled.

### 11.3.3.5 Version Control Configuration Register (MLB\_VCCR)

The Version Control Configuration Register (VCCR) allows system software to verify the version of the MediaLB.

Address: 4004\_3000h base + 1Ch offset = 4004\_301Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0

**MLB\_VCCR field descriptions**

Field	Description
31–24 UMA	User Major Revision Code. This field identifies the major revision of MLB Device. The current major revision code is 02h.
23–16 UMI	User Minor Revision Code. This field identifies the minor revision of MLB Device. The current minor revision code is 00h.
15–8 MMA	MLB Major Revision Code. This field identifies the major revision of the MLB Device. The current major revision code is 02h.
MMI	MLB Minor Revision Code. This field identifies the minor revision of the MLB Device. The current minor revision code is 02h.

### 11.3.3.6 Synchronous Base Address Configuration Register (MLB\_SBCR)

The Synchronous Base Address Configuration Register (SBCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

Address: 4004\_3000h base + 20h offset = 4004\_3020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**MLB\_SBCR field descriptions**

Field	Description
31–16 SRBA	Synchronous Receive Base Address. This base address is shared by all synchronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

*Table continues on the next page...*

**MLB\_SBCR field descriptions (continued)**

Field	Description
STBA	Synchronous Transmit Base Address. This base address is shared by all synchronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

**11.3.3.7 Asynchronous Base Address Configuration Register (MLB\_ABCR)**

The Asynchronous Base Address Configuration Register (ABCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

Address: 4004\_3000h base + 24h offset = 4004\_3024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ARBA																ATBA															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**MLB\_ABCR field descriptions**

Field	Description
31–16 ARBA	Asynchronous Receive Base Address. This base address is shared by all asynchronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
ATBA	Asynchronous Transmit Base Address. This base address is shared by all asynchronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

**11.3.3.8 Control Base Address Configuration Register (MLB\_CBCR)**

The Control Base Address Configuration Register (CBCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

Address: 4004\_3000h base + 28h offset = 4004\_3028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**MLB\_CBCR field descriptions**

Field	Description
31–16 CRBA	Control Receive Base Address. This base address is shared by all control RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

*Table continues on the next page...*

**MLB\_CBCR field descriptions (continued)**

Field	Description
CTBA	Control Transmit Base Address. This base address is shared by all control TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

**11.3.3.9 Isochronous Base Address Configuration Register (MLB\_IBCR)**

The Isochronous Base Address Configuration Register (IBCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

Address: 4004\_3000h base + 2Ch offset = 4004\_302Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IRBA																ITBA															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**MLB\_IBCR field descriptions**

Field	Description
31–16 IRBA	Isochronous Receive Base Address. This base address is shared by all Isochronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
ITBA	Isochronous Transmit Base Address. This base address is shared by all Isochronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

**11.3.3.10 Channel Interrupt Configuration Register (MLB\_CICR)**

The Channel Interrupt Configuration Register (CICR) reflects the channel interrupt status of the individual MLB logical channels. These bits are set by hardware when a channel interrupt is generated. The channel interrupt bits are sticky and can only be reset by software.

Address: 4004\_3000h base + 30h offset = 4004\_3030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																CSU															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## MLB\_CICR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
CSU	Channel Status Update for Logical Channels 15 through 0. When set, these bits indicate that hardware has generated an interrupt for the appropriate channel. These bits are sticky and can only be cleared by a software write. Writing to the CICR register has no affect. To clear a particular bit in the CICR, software must clear all of the unmasked status bits in the corresponding CSCRn register.  0 Channel n has not generated an interrupt. 1 Channel n has generated an interrupt.

## 11.3.3.11 Channel Entry Configuration Register (MLB\_CECRn)

The Channel Entry Configuration Register (CECRn) defines basic attributes about a given logical channel, such as the channel enable, channel type, channel direction, and channel address. The definition of some of the bit fields in the CECRn register vary dependant on the selected channel type.

Address: 4004\_3000h base + 40h offset + (16d × i), where i=0d to 15d

MLB\_CECR<sub>n</sub> field descriptions

Field	Description
31 CE	Channel n Enable.  0 Channel n disabled (default) 1 Channel n enabled
30 TR	Channel n Transmit Select.  0 Receive 1 Transmit
29–28 CT	Channel n Type Select.  00 Synchronous 01 Isochronous 10 Asynchronous 11 Control
27 Rsvd_FSE_FCE	The meaning of this bit depends on the type of channel:  Rsvd - For Asynchronous and Control Channels  FSE - For Synchronous Channels - Frame Synchronization Enable. When set, enables Streaming Channel Frame Synchronization for this logical synchronous channel  FCE - For Isochronous Channels - Flow Control Enable. When set, allows an isochronous RX channel to generate the ReceiverBusy (10h) response.
26–25 MDS	Channel n Mode Select.  00 ping-pong buffering used 01 circular buffering used 10-11 Reserved
24–23 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
22 MLFS	Mask Lost Frame Synchronization. When set, masks <i>Lost Frame Synchronization</i> channel interrupts for this logical channel.  0 Enable <i>Lost Frame Synchronization</i> channel interrupts for this logical channel 1 Disable <i>Lost Frame Synchronization</i> channel interrupts for this logical channel
21 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
20 MBE	Mask Buffer Error. When set, masks <i>Buffer Error</i> channel interrupts for this logical channel.  0 Enable <i>Buffer Error</i> channel interrupts for this logical channel 1 Disable <i>Buffer Error</i> channel interrupts for this logical channel
19 MBS	Mask Buffer Start. When set, masks <i>Buffer Start</i> channel interrupts for this logical channel.  0 Enable <i>Buffer Start</i> channel interrupts for this logical channel 1 Disable <i>Buffer Start</i> channel interrupts for this logical channel
18 MBD	Mask Buffer End. When set, masks <i>BufferDone</i> channel interrupts for this logical channel.  0 Enable <i>BufferDone</i> channel interrupts for this logical channel 1 Disable <i>BufferDone</i> channel interrupts for this logical channel
17 MDB	Mask Detect Break. When set, masks detect break channel interrupts for this logical channel. This bit is valid for asynchronous and control channels only.

Table continues on the next page...

## MLB\_CECRn field descriptions (continued)

Field	Description
	0 Enable detect break channel interrupts for this logical channel 1 Disable detect break channel interrupts for this logical channel
16 MPE	Mask Protocol Error. When set, masks Protocol error channel interrupts for this logical channel. This bit is valid for all RX channel types and valid for only asynchronous and control TX channels.  0 Enable protocol error channel interrupts for this logical channel 1 Disable protocol error channel interrupts for this logical channel
15 Rsvd_FSCD_IPL	The meaning of this bit depends on the type of channel: Rsvd: For Asynchronous and Control channels only IPL[7]: For Isochronous channels only - Isochronous Packet Length bit 7 field Isochronous Packet Length. For Isochronous TX channels, defines the number of packet bytes. The smallest isochronous packet size per frame is 5 bytes (IPL[7:0] >= 5). A packet length of 256 bytes can be represented as IPL[7:0]=00h. For Isochronous RX channels, software must program IPL[7:2] to indicate the expected number of bytes per packet, where IPL[1:0] always equals'00'. FSCD: For Synchronous channels only - Frame Synchronization Channel Disable. When set, disables this logical channel (set CECRn.CE = 0) when Lost Frame Synchronization occurs.  0 Do not disable this logical channel when frame synchronization is lost 1 Disable this logical channel when frame synchronization is lost
14–13 Rsvd_IPL	The meaning of this bit depends on the type of channel: Rsvd: For Asynchronous, control and synchronous channels only IPL[6:5]: For Isochronous channels only - Isochronous Packet Length bit6-bit5 fields
12–8 Rsvd_FSPC_IPL	The meaning of this bit depends on the type of channel: Rsvd: For Asynchronous, Control channels only FSPC: For Synchronous channels only - Frame Synchronization Physical Channels Count bit4-bit0 fields. IPL: For Isochronous channels only - Isochronous Packets Length bit4-bit0 fields
CA	Channel Address. These bits determine the <i>ChannelAddress</i> associated with this logical channel. This value is matched against the <i>ChannelAddress</i> received each physical channel from the MLB Controller. There is a <i>ChannelAddress</i> match if and only if the <i>ChannelAddress</i> recovered from the MediaLB input, <i>MLBSIG</i> , equals the <i>ChannelAddress</i> defined by: CA[15:0] = {7'h00, CA[8:1], 1'b0}.

11.3.3.12 Channel Status Configuration Register (MLB\_CSCRn)

The Channel Status Configuration Register (CSCRn) reflects the status of the given logical channel. The definition of some of the bit fields in the CSCRn register vary dependant on the selected channel type.<sup>6, 6</sup>

Address: 4004\_3000h base + 44h offset + (16d × i), where i=0d to 15d

6. If RDY is set before processing of the Current Buffer is complete, status for the Current Buffer will be reported using STS[11:8] (status bits for the Previous Buffer), and STS[3:0] (Status bits for the Current Buffer) will not be updated. The STS[3:0] bits are only updated when processing of the Current Buffer is complete and the RDY bit has not yet been set.

6. A *Done* status is always generated when the processing of a buffer has finished, even if a *Break* or *Error* condition was detected during the packet processing. If *Break* or *Error* occurred, the *Done* status bits will be set *in addition to* the *Break* or *Error* status bits.

### MLB\_CSCRn field descriptions

Field	Description
31 BM	Buffer Empty. When set, the local channel buffer (for channel n) is empty. This bit is set and cleared by hardware. At reset, the local channel buffer is empty (BM = 1).
30 BF	Buffer Full. When set, the local channel buffer (for channel n) is full. This bit is set and cleared by hardware.
29–20 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
19–18 IVB	Isochronous Valid Bytes. These bits are loaded by hardware with the number of valid bytes in the last packet of a broken Isochronous RX channel. Used in conjunction with CCBCRn.BCA, IVB[1:0] can be used by software to determine the final valid byte of the local channel buffer. (Valid for local channel buffers configured for isochronous RX data).  00 Final valid byte = (CCBCRn.BCA - 5) 01 Final valid byte = (CCBCRn.BCA - 4) 10 Final valid byte = (CCBCRn.BCA - 3) 11 Final valid byte = (CCBCRn.BCA - 2)
17 GIRB	GIRB: For isochronous data - Generate Isochronous Receive Break. When set, this bit causes hardware to terminate the current packet, flush the local channel buffer, clear the RDY bit, and load IVB[1:0]. This bit is set by system software and cleared by hardware.  GB: For asynchronous and control data - Generate Break. When the local channel buffer is configured for TX data, the setting of this bit causes hardware to send the AsyncBreak (26h) or ControlBreak (36h) command and stop the transfer. When the local channel buffer is configured for RX data, the setting of this bit causes hardware to send the MLB RxStatus ReceiverBreak (70h) and stop the transfer. This bit is set by system software and cleared by hardware.  TX Break command will be generated only when RXBusy is received as response from the receiver.
16 RDY	RDY  0 Next buffer is not ready in system memory 1 Next buffer is ready in system memory

Table continues on the next page...

## MLB\_CSCRn field descriptions (continued)

Field	Description
15–12 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
11 PBS	Previous Buffer Start. When set, this bit indicates the first quadlet of the <i>Previous Buffer</i> has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.  0 First quadlet of the <i>Previous Buffer</i> has not been successfully transmitted or received 1 First quadlet of the <i>Previous Buffer</i> has been successfully transmitted or received
10 PBD	Previous Buffer Done. When set, this bit indicates that the last quadlet of the <i>Previous Buffer</i> has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.  0 Last quadlet of the <i>Previous Buffer</i> has not been successfully transmitted or received 1 Last quadlet of the <i>Previous Buffer</i> has been successfully transmitted or received
9 PBDB	Previous Buffer Detect Break. When set, this bit indicates that either a TX channel has detected a receiver break response, <i>ReceiverBreak</i> (70h), or an RX channel has detected a transmitter break command, <i>ControlBreak</i> (36h) or <i>AsyncBreak</i> (26h), while processing the <i>Previous Buffer</i> . The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types  0 Break response was not detected while processing the Previous Buffer 1 Break response was detected while processing the Previous Buffer
8 PBPE	Previous Buffer Protocol Error. When set, this bit indicates that either a TX channel has detected an RxStatus of <i>ReceiverProtocolError</i> (72h), a RX channel has detected an invalid command for this channel type, or an additional <i>AsyncStart</i> (20h) or <i>ControlStart</i> (30h) command has been received while in the middle of a packet. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all RX channels and valid for only asynchronous and control TX channels.  0 Protocol error was not detected while processing the Previous Buffer 1 Protocol error was detected while processing the Previous Buffer
7 Reserved	This field is reserved. Reserved. Should be written as zero for compatibility.
6 LFS	Lost Frame Synchronization. When set, this bit indicates that the logical channel has lost synchronization with the MLB frame. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for synchronous channels only.  0 Frame synchronization not lost 1 Frame synchronization lost
5 ABE	AHB Bus Error. When set, this bit indicates that an AHB bus error has been detected. The setting of this bit generates a non-maskable channel interrupt to system software.  Read data (TX channels) is assumed corrupt.  Write data (RX channels) is assumed lost.
4 BE	Buffer Error. When set, this bit indicates that either a TX channel has detected a buffer underflow (for example, attempt to pop data from an empty buffer), or an RX channel has detected a buffer overflow (for example, attempt to push data onto a full buffer). The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for synchronous RX/TX and isochronous RX (CECRn.FCE = 0) channels only.  0 TX underflow or RX overflow not detected 1 TX underflow or RX overflow detected

Table continues on the next page...

## MLB\_CSCRn field descriptions (continued)

Field	Description
3 CBS	<p>Current Buffer Start. When set, this bit indicates that the DMA controller has started processing the <i>Current Buffer</i>. This bit is set after the contents of CNBCRn have been loaded into CCBCRn, the CSCRn.RDY bit has been cleared (for ping-pong buffering), and hardware is available to accept the next buffer. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.</p> <p>0 First quadlet of the Current Buffer has not been successfully transmitted or received 1 First quadlet of the Current Buffer has been successfully transmitted or received</p>
2 CBD	<p>Current Buffer Done. When set, this bit indicates that the last quadlet from the last packet (in the <i>Current Buffer</i>) has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.</p> <p>0 Last quadlet of the <i>Current Buffer</i> has not been successfully transmitted or received 1 Last quadlet of the <i>Current Buffer</i> has been successfully transmitted or received</p>
1 CBDB	<p>Current Buffer Detect Break. When set, this bit indicates that either a TX channel has detected a receiver break response, <i>ReceiverBreak</i> (70h), or an RX channel has detected a transmitter break command, <i>ControlBreak</i> (36h) or <i>AsyncBreak</i> (26h), while processing the <i>Current Buffer</i>. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for asynchronous and control channels only.</p> <p>0 Break response was not detected while processing the Current Buffer 1 Break response was detected while processing the Current Buffer</p>
0 CBPE	<p>Current Buffer Protocol Error. This bit indicates that either a TX channel has detected an RxStatus of <i>ReceiverProtocolError</i> (72h), an RX channel has detected an invalid command for a given channel type, or an additional <i>ControlStart</i> (30h) or <i>AsyncStart</i> (20h) command has been received while in the middle of a packet. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all RX channel types and valid for only asynchronous and control TX channels.</p> <p>0 Protocol error was not detected while processing the Current Buffer 1 Protocol error was detected while processing the Current Buffer</p>

### 11.3.3.13 Channel Current Buffer Configuration Register (MLB\_CCBCR<sub>n</sub>)

The Channel Current Buffer Configuration Register (CCBCR<sub>n</sub>) allows system software to monitor the address pointer and buffer length of the *Current Buffer* in system memory for the logical channel.

Address: 4004\_3000h base + 48h offset + (16d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BCA1														BCA0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BFA1														BFA0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MLB\_CCBCR<sub>n</sub> field descriptions

Field	Description
31–18 BCA1	Buffer Current Address. The BCA field defines a 16-bit address pointer, which identifies the lower half of the beginning address of the <i>Current Buffer</i> in system memory. The BCA[15:2] bits are loaded from CNBCR <sub>n</sub> .BSA[15:2] when the Next Buffer is ready for processing. This Current Buffer address pointer should always be quadlet aligned (for example, BCA[1:0] equals 2'b00). During the processing of the <i>Current Buffer</i> , the BCA field marks which quadlet of the buffer is currently being processed.
17–16 BCA0	For Synchronous, Asynchronous, and Control Channels - Hard-wired to '00' For Isochronous Channels - Buffer Current Address bits 1:0
15–2 BFA1	Buffer Final Address. The BFA field defines a 16-bit address pointer, which identifies the lower half of the ending address of the <i>Current Buffer</i> in system memory. The BFA[15:2] bits are loaded from CNBCR <sub>n</sub> .BEA[15:2] when the Next Buffer is read for processing. This Current Buffer address pointer, except when associated with isochronous channels, should always be quadlet aligned (for example, BFA[1:0] equals 2'b00). During the processing of the Current Buffer, the point at which the BCA field becomes equal to (or greater than) the BFA field indicates that the processing of the Current Buffer will end upon successful completion of the current quadlet (for isochronous and synchronous channels) or upon successful completion of the current packet (for asynchronous and control channels). It is the responsibility of system software to ensure the system memory buffers (for RX asynchronous and control channels) can accommodate overflow in the size of the largest packet supported. Additionally, single-packet buffering can be used by simply programming CNBCR <sub>n</sub> .BSA[15:2] = CNBCR <sub>n</sub> .BEA[15:2].  1. Isochronous transfers do not support single packet buffering and system memory buffer size must be the even multiple of packet length mentioned in IPL field.  2. Synchronous data do not have a concept of single and multiple packet, so BFA should always have the end address of current buffer.
BFA0	For Synchronous, Asynchronous, and Control Channels - Hard-wired to '00' For Isochronous Channels - Buffer Final Address bits 1:0

### 11.3.3.14 Channel Next Buffer Configuration Register (MLB\_CNBCRn)

The Channel Next Buffer Configuration Register (CNBCRn) allows system software to set the start and end addresses of the *Next Buffer* in system memory for the logical channel.

Address: 4004\_3000h base + 4Ch offset + (16d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BSA																BEA															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### MLB\_CNBCRn field descriptions

Field	Description
31–16 BSA	Buffer Start Address. The BSA field defines a 16-bit address pointer, which identifies the lower half of the beginning address of the <i>Next Buffer</i> in system memory. Once system software detects CSCRn.RDY has been cleared by hardware (for ping-pong buffering), the beginning address of the <i>Next Buffer</i> may be loaded into BSA[15:2]. System software should then set CSCRn.RDY. Once processing of the <i>Current Buffer</i> for the logical channel is complete, the BSA[15:2] field is loaded into the CCBCRn.BCA[15:2] field and processing of the next buffer can begin. This <i>Next Buffer</i> address pointer must always be quadlet aligned (for example, BSA[1:0] must be written as 2'b00).
BEA	Buffer End Address. The BEA field defines a 16-bit address pointer, which identifies the lower half of the ending address of the <i>Next Buffer</i> in system memory. Once system software detects CSCRn.RDY has been cleared by hardware (for ping-pong buffering), the ending address of the <i>Next Buffer</i> may be loaded into BEA[15:2]. System software should then set CSCRn.RDY. Once processing of the <i>Current Buffer</i> for the logical channel is complete, the BEA[15:2] field is loaded into the CCBCRn.BFA[15:2] field and processing of the next buffer can begin. The BEA[15:2] bits are loaded into CCBCRn.BFA[15:2] when the <i>Current Buffer</i> is finished being processed. This <i>Next Buffer</i> address pointer, except when associated with isochronous channels, should always be quadlet aligned (for example, BEA[1:0] defaults to 2'b00).

### 11.3.3.15 Local Channel Buffer Configuration Register (MLB\_LCBCRn)

The Local Channel Buffer Configuration Register (LCBCRn) allows software to optimize use of the Local Channel Buffer RAM. This register should only be written by software while the logical channel is disabled (for example, CECR3.CE clear disables Channel 3; therefore software may write LCBCR3). Writing to this register while the corresponding logical channel is enabled may result in unexpected behavior.

#### NOTE

Reset value for this register is device specific. Please see the module configuration section for details.

Address: 4004\_3000h base + 280h offset + (4d × i), where i=0d to 15d

### MLB\_LCBCR<sub>n</sub> field descriptions

Field	Description
31–30 Reserved	This field is reserved. Reserved but should not be written.
29–22 TH	Buffer Threshold. This field defines the threshold value of the local channel buffer. This value is used by the controller to issue an IO service request.  000h Rx service request is generated if the buffer is full and a TX service request is generated when the buffer is empty. 0001h threshold 2 quadlets 0002h 4 quadlets 0003h 6 quadlets - - and so on
21–20 Reserved	This field is reserved. Reserved but should not be written.
19–13 BD	Buffer Depth. This field defines the depth of the local channel buffer space in the local buffer RAM.  00h Depth = 4 quadlets 01h Depth = 8 quadlets 02h Depth = 12 quadlets . . 7Fh Depth = 512 quadlets
12–9 Reserved	This field is reserved. Reserved but should not be written.
SA	Buffer Start Address. This field defines the starting address of the channel buffer space in the local buffer RAM. At reset, the LCBCR.SA[9:0] field is loaded with the channel number multiplied by 32 (for channel number multiplied by 128 quadlets).  000h Start Address = 0 quadlets 001h Start Address = 4 quadlets 002h Start Address = 8 quadlets . . 3FFh Start Address = 2044 quadlets

**MLB\_LCBCRn field descriptions (continued)**

Field	Description
-------	-------------

## 11.3.4 Functional Description

### 11.3.4.1 Local Channel Buffer RAM

A single-port RAM is used to implement the memory space for local channel buffering. The size of the RAM is 2k x 36-bits (1 quadlet of data; 4-bit tag). The initial start address, depth and threshold values for logical channel buffer RAM are determined by parameters SA and BD. See [Table 11-80](#) for parameters that indicate the start address, depth and threshold reset values. After reset, the start address, depth for the logical channels buffered in the RAM are controlled through the LCBCRn registers, the initial values can be overwritten by software.

**Table 11-80. Local Channel Buffer RAM Parameters**

Logical Channel	SA	BD
0	0	16
1	16	16
2	32	144
3	176	144
4	320	144
5	464	144
6	608	144
7	752	144
8	896	144
9	1040	144
10	1184	144
11	1328	144
12	1472	144
13	1616	144
14	1760	144
15	1904	144

See [Figure 11-35](#) for more information on using the LCBCRn register to configure the local RAM buffer.

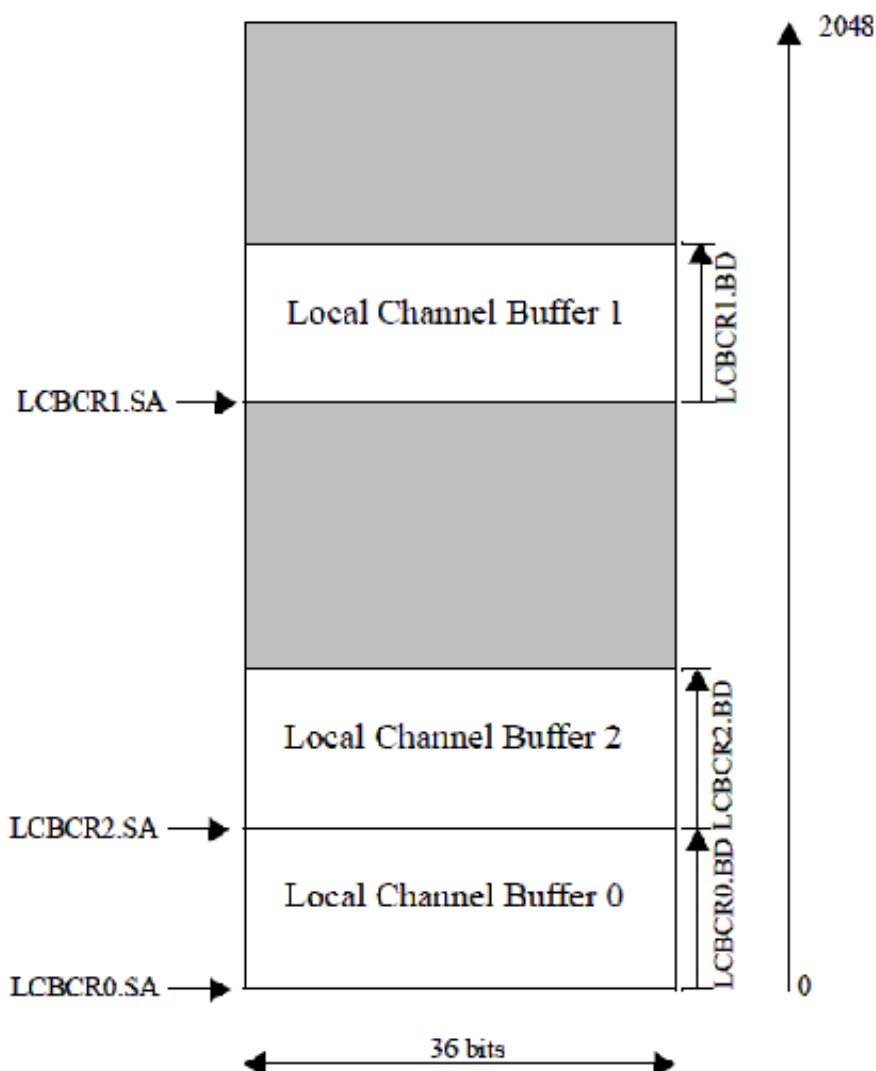

Figure 11-35. Programming Example for LCBCRn

#### 11.3.4.1.1 Local Buffer Start Address

The initial buffer start address of each local channel buffer is defined by the default (after reset) start address of each local channel buffer (`LCBCRn.SA [8:0]`). The start address is the location of the beginning of the buffer in the local buffer RAM. Software may change the start address of each local channel buffer after reset by writing to `LCBCRn.SA[8:0]` directly.

### 11.3.4.1.2 Local Channel Buffer Depth

The initial buffer depth of each local channel buffer is configured by the default (after reset) depth of each local channel buffer (LCBCRn.BD[6:3] and LCBCRn.BD[2:0]) in quadlets. The buffer depth should be set based on the worst-case peripheral interface read/write latency. Software may change the depth of each local channel buffer after reset by writing to LCBCRn.BD[6:3] and LCBCRn.BD[2:0] directly.

### 11.3.4.2 Streaming Channel Frame Synchronization

Certain types of streaming applications require data to be synchronous with the MediaLB frame, including: stereo, 5.1 audio, and Generic Synchronous Packet Format (GSPF) DTCP. The MediaLB *Streaming Channel Frame Synchronization* feature provides this option.

For example, 24-bit stereo channels require two MLB physical channels (PC) to transmit left (0xLLLLLn) and right (0xRRRRRn) speaker data. Assuming the MLB Controller allocates Physical Channel 1 (PC1) and Physical Channel 2 (PC2) to this stereo channel, the data is synchronized to the MLB frame as shown in [Table 11-81](#).

**Table 11-81. Example of 24-bit stereo data synchronous to 256Fs MediaLB frame**

Frame	PC=0	PC=1	PC=2	PC=3	PC=4	PC=5	PC=6	PC=7
n=0		0xLLLLLLRR	0xRRRRRxxx					
n=1		0xLLLLLLRR	0xRRRRRxxx					
n=2		0xLLLLLLRR	0xRRRRRxxx					
n=3		0xLLLLLLRR	0xRRRRRxxx					

Without frame synchronization, the MediaLB may begin transmitting or receiving data that is not aligned with the MLB frame. Misalignment, as depicted in [Table 11-82](#), may result in data corruption.

**Table 11-82. Example of 24-bit stereo data asynchronous to 256Fs MediaLB frame**

Frame	PC=0	PC=1	PC=2	PC=3	PC=4	PC=5	PC=6	PC=7
n=0			0xLLLLLLRR					
n=1		0xRRRRRxxx	0xLLLLLLRR					
n=2		0xRRRRRxxx	0xLLLLLLRR					
n=3		0xRRRRRxxx	0xLLLLLLRR					

The MediaLB supports *Streaming Channel Frame Synchronization* as a programmable option for each logical channel configured for synchronous dataflow. System software can enable the frame synchronization feature for a synchronous logical channel by setting CECRn.FSE. When enabled, the synchronous logical channel begins transmitting and receiving data only at a MediaLB frame boundary.

When the loss of MLB frame synchronization occurs, the MLB detects it and optionally notifies system software through a maskable channel interrupt. In order to use this option, system software must:

- program CECRn.FSPC[4:0] with the expected number of physical channels per frame for the logical channel, and
- unmask the CSCRn.STS[6] bit by setting CECRn.MLFSto 0.

A channel interrupt is generated when the actual number of physical channels detected during a MLB frame does not match the expected value. An additional channel interrupt is generated if the local channel buffer overflows (for RX channels) or underflows (for TX channels).

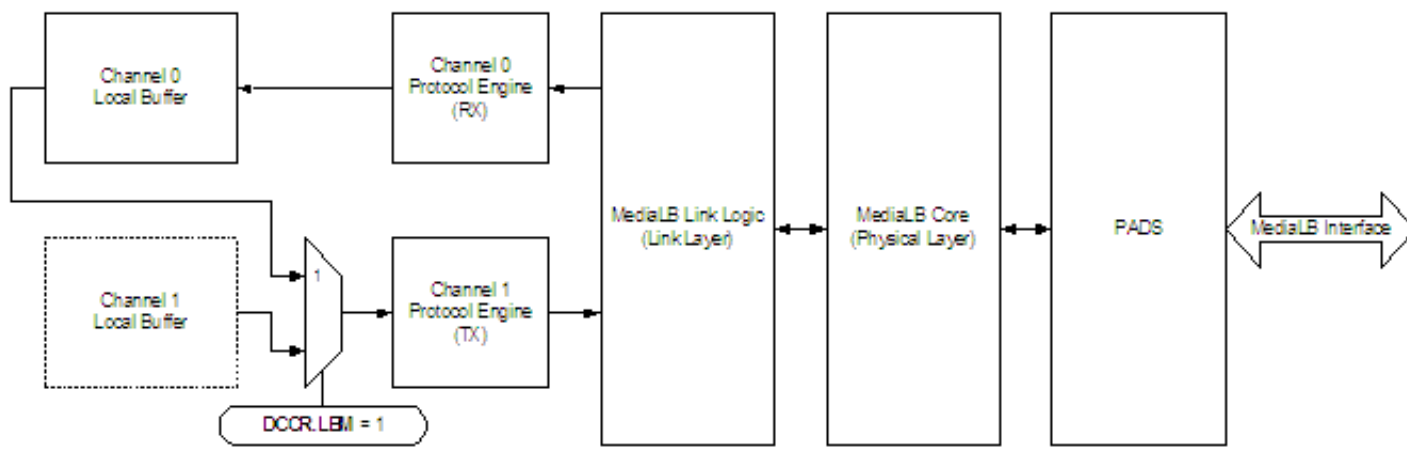

Additionally, software may instruct the MLB to automatically disable a logical channel when MediaLB frame synchronization is lost. To enable this feature, software must set CSCRn.FSCD, which causes the hardware to automatically clear the Channel Enable bit (CECRn.CE) when synchronization is lost.

Frame synchronization is not supported for asynchronous, control, or isochronous channels.

### 11.3.4.3 Loop-Back Test Mode

In order to facilitate silicon debug of the MLB Device, hardware supports the *Loop-Back Test Mode*. This mode allows testing of the MLB pads, physical layer, link layer, channel protocol, and local channel buffer. When the DCCR.LBM bit is set, a data path is enabled which allows RX data from even Channel N to be sent out as TX data on Channel N+1, where  $N = \{0, 2, 4, 6, \dots, 12, 14\}$ .

Figure 11-36 illustrates the *Loop-Back Test Mode* data path.

**Figure 11-36. Loop-Back Test Mode Data Path**

For *Loop-Back Test Mode* operation, software must perform the following steps:

- Set the logical *ChannelAddresses* for Channel N and N+1. (They cannot be the same address.)
- Enable Channel N for receiving synchronous, asynchronous, control, or isochronous data.
- Enable Channel N+1 for transmitting the same channel data type as Channel N.
- Set the Loop-Back Mode bit (DCCR.LBM).

Restrictions on the *Loop-Back Test Mode* are as follows:

- No protocol errors or breaks are allowed on either the RX or TX channel.
- Little-Endian mode must be disabled (DCCR.MLE clear).
- Isochronous packet lengths must be quadlet multiples.

Next Buffer Ready bits for Channels N and N+1 must remain clear (CSCR0.RDY = CSCL1.RDY = 0)

## 11.4 10/100-Mbps Ethernet MAC (ENET)

### 11.4.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

## 11.4.2 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

### 11.4.2.1 Features

The MAC-NET core includes the following features.

#### 11.4.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble

- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options

- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors

#### **11.4.2.1.2 IP protocol performance optimization features**

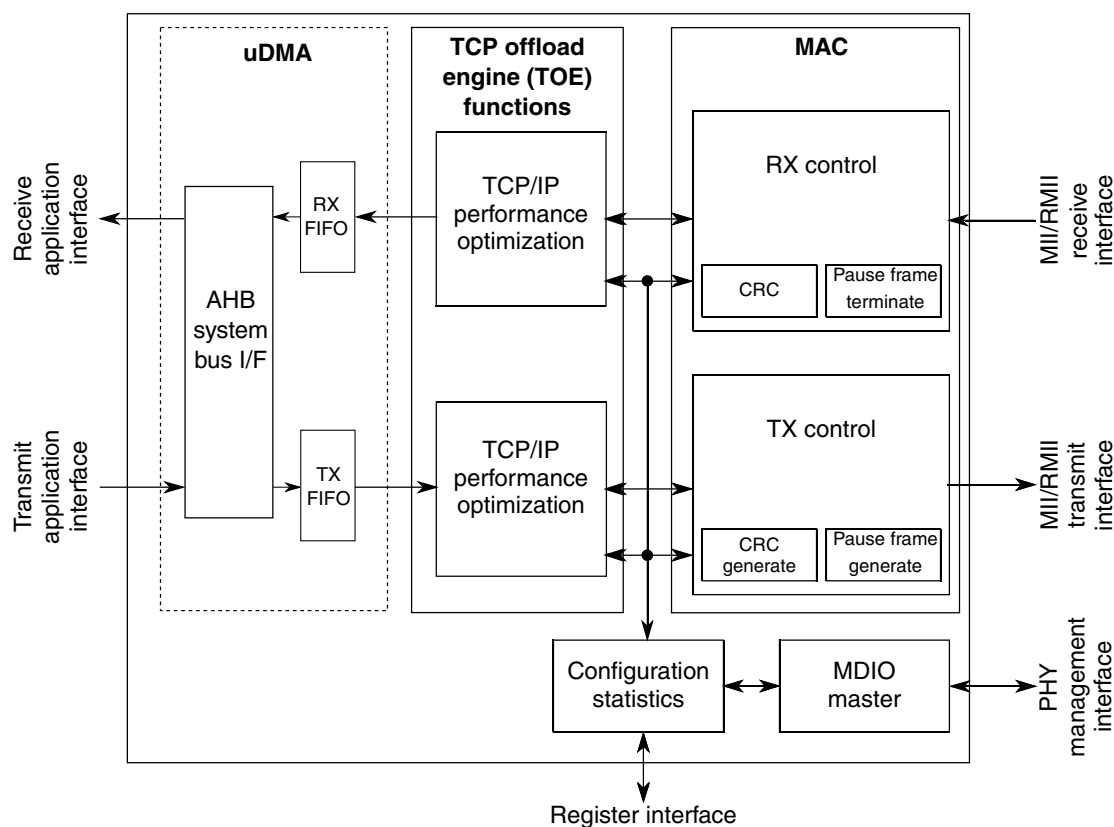

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

#### **11.4.2.1.3 IEEE 1588 features**

- Supports all IEEE 1588 frames.

- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

### 11.4.2.2 Block diagram

**Figure 11-37. Ethernet MAC-NET core block diagram**

### 11.4.3 External signal description

#### NOTE

The MII column pertains only to devices that support MII.

MII	RMII	Description	I/O
MII_COL	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.	I
MII_CRS	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle.  In RMII mode, this signal is present on the RMII_CRS_DV pin.	I
MII_MDC	RMII_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	O
MII_MDIO	RMII_MDIO	Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.	I/O
MII_RXCLK	—	In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.	I
MII_RXDV	RMII_CRS_DV	Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.  In RMII mode, this pin also generates the CRS signal.	I
MII_RXD[3:0]	RMII_RXD[1:0]	Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.	I
MII_RXER	RMII_RXER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	I

*Table continues on the next page...*

## 10/100-Mbps Ethernet MAC (ENET)

MII	RMII	Description	I/O
MII_TXCLK	—	Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.	I
MII_TXD[3:0]	RMII_TXD[1:0]	Serial output Ethernet data. Only valid during TXEN assertion.	O
MII_TXEN	RMII_TXEN	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.	O
MII_TXER	—	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	O
—	RMII_REF_CLK	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	I
1588_TMR <sub>n</sub>	1588_TMR <sub>n</sub>	<p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<sub>n</sub> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<sub>n</sub> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<sub>n</sub>.</p> <p>An interrupt can be triggered if ENET_TCSR<sub>n</sub>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<sub>n</sub>[TDRE] is set.</p>	I/O
ENET_1588_CLKIN	ENET_1588_CLKIN	Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds	I

## 11.4.4 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 11-83. Register map summary**

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

### ENET memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400D_0004	Interrupt Event Register (ENET0_EIR)	32	w1c	0000_0000h	<a href="#">11.4.4.1/ 2244</a>

**11.4.4.1 Interrupt Event Register (ENETx\_EIR)**

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

**NOTE**

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: Base address + 4h offset

**ENETx\_EIR field descriptions**

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. <b>NOTE:</b> The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
27 TXF	Transmit Frame Interrupt

Table continues on the next page...

**ENETx\_EIR field descriptions (continued)**

Field	Description
	Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
26 TXB	Transmit Buffer Interrupt  Indicates a transmit buffer descriptor has been updated.
25 RXF	Receive Frame Interrupt  Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
24 RXB	Receive Buffer Interrupt  Indicates a receive buffer descriptor is not the last in the frame has been updated.
23 MII	MII Interrupt.  Indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet Bus Error  Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
21 LC	Late Collision  Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision Retry Limit  Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
19 UN	Transmit FIFO Underrun  Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
18 PLR	Payload Receive Error  Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
17 WAKEUP	Node Wakeup Request Indication  Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
16 TS_AVAIL	Transmit Timestamp Available  Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
15 TS_TIMER	Timestamp Timer  The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
14–13 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

#### 11.4.4.2 Interrupt Mask Register (ENETx\_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Field	Description
	corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
22 EBERR	EBERR Interrupt Mask  Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
21 LC	LC Interrupt Mask  Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
20 RL	RL Interrupt Mask  Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 UN	UN Interrupt Mask  Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 PLR	PLR Interrupt Mask  Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 WAKEUP	WAKEUP Interrupt Mask  Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_AVAIL	TS_AVAIL Interrupt Mask  Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_TIMER	TS_TIMER Interrupt Mask  Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14–13 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

*Table continues on the next page...*

R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_RDAR field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RDAR	Receive Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.4.4.4 Transmit Descriptor Active Register (ENETx\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: Base address + 14h offset

ENETx\_TDAR field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TDAR	Transmit Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.4.4.5 Ethernet Control Register (ENETx\_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: Base address + 24h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved														Reserved	
W																
Reset	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

R	Reserved				Reserved	Reserved	Reserved	Reserved	Reserved	DBGEN		EN1588	SLEEP	MAGICEN	ETHEREN	RESET
W											0					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_ECR field descriptions

Field	Description
31–18 Reserved	This field is reserved. Always write 1111000000000b to this field.
17–12 Reserved	This field is reserved. Always write 0 to this field.
11 Reserved	This field is reserved. Always write 0 to this field.
10 Reserved	This field is reserved. Always write 0 to this field.
9 Reserved	This field is reserved. Always write 0 to this field.
8 DBSWP	Descriptor Byte Swapping Enable Swaps the byte locations of the buffer descriptors. <b>NOTE:</b> This field must be written to 1 after reset. 0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
7 Reserved	This field is reserved. Always write 0 to this field.
6 DBGEN	Debug Enable Enables the MAC to enter hardware freeze mode when the device enters debug mode.

*Table continues on the next page...*

**ENETx\_ECR field descriptions (continued)**

Field	Description
	0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
5 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
4 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
3 SLEEP	Sleep Mode Enable 0 Normal operating mode. 1 Sleep mode.
2 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection. <b>NOTE:</b> MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. 0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.
1 ETHEREN	Ethernet Enable Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions: <ul style="list-style-type: none"> <li>• RESET is set by software</li> <li>• An error condition causes the EBERR field to set.</li> </ul> <b>NOTE:</b> <ul style="list-style-type: none"> <li>• ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only <i>after</i> all other ENET-related registers have been configured.</li> <li>• If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts.</li> </ul> 0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. 1 MAC is enabled, and reception and transmission are possible.
0 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

**11.4.4.6 MII Management Frame Register (ENETx\_MMFR)**

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### ENETx\_MMFR field descriptions

Field	Description
31–30 ST	Start Of Frame Delimiter See <a href="#">Table 11-121</a> (Clause 22) or <a href="#">Table 11-123</a> (Clause 45) for correct value.
29–28 OP	Operation Code See <a href="#">Table 11-121</a> (Clause 22) or <a href="#">Table 11-123</a> (Clause 45) for correct value.
27–23 PA	PHY Address See <a href="#">Table 11-121</a> (Clause 22) or <a href="#">Table 11-123</a> (Clause 45) for correct value.
22–18 RA	Register Address See <a href="#">Table 11-121</a> (Clause 22) or <a href="#">Table 11-123</a> (Clause 45) for correct value.
17–16 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

#### 11.4.4.7 MII Speed Control Register (ENETx\_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of IPS bus clock frequency.

**Table 11-84. Programming Examples for MSCR**

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

### ENETx\_MSCR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 HOLDTIME	Hold time On MDIO Output  IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased.  000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
7 DIS_PRE	Disable Preamble  Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it.  0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.

*Table continues on the next page...*

**ENETx\_MSCR field descriptions (continued)**

Field	Description
6–1 MII_SPEED	MII Speed  Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of:  $1/((\text{MII\_SPEED} + 1) \times 2)$ of the internal module clock frequency
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**11.4.4.8 MIB Control Register (ENETx\_MIBC)**

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB\_DIS field resets to 1.

Address: Base address + 64h offset

### ENETx\_MIBC field descriptions

Field	Description
31 MIB_DIS	<p>Disable MIB Logic</p> <p>If this control field is set,</p> <p>0 MIB logic is enabled.</p> <p>1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.</p>
30 MIB_IDLE	<p>MIB Idle</p> <p>0 The MIB block is updating MIB counters.</p> <p>1 The MIB block is not currently updating any MIB counters.</p>
29 MIB_CLEAR	<p>MIB Clear</p> <p><b>NOTE:</b> This field is not self-clearing. To clear the MIB counters set and then clear this field.</p> <p>0 See note above.</p> <p>1 All statistics counters are reset to 0.</p>
Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

11.4.4.9 Receive Control Register (ENETx\_RCR)

Address: Base address + 84h offset

ENETx\_RCR field descriptions

Field	Description
31 GRS	Graceful Receive Stopped  Read-only status indicating that the MAC receive datapath is stopped.
30 NLC	Payload Length Check Disable  Enables/disables a payload length check.  0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLC] field.
29–16 MAX_FL	Maximum Frame Length

Table continues on the next page...

## ENETx\_RCR field descriptions (continued)

Field	Description
	Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
15 CFEN	MAC Control Frame Enable  Enables/disables the MAC control frame.  0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
14 CRCFWD	Terminate/Forward Received CRC  Specifies whether the CRC field of received frames is transmitted or stripped.  <b>NOTE:</b> If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed.  0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
13 PAUFWD	Terminate/Forward Pause Frames  Specifies whether pause frames are terminated or forwarded.  0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
12 PADEN	Enable Frame Padding Remove On Receive  Specifies whether the MAC removes padding from received frames.  0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
11–10 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
9 RMII_10T	Enables 10-Mbit/s mode of the RMII .  0 100-Mbit/s operation. 1 10-Mbit/s operation.
8 RMII_MODE	RMII Mode Enable  Specifies whether the MAC is configured for MII mode or RMII operation .  0 MAC configured for MII mode. 1 MAC configured for RMII operation.
7 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
6 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
5 FCE	Flow Control Enable

Table continues on the next page...

**ENETx\_RCR field descriptions (continued)**

Field	Description
	If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
4 BC_REJ	Broadcast Frame Reject  If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
3 PROM	Promiscuous Mode  All frames are accepted regardless of address matching.  0 Disabled. 1 Enabled.
2 MII_MODE	Media Independent Interface Mode  This field must always be set.  0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.
1 DRT	Disable Receive On Transmit  0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)
0 LOOP	Internal Loopback  This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.  0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.

### 11.4.4.10 Transmit Control Register (ENETx\_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: Base address + C4h offset

**ENETx\_TCR field descriptions**

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	This field is reserved. This field is read/write and must be set to 0.
9 CRCFWD	Forward Frame From Application With CRC 0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.

*Table continues on the next page...*

**ENETx\_TCR field descriptions (continued)**

Field	Description
8 ADDINS	Set MAC Address On Transmit  0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
7–5 ADDSEL	Source MAC Address Select On Transmit  If ADDINS is set, indicates the MAC address that overwrites the source MAC address.  000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
4 RFC_PAUSE	Receive Frame Control Pause  This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
3 TFC_PAUSE	Transmit Frame Control Pause  Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.  0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
2 FDEN	Full-Duplex Enable  If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
1 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
0 GTS	Graceful Transmit Stop  When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

### 11.4.4.11 Physical Address Lower Register (ENETx\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: Base address + E4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PADDR1																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_PALR field descriptions**

Field	Description
PADDR1	Pause Address  Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

### 11.4.4.12 Physical Address Upper Register (ENETx\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: Base address + E8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ENETx\_PAUR field descriptions**

Field	Description
31–16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
TYPE	Type Field In PAUSE Frames  These fields have a constant value of 0x8808.

### 11.4.4.13 Opcode/Pause Duration Register (ENETx\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: Base address + ECh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ENETx\_OPD field descriptions**

Field	Description
31–16 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

### 11.4.4.14 Descriptor Individual Upper Address Register (ENETx\_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: Base address + 118h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ENETx\_IAUR field descriptions**

Field	Description
IADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

### 11.4.4.15 Descriptor Individual Lower Address Register (ENETx\_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: Base address + 11Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ENETx\_IALR field descriptions

Field	Description
IADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0.

### 11.4.4.16 Descriptor Group Upper Address Register (ENETx\_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: Base address + 120h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ENETx\_GAUR field descriptions

Field	Description
GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

### 11.4.4.17 Descriptor Group Lower Address Register (ENETx\_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: Base address + 124h offset

ENETx\_GALR field descriptions

Field	Description
GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

### 11.4.4.18 Transmit FIFO Watermark Register (ENETx\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: Base address + 144h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**ENETx\_TFWR field descriptions**

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 STRFWD	Store And Forward Enable  0   Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1   Enabled.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TFWR	Transmit FIFO Write  If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins.  <b>NOTE:</b> If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given.  000000   64 bytes written. 000001   64 bytes written. 000010   128 bytes written. 000011   192 bytes written. ...       ... 011111   1984 bytes written.

**11.4.4.19 Receive Descriptor Ring Start Register (ENETx\_RDSR)**

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

**NOTE**

This register must be initialized prior to operation

## 10/100-Mbps Ethernet MAC (ENET)

Address: Base address + 180h offset

Table continues on the next page...

**ENETx\_TDSR field descriptions (continued)**

Field	Description
2 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**11.4.4.21 Maximum Receive Buffer Size Register (ENETx\_MRBR)**

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- R\_BUF\_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX\_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, the lower four bits are set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

**NOTE**

This register must be initialized before operation.

Address: Base address + 188h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ENETx\_RSEM field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_SECTION_EMPTY	Value Of The Receive FIFO Section Empty Threshold  Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued.  A value of 0 disables automatic pause frame generation.  When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client.  <b>NOTE:</b> The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

### 11.4.4.24 Receive FIFO Almost Empty Threshold (ENETx\_RAEM)

Address: Base address + 198h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ENETx\_RAEM field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_ALMOST_EMPTY	Value Of The Receive FIFO Almost Empty Threshold  Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

### 11.4.4.25 Receive FIFO Almost Full Threshold (ENETx\_RAFL)

Address: Base address + 19Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																RX_ALMOST_FULL															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

#### ENETx\_RAFL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_ALMOST_FULL	Value Of The Receive FIFO Almost Full Threshold  Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

### 11.4.4.26 Transmit FIFO Section Empty Threshold (ENETx\_TSEM)

Address: Base address + 1A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TX_SECTION_EMPTY															
W

#### ENETx\_TAEM field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold  Value, in 64-bit words, of the transmit FIFO almost empty threshold.  When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See <a href="#">Transmit FIFO</a> for more information.  A minimum value of 4 should be set.

### 11.4.4.28 Transmit FIFO Almost Full Threshold (ENETx\_TAFL)

Address: Base address + 1A8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ENETx\_TAFL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_ALMOST_FULL	<p>Value Of The Transmit FIFO Almost Full Threshold</p> <p>Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).</p> <p>When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information.</p> <p><b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.</p>

### 11.4.4.29 Transmit Inter-Packet Gap (ENETx\_TIPG)

Address: Base address + 1ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### ENETx\_TIPG field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
IPG	<p>Transmit Inter-Packet Gap</p> <p>Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12.</p> <p><b>NOTE:</b> The IPG value read will be the value that was written, even if it is out of range.</p>

11.4.4.30 Frame Truncation Length (ENETx\_FTRL)

Address: Base address + 1B0h offset

ENETx\_FTRL field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TRUNC_FL	Frame Truncation Length  Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].  <b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

11.4.4.31 Transmit Accelerator Function Configuration (ENETx\_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: Base address + 1C0h offset

### ENETx\_TACC field descriptions

Field	Description
31–5 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
4 PROCHK	Enables insertion of protocol checksum.  0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
3 IPCHK	Enables insertion of IP header checksum.  0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
2–1 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
0 SHIFT16	TX FIFO Shift-16  0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

### 11.4.4.32 Receive Accelerator Function Configuration (ENETx\_RACC)

Address: Base address + 1C4h offset

### ENETx\_RACC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
7 SHIFT16	RX FIFO Shift-16

Table continues on the next page...

**ENETx\_RACC field descriptions (continued)**

Field	Description
	<p>When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary.</p> <p><b>NOTE:</b> This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received.</p> <p>0 Disabled.</p> <p>1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.</p>
6 LINEDIS	<p>Enable Discard Of Frames With MAC Layer Errors</p> <p>0 Frames with errors are not discarded.</p> <p>1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.</p>
5–3 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
2 PRODIS	<p>Enable Discard Of Frames With Wrong Protocol Checksum</p> <p>0 Frames with wrong checksum are not discarded.</p> <p>1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).</p>
1 IPDIS	<p>Enable Discard Of Frames With Wrong IPv4 Header Checksum</p> <p>0 Frames with wrong IPv4 header checksum are not discarded.</p> <p>1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).</p>
0 PADREM	<p>Enable Padding Removal For Short IP Frames</p> <p>0 Padding not removed.</p> <p>1 Any bytes following the IP payload section of the frame are removed from the frame.</p>

### 11.4.4.50 Tx Octets Statistic Register (ENETx\_RMON\_T\_OCTETS)

Address: Base address + 244h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TXOCTS																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_T\_OCTETS field descriptions

Field	Description
TXOCTS	Number of transmit octets

### 11.4.4.51 Reserved Statistic Register (ENETx\_IEEE\_T\_DROP)

Address: Base address + 248h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_DROP field descriptions

Field	Description
Reserved	This read-only field always has the value 0.

### ENETx\_IEEE\_T\_DROP field descriptions (continued)

Field	Description
	This field is reserved.

### 11.4.4.52 Frames Transmitted OK Statistic Register (ENETx\_IEEE\_T\_FRAME\_OK)

Address: Base address + 24Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ENETx\_IEEE\_T\_FRAME\_OK field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted OK  <b>NOTE:</b> Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

### 11.4.4.53 Frames Transmitted with Single Collision Statistic Register (ENETx\_IEEE\_T\_1COL)

Address: Base address + 250h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ENETx\_IEEE\_T\_1COL field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with one collision

### 11.4.4.54 Frames Transmitted with Multiple Collisions Statistic Register (ENETx\_IEEE\_T\_MCOL)

Address: Base address + 254h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_MCOL field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with multiple collisions

### 11.4.4.55 Frames Transmitted after Deferral Delay Statistic Register (ENETx\_IEEE\_T\_DEF)

Address: Base address + 258h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_DEF field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with deferral delay

### 11.4.4.56 Frames Transmitted with Late Collision Statistic Register (ENETx\_IEEE\_T\_LCOL)

Address: Base address + 25Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_LCOL field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with late collision

**11.4.4.57 Frames Transmitted with Excessive Collisions Statistic Register (ENETx\_IEEE\_T\_EXCOL)**

Address: Base address + 260h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_EXCOL field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with excessive collisions

**11.4.4.58 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENETx\_IEEE\_T\_MACERR)**

Address: Base address + 264h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_MACERR field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with transmit FIFO underrun

### 11.4.4.59 Frames Transmitted with Carrier Sense Error Statistic Register (ENETx\_IEEE\_T\_CSERR)

Address: Base address + 268h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_CSERR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with carrier sense error

### 11.4.4.60 Reserved Statistic Register (ENETx\_IEEE\_T\_SQE)

Address: Base address + 26Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_SQE field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	This read-only field is reserved and always has the value 0. <b>NOTE:</b> Counter not implemented as no SQE information is available.

### 11.4.4.61 Flow Control Pause Frames Transmitted Statistic Register (ENETx\_IEEE\_T\_FDXFC)

Address: Base address + 270h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_FDXFC field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of flow-control pause frames transmitted

**11.4.4.62 Octet Count for Frames Transmitted w/o Error Statistic Register (ENETx\_IEEE\_T\_OCTETS\_OK)**

Address: Base address + 274h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_OCTETS\_OK field descriptions**

Field	Description
COUNT	Octet count for frames transmitted without error  <b>NOTE</b> Counts total octets (includes header and FCS fields).

**11.4.4.63 Rx Packet Count Statistic Register (ENETx\_RMON\_R\_PACKETS)**

Address: Base address + 284h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**ENETx\_RMON\_R\_PACKETS field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of packets received

### 11.4.4.64 Rx Broadcast Packets Statistic Register (ENETx\_RMON\_R\_BC\_PKT)

Address: Base address + 288h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ENETx\_RMON\_R\_BC\_PKT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive broadcast packets

### 11.4.4.65 Rx Multicast Packets Statistic Register (ENETx\_RMON\_R\_MC\_PKT)

Address: Base address + 28Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ENETx\_RMON\_R\_MC\_PKT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive multicast packets

### 11.4.4.66 Rx Packets with CRC/Align Error Statistic Register (ENETx\_RMON\_R\_CRC\_ALIGN)

Address: Base address + 290h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**ENETx\_RMON\_R\_CRC\_ALIGN field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets with CRC or align error

**11.4.4.67 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENETx\_RMON\_R\_UNDERSIZE)**

Address: Base address + 294h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_RMON\_R\_UNDERSIZE field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets with less than 64 bytes and good CRC

**11.4.4.68 Rx Packets Greater Than MAX\_FL and Good CRC Statistic Register (ENETx\_RMON\_R\_OVERSIZE)**

Address: Base address + 298h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W

**ENETx\_ATCR field descriptions**

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SLAVE	Enable Timer Slave Mode  0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
12 Reserved	This field is reserved. Always write 0 to this field.

Table continues on the next page...

## ENETx\_ATCR field descriptions (continued)

Field	Description
11 CAPTURE	<p>Capture Timer Value</p> <p>When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.</p> <p><b>NOTE:</b> To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles.</p> <p>0 No effect. 1 The current time is captured and can be read from the ATVR register.</p>
10 Reserved	<p>This field is reserved. Always write 0 to this field.</p>
9 RESTART	<p>Reset Timer</p> <p>Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.</p> <p><b>NOTE:</b> The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.</p>
8 Reserved	<p>This field is reserved.</p>
7 PINPER	<p>Enables event signal output assertion on period event.</p> <p><b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.</p> <p>0 Disable. 1 Enable.</p>
6 Reserved	<p>This field is reserved.</p>
5 Reserved	<p>This field is reserved.</p> <p><b>NOTE:</b> This field must be written always with one.</p>
4 PEREN	<p>Enable Periodical Event</p> <p>0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit.</p> <p><b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.</p>
3 OFFRST	<p>Reset Timer On Offset Event</p> <p>0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.</p>
2 OFFEN	<p>Enable One-Shot Offset Event</p>

Table continues on the next page...

**ENETx\_ATCR field descriptions (continued)**

Field	Description
0	Disable.
1	The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
1 Reserved	This field is reserved.
0 EN	Enable Timer
0	The timer stops at the current value.
1	The timer starts incrementing.

#### ENETx\_ATPER field descriptions

Field	Description
PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 ( $1 \times 10^9$ ) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.  <b>NOTE:</b> The value of PERIOD has the following constraint: $2^{32} - \text{ENET\_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET\_ATINC}[\text{INC}] \geq \text{PERIOD} > 0$ .

### 11.4.4.91 Timer Correction Register (ENETx\_ATCOR)

Address: Base address + 410h offset

**ENETx\_TCCRn field descriptions**

Field	Description
TCC	<p>Timer Capture Compare</p> <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p>

## 11.4.5 Functional description

This section provides a complete functional description of the MAC-NET core.

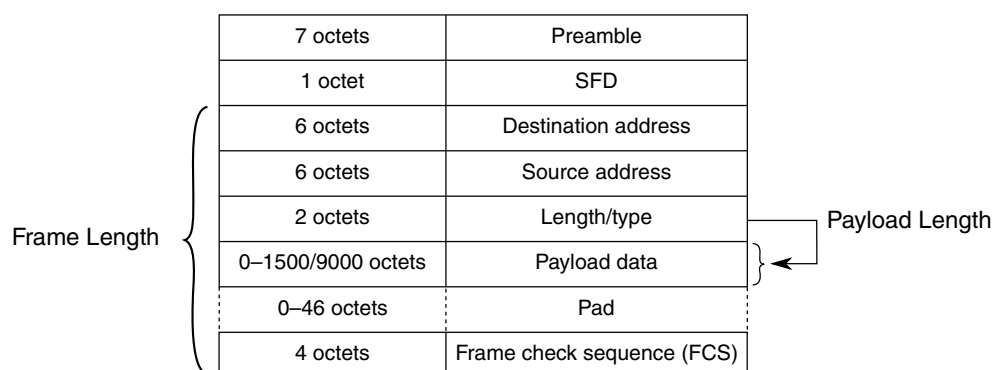

### 11.4.5.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

**Figure 11-38. MAC frame format overview**

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

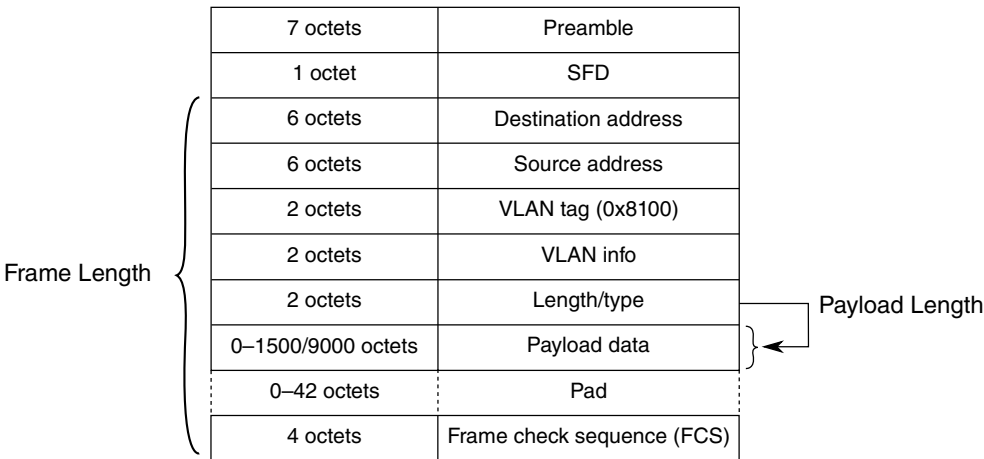

Figure 11-39. VLAN-tagged MAC frame format overview

Table 11-85. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. <ul style="list-style-type: none"><li>• If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li><li>• If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li></ul>
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

11.4.5.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 11-86. Pause Frame Format (Values in Hex)**

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

#### 11.4.5.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

#### 11.4.5.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 11.4.5.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 11-87. Ethernet type value examples**

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

### 11.4.5.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 11-88. IPv4 header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Version				IHL				TOS								Length																			
Fragment ID																Flags				Fragment offset															
TTL								Protocol								Header checksum																			
Source address																																			
Destination address																																			
Options																																			

**Table 11-89. IPv4 header fields**

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

### 11.4.5.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or ICMP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

**Figure 11-40. IPv6 header format**

**Table 11-90. IPv6 header fields**

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

#### 11.4.5.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

**Table 11-91. ICMP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type								Code								Checksum															
ICMP message data																															

**Table 11-92. IP header fields**

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

#### 11.4.5.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 11-93. UDP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source port												Destination port																			
Length												Checksum																			

**Table 11-94. UDP header fields**

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

#### 11.4.5.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 11-95. TCP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source port																Destination port															
Sequence number																															
Acknowledgement number																															
Offset				Reserved				Flags				Window																			
Checksum																Urgent pointer															
Options																															

**Table 11-96. TCP header fields**

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags

*Table continues on the next page...*

**Table 11-96. TCP header fields (continued)**

Field name	Description
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

### 11.4.5.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 11.4.5.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 11.4.5.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

[Table 11-97](#) shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 11-97. UDP/IP multicast domains**

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

**Table 11-98. UDP port numbers**

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

### 11.4.5.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 11-99. PTPv2 multicast domains**

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

### 11.4.5.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

#### 11.4.5.3.2.1 PTPv1 header

**Table 11-100. Common PTPv1 message header**

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							

*Table continues on the next page...*

**Table 11-100. Common PTPv1 message header (continued)**

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in [Table 11-101](#) :

**Table 11-101. PTPv1 message type identification**

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

#### 11.4.5.3.2.2 PTPv2 header

**Table 11-102. Common PTPv2 message header**

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field `messageId` as follows:

**Table 11-103. PTPv2 message type identification**

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the `TWO_STEP` bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 11-104. PTPv2 message flags field definitions**

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

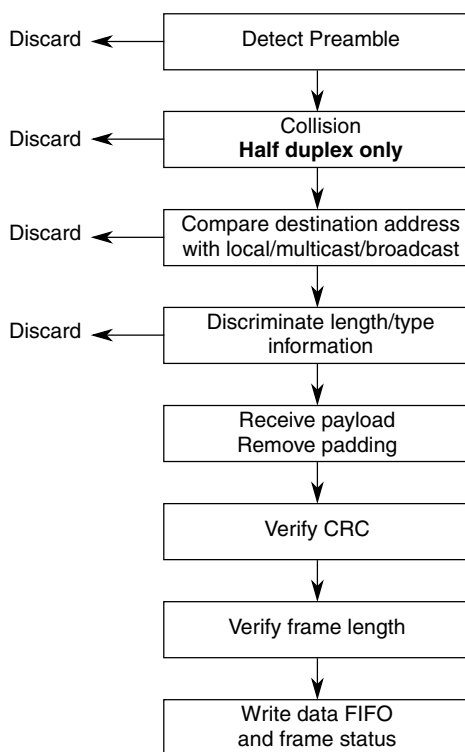

#### 11.4.5.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing

- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

**Figure 11-41. MAC receive flow**

#### 11.4.5.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

#### 11.4.5.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

#### 11.4.5.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

##### 11.4.5.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ( $\text{RCR}[\text{PROM}] = 1$ ) no address checking is performed and all unicast frames are accepted.

##### 11.4.5.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in  $\text{ENET}_n\text{\_GAUR/GALR}$  (group address hash match) or  $\text{ENET}_n\text{\_IAUR/IALR}$  (individual address hash match).

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET $n$ \_GAUR (msb = 1) or ENET $n$ \_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled (ENET $n$ \_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET $n$ \_GAUR/GALR and ENET $n$ \_IAUR/IALR settings.

#### 11.4.5.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC\_REJ is cleared or ENET $n$ \_RCR[PROM] is set. If PROM is cleared when ENET $n$ \_RCR[BC\_REJ] is set, all broadcast frames are rejected.

**Table 11-105. Broadcast address reject programming**

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

#### 11.4.5.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC\_REJ is set
- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 11.4.5.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 11.4.5.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET<sub>n</sub>\_FTRL[TRUNC\_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

#### 11.4.5.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

#### 11.4.5.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET $n$ \_RCR[FCE] is cleared and are forwarded to the client interface when ENET $n$ \_RCR[PAUFWD] is set.

#### 11.4.5.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET $n$ \_RCR[CRCFWD] is cleared and ENET $n$ \_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $$\text{FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}, x^{30}, \dots, x^1, x^0$ .

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

#### 11.4.5.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENET $n$ _RCR[PADEN]`.

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

#### 11.4.5.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if `ENET $n$ _TCR[TFC_PAUSE]` is set with `ENET $n$ _OPD[PAUSE_DUR]` set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if `TFC_PAUSE` is set with `PAUSE_DUR` cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 11-42. Frame transmit overview**

#### 11.4.5.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC ( $\text{TxBd}[TC] = 1$ ), the user application is responsible for providing frames with a minimum length of 64 octets.

#### 11.4.5.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields ( $\text{ENET}_n\text{-TCR}[\text{ADDINS}] = 1$ )
- Transparently forwarded to the Ethernet line ( $\text{ENET}_n\text{-TCR}[\text{ADDINS}] = 0$ )

#### 11.4.5.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

#### 11.4.5.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in `ENETn_TIPG`) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

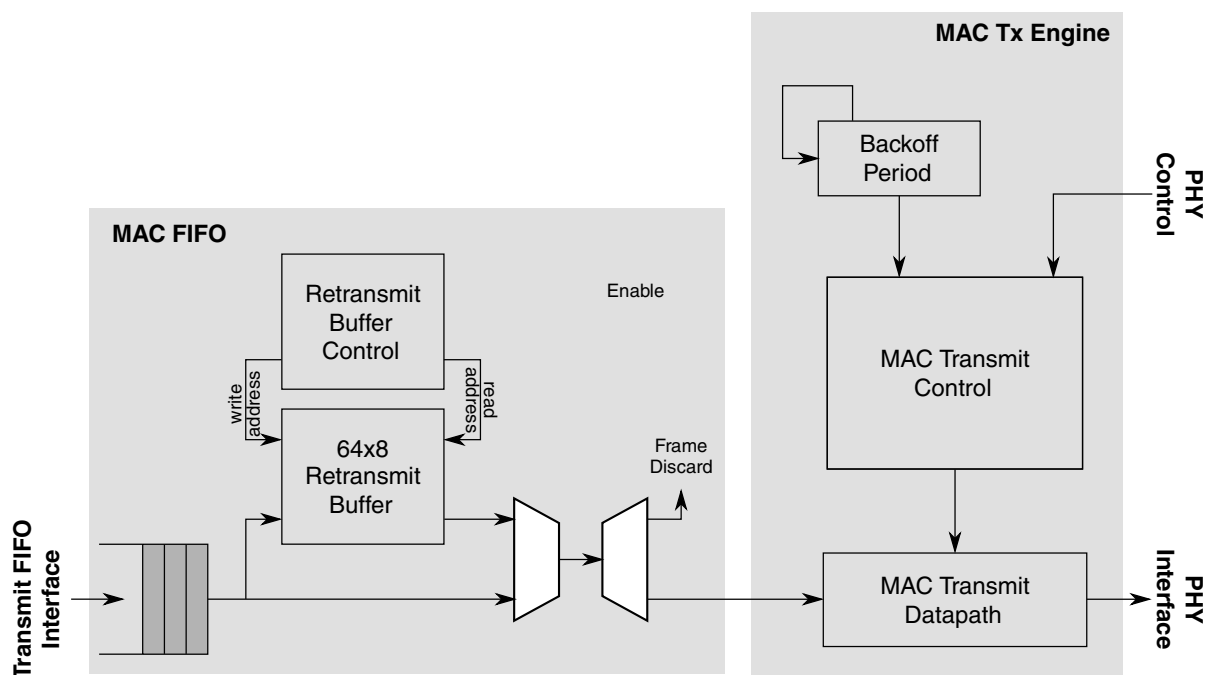

#### 11.4.5.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets `TxBD[LCE]`.

**Figure 11-43. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

### warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

### 11.4.5.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

#### 11.4.5.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

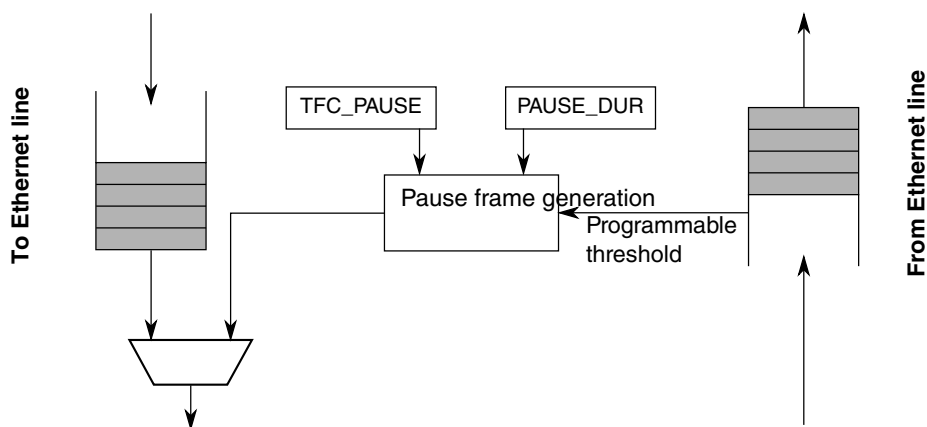

Optionally and independent of `ENETn_RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

### 11.4.5.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET $_n$ \_TCR[TFC\_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC\_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET $_n$ \_OPD[PAUSE\_DUR].

**Figure 11-44. Pause frame generation overview**

#### Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

### 11.4.5.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

#### 11.4.5.7.1 Sleep mode

To put the MAC in Sleep mode, set `ENETn_ECR[SLEEP]`. At the same time `ENETn_ECR[MAGICEN]` should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the `ENETn_ECR` register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

#### 11.4.5.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in `PADDR1/2`

When a magic packet is detected, `EIR[WAKEUP]` is set and none of the statistic registers are incremented.

#### 11.4.5.7.3 Wakeup

When a magic packet is detected, indicated by `ENETn_EIR[WAKEUP]`, `ENETn_ECR[SLEEP]` should be cleared to resume normal operation of the MAC. Clearing the `SLEEP` bit automatically masks `ENETn_ECR[MAGICEN]`, disabling magic packet detection.

## 11.4.5.8 IP accelerator functions

The following sections describe the IP accelerator functions.

### 11.4.5.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 11-106. IPv4 pseudo-header for checksum calculation**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
Zero								Protocol								TCP/UDP length															

**Table 11-107. IPv6 pseudo-header for checksum calculation**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
TCP/UDP length																															
Zero																								Next header							

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

#### 11.4.5.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

#### 11.4.5.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET $n$ \_TACC and ENET $n$ \_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 11-108](#).

**Table 11-108. 64-bit interface data structure with SHIFT16 enabled**

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

##### 11.4.5.8.3.1 Receive processing

When ENET $n$ \_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

## Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

### 11.4.5.8.3.2 Transmit processing

When `ENETn_TACC[SHIFT16]` is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

### 11.4.5.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (`ENETn_RSFL` cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than `MAX_FL`
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (`RX_ERR` asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (`ENETn_RACC`), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### 11.4.5.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

### Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

#### 11.4.5.8.6 IPv6 support

The following sections describe the IPv6 support.

##### 11.4.5.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

#### 11.4.5.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

### 11.4.5.9 Resets and stop controls

The following sections describe the resets and stop controls.

#### 11.4.5.9.1 Hardware reset

To reset the Ethernet module, set `ENETn_ECR[RESET]`.

#### 11.4.5.9.2 Soft reset

When `ENETn_ECR[ETHER_EN]` is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

### 11.4.5.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

### 11.4.5.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER\_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

#### 11.4.5.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.

- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

#### 11.4.5.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

## Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

### 11.4.5.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

### 11.4.5.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

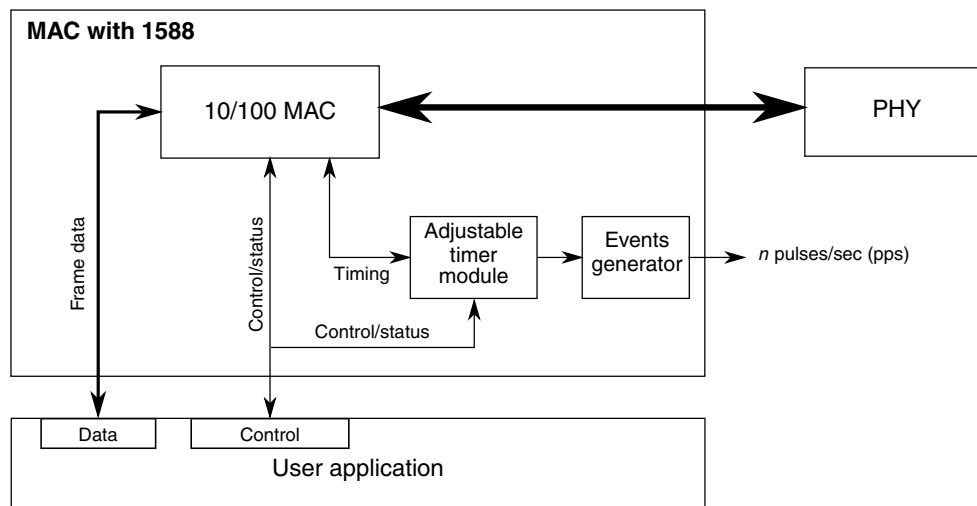

Figure 11-45. IEEE 1588 functions overview

### 11.4.5.10.1 Adjustable timer module

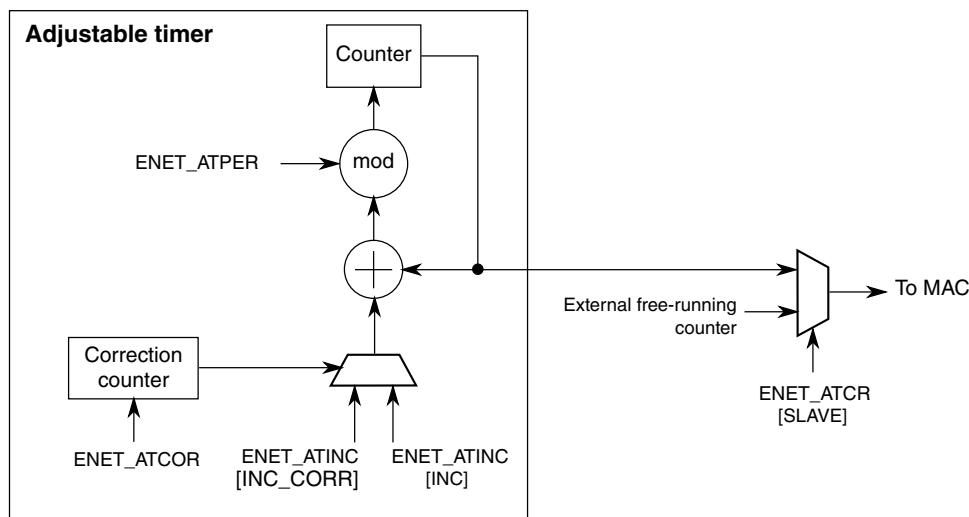

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 11.4.5.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

**Figure 11-46. Adjustable timer implementation detail**

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in  $\text{ENET}_n\text{\_ATINC}$ . The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in  $\text{ENET}_n\text{\_ATPER}$ , defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one

second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(\text{Current} + \text{Inc} - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in `ENETn_ATCOR`, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in `ENETn_ATINC`. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (`ENETn_ATCR[SLAVE] = 1`), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When slave mode is enabled, you still must set `ENETn_ATINC[INC]` to the value of the master, since it is used for internal comparisons.

#### 11.4.5.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENETn_ATSTMP`. `ENETn_EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENETn_EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENETn_ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

#### 11.4.5.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

#### 11.4.5.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

#### 11.4.5.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

##### 11.4.5.10.5.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

##### 11.4.5.10.5.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

### 11.4.5.10.5.3 DMA requests

A DMA request can be enabled by setting  $TCSRn[TDRE]$ . The corresponding DMA request is generated when the  $TCSRn[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSRn[TF]$  flag is cleared.

### 11.4.5.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

#### 11.4.5.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

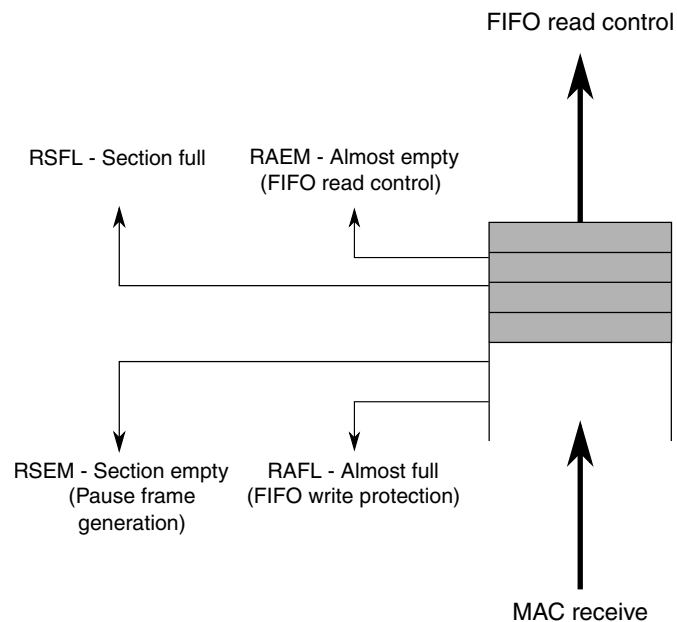

**Table 11-109. Receive FIFO thresholds definition**

Register	Description
ENET $n$ _RSFL [RX_SECTION_F ULL]	<p>When the FIFO level reaches the ENET<math>n</math>_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET<math>n</math>_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET<math>n</math>_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET<math>n</math>_RSFL (cut-through operation) it should be greater than ENET<math>n</math>_RAEM.</p>
ENET $n$ _RAEM [RX_ALMOST_E MPTY]	<p>When the FIFO level reaches the ENET<math>n</math>_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET<math>n</math>_RAEM to a minimum of six.</p>
ENET $n$ _RAFL	<p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET<math>n</math>_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p>

*Table continues on the next page...*

**Table 11-109. Receive FIFO thresholds definition (continued)**

Register	Description
[RX_ALMOST_FULL]	The corresponding error status is set when the frame is delivered to the application. Set ENET $n$ _RAFL to a minimum of 4.
ENET $n$ _RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET $n$ _RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client.  When the FIFO level goes below the value programmed in ENET $n$ _RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client.  Clearing ENET $n$ _RSEM disables any pause frame generation.

**Figure 11-47. Receive FIFO overview**

### 11.4.5.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

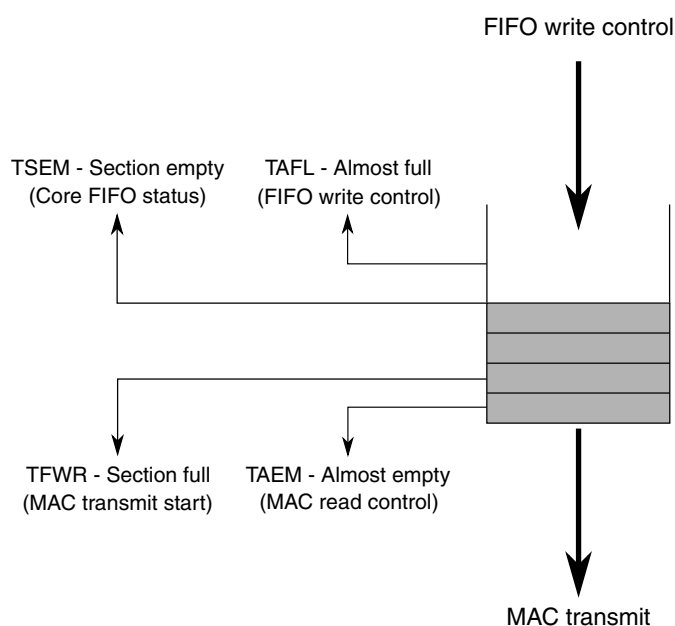

**Table 11-110. Transmit FIFO thresholds definition**

Register	Description
ENET $n$ _TAEM [TX_ALMOST_EMPTY]	When the FIFO level reaches the ENET $n$ _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET $n$ _TAEM to a minimum of 4.
ENET $n$ _TAFL [TX_ALMOST_FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET $n$ _TAFL number of words, the MAC deasserts its control signal to the application.

*Table continues on the next page...*

**Table 11-110. Transmit FIFO thresholds definition (continued)**

Register	Description
_FULL]	<p>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.</p> <p>Set ENET<sub>n</sub>_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.</p>
ENET <sub>n</sub> _TSEM [TX_SECTION _EMPTY]	<p>When the FIFO level reaches the ENET<sub>n</sub>_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.</p> <p>When ENET<sub>n</sub>_TSEM is 0, the signal is never deasserted.</p>
ENET <sub>n</sub> _TFWR	<p>When the FIFO level reaches the ENET<sub>n</sub>_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).</p> <p>If a complete frame has a size smaller than the ENET<sub>n</sub>_TFWR threshold, the MAC also transmits the frame to the line.</p> <p>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.</p>

**Figure 11-48. Transmit FIFO overview**

### 11.4.5.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET<sub>n</sub>\_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET<sub>n</sub>\_RCR register fields:

Table 11-111. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.  In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

Figure 11-49. Loopback options

11.4.5.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENET<sub>n</sub>\_ECR[1588EN].

NOTE

- The legacy buffer descriptor tables show the byte order for little-endian chips. DBSWP must be set to 1 after reset to enable little-endian mode.

11.4.5.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 11-115 contains the descriptions for each field.

Table 11-112. Legacy FEC receive buffer descriptor (RxBD)

Byte 1								Byte 0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

**Table 11-112. Legacy FEC receive buffer descriptor (RxBD) (continued)**

Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

### 11.4.5.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. [Table 11-117](#) contains the descriptions for each field.

**Table 11-113. Legacy FEC transmit buffer descriptor (TxBD)**

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Offset + 4	Tx Data Buffer Pointer — low halfword															
Offset + 6	Tx Data Buffer Pointer — high halfword															

1. This field is not supported by the uDMA.

## 11.4.5.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set `ENETn_ECR[1588EN]`.

### NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

### 11.4.5.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 11-115](#) contains the descriptions for each field.

**Table 11-114. Enhanced uDMA receive buffer descriptor (RxBD)**

	Byte 1								Byte 0

**Table 11-115. Receive buffer descriptor field definitions**

Word	Field	Description
Offset + 0	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	15 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET <sub>n</sub> _RDSR.
Offset + 2	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	11 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	10–9	Reserved, must be cleared.

Table continues on the next page...

**Table 11-115. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 2	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set.  0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.  The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	7 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 2	6 MC	Set if the DA is multicast and not BC.
Offset + 2	5 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 2	4 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	3	Reserved, must be cleared.
Offset + 2	2 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	1 OV	Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	0 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	15–0 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 6	15–0 Data buffer pointer high	Receive data buffer pointer, high halfword <sup>1</sup>
Offset + 8	15–13 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + 8	12–6	Reserved, must be cleared.
Offset + 8	5 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	4 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.

Table continues on the next page...

**Table 11-115. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 8	3	Reserved, must be cleared.
Offset + 8	2 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	1 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	0 FRAG	IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + A	15 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	14–11	Reserved, must be cleared.
Offset + A	10 PE	PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + A	9 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	8 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	7 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb</i> / <i>dma_int_rxfevent</i> .
Offset + A	6–0	Reserved, must be cleared.
Offset + C	15–0 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	15–11 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> This field is only valid if the L field is set.
Offset + E	10–8	Reserved, must be cleared.
Offset + E	7–0 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).

Table continues on the next page...

**Table 11-115. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14	15–0 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16		
Offset + 18 – Offset + 1E	15–0	Reserved, must be cleared.

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

#### 11.4.5.14.2 Enhanced transmit buffer descriptor

**Table 11-116. Enhanced transmit buffer descriptor (TxBD)**

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Offset + 16	1588 timestamp – high halfword															
Offset + 18	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1A	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1C	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

**Table 11-117. Enhanced transmit buffer descriptor field definitions**

Word	Field	Description
Offset + 0	15–0	Data length, written by user.
	Data Length	Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 2	15	Ready. Written by the MAC and you.

*Table continues on the next page...*

**Table 11-117. Enhanced transmit buffer descriptor field definitions (continued)**

Word	Field	Description
	R	<p>0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered.</p> <p>1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.</p>
Offset + 2	14 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	13 W	<p>Wrap. Written by user.</p> <p>0 The next buffer descriptor is found in the consecutive location</p> <p>1 The next buffer descriptor is found at the location defined in ETDSR.</p>
Offset + 2	12 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	11 L	<p>Last in frame. Written by user.</p> <p>0 The buffer is not the last in the transmit frame</p> <p>1 The buffer is the last in the transmit frame</p>
Offset + 2	10 TC	<p>Transmit CRC. Written by user, and valid only when L is set.</p> <p>0 End transmission immediately after the last data byte</p> <p>1 Transmit the CRC sequence after the last data byte</p> <p>This field is valid only when the L field is set.</p>
Offset + 2	9 ABC	<p>Append bad CRC.</p> <p><b>Note:</b> This field is not supported by the uDMA and is ignored.</p>
Offset + 2	8–0	Reserved, must be cleared.
Offset + 4	15–0 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 6	15–0 Data buffer pointer high	Tx data buffer pointer, high halfword. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 8. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller.
Offset + 8	15 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	14	Reserved, must be cleared.
Offset + 8	13 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + 8	12 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.

*Table continues on the next page...*

**Table 11-117. Enhanced transmit buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 8	11 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	10 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	9 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	8 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.
Offset + 8	7–0	Reserved, must be cleared.
Offset + A	15	Reserved, must be cleared.
Offset + A	14 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + A	13 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	12 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	11 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	10–0	Reserved, must be cleared.
Offset + C	15–0	Reserved, must be cleared.
Offset + E	15–0	Reserved, must be cleared.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14	1588 timestamp	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16		
Offset + 18–Offset + 1E	15–0	Reserved, must be cleared.

### 11.4.5.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

#### 11.4.5.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 11-118. FIFO interface data structure**

	63	56 55	48 47	40 39	32 31	24 23	16 15	8 7	0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	
...	...								

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

### Note

On transmit, if ENET $n$ \_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET $n$ \_PAUR and ENET $n$ \_PALR registers.

**Table 11-119. FIFO interface frame format**

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 11-120. FIFO interface VLAN frame format**

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

### Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

#### 11.4.5.15.2 Data structure examples

**Figure 11-50. Normal Ethernet frame 64-bit mapping example**

**Figure 11-51. VLAN-tagged frame 64-bit mapping example**

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 11.4.5.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxB[ME] is also set with the last data of the frame.

### 11.4.5.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

### 11.4.5.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in Figure 11-52) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 11-52. Transmit FIFO underflow protection

### 11.4.5.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

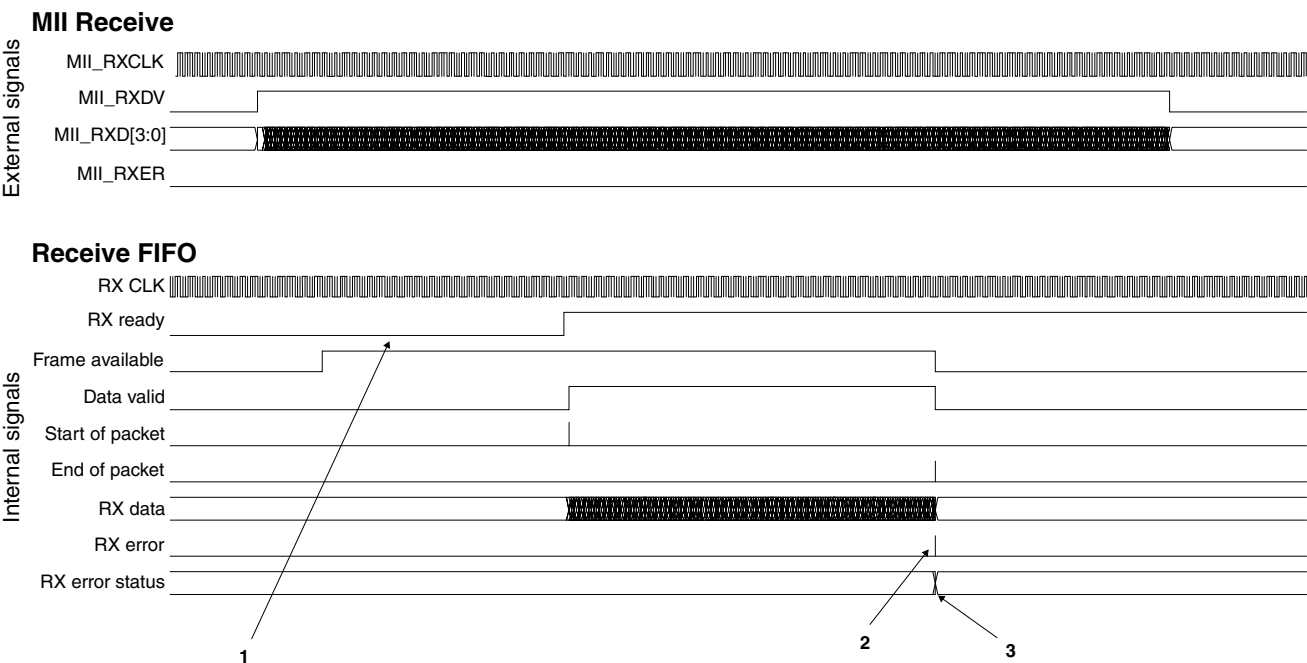

**Note**

Overflow is a fatal error and must be addressed by resetting the core or clearing ENETn\_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

**11.4.5.16.3 Receive FIFO overflow**

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

**Figure 11-53. Receive FIFO overflow protection**

**11.4.5.17 Reference clock**

The input clocks to the ENET module must meet the specifications in the following table.

Ethernet speed mode	Ethernet bus clock	Minimum ENET system clock
10 Mbit/s	2.5 MHz	5 MHz
100 Mbit/s	25.0 MHz	50 MHz

### 11.4.5.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

#### 11.4.5.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 11-121. MDIO clause 22 frame structure**

ST	OP	PHYADR	REGADR	TA	DATA
----	----	--------	--------	----	------

**Table 11-122. MDIO frame field descriptions**

Field	Description
ST (2 bits)	Start indication field, programmed with ENET <sub>n</sub> _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET <sub>n</sub> _MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET <sub>n</sub> _MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET <sub>n</sub> _MMFR[RA]. Each PHY can implement up to 32 registers.

*Table continues on the next page...*

**Table 11-122. MDIO frame field descriptions (continued)**

Field	Description
TA (2 bits)	Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET $n$ _MMFR[DATA]. Written to or read from the PHY

### 11.4.5.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 11-123. MDIO clause 45 frame structure**

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA
----	----	-------	-------	----	-----------

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 11-124. MDIO clause 45 frame field descriptions**

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET $n$ _MMFR[OP]. See <a href="#">Table 11-125</a> for more information.  00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.

*Table continues on the next page...*

**Table 11-124. MDIO clause 45 frame field descriptions (continued)**

Field	Description
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET $n$ _MMFR[DATA], written to or read from the PHY.

**Table 11-125. MDIO Clause 45 Transactions**

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

### 11.4.5.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET $n$ \_MSCR[MII\_SPEED].

### 11.4.5.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

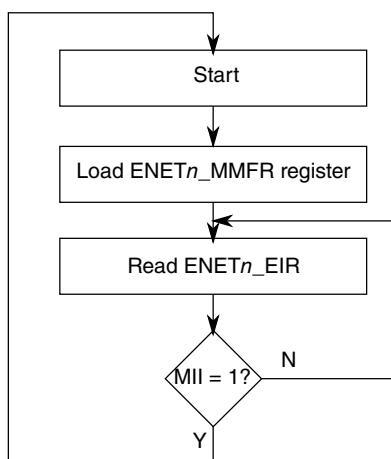

Figure 11-54. MDIO access overview

### 11.4.5.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

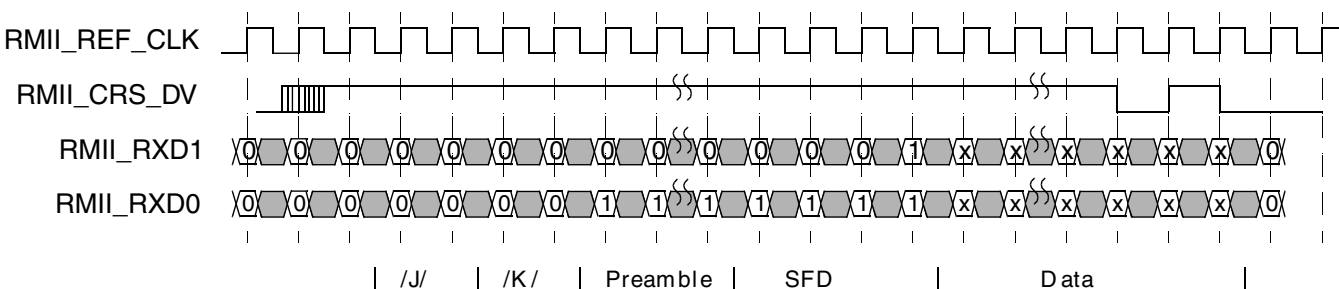

The following table shows how to configure ENET registers to select each interface.

Mode	RCR[RMII_10T]	RCR[RMII_MODE]
MII - 10 Mbit/s	—	0
MII - 100 Mbit/s	—	0
RMII - 10 Mbit/s	1	1
RMII - 100 Mbit/s	0	1

#### 11.4.5.19.1 RMII interface

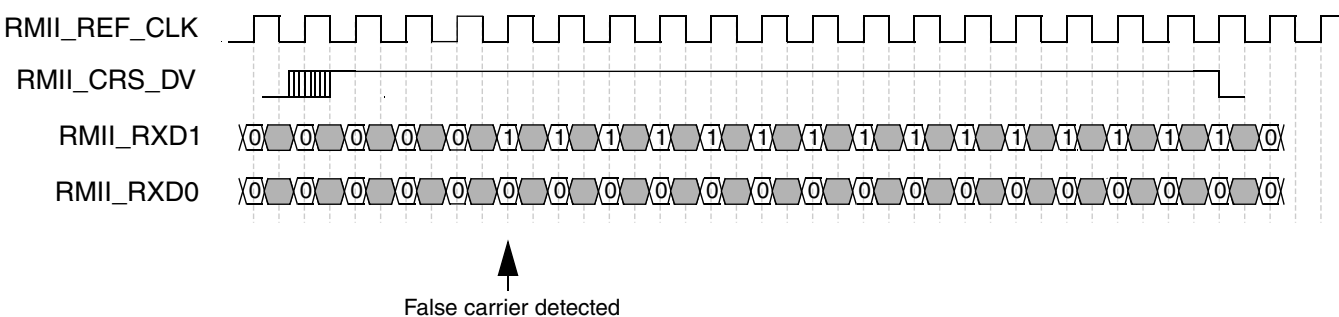

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

**Figure 11-55. RMII receive operation**

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

**Figure 11-56. RMI receive operation with false carrier**

In RMT transmit mode, TXD[1:0] provides valid data for each REF\_CLK period while TXEN is asserted.

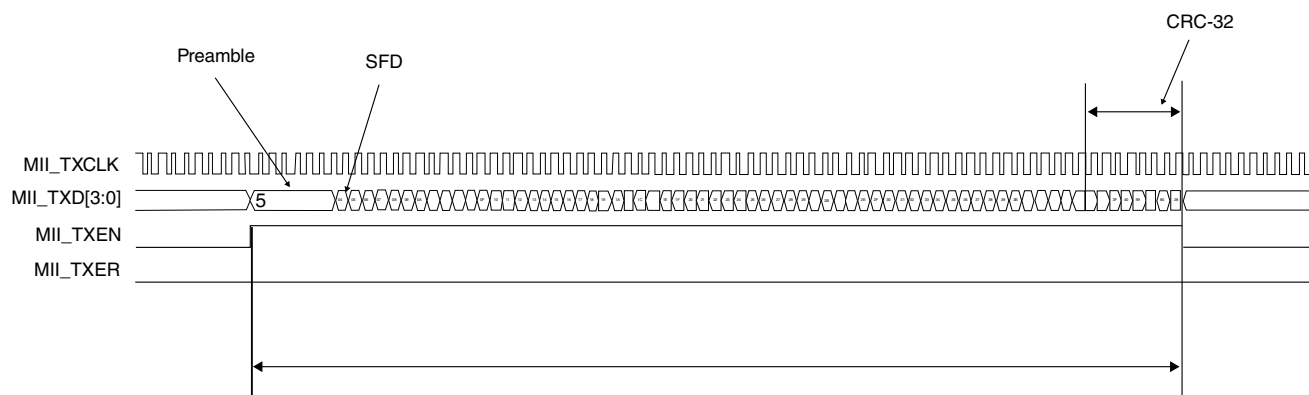

**Figure 11-57. RMI transmit operation**

### 11.4.5.19.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 11-58. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 11-59. MII transmit operation — errored frame**

### 11.4.5.19.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

Figure 11-60. MII transmit operation — transmission with collision

### 11.4.5.19.3 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

Figure 11-61. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

Figure 11-62. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

## 11.5 Ethernet Switch (ESW) (F-Series only)

### 11.5.1 Introduction

The Ethernet Switch (ESW) provides optional Layer 2 Ethernet switching between the connected Ethernet MACs and the SoC. It is VLAN aware and has numerous features as described in [Features](#).

The switch port assignment is listed in [Table 11-126](#).

Table 11-126. Port Assignment

Switch Port	Assignment
0	DMA 0
1	MAC-NET 0
2	MAC-NET 1
3	DMA 1
(bypass port)	

### 11.5.1.1 Block Diagram

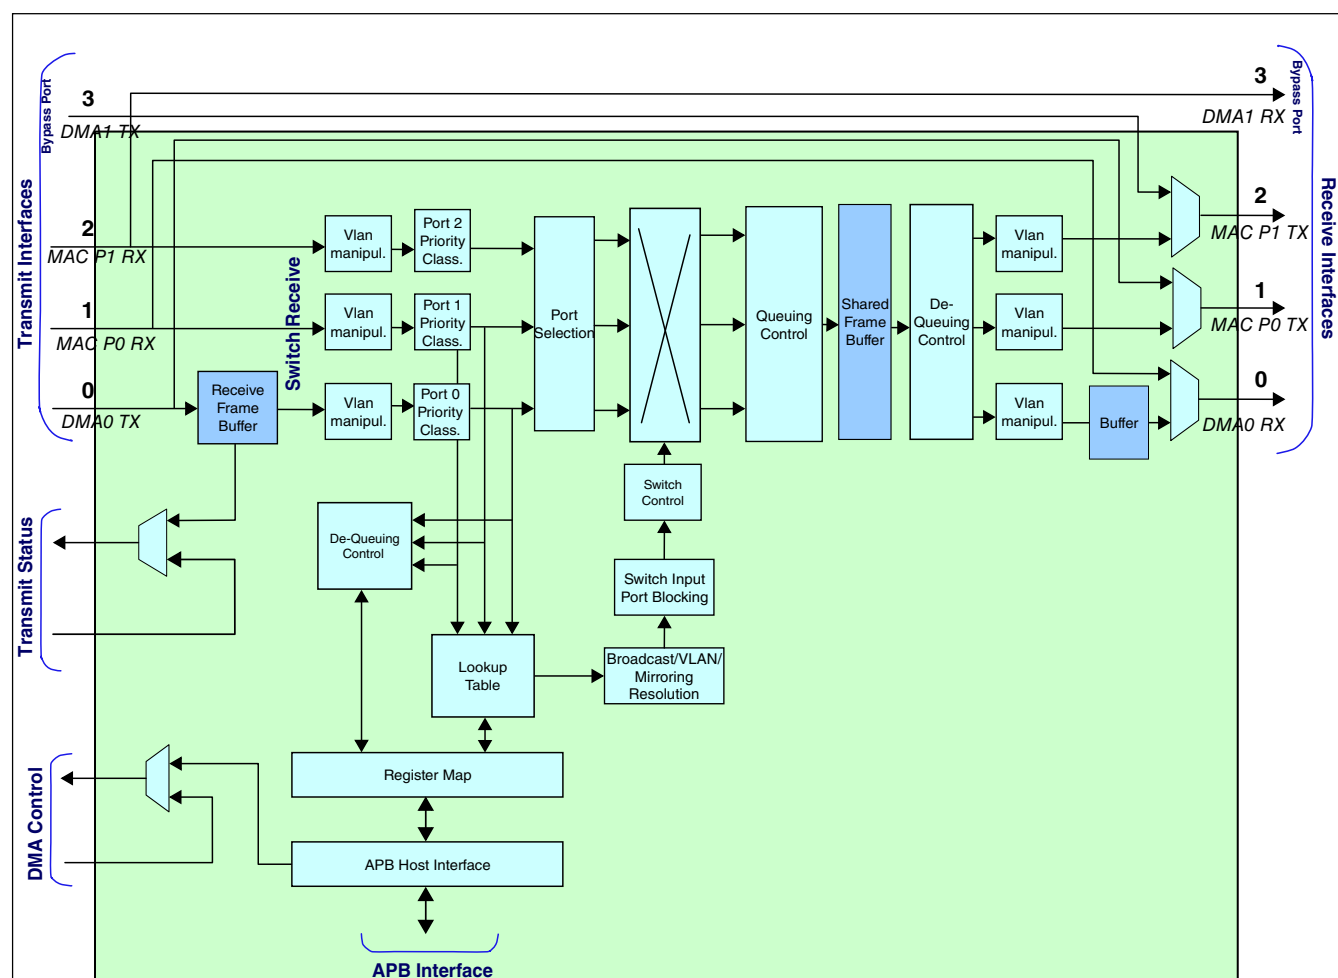

Figure 11-63. Block Diagram

#### Note

- The left side is termed "Transmit Interfaces" as the interfaces are driven by the DMA transmit interfaces in pass-through mode. If the switch is enabled, these

interfaces connect to the switch internal receive interfaces. The right side is named "Receive Interfaces" as the interfaces represent (are driven from) the respective MAC receive interfaces in pass-through mode connected to the DMA RX. If the switch is enabled these are driven by the switch internal transmit interfaces. See [Introduction](#) for a description of the operational modes.

- All descriptions related to switch functions refer to the switch internal receive/transmit interfaces.
- Receive Frame buffer (DMA0 TX interface). Can hold at least one complete frame transferred from DMA0 to the switch. This is a local 64-bit wide FIFO to absorb a burst from the DMA, provide the necessary transaction handshake to the DMA, and forward the frame then to the switch logic.
- Decoupling buffer only (DMA0 RX interface) to absorb switch latency (e.g. 16/32 words) resulting from a rdy deassertion from DMA0.
- The APB host interface module implements an indirect addressing scheme to the internal registers to allow arbitrary length access cycles (e.g. address table read/write and configuration register read/write). However the DMA control registers are directly mapped and accessed through APB.

### 11.5.1.2 Features

- Integrated Ethernet switch engine compatible with 10/100 MAC-NET core
- Three port switch with a fourth DMA bypass port
- Can be configured to operate as a 3-port switch (switch mode) or as two independent ports (passthrough mode)
- Filters and forward traffic at wire-speed on all ports
- Per-queue tail-drop congestion management
- Implements hardware switching look-up mechanism providing a learning capacity of up to 2K MAC addresses

- Supports configurable VLAN switching when MAC address lookup should be omitted
- Classification and priority assignment based on port number, MAC address, IPv4 DiffServ code point field, IPv6 Class of Service and VLAN Priority (IEEE802.1q)
- Efficient output queue frame buffering with shared Frame buffer of 24 Kbyte
- Each port implements four priority queues with configurable weighted round-robin selection
- Support Ethernet multicast and broadcast with flooding control to avoid unnecessary duplication of frames
- Programmable multicast destination port mask to restrict frame duplication for individual multicast addresses
- Multicast and broadcast resolution with VLAN domain filtering providing a strict separation of up to 32 VLANs
- IP snooping with programmable protocol and port number registers
- Programmable ingress and egress VLAN tag addition, removal and manipulation supporting single and double-tagged VLAN frames
- Event and status signals which can monitor port activity, severe error conditions, or any user-specific event
- Static or dynamic (learning, aging) switching tables
- Support for IEEE 1588 precise time-stamping applications
- Supports aggregation and redundant backplane applications

### 11.5.2 Modes of Operation

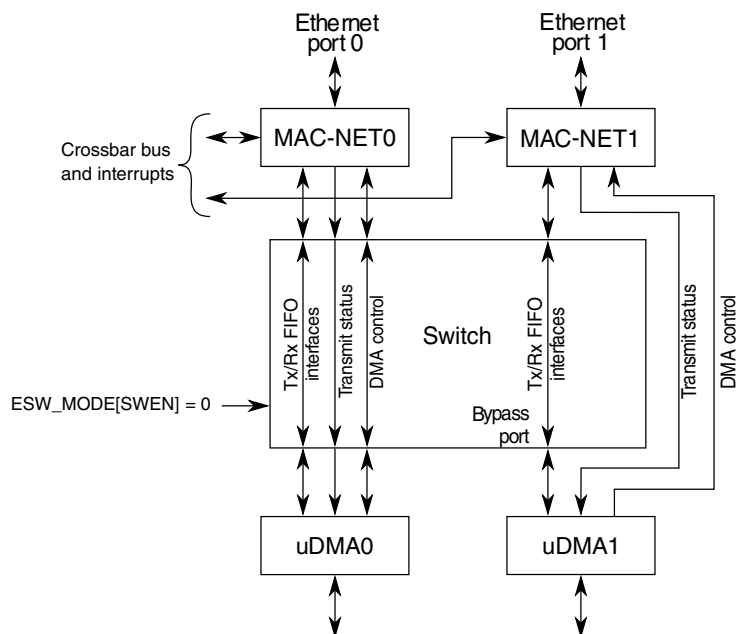

The switch can be configured to operate in the following modes using ESW\_MODE[SWEN].

- Passthrough mode — The switch logic is disabled and bypassed
- Switch mode — The switch logic is enabled

### 11.5.2.1 Passthrough mode

When ESW\_MODE[SWEN] is written to 0, the switch logic is bypassed and the switch power is minimized.

Register access to the switch core as well as interrupts requests are disabled. To control the frame transfer from DMA0 and DMA1, the MAC-NET 0 and the MAC-NET 1 APB interfaces and interrupt signals should be used.

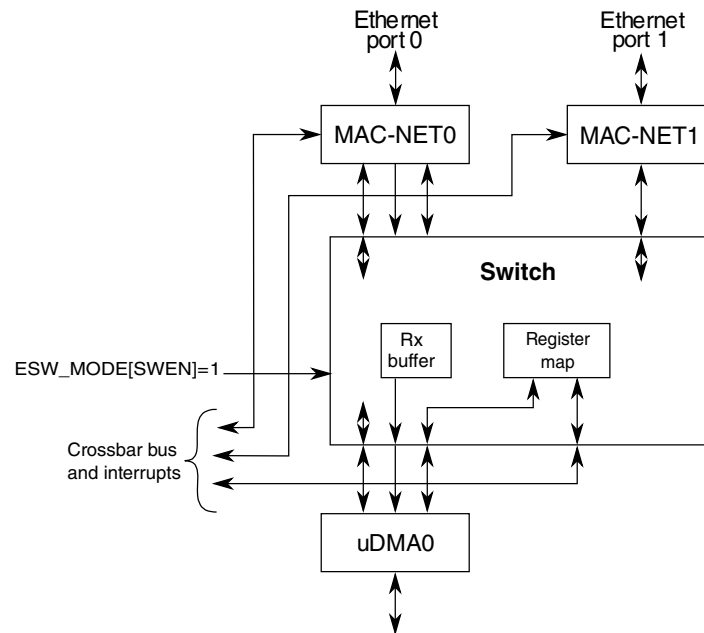

**Figure 11-64. Passthrough Mode Configuration Overview**

### 11.5.2.2 Switch Mode

When the switch is programmed to operate in switch mode (ESW\_MODE[SWEN] set to 1), the bypass mode (port 1) interface is disabled and should not be used.

Frame transfers to and from the line are performed on port 0 only (DMA 0). The transmit status signals are generated from the switch port 0 receive buffer and the DMA control signals from the switch register space. The MAC-NET 0 and MAC-NET 1 transmit status and DMA control signals are not used.

The MAC-NET 0 and MAC-NET 1 APB interfaces and interrupts are enabled and can monitor the line activity and gather the line statistic information.

**Figure 11-65. Switch Mode Configuration Overview**

#### 11.5.2.2.1 Port 0 Input Buffer

A dedicated input buffer of at least 2 KB storage is implemented at the port 0 (DMA 0) input interface, when the switch is operating in switch mode. In bypass mode, this buffer is bypassed.

The input buffer is normally operated in store-and-forward mode, absorbing a DMA burst and forwarding the frame to the switch (internally) when the complete frame is stored in the input buffer.

#### 11.5.2.2.2 Port 0 Input Backpressure/Congestion Indication

When frames are transferred from DMA0 to the switch's port 0 transmit interface, the input buffer indicates when data is to be written to the port 0 input. When the buffer reaches an almost full threshold, it indicates a stop request to DMA0. DMA0 may write a few more words (typically up to four), and then stops writing.

In addition, a special backpressure mechanism for port 0 is included to pause DMA0 transfers when the output queues' shared memory (see [Output Frame Queuing](#)) becomes full to a programmable threshold. Respecting the output queues' shared memory fill level can avoid the switch (due to memory congestion) discarding frames written by the DMA0. The threshold is configured through ESW\_P0BCT.

If the shared memory has less than ESW\_P0BCT number of free cells available, the switch stops serving port 0. That is, the switch does not start to read a frame from the port 0 input buffer. The port 0 input buffer continues to accept data from DMA0 until it becomes full.

### Note

The backpressure only considers the total amount of memory available, not a specific queue. Hence, it may still happen that an outgoing frame from DMA0 is discarded by the switch, if the output queue for the frame is congested while the total amount of memory has free space available.

The backpressure threshold (ESW\_P0BCT) should be set higher than the memory full threshold (ESW\_LMT) to stop the DMA0 before a memory full situation.

## 11.5.3 ESW memory map and registers

### NOTE

The ENET\_QOS and ENET\_DMA $n$ CFG registers in both ENET modules must be configured for proper ENET Switch operation.
