

# EFR32xG1 Wireless Gecko Reference Manual

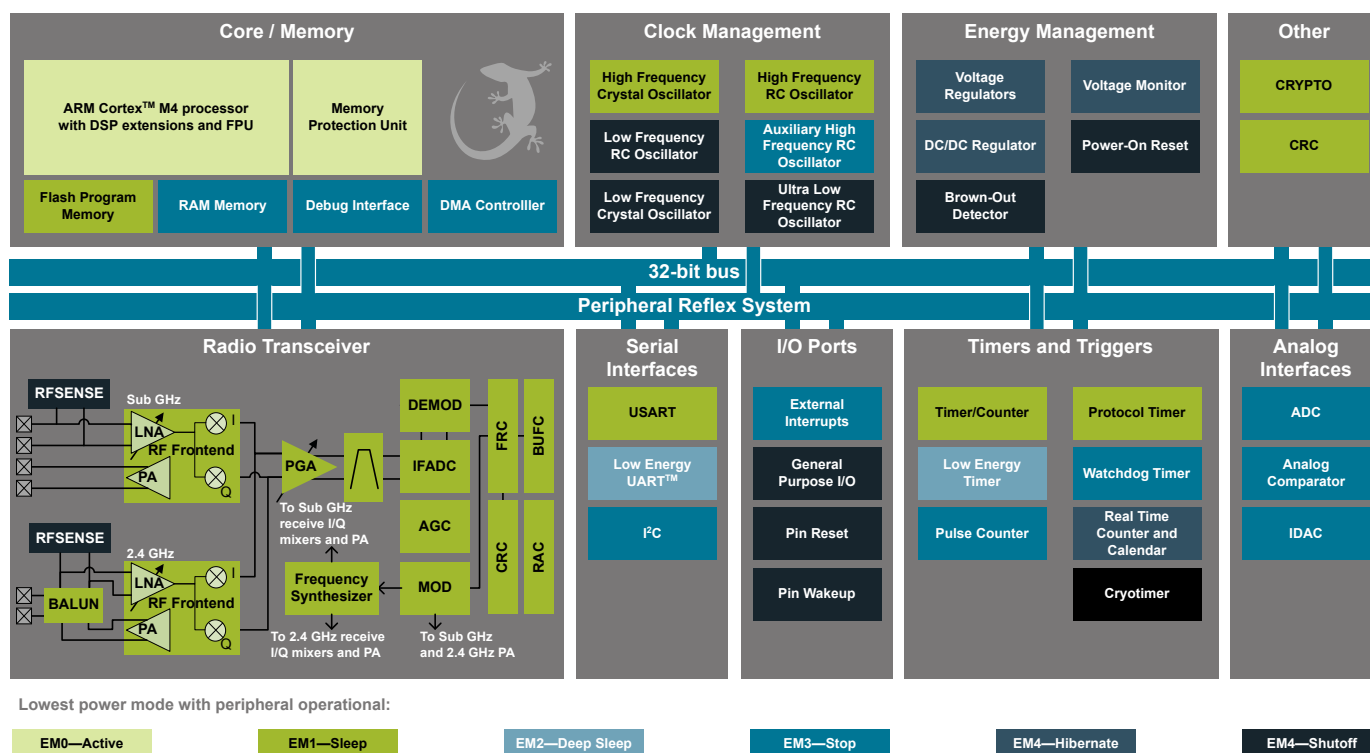

The Wireless Gecko portfolio of SoCs (EFR32) include Mighty Gecko (EFR32MG1), Blue Gecko (EFR32BG1), and Flex Gecko (EFR32FG1) families. With support for Bluetooth Smart (BLE), ZigBee, Thread and proprietary protocols, the Wireless Gecko portfolio is ideal for enabling energy-friendly wireless networking for IoT devices.

The single-die solution provides industry-leading energy efficiency, ultra-fast wakeup times, a scalable high-power amplifier, an integrated balun and no-compromise MCU features.

## KEY FEATURES

- 32-bit ARM® Cortex-M4 core with 40 MHz maximum operating frequency
- Scalable Memory and Radio configuration options available in several footprint compatible QFN packages
- 12-channel Peripheral Reflex System enabling autonomous interaction of MCU peripherals
- Autonomous Hardware Crypto Accelerator and Random Number Generator
- Integrated balun for 2.4 GHz and integrated PA with up to 19.5 dBm transmit power for 2.4 GHz and 20 dBm transmit power for Sub-GHz radios
- Integrated DC-DC with RF noise mitigation

## 1. About This Document

### 1.1 Introduction

This document contains reference material for the EFR32 Wireless Geckos. All modules and peripherals in the EFR32 devices are described in general terms. Not all modules are present in all devices and the feature set for each device might vary. Such differences, including pinout, are covered in the device data sheets.

## 1.2 Conventions

### Register Names

Register names are given with a module name prefix followed by the short register name:

TIMERn\_CTRL - Control Register

The "n" denotes the module number for modules which can exist in more than one instance.

Some registers are grouped which leads to a group name following the module prefix:

BUFC\_BUFx\_WRITEDATA - Buffer Write Data

The "x" denotes the buffer number (0,1,...)

### Bit Fields

Registers contain one or more bit fields which can be 1 to 32 bits wide. Bit fields wider than 1 bit are given with start (x) and stop (y) bit [y:x].

Bit fields containing more than one bit are unsigned integers unless otherwise is specified.

Unspecified bit field settings must not be used, as this may lead to unpredictable behaviour.

### Address

The address for each register can be found by adding the base address of the module found in the Memory Map (see [Figure 4.2 System Address Space with Core and Code Space Listing on page 19](#)), and the offset address for the register (found in module Register Map).

### Access Type

The register access types used in the register descriptions are explained in [Table 1.1 Register Access Types on page 2](#).

**Table 1.1. Register Access Types**

Access Type	Description
R	Read only. Writes are ignored
RW	Readable and writable
RW1	Readable and writable. Only writes to 1 have effect
(R)W1	Sometimes readable. Only writes to 1 have effect. Currently only used for IFC registers (see <a href="#">3.3.1.2 IFC Read-clear Operation</a> )
W1	Read value undefined. Only writes to 1 have effect
W	Write only. Read value undefined.
RWH	Readable, writable, and updated by hardware
RW(nB), RWH(nB), etc.	"(nB)" suffix indicates that register explicitly does not support peripheral bit set or clear (see <a href="#">4.2.2 Peripheral Bit Set and Clear</a> )
RW(a), R(a), etc.	"(a)" suffix indicates that register has actionable reads (see <a href="#">7.3.6 Debugger reads of actionable registers</a> )

### Number format

**0x** prefix is used for hexadecimal numbers

**0b** prefix is used for binary numbers

Numbers without prefix are in decimal representation.

### Reserved

Registers and bit fields marked with **reserved** are reserved for future use. These should be written to 0 unless otherwise stated in the Register Description. Reserved bits might be read as 1 in future devices.

## Reset Value

The reset value denotes the value after reset.

Registers denoted with X have unknown value out of reset and need to be initialized before use. Note that read-modify-write operations on these registers before they are initialized results in undefined register values.

## Pin Connections

Pin connections are given with a module prefix followed by a short pin name:

CMU\_CLKOUT1 (Clock management unit, clock output pin number 1)

The location for the pin names given in the module documentation can be found in the device-specific datasheet.

## 1.3 Related Documentation

Further documentation on the EFR32 Wireless Gecko portfolio and the ARM Cortex-M4 can be found at the Silicon Labs and ARM web pages:

[www.silabs.com](http://www.silabs.com)

[www.arm.com](http://www.arm.com)

## 2. System Overview

### Quick Facts

#### What?

The EFR32 Wireless Gecko is a highly integrated, configurable and low power wireless System-on-Chip (SoC) with a robust set of MCU and radio peripherals.

#### Why?

The Radio enables support for Bluetooth Smart (BLE), ZigBee, Thread and Proprietary Protocols in 2.4 GHz and sub-GHz frequency bands while the MCU system allows customized protocols and applications to run efficiently.

#### How?

Dynamic or fixed packet lengths, optional address recognition, and flexible CRC and crypto schemes makes the EFR32 ideal for many low power wireless IoT applications. High performance analog and digital peripherals allows complete applications to run on the EFR32 SoC.

## 2.1 Introduction

The high level features of EFR32 include:

- High performance radio transceiver
  - Dual-band operation
  - Low power consumption in transmit, receive, and standby modes
  - Excellent receiver performance, including sensitivity, selectivity and blocking
  - Excellent transmitter performance, including programmable output power, low phase noise and PA ramping
  - Ultra Low Energy RF Detection for wake-up from any Energy Mode, through RFSense
- Configurable protocol support, including standards and customer developed protocols
  - Preamble and frame synchronization insertion in transmit and recovery in receive
  - Flexible CRC support, including configurable polynomial and multiple CRCs for single data frames
  - Basic address filtering performed in hardware
- High performance, low power MCU system
  - High Performance 32-bit ARM Cortex-M4 CPU
  - Flexible and efficient energy management
  - Complete set of digital peripherals
  - Peripheral Reflex System (PRS)
  - Precision analog interfaces
- Low external component count
  - Fully integrated 2.4 GHz BALUN
  - Integrated tunable crystal loading capacitors

A further introduction to the MCU and radio system is included in the following sections.

**Note:**

Detailed performance numbers, current consumption, pinout etc. is available in the device datasheet.

## 2.2 Block Diagrams

The block diagram for the EFR32 System-On-Chip series is shown in (Figure 2.1 EFR32 System-On-Chip Block Diagram on page 6).

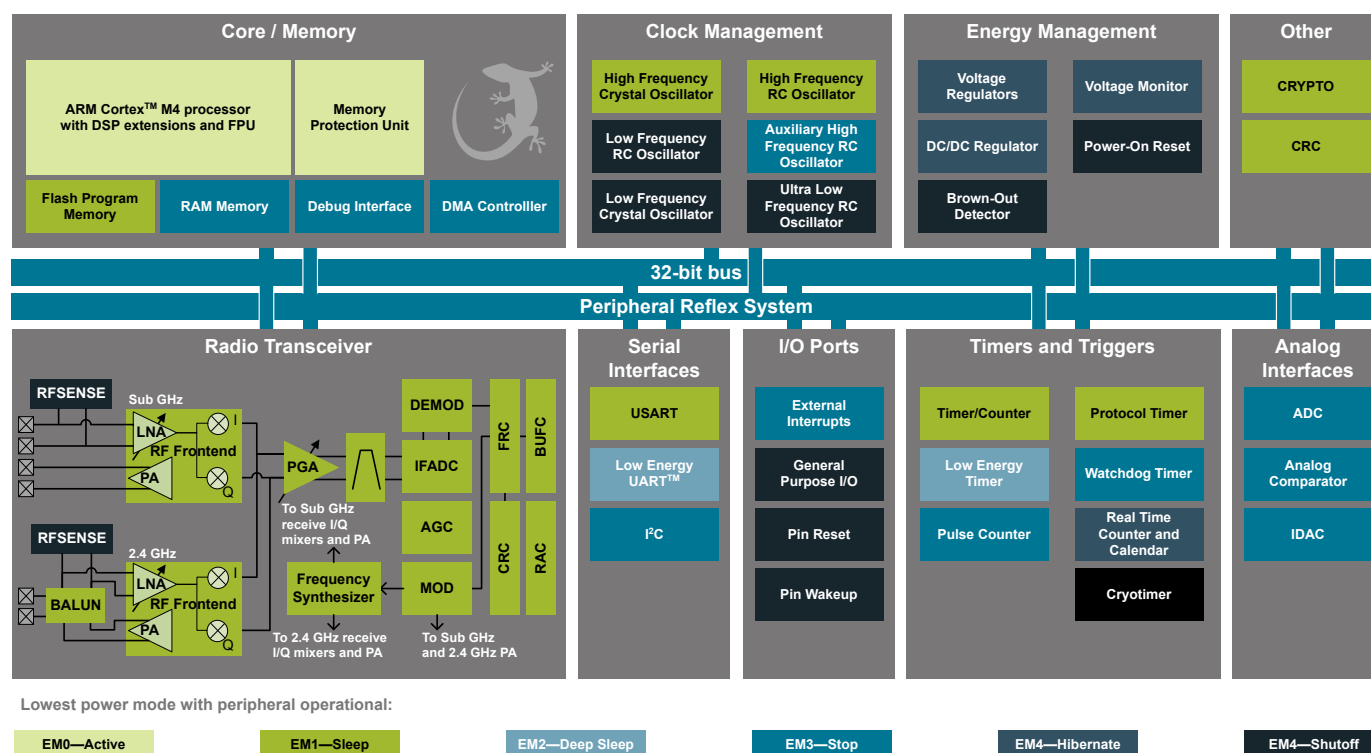

Figure 2.1. EFR32 System-On-Chip Block Diagram

## 2.3 MCU Features overview

- **ARM Cortex-M4 CPU platform**
  - High Performance 32-bit processor @ up to 40 MHz
  - Memory Protection Unit
  - Wake-up Interrupt Controller
- **Flexible Energy Management System**
  - 5 Energy Modes from EM0 to EM4 provide flexibility between higher performance and low power
  - Power routing configurations including DCDC control
  - Voltage Monitoring and Brown Out Detection
  - State Retention
- **Up to 256 KB Flash**
- **Up to 32 KB RAM**
- **Up to 31 General Purpose I/O pins**
  - Configurable push-pull, open-drain, pull-up/down, input filter, drive strength
  - Configurable peripheral I/O locations
  - 16 asynchronous external interrupts
  - Output state retention and wake-up from Shutoff Mode
- **8 Channel DMA Controller**
  - Alternate/primary descriptors with scatter-gather/ping-pong operation
- **12 Channel Peripheral Reflex System**
  - Autonomous inter-peripheral signaling enables smart operation in low energy modes
- **CRYPTO Advanced Encryption Standard Accelerator**
  - AES encryption / decryption, with 128 or 256 bit keys
  - Multiple AES modes of operation, including Counter (CTR), Galois/Counter Mode (GCM), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB).
  - Accelerated SHA-1 and SHA-2 (SHA-224 / SHA-256)
  - Accelerated Elliptic Curve Cryptography (ECC), with binary or prime fields
  - Flexible 256-bit ALU and sequencer
- **General Purpose Cyclic Redundancy Check**
  - Programmable 16-bit polynomial, fixed 32-bit polynomial
  - The General Purpose Cyclic Redundancy Check (GPCRC) module comes in addition to the radio CRC
- **Communication interfaces**
  - 2 Universal Synchronous/Asynchronous Receiver/Transmitter
    - UART/SPI/SmartCard (ISO 7816)/IrDA/I2S
    - Triple buffered full/half-duplex operation
    - Hardware flow control
    - 4-16 data bits
  - 1 Low Energy UART
    - Autonomous operation with DMA in Deep Sleep Mode
  - 1 I<sup>2</sup>C Interface with SMBus support
    - Address recognition in Stop Mode
- **Timers/Counters**
  - 2 16-bit Timer/Counter
    - 3 or 4 Compare/Capture/PWM channels
    - Dead-Time Insertion on TIMER0
  - 16-bit Low Energy Timer
  - 32-bit Ultra Low Energy Timer/Counter (CRYOTIMER) for periodic wake-up from any Energy Mode
  - 32-bit Real-Time Counter and Calendar
  - 16+16+32 bit Protocol Timer
  - 16-bit Pulse Counter
    - Asynchronous pulse counting/quadrature decoding
  - Watchdog Timer with dedicated RC oscillator
- **Ultra low power precision analog peripherals**

- 12-bit 1 Msamples/s Analog to Digital Converter
  - 8 input channels and on-chip temperature sensor
  - Single ended or differential operation
  - Conversion tailgating for predictable latency
- Current Digital to Analog Converter
  - Source or sink a configurable constant current
- 2 Analog Comparator
  - Programmable speed/current
  - Capacitive sensing with up to 8 inputs
- Analog Port
- **Ultra efficient Power-on Reset and Brown-Out Detector**
- **Debug Interface**
  - 4-pin Joint Test Action Group (JTAG) interface
  - 2-pin serial-wire debug (SWD) interface

## 2.4 Oscillators and Clocks

EFR32 has six different oscillators integrated, as shown in [Table 2.1 EFR32 Oscillators on page 8](#).

**Table 2.1. EFR32 Oscillators**

Oscillator	Frequency	Optional?	External components	Description
HFXO	38 MHz - 40 MHz	No	Crystal	High accuracy, low jitter high frequency crystal oscillator. Tunable crystal loading capacitors are fully integrated. The HFXO is required for all types of RF communication to be active.
HFRCO	1 MHz - 38 MHz	No	-	Medium accuracy RC oscillator, typically used for timing during startup of the HFXO and as a clock source as long as no RF communication is active.
AUXHFRCO	1 MHz - 38 MHz	No	-	Medium accuracy RC oscillator, typically used as alternative clock source for Analog to Digital Converter or Debug Trace.
LFRCO	32768 Hz	No	-	Medium accuracy frequency reference typically used for medium accuracy RTCC timing.
LFXO	32768 Hz	Yes	Crystal	High accuracy frequency reference typically used for high accuracy RTCC timing. Tunable crystal loading capacitors are fully integrated.
ULFRCO	1000 Hz	No	-	Ultra low frequency oscillator typically used for the watchdog timer.

The RC oscillators can be calibrated against either of the crystal oscillators in order to compensate for temperature and voltage supply variations. Hardware support is included to measure the frequency of various oscillators against each other.

Oscillator and clock management is available through the Clock Management Unit (CMU), see section [12. CMU - Clock Management Unit](#) for details.

## 2.5 RF Frequency Synthesizer

The Fractional-N RF Frequency Synthesizer (SYNTH) provides a low phase noise LO signal to be used in both receive and transmit modes.

The capabilities of the SYNTH include:

- High performance, low phase noise
- Fast frequency settling
- Fast and fully automated calibration
- Sub 100 Hz frequency resolution across the supported frequency bands

## 2.6 Modulation Modes

EFR32 supports a wide range of modulation modes in transmit and receive:

- 2-FSK, 2-GFSK, 4-FSK, 4-GFSK, MSK, GMSK, O-QPSK with half-sine shaping, ASK / OOK, DBPSK TX
- NRZ or Manchester support
- UART mode over air for legacy protocols
- Baudrates ranging from below 100 Baud/s to 2 MBaud/s, allowing data rates up to 4 MBit/s
- Configurable frequency deviation
- Configurable Direct Sequence Spread Spectrum (DSSS), with spread sequences up to 32 chips encoding up to 4 information bits
- Configurable 4-FSK symbol encoding

## 2.7 Transmit Mode

In transmit mode EFR32 performs the following functionality:

- Automatic PA power ramping during the start and end of a frame transmit
- Programmable output power
- Optional preamble and synchronization word insertion
- Accurate transmit frame timing to support time synchronized radio protocols
- Optional Carrier Sense Multiple Access - Collision Avoidance (CSMA-CA) or Listen Before Talk (LBT) hardware support
- Integrated transmit test modes, as described in [2.17 RF Test Modes](#)

## 2.8 Receive Mode

In receive mode EFR32 performs the following functionality:

- A single-ended (2.4 GHz) or differential (Sub-GHz) LNA amplifies the input RF signal. The amplified signal is then mixed to a low-IF signal through the quadrature down-conversion mixer. Further signal filtering is performed before conversion to a digital signal through the I/Q ADC.
- Digitally configurable receiver bandwidth from 100 Hz to 2.5 MHz
- Timing recovery on received data, including simultaneous support for two different frame synchronization words
- Automatic frequency offset compensation, to compensate for carrier frequency offset between the transmitter and receiver
- Support for a wide range of modulation formats as described in section [2.6 Modulation Modes](#)

## 2.9 Data Buffering

EFR32 supports buffered transmit and receive modes through its buffer controller (BUFC), with four individually configurable buffers. The BUFC uses the system RAM as storage, and each buffer can be individually configured with parameters such as:

- Buffer size
- Buffer interrupt thresholds
- Buffer RAM location
- Overflow and underflow detection

In receive mode, data following frame synchronization is moved directly from the demodulator to the buffer storage.

In transmit mode, data following the inserted preamble and synchronization word is moved directly from the buffer storage to the modulator.

## 2.10 Unbuffered Data Transfer

For most system designs it is recommended to use the data buffering within EFR32 to provide a convenient user interface.

In cases where data buffering within EFR32 is not desired, it is possible to set up direct unbuffered data transfers using a single-pin or two-pin interface on EFR32. A bit clock output is provided on the Serial Clock (SC) output pin, and a serial bitstream is provided to EFR32 in a transmit mode and from EFR32 in a receive mode.

In unbuffered data transfer modes the hardware support provided by EFR32 to perform preamble and frame synchronization insertion in transmit mode and detection in receive mode can still optionally be used.

## 2.11 Frame Format Support

EFR32 has an extensive support for frame handling in transmit and receive modes, which allows effective handling of even advanced protocols. The support includes:

- Preamble and frame synchronization inserted into transmitted frames
- Full frame synchronization of received frames
- Simple address matching of received frames in hardware, further configurable address and frame filtering supported through sequencer
- Support for variable length frames
- Automated CRC calculation and verification
- Configurable bit ordering, with the most or least significant bit transmitted and received first

The frame format support is controlled by the Frame Controller (FRC).

## 2.12 Hardware CRC Support

EFR32 supports a configurable CRC generation in transmit and verification in receive mode:

- 8, 16, 24 or 32 bit CRC value
- Configurable polynomial and initialization value
- Optional inversion of CRC value over air
- Configurable CRC byte ordering
- Support for multiple CRC values calculated and verified per transmitted or received frame
- The CRC module is typically controlled by the Frame Controller (FRC) for in-line operations in transmit and receive modes. Alternatively, the CRC module may be accessed directly from software to calculate and verify CRC data.

## 2.13 Convolutional Encoding / Decoding

EFR32 includes hardware support for convolutional encoding and decoding, for forward error correction (FEC). This feature is performed by the Frame Controller (FRC) module:

- Constraint length configurable up to 7, for the highest robustness
- Configurable puncturing, to achieve rates between 1/2 rate and full rate
- Configurable soft decision or hard decision decoding
- Convolutional coding may be used together with the symbol interleaver to improve robustness against burst errors

## 2.14 Binary Block Encoding / Decoding

EFR32 includes hardware support for binary block encoding and decoding, both performed real-time in the the transmit and receive path. This is performed in the Frame Controller (FRC) module:

The block coding works on blocks of up to 16 bits of data and adds parity bits to be capable of single or multiple bit corrections by the receiver.

- One or more parity bits can be added and verified
- Bit error correction
- Lookup-codes can be used to implement virtually any block coding scheme

## 2.15 Data Encryption and Authentication

EFR32 has hardware support for AES encryption, decryption and authentication modes. These security operations can be performed on data in RAM or any data buffer, without further CPU intervention. The key size is 128 bits.

AES modes of operations directly supported by the EFR32 hardware are listed in [Table 2.2 AES modes of operation with hardware support on page 11](#). In addition to these modes, other modes can also be implemented by using combinations of modes. For example, the CCM mode can be implemented using the CTR and CBC-MAC modes in combination.

**Table 2.2. AES modes of operation with hardware support**

AES Mode	Encryption / Decryption	Authentication	Comment
ECB	Yes	-	Electronic Code Book
CTR	Yes	-	Counter mode
CCM	Yes	Yes	Counter with CBC-MAC
CCM*	Yes	Yes	CCM with encryption-only and integrity-only capabilities
GCM	Yes	Yes	Galois Counter Mode
CBC	Yes	-	Cipher Block Chaining
CBC-MAC	-	Yes	Cipher Block Chaining, Message Authentication Code
CMAC	-	Yes	Cipher-basec MAC
CFB	Yes	-	Cipher Feedback
OFB	Yes	-	Output Feedback

The CRYPTO module can operate directly on data buffers provided by the BUFC module. It is also possible to provide data directly from the embedded Cortex-M4 or via DMA.

## 2.16 Timers

EFR32 includes multiple timers, as can be seen from [Table 2.3 EFR32 Timers Overview on page 12](#).

**Table 2.3. EFR32 Timers Overview**

Timer	Number of instances	Typical clock source	Overview
RTCC	1	Low frequency (LFXO or LFRCO)	32 bit Real Time Counter and Calendar, typically used to accurately time inactive periods in the radio communication protocol and enable wakeup on compare match.
PROTIMER	1	High frequency (HFXO or HFRCO)	16+16+32 bit Protocol Timer, typically used to accurately control detailed RF protocol timing in transmit and receive modes.
TIMER	2	High frequency (HFXO or HFRCO)	16 bit general purpose timer.
Systick timer	1	High frequency (HFXO or HFRCO)	32 bit systick timer integrated in the Cortex-M4. Typically used as an Operating System timer.
WDOG	1	Low frequency (LFXO, LFRCO or ULFRCO)	Watch dog timer. Once enabled, this module must be periodically accessed. If not, this is considered an error and the EFR32 is reset in order to recover the system.
LETIMER	1	Low frequency (LFXO, LFRCO or ULFRCO)	Low energy general purpose timer.

Advanced interconnect features allows synchronization between timers. This includes:

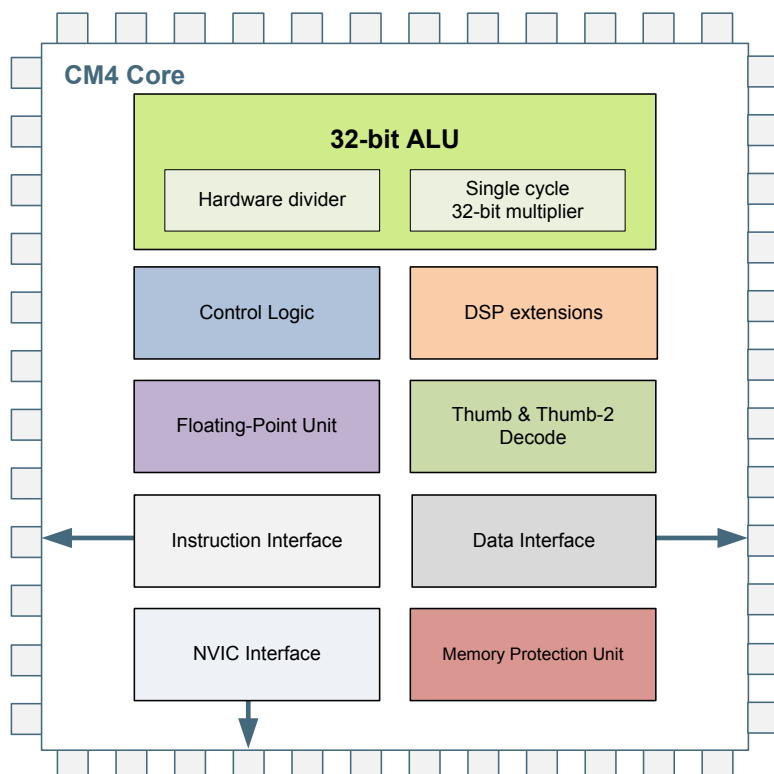

- Start / stop any high frequency timer synchronized with the RTCC
- Trigger RSM state transitions based on compare timer compare match, for instance to provide clock cycle accuracy on frame transmit timing

## 2.17 RF Test Modes

EFR32 supports a wide range of RF test modes typically used for characterization and regulation compliance testing, including:

- Unmodulated carrier transmit
- Modulated carrier transmit, with internal configurable pseudo random data generator
- Continuous data reception for Bit Error Rate (BER) measurements
- Storing of raw receiver data to RAM
- Transmit of raw frequency data from RAM

### 3. System Processor

#### Quick Facts

##### What?

The industry leading Cortex-M4 processor from ARM is the CPU in the EFR32 devices.

##### Why?

The ARM Cortex-M4 is designed for exceptionally short response time, high code density, and high 32-bit throughput while maintaining a strict cost and power consumption budget.

##### How?

Combined with the ultra low energy peripherals available in EFR32 devices, the Cortex-M4 processor's Harvard architecture, 3 stage pipeline, single cycle instructions, Thumb-2 instruction set support, and fast interrupt handling make it perfect for 8-bit, 16-bit, and 32-bit applications.

#### 3.1 Introduction

The ARM Cortex-M4 32-bit RISC processor provides outstanding computational performance and exceptional system response to interrupts while meeting low cost requirements and low power consumption.

The ARM Cortex-M4 implemented is revision r0p1.

### 3.2 Features

- Harvard architecture
  - Separate data and program memory buses (No memory bottleneck as in a single bus system)
- 3-stage pipeline
- Thumb-2 instruction set
  - Enhanced levels of performance, energy efficiency, and code density
- Single cycle multiply and hardware divide instructions
  - 32-bit multiplication in a single cycle
  - Signed and unsigned divide operations between 2 and 12 cycles
- Atomic bit manipulation with bit banding
  - Direct access to single bits of data
  - Two 1MB bit banding regions for memory and peripherals mapping to 32MB alias regions
  - Atomic operation, cannot be interrupted by other bus activities
- 1.25 DMIPS/MHz
- Memory Protection Unit
  - Up to 8 protected memory regions
- 24 bits System Tick Timer for Real Time OS
- Excellent 32-bit migration choice for 8/16 bit architecture based designs
  - Simplified stack-based programmer's model is compatible with traditional ARM architecture and retains the programming simplicity of legacy 8-bit and 16-bit architectures
- Aligned or unaligned data storage and access
  - Contiguous storage of data requiring different byte lengths
  - Data access in a single core access cycle
- Integrated power modes
  - Sleep Now mode for immediate transfer to low power state
  - Sleep on Exit mode for entry into low power state after the servicing of an interrupt
  - Ability to extend power savings to other system components
- Optimized for low latency, nested interrupts

### 3.3 Functional Description

For a full functional description of the ARM Cortex-M4 implementation in the EFR32 family, the reader is referred to the ARM Cortex-M4 documentation.

### 3.3.1 Interrupt Operation

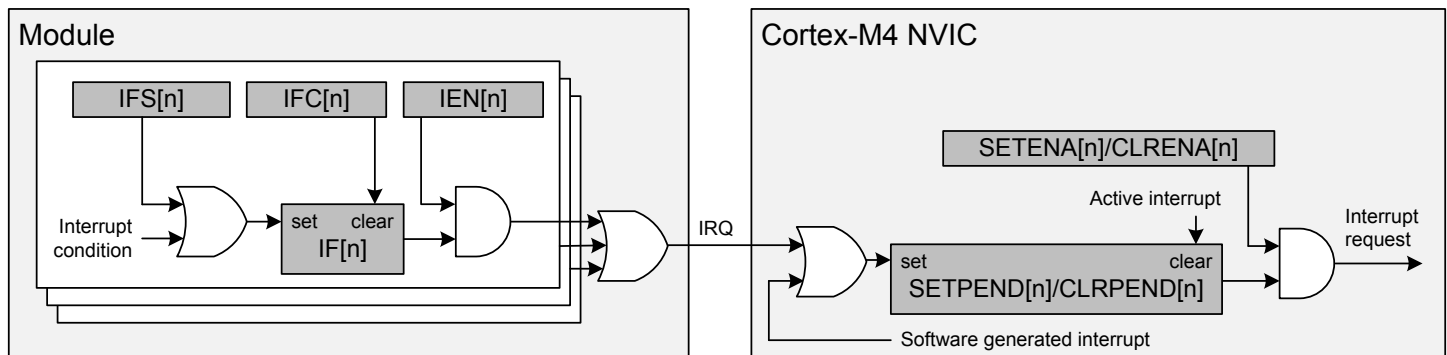

Figure 3.1. Interrupt Operation

The interrupt request (IRQ) lines are connected to the Cortex-M4. Each of these lines (shown in [Table 3.1 Interrupt Request Lines \(IRQ\) on page 16](#)) is connected to one or more interrupt flags in one or more modules. The interrupt flags are set by hardware on an interrupt condition. It is also possible to set/clear the interrupt flags through the IFS/IFC registers. Each interrupt flag is then qualified with its own interrupt enable bit (IEN register), before being OR'ed with the other interrupt flags to generate the IRQ. A high IRQ line will set the corresponding pending bit (can also be set/cleared with the SETPEND/CLRPEND bits in ISPR0/ICPR0) in the Cortex-M4 NVIC. The pending bit is then qualified with an enable bit (set/cleared with SETENA/CLRENA bits in ISER0/ICER0) before generating an interrupt request to the core. [Figure 3.1 Interrupt Operation on page 15](#) illustrates the interrupt system. For more information on how the interrupts are handled inside the Cortex-M4, the reader is referred to the **EFR32 Cortex-M4 Reference Manual**.

#### 3.3.1.1 Avoiding Extraneous Interrupts

There can be latencies in the system such that clearing an interrupt flag could take longer than leaving an Interrupt Service Routine (ISR). This can lead to the ISR being re-entered as the interrupt flag has yet to clear immediately after leaving the ISR. To avoid this, when clearing an interrupt flag at the end of an ISR, the user should execute ARM's Data Synchronization Barrier (DSB) instruction. Another approach is to clear the interrupt flag immediately after identifying the interrupt source and then service the interrupt as shown in the pseudo-code below. The ISR typically is sufficiently long to more than cover the few cycles it may take to clear the interrupt status, and also allows the status to be checked for further interrupts before exiting the ISR.

```
irqXServiceRoutine() {
    do {
        clearIrqXStatus();
        serviceIrqX();
    } while(irqXStatusIsActive());
}
```

#### 3.3.1.2 IFC Read-clear Operation

In addition to the normal interrupt setting and clearing operations via the IFS/IFC registers, there is an additional atomic Read-clear operation that can be enabled by setting IFCREADCLEAR=1 in the MSC\_CTRL register. When enabled, reads of peripheral IFC registers will return the interrupt vector (mirroring the IF register), while at the same time clearing whichever interrupt flags are set. This operation is functionally equivalent to reading the IF register and then writing the result immediately back to the IFC register.

### 3.3.2 Interrupt Request Lines (IRQ)

Table 3.1. Interrupt Request Lines (IRQ)

IRQ #	Source
0	EMU
2	WDOG0
8	LDMA
9	GPIO_EVEN
10	TIMER0
11	USART0_RX
12	USART0_TX
13	ACMP0
14	ADC0
15	IDAC0
16	I2C0
17	GPIO_ODD
18	TIMER1
19	USART1_RX
20	USART1_TX
21	LEUART0
22	PCNT0
23	CMU
24	MSC
25	CRYPTO
26	LETIMER0
29	RTCC
31	CRYOTIMER
33	FPUEH

## 4. Memory and Bus System

### Quick Facts

#### What?

A low latency memory system including low energy Flash and RAM with data retention which makes the energy modes attractive.

#### Why?

RAM retention reduces the need for storing data in Flash and enables frequent use of the ultra low energy modes EM2 DeepSleep and EM3 Stop.

#### How?

Low energy and non-volatile Flash memory stores program and application data in all energy modes and can easily be reprogrammed in system. Low leakage RAM with data retention in EM0 Active to EM3 Stop removes the data restore time penalty, and the DMA ensures fast autonomous transfers with predictable response time.

## 4.1 Introduction

The EFR32 contains an AMBA AHB Bus system to allow bus masters to access the memory mapped address space. A multilayer AHB bus matrix connects the 5 master bus interfaces to the AHB slaves (Figure 4.1 EFR32 Bus System on page 18). The bus matrix allows several AHB slaves to be accessed simultaneously. An AMBA APB interface is used for the peripherals, which are accessed through an AHB-to-APB bridge connected to the AHB bus matrix. The 5 AHB bus masters are:

- **Cortex-M4 ICode:** Used for instruction fetches from Code memory (valid address range: 0x00000000 - 0x1FFFFFFF)
- **Cortex-M4 DCode:** Used for debug and data access to Code memory (valid address range: 0x00000000 - 0x1FFFFFFF)
- **Cortex-M4 System:** Used for data and debug access to system space. It can access entire memory space except Code memory (valid address range: 0x20000000 - 0xFFFFFFFF)
- **DMA:** Can access entire memory space except internal core memory region and Code memory (valid address range: 0x20000000 - 0xDFFFFFFF)
- **Sequencer Code:** Used for instruction fetches and data accesses. Instruction fetches still come from data memory. (valid address range: 0x20000000 - 0x3FFFFFFF)
- **Sequencer System:** Can access entire memory space except internal core memory region and code space (valid address range: 0x20000000 - 0xDFFFFFFF)
- **BUFC:** Can access RAM and RAMH (valid address range: 0x20000000 - 0x20007FFF)
- **FRC:** Can access RAM and RAMH (valid address range: 0x20000000 - 0x20007FFF)

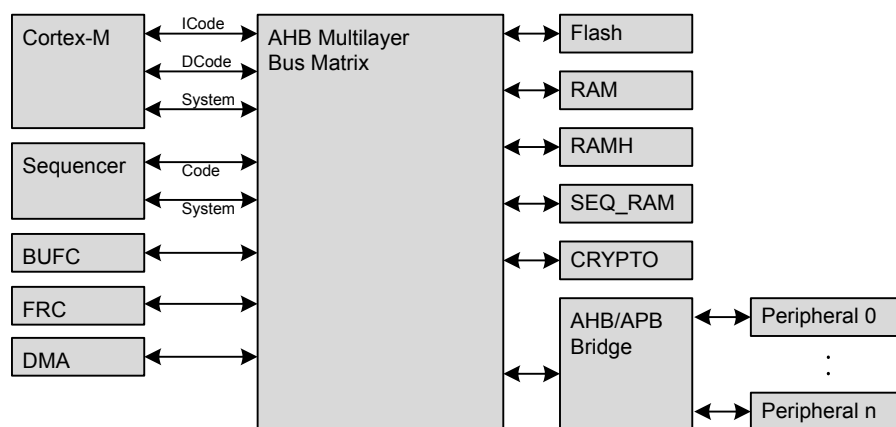

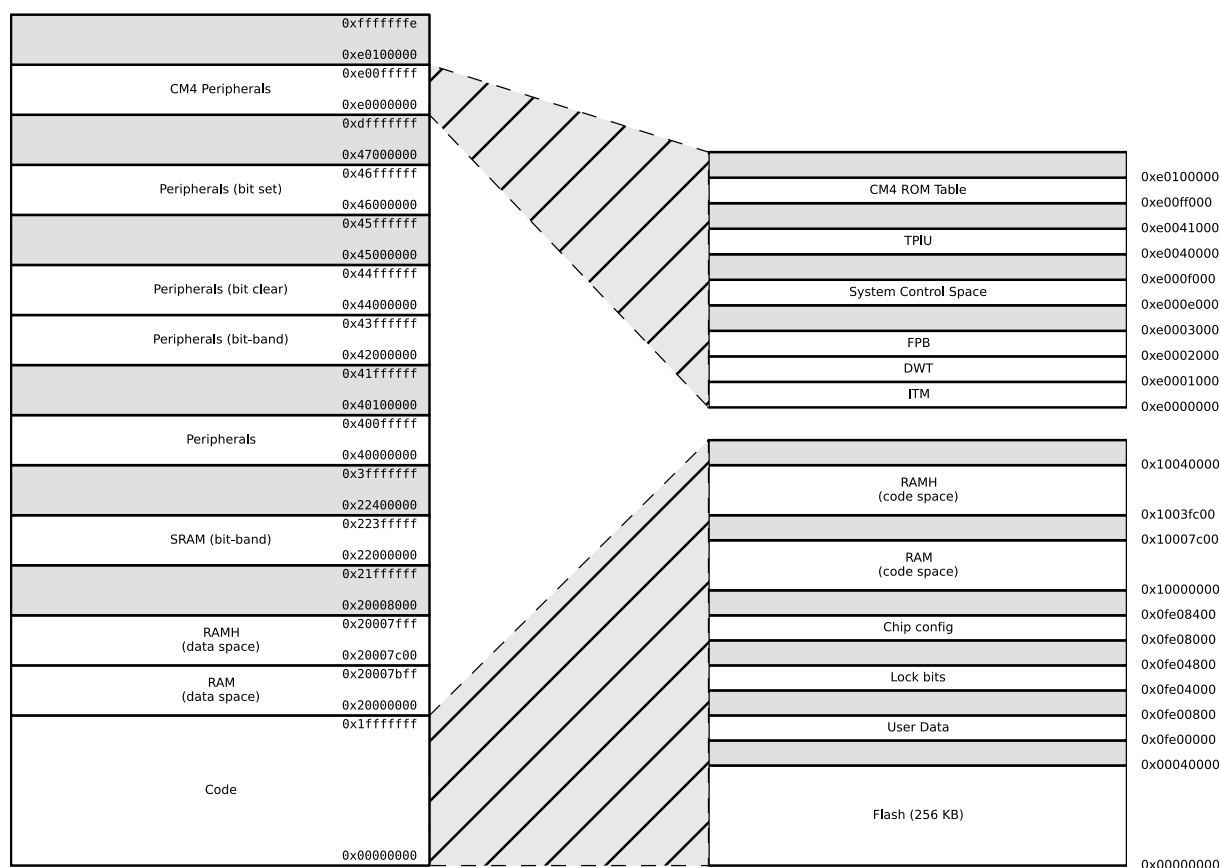

Figure 4.1. EFR32 Bus System

## 4.2 Functional Description

The memory segments are mapped together with the internal segments of the Cortex-M4 into the system memory map shown by [Figure 4.2 System Address Space with Core and Code Space Listing on page 19](#).

**Figure 4.2. System Address Space with Core and Code Space Listing**

Additionally, the peripheral address map is detailed by [Figure 4.3 System Address Space with Peripheral Listing on page 20](#).

**Figure 4.3. System Address Space with Peripheral Listing**

The embedded SRAM is located at address 0x20000000 in the memory map of the EFR32. When running code located in SRAM starting at this address, the Cortex-M4 uses the System bus interface to fetch instructions. This results in reduced performance as the Cortex-M4 accesses stack, other data in SRAM and peripherals using the System bus interface. To be able to run code from SRAM efficiently, the SRAM is also mapped in the code space at address 0x10000000. When running code from this space, the Cortex-M4 fetches instructions through the I/D-Code bus interface, leaving the System bus interface for data access. The SRAM mapped into the code space can however only be accessed by the CPU, i.e. not the DMA.

The RAM is split in the RAM and RAMH, each having an individual bus connection. This enables simultaneous access to the RAM and RAMH, e.g. if the CPU is accessing the RAM, the DMA can access RAMH without any bus congestion and reduced performance.

The Sequencer RAM is used by the Sequencer for both instructions and data. This RAM is also available for general use by most AHB masters.

### 4.2.1 Bit-banding

The SRAM bit-band alias and peripheral bit-band alias regions are located at 0x22000000 and 0x42000000 respectively. Read and write operations to these regions are converted into masked single-bit reads and atomic single-bit writes to the embedded SRAM and peripherals of the EFR32.

**Note:** Bit-banding is only available through the CPU. No other AHB masters (e.g., DMA) can perform Bit-banding operations.

Using a standard approach to modify a single register or SRAM bit in the aliased regions, would require software to read the value of the byte, half-word or word containing the bit, modify the bit, and then write the byte, half-word or word back to the register or SRAM address. Using bit-banding, this can be done in a single operation, consuming only two bus cycles. As read-writeback, bit-masking and bit-shift operations are not necessary in software, code size is reduced and execution speed improved.

The bit-band regions allow each bit in the SRAM and Peripheral areas of the memory map to be addressed. To set or clear a bit in the embedded SRAM, write a 1 or a 0 to the following address:

$$\text{bit\_address} = 0x22000000 + (\text{address} - 0x20000000) \times 32 + \text{bit} \times 4$$

where address is the address of the 32-bit word containing the bit to modify, and bit is the index of the bit in the 32-bit word.

To modify a bit in the Peripheral area, use the following address:

$$\text{bit\_address} = 0x42000000 + (\text{address} - 0x40000000) \times 32 + \text{bit} \times 4$$

## 4.2.2 Peripheral Bit Set and Clear

The EFR32 supports bit set and bit clear access to all peripherals except those listed in [Table 4.1 Peripherals that Do Not Support Bit Set and Bit Clear on page 22](#). The bit set and bit clear functionality (also called Bit Access) enables modification of bit fields (single bit or multiple bit wide) without the need to perform a read-modify-write (though it is functionally equivalent). Also, the operation is contained within a single bus access (for HF peripherals), unlike the Bit-banding operation described in section [4.2.1 Bit-banding](#) which consumes two bus accesses per operation. All AHB masters can utilize this feature.

The bit clear aliasing region starts at 0x44000000 and the bit set aliasing region starts at 0x46000000. Thus, to apply a bit set or clear operation, write the bit set or clear mask to the following addresses:

```
bit_clear_address = address + 0x04000000
```

```
bit_set_address = address + 0x06000000
```

For bit set operations, bit locations that are 1 in the bit mask will be set in the destination register:

```
register = (register OR mask)
```

For bit clear operations, bit locations that are 1 in the bit mask will be cleared in the destination register:

```
register = (register AND (NOT mask))
```

**Note:** It is possible to combine bit clear and bit set operations in order to arbitrarily modify multi-bit register fields, without affecting other fields in the same register. In this case, care should be taken to ensure that the field does not have intermediate values that can lead to erroneous behavior. For example, if bit clear and bit set operations are used to change an analog tuning register field from 25 to 26, the field would initially take on a value of zero. If the analog module is active at the time, this could lead to undesired behavior.

The peripherals listed in [Table 4.1 Peripherals that Do Not Support Bit Set and Bit Clear on page 22](#) do not support Bit Access for any registers. All other peripherals do support Bit Access, however, there may be cases of certain registers that do not support it. Such registers have a note regarding this lack of support.

**Table 4.1. Peripherals that Do Not Support Bit Set and Bit Clear**

Module
EMU
RMU
CRYOTIMER

### 4.2.3 Peripherals

The peripherals are mapped into the peripheral memory segment, each with a fixed size address range according to [Table 4.2 Peripherals on page 23](#), [Table 4.3 Low Energy Peripherals on page 23](#), and [Table 4.4 Core Peripherals on page 23](#).

**Table 4.2. Peripherals**

Address Range	Module Name
0x400E6000 - 0x400E6400	PRS
0x4001E000 - 0x4001E400	CRYOTIMER
0x4001C000 - 0x4001C400	GPCRC
0x40018400 - 0x40018800	TIMER1
0x40018000 - 0x40018400	TIMER0
0x40010400 - 0x40010800	USART1
0x40010000 - 0x40010400	USART0
0x4000C000 - 0x4000C400	I2C0
0x4000A000 - 0x4000B000	GPIO
0x40006000 - 0x40006400	IDAC0
0x40002000 - 0x40002400	ADC0
0x40000400 - 0x40000800	ACMP1
0x40000000 - 0x40000400	ACMP0

**Table 4.3. Low Energy Peripherals**

Address Range	Module Name
0x40052000 - 0x40052400	WDOG0
0x4004E000 - 0x4004E400	PCNT0
0x4004A000 - 0x4004A400	LEUART0
0x40046000 - 0x40046400	LETIMER0
0x40042000 - 0x40042400	RTCC

**Table 4.4. Core Peripherals**

Address Range	Module Name
0x400F0000 - 0x400F0400	CRYPTO
0x400E2000 - 0x400E3000	LDMA
0x400E1000 - 0x400E1400	FPUEH
0x400E0000 - 0x400E0800	MSC

### 4.2.4 Bus Matrix

The Bus Matrix connects the memory segments to the bus masters as detailed in [4.1 Introduction](#).

#### 4.2.4.1 Arbitration

The Bus Matrix uses a round-robin arbitration algorithm which enables high throughput and low latency, while starvation of simultaneous accesses to the same bus slave are eliminated. Round-robin does not assign a fixed priority to each bus master. The arbiter does not insert any bus wait-states during peak interaction. However, one wait state is inserted for master accesses occurring after a prolonged inactive time. This wait state allows for increased power efficiency during master idle time.

#### 4.2.4.2 Access Performance

The Bus Matrix is a multi-layer energy optimized AMBA AHB compliant bus with an internal bandwidth of 5x a single AHB interface.

The Bus Matrix accepts new transfers to be initiated by each master in each cycle without inserting any wait-states. However, the slaves may insert wait-states depending on their internal throughput and the clock frequency.

The Cortex-M4, DMA Controller, and peripherals (not peripherals in the low frequency clock domain) run on clocks which can be pre-scaled separately. Clocks and prescaling are described in more detail in [12. CMU - Clock Management Unit](#).

In general, when accessing a peripheral, the latency in number of HFBUSCLK cycles, not including master arbitration, is given by:

$$\begin{aligned} N_{\text{bus cycles}} &= N_{\text{slave cycles}} \times f_{\text{HFBUSCLK}}/f_{\text{HFPERCLK}}, \text{ best-case write accesses} \\ N_{\text{bus cycles}} &= N_{\text{slave cycles}} \times f_{\text{HFBUSCLK}}/f_{\text{HFPERCLK}} + 1, \text{ best-case read accesses} \\ N_{\text{bus cycles}} &= (N_{\text{slave cycles}} + 1) \times f_{\text{HFBUSCLK}}/f_{\text{HFPERCLK}} - 1, \text{ worst-case write accesses} \\ N_{\text{bus cycles}} &= (N_{\text{slave cycles}} + 1) \times f_{\text{HFBUSCLK}}/f_{\text{HFPERCLK}}, \text{ worst-case read accesses} \end{aligned}$$

where  $N_{\text{slave cycles}}$  is the number of cycles required to access the particular slave, including any wait cycles introduced by the slave.

**Figure 4.4. Bus Access Latency (General Case)**

Note that a latency of **1** cycle corresponds to **0** wait states.

Additionally, for back-to-back accesses to the same peripheral, the throughput in number of cycles per transfer is given by:

$$\begin{aligned} N_{\text{bus cycles}} &= N_{\text{slave cycles}} \times f_{\text{HFBUSCLK}}/f_{\text{HFPERCLK}}, \text{ write accesses} \\ N_{\text{bus cycles}} &= (N_{\text{slave cycles}} + 1) \times f_{\text{HFBUSCLK}}/f_{\text{HFPERCLK}}, \text{ read accesses} \end{aligned}$$

**Figure 4.5. Bus Access Throughput (Back-to-Back Transfers)**

Lastly, in the highest performing case, where HFPERCLK equals HFBUSCLK and the slave doesn't introduce any additional wait states, the access latency in number of cycles is given by:

$$\begin{aligned} N_{\text{bus cycles}} &= 1, \text{ write accesses} \\ N_{\text{bus cycles}} &= 2, \text{ read accesses} \end{aligned}$$

**Figure 4.6. Bus Access Latency (Max Performance)**

Note that the cycle counts in the equations above is in terms of the HFBUSCLK. When the core is prescaled from the bus clock, the core will see a reduced number of latency cycles given by:

$$N_{\text{core cycles}} = \text{ceiling}( N_{\text{bus cycles}} \times f_{\text{HFCORECLK}}/f_{\text{HFBUSCLK}} )$$

where master arbitration is not included.

**Figure 4.7. Core Access Latency**

#### 4.2.4.3 Bus Faults

System accesses from the core can receive a bus fault in the following condition(s):

- The core attempts to access an address that is not assigned to any peripheral or other system device. These faults can be enabled or disabled by setting the ADDRFAULTEN bit appropriately in MSC\_CTRL.
- The core attempts to access a peripheral or system device that has its clock disabled. These faults can be enabled or disabled by setting the CLKDISFAULTEN bit appropriately in MSC\_CTRL.

In addition to any condition-specific bus fault control bits, the bus fault interrupt itself can be enabled or disabled in the same way as all other internal core interrupts.

### 4.3 Access to Low Energy Peripherals (Asynchronous Registers)

The Low Energy Peripherals are capable of running when the high frequency oscillator and core system is powered off, i.e. in energy mode EM2 DeepSleep and in some cases also EM3 Stop. This enables the peripherals to perform tasks while the system energy consumption is minimal.

The Low Energy Peripherals are listed in [Table 4.3 Low Energy Peripherals on page 23](#).

All Low Energy Peripherals are memory mapped, with automatic data synchronization. Because the Low Energy Peripherals are running on clocks asynchronous to the high frequency system clock, there are some constraints on how register accesses are performed, as described in the following sections.

#### 4.3.1 Writing

Every Low Energy Peripheral has one or more registers with data that needs to be synchronized into the Low Energy clock domain to maintain data consistency and predictable operation. There are two different synchronization mechanisms on the EFR32xG1 Wireless Gecko, immediate synchronization, and delayed synchronization. Immediate synchronization is available for the RTCC and LETIMER, and results in an immediate update of the target registers. Delayed synchronization is used for the remaining Low Energy Peripherals, and for these peripherals, a write operation requires 3 positive edges of the clock on the Low Energy Peripheral being accessed. Registers requiring synchronization are marked "Async Reg" in their description header.

**Note:** On the Gecko series of devices, all LE peripherals are subject to delayed synchronization.

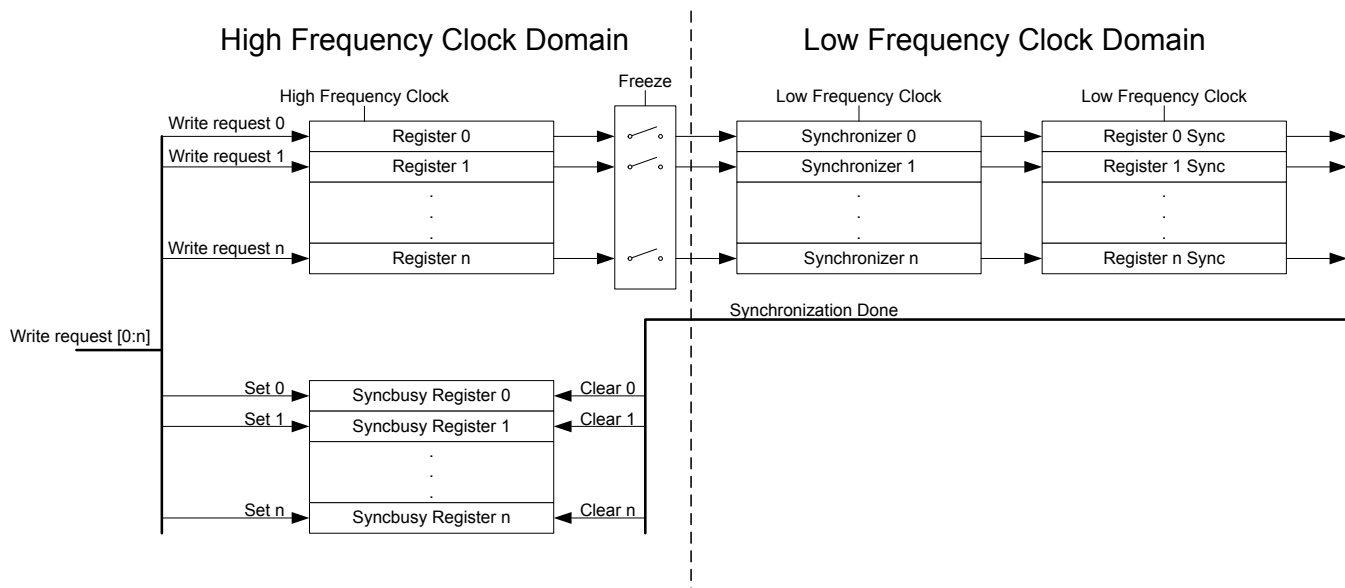

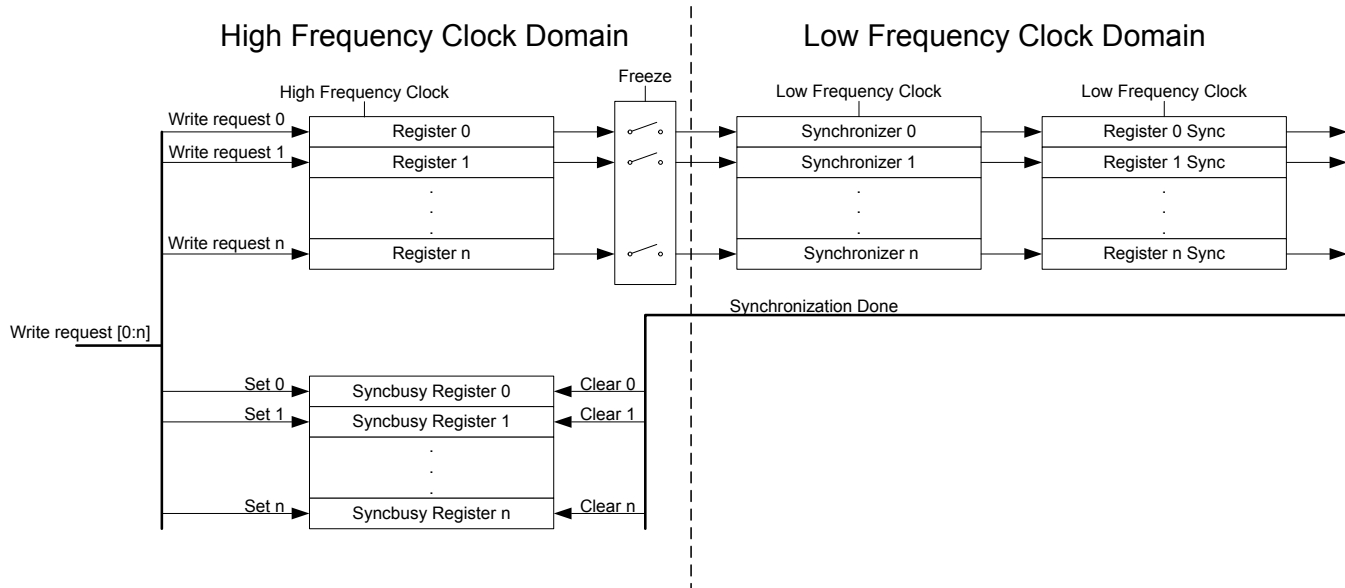

Figure 4.8. Write operation to Low Energy Peripherals

#### 4.3.1.1 Delayed Synchronization

After writing data to a register which value is to be synchronized into the Low Energy Peripheral using delayed synchronization, a corresponding busy flag in the <module\_name>\_SYNCBUSY register (e.g. LETIMER\_SYNCBUSY) is set. This flag is set as long as synchronization is in progress and is cleared upon completion.

**Note:** Subsequent writes to the same register before the corresponding busy flag is cleared is not supported. Write before the busy flag is cleared may result in undefined behavior. In general the SYNCBUSY register only needs to be observed if there is a risk of multiple write access to a register (which must be prevented). It is not required to wait until the relevant flag in the SYNCBUSY register is cleared after writing a register. E.g., EM2 DeepSleep can be entered directly after writing a register.

See [Figure 4.9 Write operation to Low Energy Peripherals](#) on page 26 for an overview of the writing mechanism operation.

**Figure 4.9. Write operation to Low Energy Peripherals**

#### 4.3.1.2 Immediate Synchronization

In contrast to the peripherals with delayed synchronization, peripherals with immediate synchronization don't experience a delay from a value is written to it takes effect in the peripheral. They are updated immediately on the peripheral write access. If such a write is done close to an edge on the clock of the peripheral, the write is delayed to after the clock edge. This will introduce wait-states on the peripheral access.

Peripherals with immediate synchronization each have a SYNCBUSY register. Commands written to a peripheral with immediate synchronization are not executed before the first peripheral clock after the write. In this period, the SYNCBUSY flag for the command register is set, indicating that the command has not yet been performed. Secondly, to maintain compatibility with the Gecko series, the rest of the SYNCBUSY registers are also present, but these are always 0, indicating that register writes are always safe.

**Note:** If compatibility with the Gecko series is a requirement for a given application, the rules that apply to delayed synchronization with respect to SYNCBUSY should also be followed for the peripherals that support immediate synchronization.

### 4.3.2 Reading

When reading from a Low Energy Peripheral, the data read is synchronized regardless if it originates in the Low Energy clock domain or High Frequency clock domain. See [Figure 4.10 Read operation from Low Energy Peripherals on page 27](#) for an overview of the reading operation.

**Note:** Writing a register and then immediately reading the new value of the register may give the impression that the write operation is complete. This may not be the case. Please refer to the SYNCBUSY register for correct status of the write operation to the Low Energy Peripheral.

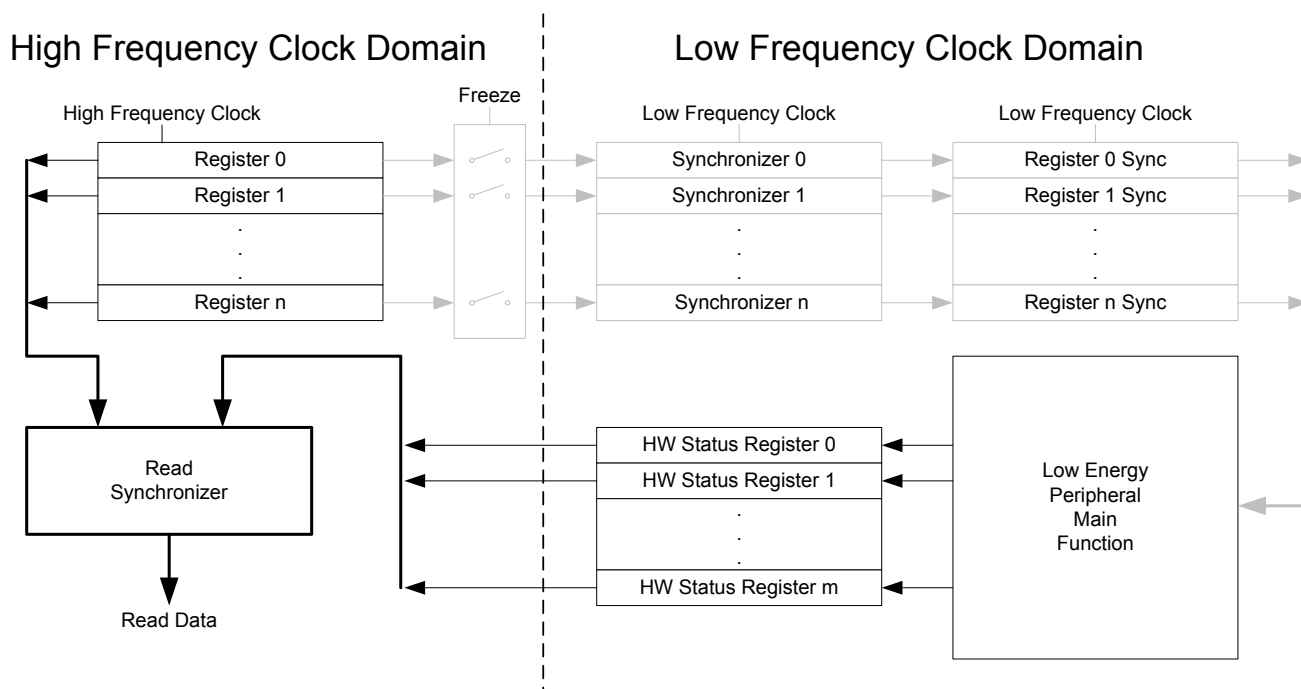

Figure 4.10. Read operation from Low Energy Peripherals

### 4.3.3 FREEZE Register

In all Low Energy Peripheral with delayed synchronization there is a `<module_name>_FREEZE` register (e.g. `RTCC_FREEZE`). The register contains a bit named `REGFREEZE`. If precise control of the synchronization process is required, this bit may be utilized. When `REGFREEZE` is set, the synchronization process is halted allowing the software to write multiple Low Energy registers before starting the synchronization process, thus providing precise control of the module update process. The synchronization process is started by clearing the `REGFREEZE` bit.

**Note:** The FREEZE register is also present on peripherals with immediate synchronization, but there it has no effect

## 4.4 Flash

The Flash retains data in any state and typically stores the application code, special user data and security information. The Flash memory is typically programmed through the debug interface, but can also be erased and written to from software.

- Up to 256 KB of memory
- Page size of 2048 bytes (minimum erase unit)
- Minimum 10K erase cycles endurance
- Greater than 10 years data retention at 85°C
- Lock-bits for memory protection
- Data retention in any state

## 4.5 SRAM

The primary task of the SRAM memory is to store application data. Additionally, it is possible to execute instructions from SRAM, and the DMA may be set up to transfer data between the SRAM, Flash and peripherals.

- Up to 32 KB of memory
- Bit-band access support
- Set of RAM blocks may be powered down when not in use
- Data retention of the entire memory in EM0 Active to EM3 Stop

The SRAM memory may be split among two or more different AHB slaves (e.g., RAM0, RAM1, ...) in order to allow simultaneous access to different sections of the memory from two different AHB masters. For example, the Cortex-M4 can access RAM0 while the DMA controller accesses RAM1 in parallel. See [Figure 4.1 EFR32 Bus System on page 18](#) for AHB slave connectivity details.

## 4.6 DI Page Entry Map

The DI page contains production calibration data as well as device identification information. See the peripheral chapters for how each calibration value is to be used with the associated peripheral.

The offset address is relative to the start address of the DI page.(see [8.3 Functional Description](#))

Offset	Name	Type	Description
0x000	CAL	RO	CRC of DI-page and calibration temperature
0x020	EXTINFO	RO	External Component description

## 5. Serial Flash

### Quick Facts

#### What?

A 512 kB serial flash memory is included in the package for certain part numbers.

#### Why?

The serial flash memory extends the non-volatile storage capabilities of the device while maintaining a small PCB footprint.

#### How?

The serial flash may be read and written in EM0 or EM1, and placed in a low power state when not used.

### 5.1 Introduction

The serial flash memory adds 512 kB of non-volatile storage space for applications with larger memory requirements. It is fully internal to the package, and requires no additional board space or GPIO resources. Software drivers provided by Silicon Labs offer a simple API interface to the serial flash. Low-level access is also possible, via the USART1 peripheral.

### 5.2 Features

- 512 kB of memory
- 4 kB sectors, can be erased individually or in 32 kB or 64 kB blocks
- 1 - 256 byte page write
- 100,000 write/erase cycle endurance
- 20 year data retention
- SPI interface
- Write protection
- 4 x 256 byte dedicated security area with user-lockable bits, one-time programmable

### 5.3 Functional Description

The serial flash is powered from IOVDD and bonded to internal GPIO which are not available externally. USART1 is connected to the associated GPIO pins and functions as a SPI interface to the flash. It is recommended to use the software libraries supplied by Silicon Laboratories for interfacing to the serial flash. The information in this section is reference for users who choose to write their own low-level software drivers.

**Note:** The [EXTINFO](#) entry in the DI page identifies the specific serial flash part number included in the package. Software should verify this field before initiating any serial flash operations.

### 5.3.1 Memory Organization

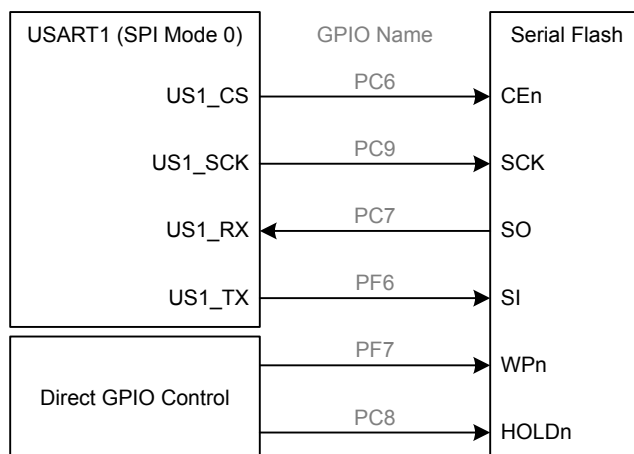

The memory array of the serial flash is divided into uniform 4 kB sectors or uniform 32/64 kB blocks consisting of eight or sixteen adjacent sectors, respectively. [Table 5.1 Block and Sector Addresses on page 68](#) diagrams the organization of this memory space.

**Table 5.1. Block and Sector Addresses**

64 kB Block Number	32 kB Block Number	4 kB Sector Number	Address Range
0	0	0	0x000000 - 0x000FFF
		:	:
	1	:	:
		15	0x00F000 - 0x00FFFF
1	2	16	0x010000 - 0x010FFF
		:	:
	3	:	:

6	12	96	0x060000 - 0x060FFF
		:	:
	13	:	:
		111	0x06F000 - 0x06FFFF
7	14	112	0x070000 - 0x070FFF
		:	:
	15	:	:
		127	0x07F000 - 0x07FFFF

### 5.3.2 Serial Interface

Serial flash operations are controlled through a SPI interface on the flash. Internal to the package, the flash interface I/O are connected to GPIO on the MCU. USART1 may be routed to the serial interface for hardware-controlled bus writes and reads.

**Figure 5.1. Serial Flash Connections**

#### 5.3.2.1 USART1 Configuration

All of the serial flash I/O connections are bonded to standard port pins internal to the packaging. The USART1 peripheral may be directly routed to the SPI interface signals (SI, SO, SCK, and CEn), while the remaining signals (WPn and HOLDn) can be controlled as GPIO. [Table 5.2 Serial Flash I/O Connections on page 69](#) shows the GPIO connections for each signal, as well as the recommended GPIO configurations and USART1 routing locations.

**Table 5.2. Serial Flash I/O Connections**

Serial Flash Signal	GPIO	Recommended Configuration and initial state	USART1_ROUTELOC0 Settings
SI (Serial Data Input)	PF6	Output, High	TXLOC = LOC30
WPn (Active-Low Write Protect)	PF7	Output, Low	n/a
SCK (Serial Clock Input)	PC9	Output, Low	CLKLOC = LOC12
HOLDn (Active-Low Hold)	PC8	Output, High	n/a
SO (Serial Data Output)	PC7	Input	RXLOC = LOC11
CEn (Active-Low Chip Enable)	PC6	Output, High	CSLOC = LOC8

To function properly with the serial flash, USART1 should be configured for synchronous master operation in SPI mode 0, with a maximum baud rate of 8 MHz. The CEn pin may be controlled manually by software, or automatically by the US1\_CS pin. If using the US1\_CS option, the CS output signal should be configured for active-low operation.

If CEn is controlled manually as a GPIO pin, it should be cleared to a logic low state by software before any data transfer is initiated, and set back to logic high after the final byte of data has been transferred. If US1\_CS is configured to automatically drive the CEn pin, software or DMA must continue to keep the USART1 buffer full for the duration of each transfer so that CEn remains low during the operation and returns high only when data transfer is complete.

Refer to [18. USART - Universal Synchronous Asynchronous Receiver/Transmitter](#) for more detailed information about USART operation and configuration.

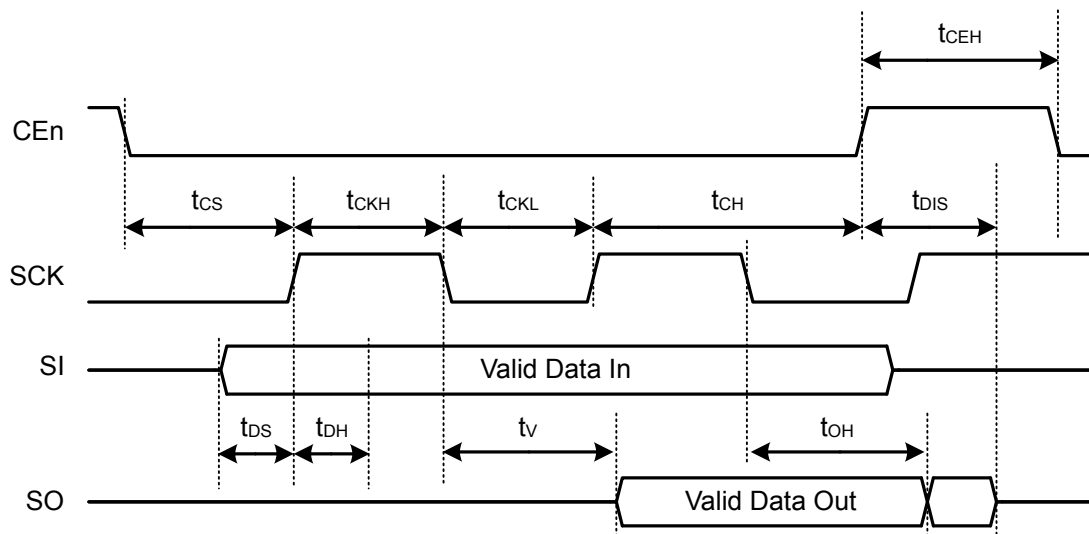

### 5.3.2.2 Timing

All data is shifted into and out of the serial flash MSB-first. Data is shifted on the falling edge of SCK and latched on the rising edge of SCK. Transfer format for a single byte is shown in [Figure 5.2 Serial Interface Data Format on page 70](#).

**Figure 5.2. Serial Interface Data Format**

When USART1 is configured as described in [5.3.2.1 USART1 Configuration](#), at no greater than an 8 MHz serial clock rate and automatic US1\_CS control, all serial flash timing parameters for CEn, SCK, SI, and SO will be met across the temperature and supply range. This is the recommended configuration for communicating with the serial flash memory. For other configurations, it is important to ensure that the serial flash timing is not violated. Refer to [Figure 5.3 Serial Flash IO Timing on page 70](#).

**Figure 5.3. Serial Flash IO Timing**

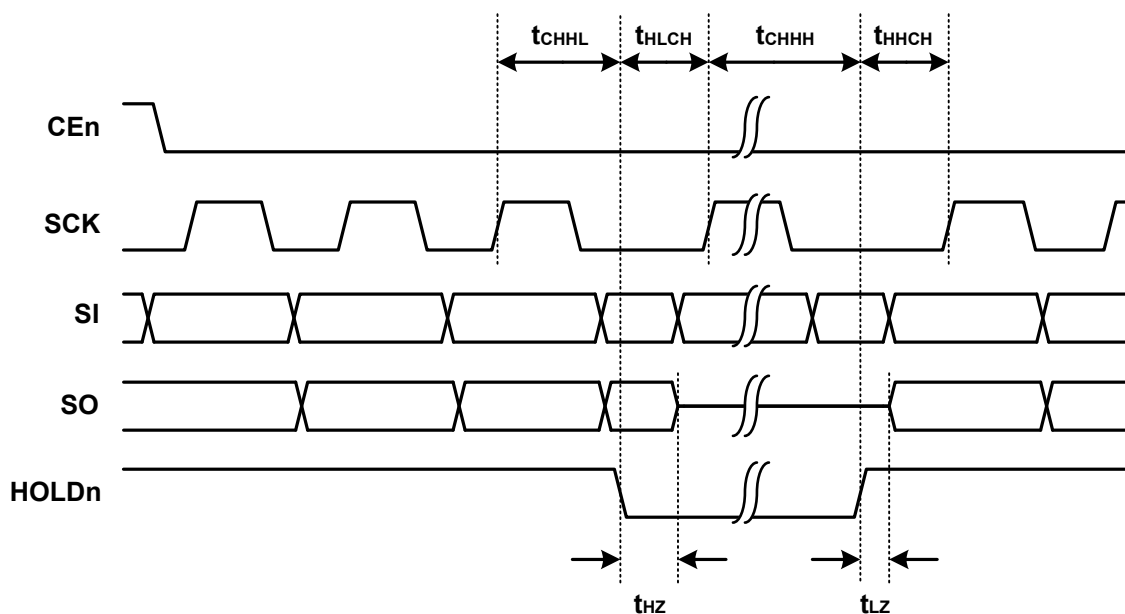

Parameter	Symbol	Min	Max	Units
SCK High Time	$t_{CKH}$	4		ns
SCK Low Time	$t_{CKL}$	4		ns
CEn High Time	$t_{CEH}$	7		ns
CEn Setup Time	$t_{CS}$	10		ns
CEn Hold Time	$t_{CH}$	5		ns
Data In Setup Time	$t_{DS}$	2		ns
Data In Hold Time	$t_{DH}$	2		ns

Parameter	Symbol	Min	Max	Units
Output Valid	$t_V$		8	ns
Output Hold Time	$t_{OH}$	2		ns
Output Disable Time	$t_{DIS}$		8	ns

### 5.3.2.3 Hold Operation

When the device is selected with CEn and a serial sequence is underway, HOLDn can be used to pause the serial communication with the master device without resetting the serial sequence. To pause, bring the HOLDn signal low while the SCK signal is low. When HOLDn is asserted, inputs to SI will be ignored, and SO will be high impedance. To resume serial communication, bring HOLDn high while the SCK signal is low. Communication with the serial flash will resume at the clock where it was halted.

Figure 5.4. Serial Flash HOLDn Timing

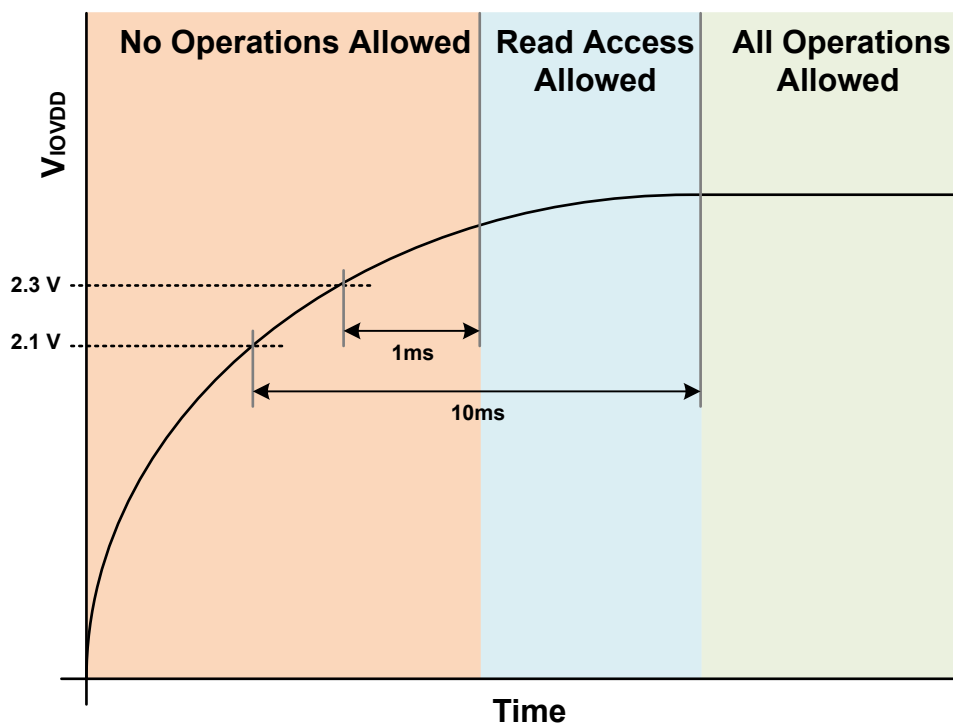

Parameter	Symbol	Min	Max	Units
HOLDn Low to SCK	$t_{HLCH}$	5		ns
SCK to HOLDn High	$t_{CHHH}$	5		ns
HOLDn High to SCK	$t_{HHCH}$	5		ns
SCK to HOLDn Low	$t_{CHHL}$	5		ns
HOLDn Low to Output High-Z	$t_{HZ}$		12	ns
HOLDn High to Output Driven	$t_{LZ}$		12	ns

### 5.3.2.4 Power Up and Power Down

The serial flash is powered by the IOVDD supply pin, and will inhibit certain operations while it is powering on. Software should not attempt to access the serial flash for at least 1 ms after IOVDD reaches 2.3 V. Additionally, program and erase operations will be rejected for up to 10 ms from the time IOVDD reaches 2.1 V. All program and erase operations are inhibited if the IOVDD supply voltage drops below 2.1 V.

Figure 5.5. Serial Flash Power Up

### 5.3.3 Instruction Set

The serial flash utilizes an 8-bit instruction register. See [Table 5.3 Instruction Set Summary on page 73](#) for details on instructions and instruction codes. All instructions, addresses, and data are shifted in with the most significant bit (MSB) first on the Serial Data Input (SI). The input data on SI is latched on the rising edge of Serial Clock (SCK) after Chip Enable (CEn) is driven low. Every instruction sequence starts with a one-byte instruction code and is followed by address bytes, data bytes, or both address bytes and data bytes, depending on the type of instruction. CEn must be driven high after the last bit of the instruction sequence has been shifted in to end the operation.

**Table 5.3. Instruction Set Summary**

Name	Instruction Code	Operation	Available During Suspend
RD	0x03	Read Data	Yes
FR	0x0B	Fast Read Data	Yes
PP	0x02	Page Program	No
SER	0xD7 / 0x20	Sector Erase	No
BER32	0x52	Block Erase 32 kB	No
BER64	0xD8	Block Erase 64 kB	No
CER	0xC7 / 0x60	Chip Erase	No
WREN	0x06	Write Enable	No
WRDI	0x04	Write Disable	No
RDSR	0x05	Read Status Register	Yes
WRSR	0x01	Write Status Register	No
RDFR	0x48	Read Function Register	Yes
WRFR	0x42	Write Function Register	No
PERSUS	0x75 / 0xB0	Program/Erase Suspend	No
PERRSM	0x7A / 0x30	Program/Erase Resume	Yes
DP	0xB9	Deep Power Down	No
RDUID	0x4B	Read Unique ID	Yes
RSTEN	0x66	Reset Enable	Yes
RST	0x99	Reset	Yes
IRP	0x62	Program Information Row	No
IRRD	0x68	Read Information Row	Yes
SECUNLOCK	0x26	Sector Unlock	No
SECLOCK	0x24	Sector Lock	No

### 5.3.4 Registers

The serial flash has two 8-bit registers to communicate status and apply write protection to different regions of the memory array, the STATUS register and the FUNCTION register.

The STATUS register is read with the RDSR command and written with the WRSR command. The FUNCTION register is read with the RDFR command and written with the WRFR command.

**STATUS - Serial Flash Status Register**

Bit	7	6	5	4	3	2	1	0
Default	0	0	0x0				0	0
Access	R/W	R/W	R/W				R	R
	Non-Volatile	Non-Volatile	Non-Volatile				Volatile	Volatile
Name	SRWD	Reserved	BP				WEL	WIP

Bit	Name	Default	Access	Description
7	SRWD	0	R/W	<b>Status Register Write Disable.</b>  Non-Volatile  The SRWD bit operates in conjunction with the Write Protection (WPn) signal to provide a hardware protection mode. When SRWD is cleared to 0, the STATUS register is not write-protected. When SRWD is set to 1 and WPn is pulled low, the STATUS register becomes read-only, and any WRSR instruction will be ignored. If SRWD is set to 1 and WPn is pulled high, the STATUS register can be changed by a WRSR instruction.
6	Reserved	This bit must always be written to 0.		
5:2	BP	0x0	R/W	<b>Block Protection.</b>  Non-Volatile  The Block Protection field is used to define the portion of the memory area to be protected. Refer to <a href="#">Table 5.4 64 kB Block Write Protection on page 83</a> for the Block Protection (BP) settings. When a defined value of BP is set, the corresponding area of serial flash memory is protected. Any program or erase operation to that area will be inhibited. A Chip Erase ( <a href="#">CER</a> ) instruction will be ignored unless BP is 0x0.
1	WEL	0	R	<b>Write Enable Latch.</b>  Volatile  WEL indicates the status of the internal write enable latch. When WEL is 0, the write enable latch is disabled and all write or erase operations are inhibited. When WEL is 1, write operations are allowed. The WEL bit is set by a Write Enable ( <a href="#">WREN</a> ) instruction. Each STATUS or FUNCTION register write, program, or erase instruction must be preceded by a WREN instruction. The WEL bit can be reset by software a Write Disable ( <a href="#">WRDI</a> ) instruction. It will automatically be reset after the completion of any write or erase operation.
0	WIP	0	R	<b>Write In Progress.</b>  Volatile  WIP indicates the progress or completion of a program or erase operation. When the WIP bit is 0, the serial flash will accept any new register write, program, or erase operation. When WIP is 1, the serial flash is busy, and new register write, program, and erase instructions will be ignored.

**FUNCTION - Serial Flash Function Register**

Bit	7	6	5	4	3	2	1	0
Default	0	0	0	0	0	0	0x0	
Access	R/W OTP	R/W OTP	R/W OTP	R/W OTP	R Volatile	R Volatile	R	
Name	IRL3	IRL2	IRL1	IRL0	ESUS	PSUS	Reserved	

Bit	Name	Default	Access	Description
7	IRL3	0	R/W OTP	<b>Information Row 3 Lock.</b>  This bit is used to lock information row 3. When set to 1, information row 3 cannot be programmed. This bit is one-time programmable (OTP). Once it is set to 1, it cannot be modified.
6	IRL2	0	R/W OTP	<b>Information Row 2 Lock.</b>  This bit is used to lock information row 2. When set to 1, information row 2 cannot be programmed. This bit is one-time programmable (OTP). Once it is set to 1, it cannot be modified.
5	IRL1	0	R/W OTP	<b>Information Row 1 Lock.</b>  This bit is used to lock information row 1. When set to 1, information row 1 cannot be programmed. This bit is one-time programmable (OTP). Once it is set to 1, it cannot be modified.
4	IRL0	0	R/W OTP	<b>Information Row 0 Lock.</b>  This bit is used to lock information row 0. When set to 1, information row 0 cannot be programmed. This bit is one-time programmable (OTP). Once it is set to 1, it cannot be modified.
3	ESUS	0	R Volatile	<b>Erase Suspend.</b>  ESUS indicates when an erase operation has been suspended. The ESUS bit is 1 after a suspend command is issued during any erase operation. Once the suspended erase operation resumes, the ESUS bit is reset to 0.
2	PSUS	0	R Volatile	<b>Program Suspend.</b>  PSUS indicates when a program operation has been suspended. The PSUS bit is 1 after a suspend command is issued during any program operation. Once the suspended program operation resumes, the PSUS bit is reset to 0.
1:0	Reserved	These bits always read 0x0.

Figure 5.9. WRFR Instruction Format

### 5.3.5 Reading Memory

Reads of the serial flash memory space are performed with either the Read Data (RD) or Fast Read (FR) instruction. The Fast Read command is intended to allow for higher serial clock frequencies to be used for reading the serial flash data. In this co-packaged configuration however, both commands are limited to the overall maximum SCK rate of 8 MHz, and either may be used to read flash contents.

To initiate a memory read using the RD instruction, software should send the RD instruction code (one byte), followed by the first memory location to be read (three bytes, MSB-first). Data will be shifted out of the serial flash beginning with the next serial clock.

To initiate a memory read using the FR instruction, software should send the FR instruction code (one byte), followed by the first memory location to be read (three bytes, MSB-first), followed by a dummy byte (one byte). Data will be shifted out of the serial flash beginning with the next serial clock.

Data is shifted out on the SO line, MSB first. Any number of bytes can be read out in one RD or FR instruction. The address is automatically incremented after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to 0x000000, allowing the entire memory to be read in one continuous instruction. The operation is terminated when CEn is driven high.

If an RD or FR instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored and will not have any effect on the current operation.

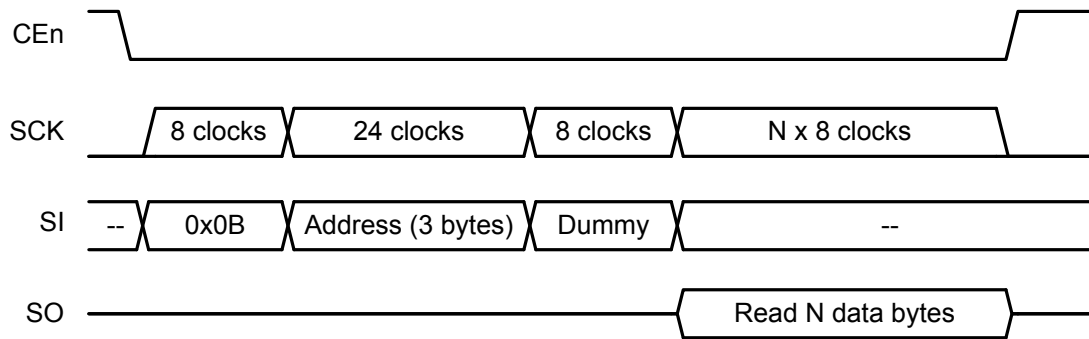

Figure 5.11. FR Instruction Format

### 5.3.6 Programming and Erasing Memory

The serial flash memory can be programmed (clearing bits to 0) in 1 to 256-byte pages. The entire 512 kB memory array may be erased (setting bits to 1) with a single command, or memory may be erased in defined 4 kB, 32 kB, or 64 kB blocks. Program or erase operations (other than full chip erase) may be suspended and resumed as needed in order to allow time-critical read operations.

**Note:** A program operation changes 1's to 0's in the flash memory array. An erase operation is required to change 0's to 1's. A byte cannot be reprogrammed with new information without first erasing the whole sector or block.

#### Programming Sequence

The Page Program instruction allows up to 256 bytes data to be programmed into memory in a single operation. The procedure to program data bytes is as follows:

1. Set the Write Enable Latch (WEL) by sending a Write Enable ([WREN](#)) instruction.
2. Send the Page Program ([PP](#)) instruction code (one byte), followed by the first memory location to be programmed (three bytes, MSB-first), and then shift the data to be programmed (1 to 256 bytes) into the flash.
3. Send Read Status Register ([RDSR](#)) instructions to the device to poll the STATUS register until the WIP bit is 0.

The write operation will start immediately after CEn is brought high in step 2. The PP instruction will not be executed until CEn goes high. The internal control logic automatically handles programming voltages and timing. During a program operation, the WIP bit in STATUS will be set to 1 and all instructions will be ignored except the RDSR instruction and the PERSUS instruction. Upon completion of the program operation, the Write Enable Latch (WEL) will also be cleared.

The starting byte can be anywhere within the page. When the end of the page is reached during a PP instruction (address ends in 0xFF), the address counter rolls over to the beginning of the page. If more than 256 bytes are received during a PP instruction, only the last 256 bytes received are programmed into the page. If the data to be programmed are less than a full page, the data of all other bytes on the same page will remain unchanged.

**Note:** The destination of the memory to be programmed must be outside the protected memory area set by the BP field in the STATUS register. Any PP instruction which attempts to program into a page that is write-protected will be ignored, unless the sector containing that page has been unlocked with a SECUNLOCK instruction.

## Erase Sequence

The memory array of the serial flash is organized into uniform 4Kbyte sectors or 32/64Kbyte uniform blocks (a block consists of eight/sixteen adjacent sectors respectively). Before a byte is reprogrammed, the sector or block that contains the byte must be erased (erasing sets bits to 1). In order to erase the serial flash, there are four erase instructions available: Sector Erase (**SER**), 32 kB Block Erase (**BER32**), 64 kB Block Erase (**BER64**) and Chip Erase (**CER**). A sector erase operation allows any individual sector to be erased without affecting the data in other sectors. A block erase operation erases any individual block. A chip erase operation erases the whole memory array of the serial flash.

To perform a sector or block erase:

1. Set the Write Enable Latch (WEL) by sending a Write Enable (**WREN**) instruction.
2. Send the SER, BER32 or BER64 instruction code (one byte), followed by the first address of the sector or block to be erased (three bytes, MSB-first).
3. Send Read Status Register (**RDSR**) instructions to the device to poll the STATUS register until the WIP bit is 0.

To perform a chip erase:

1. Set the Write Enable Latch (WEL) by sending a Write Enable (**WREN**) instruction.
2. Send the CER instruction code.
3. Send Read Status Register (**RDSR**) instructions to the device to poll the STATUS register until the WIP bit is 0.

The erase operation will start immediately after CEn is brought high for the erase instruction. The internal control logic automatically handles erase voltages and timing. During an erase operation, the WIP bit in STATUS will be set to 1 and all instructions will be ignored except the RDSR instruction and the PERSUS instruction. Upon completion of the erase operation, the Write Enable Latch (WEL) will also be cleared.

**Note:** The destination of the memory to be erased must be outside the protected memory area set by the BP field in the STATUS register. Any erase instruction which attempts to program into an area that is write-protected will be ignored, unless the sectors to be erased have been unlocked with a SECUNLOCK instruction. For a chip erase operation to execute, the entire memory array must be unlocked according to the BP field.

### 5.3.6.1 Program/Erase Suspend and Resume

The device allows the interruption of SER, BER32, BER64, and PP operations to conduct other operations. To suspend a program or erase operation, the Program/Erase Suspend (**PERSUS**) instruction is used. When the PERSUS instruction is issued, the serial flash will suspend the program or erase operation within a maximum of 100  $\mu$ s after CEn is driven high. The WIP bit in the STATUS register may also be polled by software to determine when the flash is ready to accept new commands. When a program or erase operation is suspended, the flash will respond to a limited set of other operations. Details on which instructions are allowed during suspend are found in [Table 5.3 Instruction Set Summary on page 73](#).

When a program operation has been suspended, the PSUS bit in the FUNCTION register will read back 1. If an erase operation has been suspended, the ESUS bit in the FUNCTION register will read back 1.

To resume the suspended program or erase operation, the Program/Erase Resume (**PERRSM**) operation is used. When the PERRSM instruction is issued, the serial flash will resume the program or erase operation after CEn is driven high. The WIP bit in the STATUS register may be polled by software to determine when the program or erase operation is complete.

**Note:** If multiple suspend/resume operations are used, software must wait for a minimum of 400  $\mu$ s after sending a resume command before initiating a new suspend operation.

Figure 5.20. PERRSM Instruction Format

### 5.3.7 Write Protection

The serial flash supports both hardware and software write protection mechanisms to prevent accidental program or erasure. The block protect (BP) field in the STATUS register allows part or all of the memory area to be designated as write-protected. If a block is write-protected, no program or erase operations will affect the memory contents, unless a SECUNLOCK command is issued to first unlock the target sector. [Table 5.4 64 kB Block Write Protection on page 83](#) details the areas protected by each BP setting.

**Table 5.4. 64 kB Block Write Protection**

BP field in STATUS Register (binary)	Write-Protected 64 kB Blocks
0000	None
0001	Block 7
0010	Blocks 6 and 7
0011	Blocks 4, 5, 6, and 7
0100 - 1011	All Blocks
1100	Blocks 0, 1, 2 and 3
1101	Blocks 0 and 1
1110	Block 1
1111	None

The Sector Unlock ([SECUNLOCK](#)) and Sector Lock ([SECLOCK](#)) commands are used to unlock and re-lock individual protected sectors as-needed when erasing and writing the memory. Only one sector may be unlocked with the SECUNLOCK command at a time, protecting the rest of the memory array from corruption. To unlock a sector, software should write the SECUNLOCK command (one byte), followed by the starting address of the target sector (3 bytes). The sector is locked again when a SECLOCK command is issued, or when a subsequent SECUNLOCK command unlocks a different sector. Because only one sector may be locked at a time, the SECLOCK command only requires the command byte to be sent, and does not accept an address.

Additionally, the WPn signal, in conjunction with the SRWD bit in the STATUS register, provides a means of preventing writes to the STATUS register where the software block protect (BP) field is located. [Table 5.5 Hardware STATUS Register Write Protection on page 83](#) shows how the STATUS register may be protected.

**Table 5.5. Hardware STATUS Register Write Protection**

SRWD bit in STATUS Register	WPn Signal	Status Register
0	Low	Writeable
1	Low	Protected
0	High	Writeable
1	High	Writeable

Figure 5.22. SECLOCK Instruction Format

## 5.3.8 Security Information Row and Unique ID

The serial flash has some additional storage outside of the general memory array: one 16-byte pre-programmed, read-only Unique ID space, and a Security Information Row space comprised of an additional 4 x 256 bytes of one-time programmable information.

The bits in the security information row can be written by the user, but not erased. Any program security instruction issued while program cycle is in progress is rejected without having any effect on the cycle that is in progress. The IRL0, IRL1, IRL2, and IRL3 bits in the FUNCTION register may be used to permanently lock the security information row data in 256-byte sections. When the corresponding IRL bit is set to 1, the 256 bytes in that section become read-only.

Table 5.6. Information Row Addressing

Information Row Lock	A[23:16]	A[15:8]	A[7:0]
IRL0	0x00	0x00	Byte Address
IRL1	0x00	0x10	Byte Address
IRL2	0x00	0x20	Byte Address
IRL3	0x00	0x30	Byte Address

## Reading the Information Rows

The Information Row Read (**IRRD**) instruction is used to read data stored in the security information rows. The IRRD instruction operates like the FR instruction, but targets the information row space.

, with each bit latched-in during the rising edge of SCK. Then the first data byte addressed is shifted out on the SO line, with each bit shifted out at a maximum frequency  $f_{CT}$ , during the falling edge of SCK. The address is automatically incremented by one after each byte of data is shifted out. Once the address reaches the last address of each 256 byte Information Row, the next address will not be valid and the data of the address will be garbage data. It is recommended to repeat four times IRRD operation that reads 256 byte with a valid starting address of each Information Row in order to read all data in the 4 x 256 byte Information Row array. The IRRD instruction is terminated by driving CE# high (VIH). If a IRRD instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored and will not have any effects on the current cycle. The sequence of IRRD instruction is same as FAST READ except for the instruction code

To initiate a memory read using the IRRD instruction, software should send the IRRD instruction code (one byte), followed by the first memory location to be read (three bytes, MSB-first), followed by a dummy byte (one byte). Data will be shifted out of the serial flash beginning with the next serial clock.

Data is shifted out on the SO line, MSB first. Any number of bytes can be read out in one IRRD instruction. The address is automatically incremented after each byte of data is shifted out. Once the address reaches the last address of the information row, the next address will not be valid and the data read will be garbage data. If the entire information space is to be read, it is recommended to repeat the IRRD operation four times, with the starting address of each information row. The operation is terminated when CEn is driven high.

If an IRRD instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored and will not have any effect on the current operation.

## Programming the Information Rows

The Information Row Program (**IRP**) instruction allows up to 256 bytes data to be programmed into the information row memory in a single operation. An IRP instruction operates exactly like the Page Program instruction, but targets the information row space.

The procedure to program data bytes in an information row is as follows:

1. Set the Write Enable Latch (WEL) by sending a Write Enable (**WREN**) instruction.
2. Send the Information Row Program (**IRP**) instruction code (one byte), followed by the first information row location to be programmed (three bytes, MSB-first), and then shift the data to be programmed (1 to 256 bytes) into the flash.
3. Send Read Status Register (**RDSR**) instructions to the device to poll the STATUS register until the WIP bit is 0.

The write operation will start immediately after CEn is brought high. The IRP instruction will not be executed until CEn goes high. The internal control logic automatically handles programming voltages and timing. During a program operation, the WIP bit in STATUS will be set to 1 and all instructions will be ignored except the RDSR instruction and the PERSUS instruction. Upon completion of the program operation, the Write Enable Latch (WEL) will also be cleared.

The starting byte can be anywhere within the page. When the end of the row is reached during a IRP instruction (address ends in 0xFF), the address counter rolls over to the beginning of the row. If more than 256 bytes are received during an IRP instruction, only the last 256 bytes received are programmed into the row. If the data to be programmed are less than a full row, the data of all other bytes on the same row will remain unchanged.

**Note:** The data in the security information rows is non-programmable. Once an information row is programmed, the bits cannot be erased. The information row lock bit associated with the row may be used to prevent subsequent IRP instructions from programming additional bits to 0.

## Reading the Unique ID

The Read Unique ID Number (**RDUID**) instruction accesses a factory-set read-only 16-byte number that is unique to the device. The ID number can be used in conjunction with user software methods to help prevent copying or cloning of a system. The RDUID instruction operates similar to the FR instruction. To read the Unique ID, issue the RDUID command (one byte), followed by an address (3 bytes), followed by a dummy byte, and then read 16 bytes of data. Because the Unique ID is 16 bytes in length, only the four LSBs of the address are used. If more than 16 bytes of data are read during the operation, the Unique ID will repeat.

### 5.3.8.1 Information Row Program (IRP, 0x62)

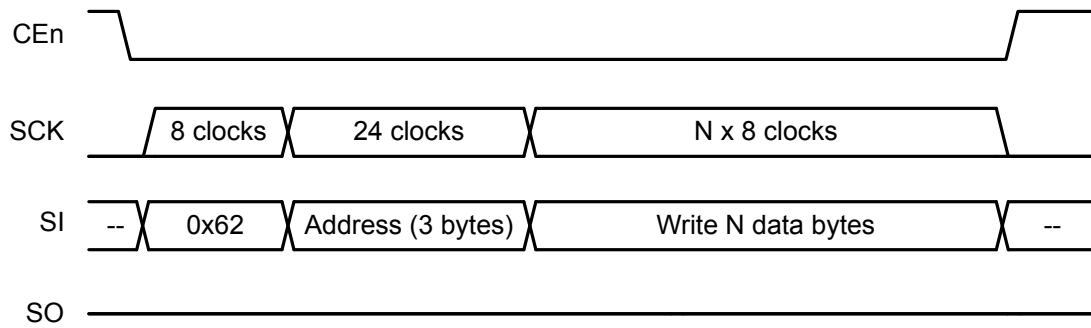

Figure 5.23. IRP Instruction Format

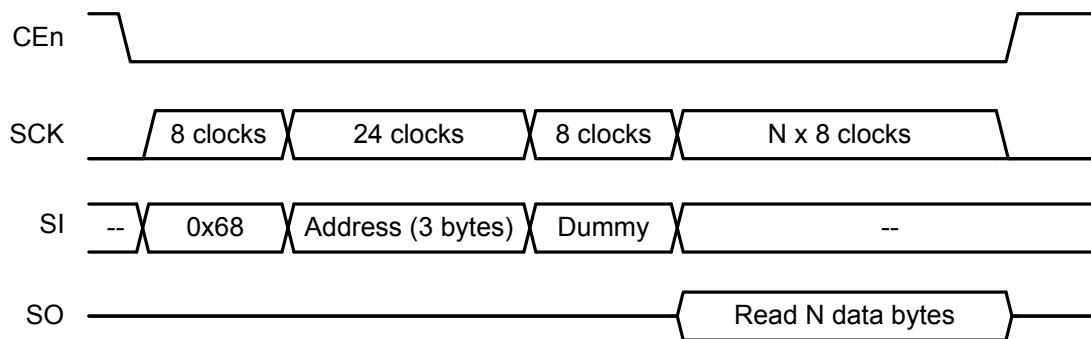

Figure 5.24. IRRD Instruction Format

### 5.3.8.3 Read Unique ID Number (RDUID, 0x4B)

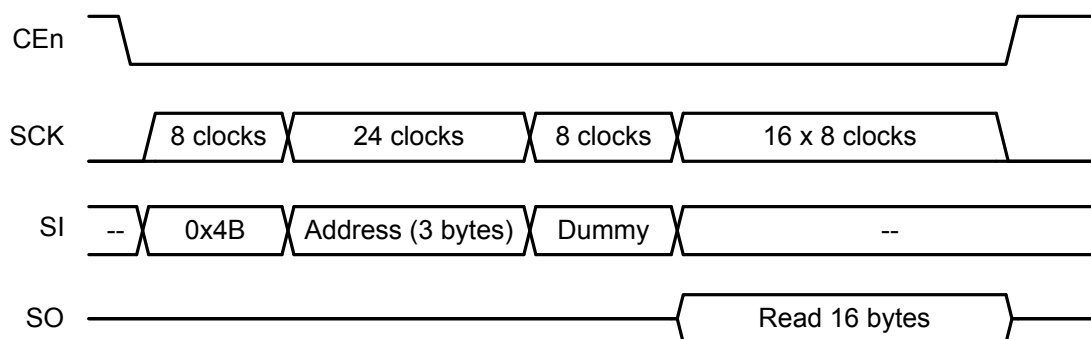

Figure 5.25. RDUID Instruction Format

### 5.3.9 Power Down

The serial flash may be put into a low-power state using the Deep Power-down ([DP](#)) instruction. When a DP instruction is issued, the power-down state will be entered within a maximum of 3  $\mu$ s after CEn is driven high.

To wake the serial flash and ready it for new instructions, the Release Deep Power Down ([RDPD](#)) is used. When an RDPD instruction is issued, the serial flash will resume normal operation within a maximum of 3  $\mu$ s after CEn is driven high. CEn must remain high during this time.

During the power-down mode, the device is not active and all instructions other than RDPD instruction are ignored.

#### 5.3.9.1 Deep Power Down (DP, 0xB9)

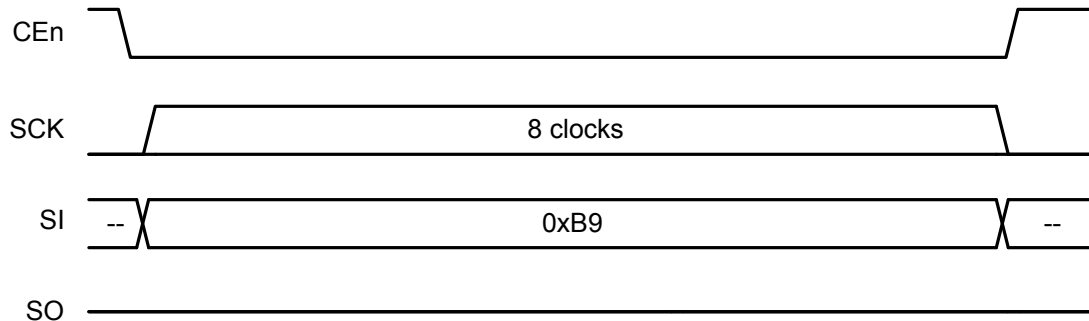

Figure 5.26. DP Instruction Format

#### 5.3.9.2 Release Deep Power Down (RDPD, 0xAB)

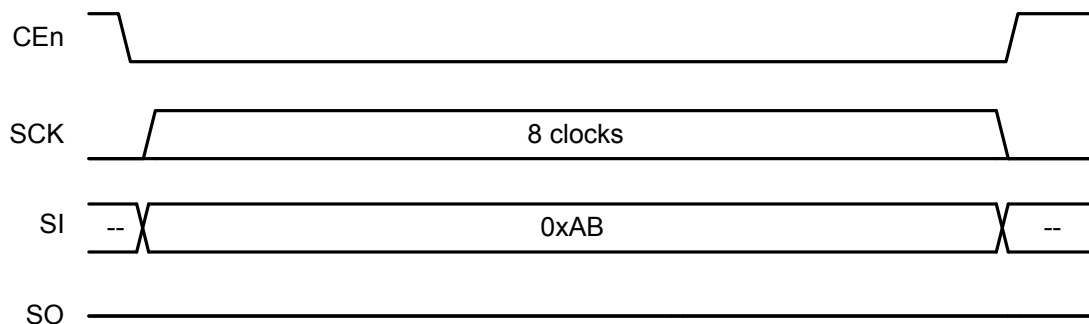

Figure 5.27. RDPD Instruction Format

### 5.3.10 Software Reset

The Reset operation is used as a system (software) reset that puts the device in normal operating mode. This operation consists of two commands: Reset-Enable ([RSTEN](#)) and Reset ([RST](#)). To initiate a reset operation, software must send the Reset-Enable command followed by the Reset command. Any command other than the Reset command after the Reset-Enable command will disable the reset.

Issuing a software reset during an active program or erase operation aborts the operation, which can result in corrupting or losing the data of the targeted address range. Depending on the prior operation, the reset timing may vary. Recovery from a write operation requires more latency time than recovery from other operations.

**Note:**

The Status and Function Registers remain unaffected.

### 5.3.10.1 Reset Enable (RSTEN, 0x66)

## 6. Radio Transceiver

### Quick Facts

#### What?

The Radio Transceiver provides access to transmit and receive data, radio settings and control interface.

#### Why?

The Radio Transceiver enables the user to communicate using a wide range of data rates, modulation and frame formats.

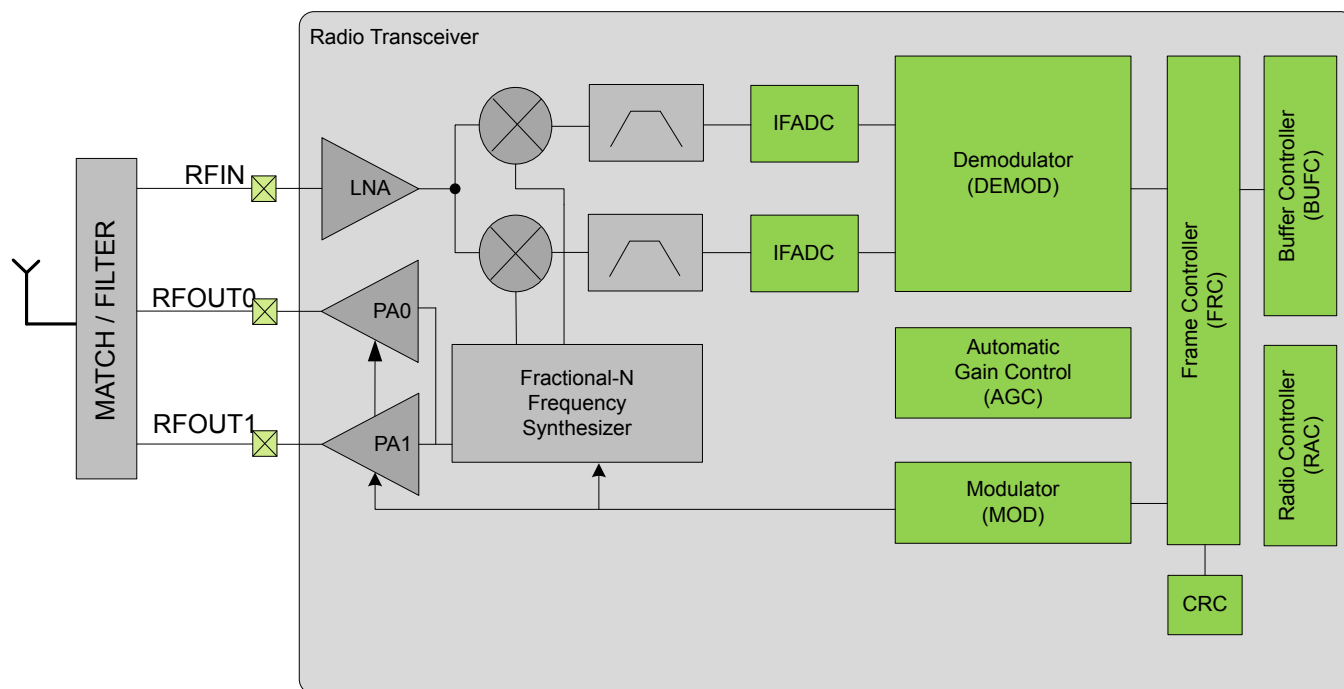

#### How?

Dynamic or fixed frame lengths, optional address recognition, flexible CRC and crypto schemes makes the EFR32 perfectly suit any application using low or medium data rate radio communication.

## 6.1 Introduction

The Radio Transceiver of the EFR32 enables the user to control a wide range of settings and options for tailoring radio operation precisely to the users need. It provides access to the transmit and receive data buffers and supports both dynamic and static frame lengths, as well as automatic address filtering and CRC insertion/verification.

As seen in the Radio Overview illustration ([Figure 6.1 Radio Overview on page 90](#)), the radio consists of several modules all responsible for specific tasks. Please refer to the abbreviations section ([Appendix 1. Abbreviations](#)) for a comprehensive description of acronyms.

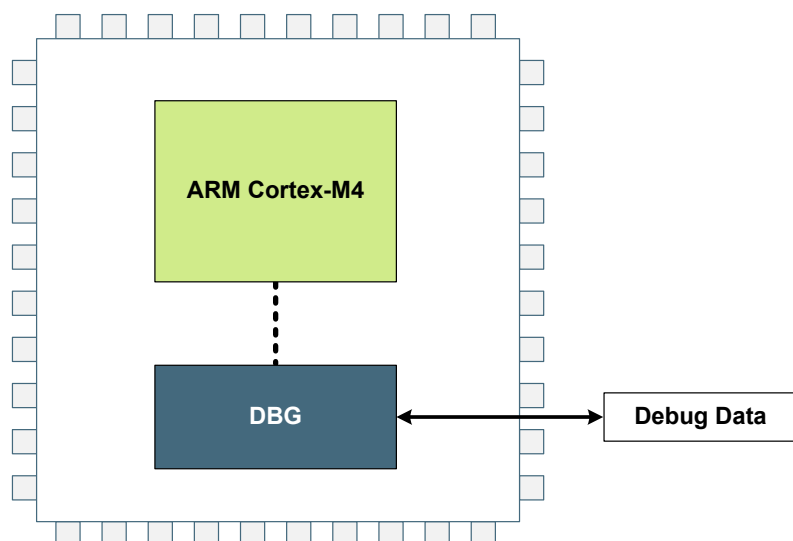

**Figure 6.1. Radio Overview**

During transmission (TX), the Radio Controller enables the Synth, Modulator and PA. The Modulator requests data from the Frame Controller, which reads data from a buffer. Based upon modulation format and data to send, the Modulator manipulates the SYNTH to output the correct frequency and phase. When the whole frame has been transmitted, the radio can automatically switch to receive mode.

In receive mode (RX), the radio controller enables the LNA, Synth, Mixer, ADC and Demodulator. The Demodulator searches for valid frames according to modulation format and data rate. If a frame is detected, the demodulated data is handed to the Frame Controller, which stores the data in the Buffer. When the complete frame has been received (determined by the Frame Controller), it is possible to either go to TX or stay in RX to search for a new frame.

The Radio Transceiver interface is accessible through software drivers provided by Silicon Labs.

## 7. DBG - Debug Interface

### Quick Facts

#### What?

The Debug Interface is used to program and debug EFR32 devices.

#### Why?

The Debug Interface makes it easy to re-program and update the system in the field, and allows debugging with minimal I/O pin usage.

#### How?

The Cortex-M4 supports advanced debugging features. EFR32 devices can use a minimum of two port pins for debugging or programming. The internal and external state of the system can be examined with debug extensions supporting instruction or data access break and watch points.

### 7.1 Introduction

The EFR32 devices include hardware debug support through a 2-pin serial-wire debug (SWD) interface or a 4-pin Joint Test Action Group (JTAG) interface.

For more technical information about the debug interface the reader is referred to:

- ARM Cortex-M4 Technical Reference Manual
- ARM CoreSight Components Technical Reference Manual
- ARM Debug Interface v5 Architecture Specification
- IEEE Standard for Test Access Port and Boundary-Scan Architecture, IEEE 1149.1-2013

### 7.2 Features

- Debug Access Port Serial Wire JTAG (DAPSWJ)
  - Implements the ADIv5 debug interface
- Authentication Access Point (AAP)
  - Implements various user commands
- Flash Patch and Breakpoint (FPB) unit
  - Implement breakpoints and code patches
- Data Watch point and Trace (DWT) unit
  - Implement watch points, trigger resources and system profiling
- Instrumentation Trace Macrocell (ITM)
  - Application-driven trace source that supports printf style debugging

### 7.3 Functional Description

### 7.3.1 Debug Pins

The following pins are the debug connections for the device:

- Serial Wire Clock Input and Test Clock Input (SWCLKTCK) : This pin is enabled after reset and has a built-in pull down.
- Serial Wire Data Input/Output and Test Mode Select Input (SWDIOTMS) : This pin is enabled after reset and has a built-in pull-up.
- Test Data Output (TDO): This pin is disabled after reset.
- Test Data Input (TDI): This pin is disabled after reset. Once enabled, the pin has a built-in pull-up.

The debug pins have pull-down and pull-up enabled by default, so leaving them enabled may increase the current consumption if left connected to supply or ground. The debug pins can be enabled and disabled through GPIO\_ROUTE\_PEN, see [28.3.4.2.3 Disabling Debug Connections](#). Please remember that upon disabling the debug pins, debug contact with the device is lost once the DAPSWJ power request bits are deasserted. If enabling the JTAG pins, the part must be power cycled to enable a SWD debug session.

### 7.3.2 Debug and EM2 DeepSleep/EM3 Stop

Leaving the debugger connected when issuing a WFI or WFE to enter EM2 DeepSleep or EM3 Stop will make the system enter a special EM2 DeepSleep. This mode differs from regular EM2 DeepSleep and EM3 Stop in that the high frequency clocks are still enabled, and certain core functionality is still powered in order to maintain debug-functionality. Because of this, the current consumption in this mode is closer to EM1 Sleep and it is therefore important to deassert the power requests in the DAPSWJ and disconnect the debugger before doing current consumption measurements.

### 7.3.3 Authentication Access Point

The Authentication Access Point (AAP) is a set of registers that provide a minimal amount of debugging and system level commands. The AAP registers contain commands to issue a FLASH erase, a system reset, a CRC of user code pages, and stalling the system bus. The user must program the APSEL bit field to 255 inside of the ARM DAPSWJ Debug Port SELECT register to access the AAP. The AAP is only accessible from a debugger and not from the core.

#### 7.3.3.1 Command Key

The AAP uses a command key to enable the DEVICEERASE and SYSRESETREQ AAP commands. The command key must be written with the correct key in order for the commands to execute.

#### 7.3.3.2 Device Erase

The device can be erased by writing AAP\_CMDKEY followed by writing the DEVICEERASE register bit. Upon writing the command bit, the ERASEBUSY bit is asserted. The ERASEBUSY bit will be de-asserted once the erase is complete. The SYSRESETREQ bit must then be set to resume a normal debugger session. The DEVICEERASE register is available at all times through the AAP once the CMDKEY is entered.

#### 7.3.3.3 System Reset

The system can be reset by writing AAP\_CMDKEY followed by writing the SYSRESETREQ register bit. This must be done after asserting DEVICEERASE or CRCREQ. Depending on the reset level setting for system reset, asserting SYSRESETREQ will either reset the entire AAP register space or just the SYSRESETREQ bit. See [10.3.1 Reset levels](#) for more details on reset levels. The SYSRESETREQ register is available at all times through the AAP once the CMDKEY is entered.

#### 7.3.3.4 System Bus Stall

The system bus can be stalled at any time using the SYSBUSSTALL register bit. Once the SYSBUSSTALL is set, the system bus will remain stalled until SYSBUSSTALL is cleared. While the system bus is stalled, only the registers inside the Cortex-M4, AAP and the debugger can be accessed. The SYSBUSSTALL register is available at all times through the AAP.

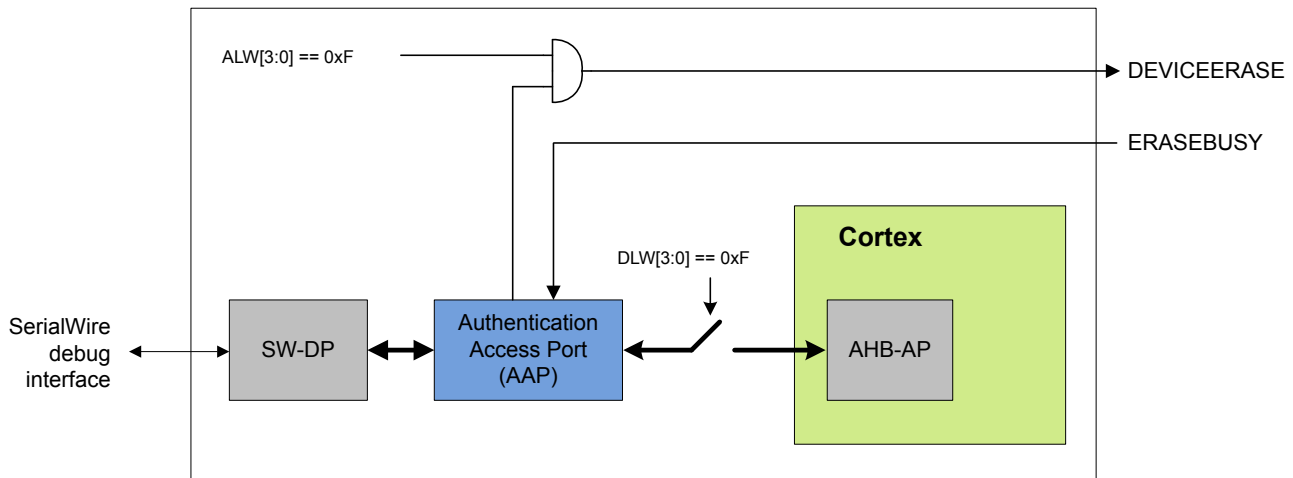

#### 7.3.3.5 User Flash Page CRC

The CRCREQ command initiates a CRC calculation on a given Flash Page. The CRC is only available on the Main, User Data, and Lock Bit pages. It is highly recommended that the system bus is stalled before any CRCREQ commands are issued. The CRC calculation uses the on chip CRC block configured in 32 bit CRC mode. The Flash Page address for the CRCREQ command is written to the CRCADDR register. After issuing the CRCREQ, the CRCBUSY flag is asserted. Once the CRCBUSY flag is de-asserted, the resulting page CRC can be found in the CRCRESULT register. Once issuing a CRC command, the CPU is stalled and remains stalled until a system reset occurs. Multiple CRC requests can occur before resetting the system. However, a CRC request that occurs while the CRCBUSY flag is asserted will be ignored. The CRC registers are available at all times through the AAP.

### 7.3.4 Debug Lock

The debug access to the Cortex-M4 is locked by clearing the Debug Lock Word (DLW) and resetting the device, see [8.3.2 Lock Bits \(LB\) Page Description](#).

When debug access is locked, the debugger can access the DAPSWJ and AAP registers. However, the connection to the Cortex-M4 core and the whole bus-system is blocked. This mechanism is controlled by the Authentication Access Port (AAP) as illustrated by [Figure 7.1 AAP - Authentication Access Port on page 93](#).

**Figure 7.1. AAP - Authentication Access Port**

If the DLW is cleared, the device is locked. If the device is locked and the AAP Lock Word (ALW) has not been cleared, it can be unlocked by writing a valid key to the AAP\_CMDKEY register and then setting the DEVICEERASE bit of the AAP\_CMD register via the debug interface. This operation erases the main block of flash, clears all lock bits, and debug access to the Cortex-M4 and bus-system is enabled. The operation takes tens of milli seconds to complete. Note that the SRAM contents will also be deleted during a device erase, while the UD-page is not erased.

The debugger may read the status of the device erase from the AAP\_STATUS register. When the ERASEBUSY bit is set low after DEVICEERASE of the AAP\_CMD register is set, the debugger may set the SYSRESETREQ bit in the AAP\_CMD register. After reset, the debugger may resume a normal debug session through the AHB-AP.

### 7.3.5 AAP Lock

Take extreme caution when using this feature. Once the AAP has been locked, the state of the FLASH can not be changed via the debugger.

### 7.3.6 Debugger reads of actionable registers

Some peripheral registers cause particular actions when read, e.g FIFOs which pop and IFC registers which clear the IF flags when read. This can cause problems when debugging and the user wants to read the value without triggering the read action. For this reason, by default, the peripherals will not execute these triggered actions when an attached debugger is performing the read accesses through the AAP. To override this behavior, the debugger can configure the MASTERTYPE bitfield of the Cortex-M4 AHB Access Port CSW register in order to emulate a core access when performing system bus transfers.

**Note:** Registers with actionable reads are noted in their register descriptions. Please refer to [Table 1.1 Register Access Types on page 2](#).

### 7.3.7 Debug Recovery

Debug recovery is the ability to stall the system bus before the Cortex-M4 executes code. For example, the first few instructions may disconnect the debugger pins. When this occurs it is difficult to connect the debugger and halt the Cortex-M4 before the Cortex-M4 starts to execute. By holding down pin reset, issuing the System Bus Stall AAP instruction, then releasing pin reset, the debugger can stall the system bus before the Cortex-M4 has a chance to execute. Because the system is under reset during this procedure the Debugger can not look for ACK's from the part. Once the system bus is stalled, the FLASH can be erased by issuing the AAP\_CMDKEY and then the writing the DEVICEERASE in the AAP\_CMD register.

## 7.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	AAP_CMD	W1	Command Register
0x004	AAP_CMDKEY	W1	Command Key Register
0x008	AAP_STATUS	R	Status Register
0x00C	AAP_CTRL	RW	Control Register
0x010	AAP_CRC_CMD	W1	CRC Command Register
0x014	AAP_CRC_STATUS	R	CRC Status Register
0x018	AAP_CRC_ADDR	RW	CRC Address Register
0x01C	AAP_CRC_RESULT	R	CRC Result Register
0x0FC	AAP_IDR	R	AAP Identification Register

## 7.5 Register Description

### 7.5.1 AAP\_CMD - Command Register

Offset	Bit Position																																	
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset																																	0	0
Access																																	W1	W1
Name																																	SYSRESETREQ	DEVICEERASE

Bit	Name	Reset	Access	Description
31:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	SYSRESETREQ	0	W1	<b>System Reset Request</b> A system reset request is generated when set to 1. This register is write enabled from the AAP_CMDKEY register.
0	DEVICEERASE	0	W1	<b>Erase the Flash Main Block, SRAM and Lock Bits</b> When set, all data and program code in the main block is erased, the SRAM is cleared and then the Lock Bit (LB) page is erased. This also includes the Debug Lock Word (DLW), causing debug access to be enabled after the next reset. The information block User Data page (UD) is left unchanged, but the User data page Lock Word (ULW) is erased. This register is write enabled from the AAP_CMDKEY register.

## 7.5.2 AAP\_CMDKEY - Command Key Register

Offset	Bit Position																															
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	W1															
Name																	WRITEKEY															

Bit	Name	Reset	Access	Description
31:0	WRITEKEY	0x00000000	W1	<b>CMD Key Register</b> The key value must be written to this register to write enable the AAP_CMD register.
	Value	Mode	Description	
	0xCFACC118	WRITEEN	Enable write to AAP_CMD	

## 7.5.3 AAP\_STATUS - Status Register

Offset	Bit Position																															
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																													0	0		
Access																													R	R		
Name																													LOCKED	ERASEBUSY		

Bit	Name	Reset	Access	Description
31:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	LOCKED	0	R	<b>AAP Locked</b> Set when the AAP is locked, .e.g the AAP Lock Word AAP Isb bits are not 0xF
0	ERASEBUSY	0	R	<b>Device Erase Command Status</b> This bit is set when a device erase is executing.

## 7.5.4 AAP\_CTRL - Control Register

Offset	Bit Position																																
0x00C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																																	0
Access																																	RW
Name																																	SYSBUSSTALL

Bit	Name	Reset	Access	Description
31:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	SYSBUSSTALL	0	RW	<b>Stall the System Bus</b> When this bit is set, the system bus is stalled. Only the Cortex registers are accessible

## 7.5.5 AAP\_CRCCMD - CRC Command Register

Offset	Bit Position																																
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																																	0
Access																																	W1
Name																																	CRCREQ

Bit	Name	Reset	Access	Description
31:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	CRCREQ	0	W1	<b>CRC Request</b> A CRC request is generated when set to 1. This register is always available.

## 7.5.6 AAP\_CRCSTATUS - CRC Status Register

Offset	Bit Position																																
0x014	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																																	0
Access																																	R
Name																																	CRCBUSY

Bit	Name	Reset	Access	Description
31:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	CRCBUSY	0	R	<b>CRC Calculation is busy</b> Set when the CRC calculation is executing. Will transition from 1 to 0 on valid data.

## 7.5.7 AAP\_CRCADDR - CRC Address Register

Offset	Bit Position																															
0x018	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	RW															
Name																	CRCADDR															

Bit	Name	Reset	Access	Description
31:0	CRCADDR	0x00000000	RW	<b>Starting Page Address for CRC Execution</b> Set this to the address the CRC executes on.

## 7.5.8 AAP\_CRCRESULT - CRC Result Register

Offset	Bit Position																																					
0x01C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset																	0x00000000																					
Access																	R																					
Name																	CRCRESULT																					

Bit	Name	Reset	Access	Description
31:0	CRCRESULT	0x00000000	R	<b>CRC Result of the CRCADDRESS</b> Result of the CRC calculation using the CRCADDRESS.

## 7.5.9 AAP\_IDR - AAP Identification Register

Offset	Bit Position																																					
0x0FC	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset																	0x26E60011																					
Access																	R																					
Name																	ID																					

Bit	Name	Reset	Access	Description
31:0	ID	0x26E60011	R	<b>AAP Identification Register</b> Access port identification register in compliance with the ARM ADI v5 specification (JEDEC Manufacturer ID) .

## 8. MSC - Memory System Controller

### Quick Facts

#### What?

The user can perform Flash memory read, read configuration and write operations through the Memory System Controller (MSC).

#### Why?

The MSC allows the application code, user data and flash lock bits to be stored in non-volatile Flash memory. Certain memory system functions, such as program memory wait-states and bus faults are also configured from the MSC peripheral register interface, giving the developer the ability to dynamically customize the memory system performance, security level, energy consumption and error handling capabilities to the requirements at hand.

#### How?

The MSC integrates a low-energy Flash IP with a charge pump, enabling minimum energy consumption while eliminating the need for external programming voltage to erase the memory. An easy to use write and erase interface is supported by an internal, fixed-frequency oscillator and autonomous flash timing and control reduces software complexity while not using other timer resources.

Application code may dynamically scale between high energy optimization and high code execution performance through advanced read modes.

A highly efficient low energy instruction cache reduces the number of flash reads significantly, thus saving energy. Performance is also improved when wait-states are used, since many of the wait-states are eliminated. Built-in performance counters can be used to measure the efficiency of the instruction cache.

### 8.1 Introduction

The Memory System Controller (MSC) is the program memory unit of the EFR32 microcontroller. The flash memory is readable and writable from both the Cortex-M4 and DMA. The flash memory is divided into two blocks; the main block and the information block. Program code is normally written to the main block. Additionally, the information block is available for special user data and flash lock bits. There is also a read-only page in the information block containing system and device calibration data, and bootloader. Read and write operations are supported in the energy modes EM0 Active and EM1 Sleep.

## 8.2 Features

- AHB read interface
  - Scalable access performance to optimize the Cortex-M4 code interface
    - Zero wait-state access up to 26 MHz
    - Advanced energy optimization functionality
      - Conditional branch target prefetch suppression
      - Cortex-M4 disfolding of if-then (IT) blocks
      - Instruction Cache
  - DMA read support in EM0 Active and EM1 Sleep
- Command and status interface
  - Flash write and erase
    - Accessible from Cortex-M4 in EM0 Active
    - DMA write support in EM0 Active and EM1 Sleep
  - Core clock independent Flash timing
    - Internal oscillator and internal timers for precise and autonomous Flash timing
      - General purpose timers are not occupied during Flash erase and write operations
  - Configurable interrupt erase abort
    - Improved interrupt predictability
  - Memory and bus fault control
- Security features
  - Lockable debug access
  - Page lock bits
  - SW Mass erase Lock bits
  - Authentication Access Port (AAP) lock bits
- End-of-write and end-of-erase interrupts

### 8.3 Functional Description

The size of the main block is device dependent. The largest size available is 256 KB (128 pages). The information block has 2048 available for user data. The information block also contains chip configuration data located in a reserved area. The main block is mapped to address 0x00000000 and the information block is mapped to address 0x0FE00000. [Table 8.1 MSC Flash Memory Mapping on page 101](#) outlines how the Flash is mapped in the memory space. All Flash memory is organized into 2048 pages.

**Table 8.1. MSC Flash Memory Mapping**

Block	Page	Base address	Write/Erase by	Software readable	Purpose/Name	Size
Main <sup>1</sup>	0	0x00000000	Software, debug	Yes	User code and data	16 KB - 256 KB
	.		Software, debug	Yes		
	127	0x0003F800	Software, debug	Yes		
Reserved	-	0x00040000	-	-	Reserved for flash expansion	~24 MB

1 Block/page erased by a device erase

#### 8.3.1 User Data (UD) Page Description

This is the user data page in the information block. The page can be erased and written by software. The page is erased by the ERA-SEPAGE command of the MSC\_WRITECMD register. Note that the page is not erased by a device erase operation. The device erase operation is described in [7.3.3 Authentication Access Point](#).

### 8.3.2 Lock Bits (LB) Page Description

This page contains the following information:

- Main block Page Lock Words (PLWs)
- User data page Lock Word (ULWs)
- Debug Lock Word (DLW)
- Mass erase Lock Word (MLW)
- Authentication Access Port (AAP) lock word (ALW)
- Bootloader enable (CLW0)
- Pin reset soft (CLW0)

The words in this page are organized as shown in [Table 8.2 Lock Bits Page Structure on page 102](#):

**Table 8.2. Lock Bits Page Structure**

127	DLW
126	ULW
125	MLW
124	ALW
122	CLW0
N	PLW[N]
...	...
1	PLW[1]
0	PLW[0]

There are 32 page lock bits per page lock word (PLW). Bit 0 refers to the first page and bit 31 refers to the last page within a PLW. Thus, PLW[0] contains lock bits for page 0-31 in the main block, PLW[1] contains lock bits for page 32-63 etc. A page is locked when the bit is 0. A locked page cannot be erased or written.

Word 127 is the debug lock word (DLW). The four LSBs of this word are the debug lock bits. If these bits are 0xF, then debug access is enabled. Debug access to the core is disabled from power-on reset until the DLW is evaluated immediately before the Cortex-M4 starts execution of the user application code. If the bits are not 0xF, then debug access to the core remains blocked.

Word 126 is the user page lock word (ULW). Bit 0 of this word is the User Data Page lock bit. Bit 1 in this word locks the Lock Bits Page. The lock bits can be reset by a device erase operation initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in [7.3.3 Authentication Access Point](#). Note that the AAP is only accessible from the debug interface, and cannot be accessed from the Cortex-M4 core.

Word 125 is the mass erase lock word (MLW). Bit 0 locks the entire flash. The mass erase lock bits will not have any effect on device erases initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in [7.3.3 Authentication Access Point](#).

Word 124 is the Authentication Access Port (AAP) lock word (ALW) and the four LSBs of this word are the lock bits. If these bits are 0xF, then AAP access is enabled. If the bits are not 0xF, AAP is disabled and it is impossible to access the device through the AAP.  
**NOTE - locking AAP is irreversible. Once AAP is locked, it will be impossible to perform an external mass erase and AAP lock cannot be reset.** The only way to program the device when AAP is locked is through a boot loader or by SW already loaded into the FLASH.

Word 122 is configuration word Zero. Bit[2] is the pinresetsoft bit. Bit[1] is the bootloader enable bit. .

### 8.3.3 Device Information (DI) Page

This read-only page holds oscillator and ADC calibration data from the production test as well as an unique device ID. The page is further described in .

### 8.3.4 Bootloader

Bootloader is readable by software but not writable. The system is configured to boot from bootloader automatically after system reset. User can bypass the bootloader by clear bit 1 in config lock word0 (CLW0) in word 122 of lockbit (LB) page.

### 8.3.5 Device Revision

Family, FamilyAlt, RevMajor, RevMajorAlt, RevMinor can be accessed through ROM Table. The Revision number is extracted from the PID2 and PID3 registers, as illustrated in [Figure 8.1 Revision Number Extraction on page 103](#). The Rev[7:4] and Rev[3:0] must be combined to form the complete revision number Revision[7:0].

PID2 (0xE00FFE8)			PID3 (0xE00FFEC)		
31:8	7:4	3:0	31:8	7:4	3:0
	Rev[7:4]			Rev[3:0]	

**Figure 8.1. Revision Number Extraction**

The Revision number is to be interpreted according to [Table 8.3 Revision Number Interpretation on page 103](#).

**Table 8.3. Revision Number Interpretation**

Revision[7:0]	Revision
0x00	A

### 8.3.6 Post-reset Behavior

Calibration values are automatically written to registers by the MSC before application code startup. The values are also available to read from the DI page for later reference by software. Other information such as the device ID and production date is also stored in the DI page and is readable from software.

If bootloader is not bypassed, the system will boot up from the bootloader at address 0x0FE10000.

### 8.3.7 Flash Startup

On transitions from EM2/3 to EM0, the flash must be powered up. The time this takes depends on the current operating conditions. To have a deterministic startup-time, set STDLY0 in MSC\_STARTUP to 0x64 and clear STDLY1, ASTWAIT, STWSEN and STWS. This will result in a 10 us delay before the flash is ready. The system will wake up before this, but the Cortex will stall on the first access to the flash until it is ready. Execute code from RAM or cache to get a quicker startup

To get the fastest possible startup when wakeup, i.e. a startup that depends on the current operating conditions, set STDLY0 to 0x28 and set ASTWAIT in MSC\_STARTUP. When configured this way, the system will poll the flash to determine when it is ready, and then start execution.

For even quicker startup, run code in beginning with a set of wait-states. Set STDLY0 to 0x32, STDLY1 to 0x32, and set ASTWAIT and STWSEN. Then configure STWS in MSC\_STARTUP to the number of waitstates to run with. With this setup, sampling will begin with the given number of waitstates after 5 us, and the system will run with this number of waitstates for the remaining 5 us before returning to normal operation

A recommended setting for MSC\_STARTUP register is to set STDLY0 to 0x32 for wait 5us and set ASTWAIT to one for active sampling Set STWSEN to zero to bypass second delay period.

Flash wakeup on demand is supported when wakeup from EM2/3 to EM0. Set bit PWRUPONDEMAND of register MSC\_CTRL to one to enable the power up on demand. When enabled during powerup, flash will enter sleep mode and waiting for either pending flash read transaction or software command to MSC\_CMD.PWRUP bit. If software command wakeup, and interrupt of MSC\_IF.PWRUPF will be flagged if the MSC\_IEN.PWRUPF is set

### 8.3.8 Wait-states

Table 8.4. Flash Wait-States

Wait-States	Frequency
WS0	no more than 26 MHz
WS1	above 26 MHz and no more than 40 MHz

#### 8.3.8.1 One Wait-state Access

After reset, the HFCORECLK is normally 19 MHz from the HFRCO and the MODE field of the MSC\_READCTRL register is set to WS1 (one wait-state). The reset value must be WS1 as an uncalibrated HFRCO may produce a frequency higher than 26 MHz. Software must not select a zero wait-state mode unless the clock is guaranteed to be 26 MHz or below, otherwise the resulting behavior is undefined. If a HFCORECLK frequency above 26 MHz is to be set by software, the MODE field of the MSC\_READCTRL register must be set to WS1 or WS1SCBTP before the core clock is switched to the higher frequency clock source.

When changing to a lower frequency, the MODE field of the MSC\_READCTRL register must be set to WS0 or WS0SCBTP only after the frequency transition has completed. If the HFRCO is used, wait until the oscillator is stable on the new frequency. Otherwise, the behavior is unpredictable.

To run at a frequency higher than 40 MHz, WS2 or WS2SCBTP must be selected to insert two wait-states for every flash access.

#### 8.3.8.2 Zero Wait-state Access

At 26 MHz and below, read operations from flash may be performed without any wait-states. Zero wait-state access greatly improves code execution performance at frequencies from 26 MHz and below. By default, the Cortex-M4 uses speculative prefetching and If-Then block folding to maximize code execution performance at the cost of additional flash accesses and energy consumption.

#### 8.3.8.3 Operation Above

To run at frequencies higher than 26 MHz, MODE in MSC\_READCTRL must be set to WS1 or WS1SCBTP.

### 8.3.9 Suppressed Conditional Branch Target Prefetch (SCBTP)

MSC offers a special instruction fetch mode which optimizes energy consumption by cancelling Cortex-M4 conditional branch target prefetches. Normally, the Cortex-M4 core prefetches both the next sequential instruction and the instruction at the branch target address when a conditional branch instruction reaches the pipeline decode stage. This prefetch scheme improves performance while one extra instruction is fetched from memory at each conditional branch, regardless of whether the branch is taken or not. To optimize for low energy, the MSC can be configured to cancel these speculative branch target prefetches. With this configuration, energy consumption is more optimal, as the branch target instruction fetch is delayed until the branch condition is evaluated.

The performance penalty with this mode enabled is source code dependent, but is normally less than 1% for core frequencies from 26 MHz and below. To enable the mode at frequencies from 26 MHz and below write WS0SCBTP to the MODE field of the MSC\_READCTRL register. For frequencies above 26 MHz, use the WS1SCBTP mode, and for frequencies above 40 MHz, use the WS2SCBTP mode. An increased performance penalty per clock cycle must be expected compared to WS0SCBTP mode. The performance penalty in WS1SCBTP/WS2SCBTP mode depends greatly on the density and organization of conditional branch instructions in the code.

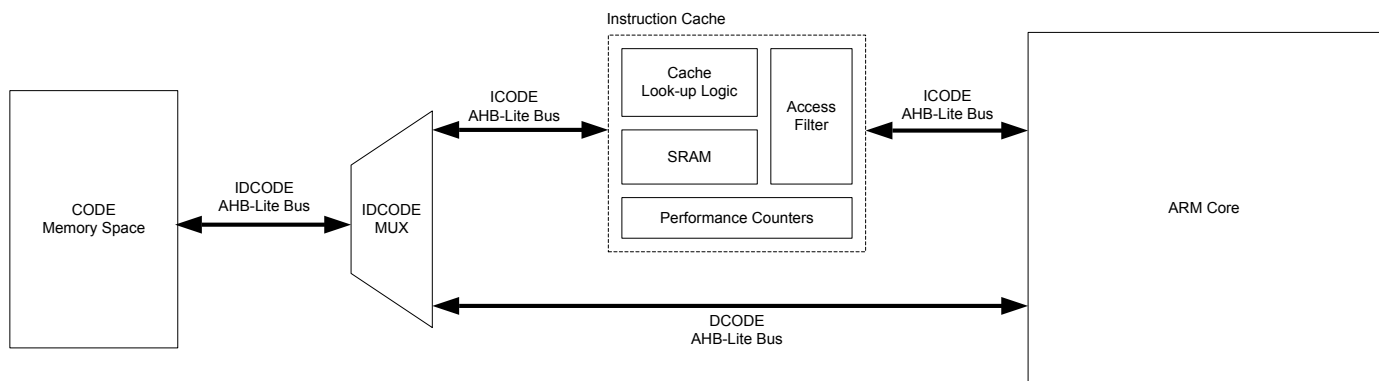

#### 8.3.10 Cortex-M4 If-Then Block Folding

The Cortex-M4 offers a mechanism known as if-then block folding. This is a form of speculative prefetching where small if-then blocks are collapsed in the prefetch buffer if the condition evaluates to false. The instructions in the block then appear to execute in zero cycles. With this scheme, performance is optimized at the cost of higher energy consumption as the processor fetches more instructions from memory than it actually executes. To disable the mode, write a 1 to the DISFOLD bit in the NVIC Auxiliary Control Register; see the Cortex-M4 Technical Reference Manual for details. Normally, it is expected that this feature is most efficient at core frequencies above 26 MHz. Folding is enabled by default.

### 8.3.11 Instruction Cache

The MSC includes an instruction cache. The instruction cache for the internal flash memory is enabled by default, but can be disabled by setting IFCDIS in MSC\_READCTRL. When enabled, the instruction cache typically reduces the number of flash reads significantly, thus saving energy. In most cases a cache hit-rate of more than 70 % is achievable. When a 32-bit instruction fetch hits in the cache the data is returned to the processor in one clock cycle. Thus, performance is also improved when wait-states are used (i.e. running at frequencies above 26 MHz).

The instruction cache is connected directly to the ICODE bus on the ARM core and functions as a memory access filter between the processor and the memory system, as illustrated in [Figure 8.2 Instruction Cache on page 105](#). The cache consists of an access filter, lookup logic, SRAM, and two performance counters. The access filter checks that the address for the access is to on-chip flash memory (instructions in RAM are not cached). If the address matches, the cache lookup logic and SRAM is enabled. Otherwise, the cache is bypassed and the access is forwarded to the memory system. The cache is then updated when the memory access completes. The access filter also disables cache updates for interrupt context accesses if caching in interrupt context is disabled. The performance counters, when enabled, keep track of the number of cache hits and misses. The cachelines are filled up continuously one word at a time as the individual words are requested by the processor. Thus, not all words of a cacheline might be valid at a given time.

**Figure 8.2. Instruction Cache**

By default, the instruction cache is automatically invalidated when the contents of the flash is changed (i.e. written or erased). In many cases, however, the application only makes changes to data in the flash, not code. In this case, the automatic invalidate feature can be disabled by setting AIDIS in MSC\_READCTRL. The cache can (independent of the AIDIS setting) be manually invalidated by writing 1 to INVCACHE in MSC\_CMD.

In general it is highly recommended to keep the cache enabled all the time. However, for some sections of code with very low cache hit-rate more energy-efficient execution can be achieved by disabling the cache temporarily. To measure the hit-rate of a code-section, the built-in performance counters can be used. Before the section, start the performance counters by writing 1 to STARTPC in MSC\_CMD. This starts the performance counters, counting from 0. At the end of the section, stop the performance counters by writing 1 to STOPPC in MSC\_CMD. The number of cache hits and cache misses for that section can then be read from MSC\_CACHEHITS and MSC\_CACHEMISSES respectively. The total number of 32-bit instruction fetches will be MSC\_CACHEHITS + MSC\_CACHEMISSES. Thus, the cache hit-ratio can be calculated as  $\text{MSC\_CACHEHITS} / (\text{MSC\_CACHEHITS} + \text{MSC\_CACHEMISSES})$ . When MSC\_CACHEHITS overflows the CHOF interrupt flag is set. When MSC\_CACHEMISSES overflows the CMOF interrupt flag is set. These flags must be cleared explicitly by software. The range of the performance counters can thus be extended by increasing a counter in the MSC interrupt routine. The performance counters only count when a cache lookup is performed. If the lookup fails, MSC\_CACHEMISSES is increased. If the lookup is successful, MSC\_CACHEHITS is increased. For example, a cache lookup is not performed if the cache is disabled or the code is executed from RAM. When caching of vector fetches and instructions in interrupt routines is disabled (ICCDIS in MSC\_READCTRL is set), the performance counters do not count when these types of fetches occur (i.e. while in interrupt context).

By default, interrupt vector fetches and instructions in interrupt routines are also cached. Some applications may get better cache utilization by not caching instructions in interrupt context. This is done by setting ICCDIS in MSC\_READCTRL. You should only set this bit based on the results from a cache hit ratio measurement. In general, it is recommended to keep the ICCDIS bit cleared. Note that look-ups in the cache are still performed, regardless of the ICCDIS setting - but instructions are not cached when cache misses occur inside the interrupt routine. So, for example, if a cached function is called from the interrupt routine, the instructions for that function will be taken from the cache.

The cache content is not retained in EM2, EM3 and EM4. The cache is therefore invalidated regardless of the setting of AIDIS in MSC\_READCTRL when entering these energy modes. Applications that switch frequently between EM0 and EM2/3 and executes the very same non-looping code almost every time will most likely benefit from putting this code in RAM. The interrupt vectors can also be put in RAM to reduce current consumption even further.

### 8.3.12 Erase and Write Operations

Both page erase and write operations require that the address is written into the MSC\_ADDRB register. For erase operations, the address may be any within the page to be erased. Load the address by writing 1 to the LADDRIM bit in the MSC\_WRITECMD register. The LADDRIM bit only has to be written once when loading the first address. After each word is written the internal address register ADDR will be incremented automatically by 4. The INVADDR bit of the MSC\_STATUS register is set if the loaded address is outside the flash and the LOCKED bit of the MSC\_STATUS register is set if the page addressed is locked. Any attempts to command erase of or write to the page are ignored if INVADDR or the LOCKED bits of the MSC\_STATUS register are set. To abort an ongoing erase, set the ERASEABORT bit in the MSC\_WRITECMD register.

When a word is written to the MSC\_WDATA register, the WDATAREADY bit of the MSC\_STATUS register is cleared. When this status bit is set, software or DMA may write the next word.

A single word write is commanded by setting the WRITEONCE bit of the MSC\_WRITECMD register. The operation is complete when the BUSY bit of the MSC\_STATUS register is cleared and control of the flash is handed back to the AHB interface, allowing application code to resume execution.

For a DMA write the software must write the first word to the MSC\_WDATA register and then set the WRITETRIG bit of the MSC\_WRITECMD register. DMA triggers when the WDATAREADY bit of the MSC\_STATUS register is set.

It is possible to write words twice between each erase by keeping at 1 the bits that are not to be changed. Let us take as an example writing two 16 bit values, 0xAAAA and 0x5555. To safely write them in the same flash word this method can be used:

- Write 0xFFFFAAAA (word in flash becomes 0xFFFFAAAA)
- Write 0x5555FFFF (word in flash becomes 0x5555AAAA)

Note that there is a maximum of two writes to the same word between each erase due to a physical limitation of the flash.

**Note:**

During a write or erase, flash read accesses will be stalled, effectively halting code execution from flash. Code execution continues upon write/erase completion. Code residing in RAM may be executed during a write/erase operation.

#### 8.3.12.1 Mass erase

A mass erase can be initiated from software using ERASEMAIN0 MSC\_WRITECMD. This command will start a mass erase of the entire flash. Prior to initiating a mass erase, MSC\_MASSLOCK must be unlocked by writing 0x631A to it. After a mass erase has been started, this register can be locked again to prevent runaway code from accidentally triggering a mass erase.

The regular flash page lock bits will not prevent a mass erase. To prevent software from initiating mass erases, use the mass erase lock bits in the mass erase lock word (MLW).

## 8.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	MSC_CTRL	RW	Memory System Control Register
0x004	MSC_READCTRL	RWH	Read Control Register
0x008	MSC_WRITECTRL	RW	Write Control Register
0x00C	MSC_WRITECMD	W1	Write Command Register
0x010	MSC_ADDRB	RW	Page Erase/Write Address Buffer
0x018	MSC_WDATA	RW	Write Data Register
0x01C	MSC_STATUS	R	Status Register
0x030	MSC_IF	R	Interrupt Flag Register
0x034	MSC_IFS	W1	Interrupt Flag Set Register
0x038	MSC_IFC	(R)W1	Interrupt Flag Clear Register
0x03C	MSC_IEN	RW	Interrupt Enable Register
0x040	MSC_LOCK	RWH	Configuration Lock Register
0x044	MSC_CACHECMD	W1	Flash Cache Command Register
0x048	MSC_CACHEHITS	R	Cache Hits Performance Counter
0x04C	MSC_CACHEMISSES	R	Cache Misses Performance Counter
0x054	MSC_MASSLOCK	RWH	Mass Erase Lock Register
0x05C	MSC_STARTUP	RW	Startup Control
0x074	MSC_CMD	W1	Command Register

8.5.2 MSC\_READCTRL - Read Control Register

Offset	Bit Position																															
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset				0				0x1														0	1									
Access				RW				RWH														RW	RW				RW	RW	RW			
Name				SCBTP				MODE														USEHPROT	PREFETCH				ICCDIS	AIDIS	IFCDIS			

Bit	Name	Reset	Access	Description
31:29	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
28	SCBTP	0	RW	<b>Suppress Conditional Branch Target Prefetch</b>  Enable suppressed Conditional Branch Target Prefetch (SCBTP) function. SCBTP saves energy by delaying Cortex-M4 conditional branch target prefetches until the conditional branch instruction is in the execute stage. When the instruction reaches this stage, the evaluation of the branch condition is completed and the core does not perform a speculative prefetch of both the branch target address and the next sequential address. With the SCBTP function enabled, one instruction fetch is saved for each branch not taken, with a negligible performance penalty.
27:26	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
25:24	MODE	0x1	RWH	<b>Read Mode</b>  After reset, the core clock is 19 MHz from the HFRCO and the MODE field of MSC_READCTRL register is set to WS1. The reset value is WS1 because the HFRCO may produce a frequency above 19 MHz before it is calibrated. A large wait states is associated with high frequency. When changing to a higher frequency, this register must be set to a large wait states first before the core clock is switched to the higher frequency. When changing to a lower frequency, this register should be set to lower wait states after the frequency transition has been completed. If the HFRCO is used as clock source, wait until the oscillator is stable on the new frequency to avoid unpredictable behavior. See Flash Wait-States table for the corresponding threshold for different wait-states.
Value		Mode		Description
0		WS0		Zero wait-states inserted in fetch or read transfers
1		WS1		One wait-state inserted for each fetch or read transfer. See Flash Wait-States table for details
23:10	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
9	USEHPROT	0	RW	<b>AHB_HPROT Mode</b>  Use ahb_hrpot to determine if the instruction is cacheable or not
8	PREFETCH	1	RW	<b>Prefetch Mode</b>  Set to configure level of prefetching.
7:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5	ICCDIS	0	RW	<b>Interrupt Context Cache Disable</b>  Set this bit to automatically disable caching of vector fetches and instruction fetches in interrupt context. Cache lookup will still be performed in interrupt context. When set, the performance counters will not count when these types of fetches occur.
4	AIDIS	0	RW	<b>Automatic Invalidate Disable</b>  When this bit is set the cache is not automatically invalidated when a write or page erase is performed.
3	IFCDIS	0	RW	<b>Internal Flash Cache Disable</b>  Disable instruction cache for internal flash memory.
2:0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

### 8.5.3 MSC\_WRITECTRL - Write Control Register

Offset	Bit Position																															
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																															0	0
Access																															RW	RW
Name																															IRQERASEABORT	WREN

Bit	Name	Reset	Access	Description
31:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	IRQERASEABORT	0	RW	<b>Abort Page Erase on Interrupt</b>  When this bit is set to 1, any Cortex-M4 interrupt aborts any current page erase operation. Executing that interrupt vector from Flash will halt the CPU.
0	WREN	0	RW	<b>Enable Write/Erase Controller</b>  When this bit is set, the MSC write and erase functionality is enabled

## 8.5.4 MSC\_WRITECMD - Write Command Register

Offset	Bit Position																																					
0x00C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset																				0					0													
Access																				W1					W1					W1	0	0	0	0	0	0	0	0
Name																				CLEARWDATA					ERASEMAIN0					ERASEABORT	WRITETRIG	WRITEONCE	WRITEEND	ERASEPAGE	LADDRIM			

Bit	Name	Reset	Access	Description
31:13	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
12	CLEARWDATA	0	W1	<b>Clear WDATA state</b> Will set WDATAREADY and DMA request. Should only be used when no write is active.
11:9	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
8	ERASEMAIN0	0	W1	<b>Mass erase region 0</b> Initiate mass erase of region 0. Before use MSC_MASSLOCK must be unlocked. To completely prevent access from software, clear bit 0 in the mass erase lock-word (MLW)
7:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5	ERASEABORT	0	W1	<b>Abort erase sequence</b> Writing to this bit will abort an ongoing erase sequence.
4	WRITETRIG	0	W1	<b>Word Write Sequence Trigger</b> Start write of the first word written to MSC_WDATA, then add 4 to ADDR and write the next word if available within a 30us timeout. When ADDR is incremented past the page boundary, ADDR is set to the base of the page. If WDOUBLE is set, two words are required every time, and ADDR is incremented by 8.
3	WRITEONCE	0	W1	<b>Word Write-Once Trigger</b> Write the word in MSC_WDATA to ADDR. Flash access is returned to the AHB interface as soon as the write operation completes. The WREN bit in the MSC_WRITECTRL register must be set in order to use this command. Only a single word is written, but the internal address is also incremented to allow a direct write of a new word without loading a new address
2	WRITEEND	0	W1	<b>End Write Mode</b> Write 1 to end write mode when using the WRITETRIG command.
1	ERASEPAGE	0	W1	<b>Erase Page</b> Erase any user defined page selected by the MSC_ADDRB register. The WREN bit in the MSC_WRITECTRL register must be set in order to use this command.
0	LADDRIM	0	W1	<b>Load MSC_ADDRB into ADDR</b> Load the internal write address register ADDR from the MSC_ADDRB register. The internal address register ADDR is incremented automatically by 4 after each word is written. When ADDR is incremented past the page boundary, ADDR is set to the base of the page.

## 8.5.5 MSC\_ADDRB - Page Erase/Write Address Buffer

Offset	Bit Position																															
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	RW															
Name																	ADDRB															

Bit	Name	Reset	Access	Description
31:0	ADDRB	0x00000000	RW	<b>Page Erase or Write Address Buffer</b>
This register holds the page address for the erase or write operation. This register is loaded into the internal MSC_ADDR register when the LADDRIM field in MSC_CMD is set.				

## 8.5.6 MSC\_WDATA - Write Data Register

Offset	Bit Position																															
0x018	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	RW															
Name																	WDATA															

Bit	Name	Reset	Access	Description
31:0	WDATA	0x00000000	RW	<b>Write Data</b>
The data to be written to the address in MSC_ADDR. This register must be written when the WDATABREADY bit of MSC_STATUS is set.				

### 8.5.7 MSC\_STATUS - Status Register

Offset	Bit Position																															
0x01C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									R	0	R	0	R	0	R	0
Access																									R	0	R	0	R	0	R	0
Name																									PCRUNNING	ERASEABORTED	WORDTIMEOUT	WDATAREADY	INVADDR	LOCKED	BUSY	

Bit	Name	Reset	Access	Description
31:7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6	PCRUNNING	0	R	<b>Performance Counters Running</b> <p>This bit is set while the performance counters are running. When one performance counter reaches the maximum value, this bit is cleared.</p>
5	ERASEABORTED	0	R	<b>The Current Flash Erase Operation Aborted</b> <p>When set, the current erase operation was aborted by interrupt.</p>
4	WORDTIMEOUT	0	R	<b>Flash Write Word Timeout</b> <p>When this bit is set, MSC_WDATA was not written within the timeout. The flash write operation timed out and access to the flash is returned to the AHB interface. This bit is cleared when the ERASEPAGE, WRITETRIG or WRITEONCE commands in MSC_WRITECMD are triggered.</p>
3	WDATAREADY	1	R	<b>WDATA Write Ready</b> <p>When this bit is set, the content of MSC_WDATA is read by MSC Flash Write Controller and the register may be updated with the next 32-bit word to be written to flash. This bit is cleared when writing to MSC_WDATA.</p>
2	INVADDR	0	R	<b>Invalid Write Address or Erase Page</b> <p>Set when software attempts to load an invalid (unmapped) address into ADDR</p>
1	LOCKED	0	R	<b>Access Locked</b> <p>When set, the last erase or write is aborted due to erase/write access constraints</p>
0	BUSY	0	R	<b>Erase/Write Busy</b> <p>When set, an erase or write operation is in progress and new commands are ignored</p>

## 8.5.8 MSC\_IF - Interrupt Flag Register

Offset	Bit Position																																	
0x030	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset																													0	0	0	0	0	0
Access																													R	R	R	R	R	R
Name																													ICACHERR	PWRUPF	CMOF	CHOF	WRITE	ERASE

Bit	Name	Reset	Access	Description
31:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5	ICACHERR	0	R	<b>iCache RAM Parity Error Flag</b> If one, iCache RAM parity Error detected
4	PWRUPF	0	R	<b>Flash Power Up Sequence Complete Flag</b> Set after MSC_CMD.PWRUP received, flash powered up complete and ready for read/write
3	CMOF	0	R	<b>Cache Misses Overflow Interrupt Flag</b> Set when MSC_CACHEMISSES overflows
2	CHOF	0	R	<b>Cache Hits Overflow Interrupt Flag</b> Set when MSC_CACHEHITS overflows
1	WRITE	0	R	<b>Write Done Interrupt Read Flag</b> Set when a write is done
0	ERASE	0	R	<b>Erase Done Interrupt Read Flag</b> Set when erase is done

### 8.5.9 MSC\_IFS - Interrupt Flag Set Register

Offset	Bit Position																															
0x034	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Access													R																			
Name													CACHEHITS																			

Bit	Name	Reset	Access	Description
31:20	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
19:0	CACHEHITS	0x000000	R	<b>Cache hits since last performance counter start command.</b> Use to measure cache performance for a particular code section.

### 8.5.15 MSC\_CACHEMISSES - Cache Misses Performance Counter

Offset	Bit Position																															
0x04C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset													0x00000																			
Access													R																			
Name													CACHEMISSES																			

Bit	Name	Reset	Access	Description
31:20	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
19:0	CACHEMISSES	0x00000	R	<b>Cache misses since last performance counter start command.</b> Use to measure cache performance for a particular code section.

### 8.5.16 MSC\_MASSLOCK - Mass Erase Lock Register

Offset	Bit Position																															
0x054	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x0001															
Access																	RWH															
Name																	LOCKKEY															

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:0	LOCKKEY	0x0001	RWH	<b>Mass Erase Lock</b>  Write any other value than the unlock code to lock access the the ERASEMAINn commands. Write the unlock code 631A to enable access. When reading the register, bit 0 is set when the lock is enabled. Locked by default.

Mode	Value	Description
Read Operation		
UNLOCKED	0	Mass erase unlocked
LOCKED	1	Mass erase locked
Write Operation		
LOCK	0	Lock mass erase
UNLOCK	0x631A	Unlock mass erase

## 8.5.17 MSC\_STARTUP - Startup Control

Offset	Bit Position																																	
0x05C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset			0x1			0	1	1							0x001													0x04D						
Access			RW			RW	RW	RW							RW														RW					
Name			STWS			STWSAEN	STWSEN	ASTWAIT							STDLY1														STDLY0					

Bit	Name	Reset	Access	Description
31	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
30:28	STWS	0x1	RW	<b>Startup Waitstates</b> Active wait for flash startup startup after SDLY0.
27	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
26	STWSAEN	0	RW	<b>Startup Waitstates Always Enable</b> Use the number of waitstates given by STWS during startup always.
25	STWSEN	1	RW	<b>Startup Waitstates Enable</b> Use the number of waitstates given by STWS during startup. During the optional STDLY1 timeout.
24	ASTWAIT	1	RW	<b>Active Startup Wait</b> Active wait for flash startup startup after SDLY0.
23:22	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
21:12	STDLY1	0x001	RW	<b>Startup Delay 0</b> Number of cycles with startup waitstates, and also the maximum number of cycles startup sampling will be attempted before starting up system.
11:10	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
9:0	STDLY0	0x04D	RW	<b>Startup Delay 0</b> Number of idle cycles from exiting sleep mode.

8.5.18 MSC\_CMD - Command Register

Offset	Bit Position

9. LDMA - Linked DMA Controller

Quick Facts

**What?**

The LDMA controller can move data without CPU intervention, effectively reducing the energy consumption for a data transfer.

**Why?**

The LDMA can perform data transfers more energy efficiently than the CPU and allows autonomous operation in low energy modes. For example the LEUART can provide full UART communication in EM2 DeepSleep, consuming only a few  $\mu\text{A}$  by using the LDMA to move data between the LEUART and RAM.

**How?**

The LDMA controller has multiple highly configurable, prioritized DMA channels. A linked list of flexible descriptors makes it possible to tailor the controller to the specific needs of an application.

9.1 Introduction

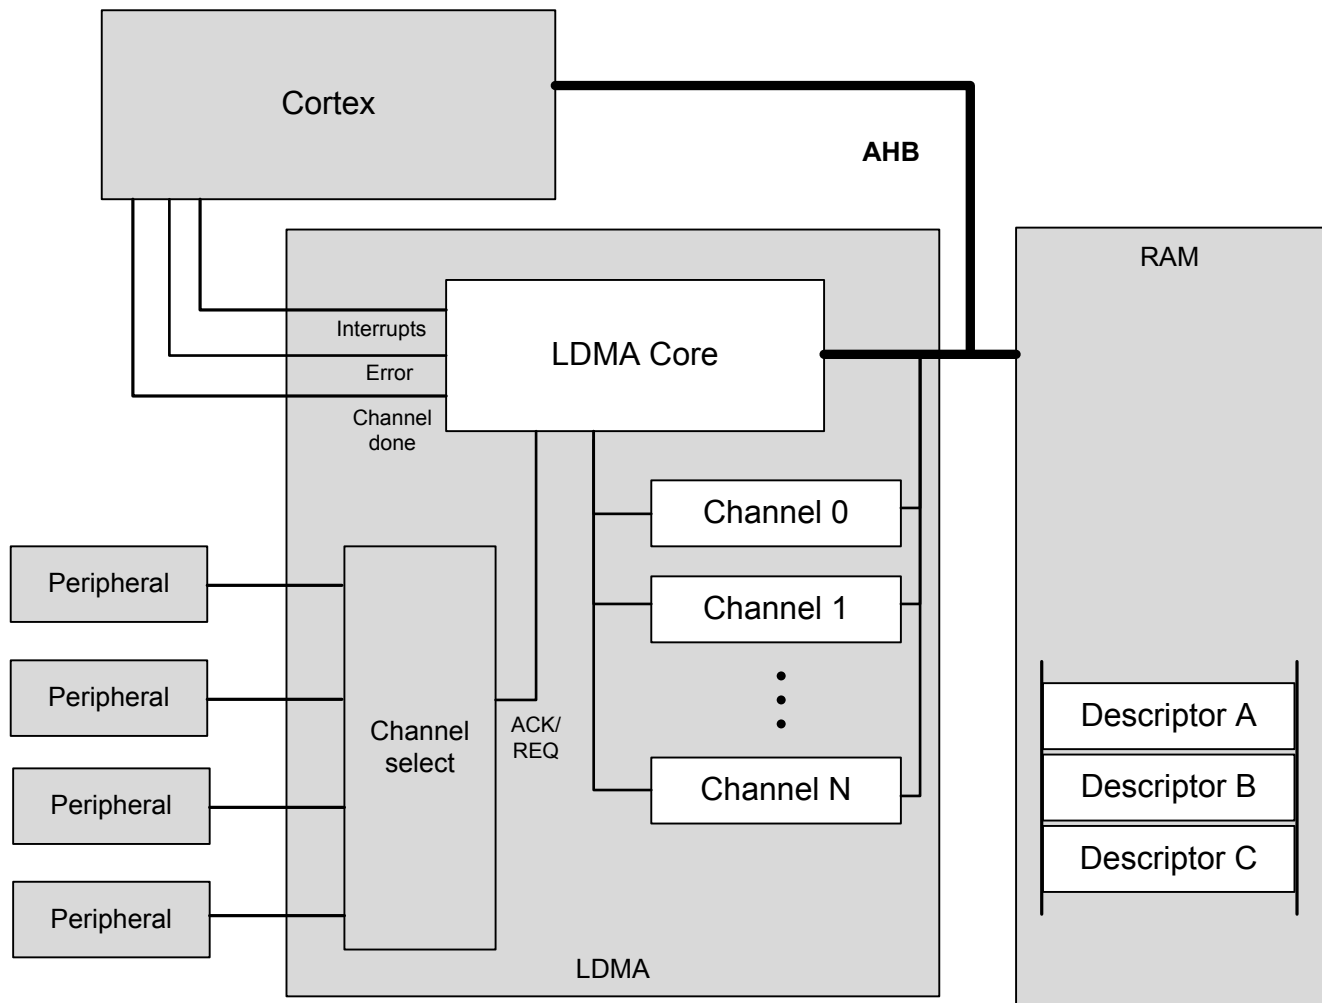

The Linked Direct Memory Access (LDMA) controller performs memory transfer operations independently of the CPU. This has the benefit of reducing the energy consumption and the workload of the CPU, and enables the system to stay in low energy modes while still routing data to memory and peripherals. For example, moving data from the LEUART to memory or memory to LEUART. Each of the DMA channels on the EFR32 can be connected to any of the EFR32 peripherals.

### 9.1.1 Features

- Flexible Source and Destination transfers
  - Memory-to-memory
  - Memory-to-peripheral
  - Peripheral-to-memory
  - Peripheral-to-peripheral
- DMA transfers triggered by peripherals, software, or linked list
- Single or multiple data transfers for each peripheral or software request
- Inter-channel and hardware event synchronization via trigger and wait functions
- Supports single or multiple descriptors
  - Single descriptor
  - Linked list of descriptors
  - Circular and ping-pong buffers
  - Scatter-Gather
  - Looping
  - Pause and restart triggered by other channels
  - Sophisticated flow control which can function without CPU interaction
- Channel arbitration includes:
  - Fixed priority
  - Simple round robin
  - Round robin with programmable multiple interleaved entries for higher priority requesters
- Programmable data size and source and destination address strides
- Programmable interrupt generation at the end of each DMA descriptor execution
- Little-endian/big-endian conversion
- DMA write-immediate function

## 9.2 Block Diagram

An overview of the LDMA and the modules it interacts with is shown in [Figure 9.1 LDMA Block Diagram on page 126](#).

**Figure 9.1. LDMA Block Diagram**

The Linked DMA Controller consists of three main parts

- A DMA core that executes transfers and communicates status to the core
- A channel select block that routes peripheral DMA requests and acknowledge signals to the DMA
- A set of internal channel configuration registers for tracking the progress of each DMA channel

The DMA has access to all system memory through the AHB bus and the AHB->APB bridge. It can load channel descriptors from memory with no CPU intervention.

### 9.3 Functional Description

The Linked DMA Controller is highly flexible. It is capable of transferring data between peripherals and memory without involvement from the processor core. This can be used to increase system performance by off-loading the processor from copying large amounts of data or avoiding frequent interrupts to service peripherals needing more data or having available data. It can also be used to reduce the system energy consumption by making the LDMA work autonomously with EM2 peripherals for data transfer in EM2 DeepSleep without having to wake up the processor core from sleep.

The Linked DMA Controller has 8 independent channels. Each of these channels can be connected to any of the available peripheral DMA transfer request input sources by writing to the channel configuration registers, see [9.3.2 Channel Configuration](#). In addition, each channel can also be triggered directly by software, which is useful for memory-to-memory transfers.

The channel descriptors determine what the Linked DMA Controller will do when it receives DMA transfer request. The initial descriptor is written directly to the LDMA's channel registers. If desired, the initial descriptor can link to additional linked descriptors stored in memory (RAM or Flash). Alternatively, software may also load the initial descriptor by writing the descriptor address to the LDMA\_CHx\_LINK register and then setting the corresponding bit the LDMA\_LINKLOAD register.

Before enabling a channel, the software must take care to properly configure the channel registers including the link address and any linked descriptors. When a channel is triggered, the Linked DMA Controller will perform the memory transfers as specified by the descriptors. A descriptor contains the memory address to read from, the memory address to write to, link address of the next descriptor, the number of bytes to be transferred, etc. The channel descriptor is described in detail in [9.3.7 Channel descriptor data structure](#).

The Linked DMA Controller supports both fixed priority and round robin arbitration. The number of fixed and round robin channels is programmable. For round robin channels, the number of arbitration slots requested for each channel is programmable. Using this scheme, it is possible to ensure that timing-critical transfers are serviced on time.

DMA transfers take place by reading a block of data at a time from the source, storing it in the LDMA's local FIFO, then writing the block out to the destination from the FIFO. Interrupts may optionally be signaled to the CPU's interrupt controller at the end of any DMA transfer or at the completion of a descriptor if the DONEIFSEN bit is set. An AHB error will always generate an interrupt.

#### 9.3.1 Channel Descriptor

Each DMA channel has descriptor registers. A transfer can be initialized by software writing to the registers or by the DMA itself copying a descriptor from RAM to memory. When using a linked list of descriptors the first descriptor should be initialized by the CPU. The DMA itself will then copy linked descriptors to its descriptor registers as required. In addition to manually initializing the first transfer, software may also cause the LDMA to load the initial descriptor by writing the descriptor address to the LDMA\_CHx\_LINK register and then setting the corresponding bit the LDMA\_LINKLOAD register.

The contents of the descriptor registers are dynamically updated during the DMA transfer. The contents of descriptors in memory are not edited by the controller.

Some descriptor field values are only used for linked descriptors. For example, the SRCMODE and DSTMODE bits of the LDMA\_CHx\_CTRL registers determine if a linked descriptor is using relative or absolute addressing. Software writes to the address registers will always use absolute addressing and never set these bits. Therefore, these bits are read only.

##### 9.3.1.1 DMA Transfer Size

A DMA transfer is the smallest unit of data that can be transferred by the LDMA. The LDMA supports byte, half-word and word sized transfers. The SIZE field in the LDMA\_CHx\_CTRL register specifies the data width of one DMA transfer.

##### 9.3.1.2 Source/Destination Increments

The SRCINC and DSTINC in the LDMA\_CHx\_CTRL register determines the increment between DMA transfers. The increment is in units of DMA transfers and using an increment size of 1 will transfer contiguous bytes, half-words, or words depending on the value of the SIZE field. Multiple unit increments are useful for transferring or packing/unpacking aligned data. For example using an increment of 4 with a size of BYTE will transfer word aligned bytes. An increment of 2 units with a size of HALFWORD is suitable for the transfer of word aligned half-word data. The LDMA can pack also pack or unpack data by using a different increment size for source and destination. For example - to convert from word aligned byte data (unpacked) to contiguous byte data (packed), set the SIZE to BYTE, SRCINC to 4, and DSTINC to 1.

SIZE may also be set to NONE which will cause the LDMA to read or write the same location for every DMA transfer. This is useful for accessing peripheral FIFO or data registers.

##### 9.3.1.3 Block Size

The block size defines the amount of data transferred in one arbitration. It consists of one or more DMA transfers. See [9.3.6.1 Arbitration Priority](#) for more details.

### 9.3.1.4 Transfer Count

The descriptor transfer count defines how many DMA transfers to perform. The number of bytes transferred by the descriptor will depend on both the transfer count XFERCNT and the SIZE field settings.  $TOTAL\_BYTES = XFERCNT * SIZE$

### 9.3.1.5 Descriptor List

A descriptor list consists of one or more descriptors which are executed in serially. This list may be a simple sequence of descriptors, a loop of descriptors, or a combination of the two.

Each descriptor in the list can be one of several types.

- Single Transfer descriptor: Transfers TOTAL\_BYTES of data and then stops.
- Linked Transfer descriptor: Transfers TOTAL\_BYTES of data and then loads the next linked descriptor.
- Loop Transfer descriptor: Transfers TOTAL\_BYTES of data and performs loop control (see [9.3.2.2 Loop Counter](#)).
- Sync descriptor: Handle synchronization of the list with other entities (see [9.3.7.2 SYNC descriptor structure](#)).
- WRI descriptor: Writes a value to a location in memory (see [9.3.7.3 WRI descriptor structure](#)).

### 9.3.1.6 Addresses

Before initiating a transfer, software should write the source address, destination address, and if applicable the link address to the descriptor registers. Alternatively, software may load a descriptor from memory by writing the descriptor address to the LDMA\_CHx\_LINK register and setting the corresponding bit in the LDMA\_LINKLOAD register.

During a DMA transfer, the DMA source and destination address registers are pointers to the next transfer address. The LDMA will update the SRC and DST addresses after each transfer. If software halts a DMA transfer by clearing the enable bit, the SRC and DST addresses will indicate the next transfer address.

When a descriptor is finished the DMA will either halt or load the next (linked) descriptor depending on the value of the LINK field in the LDMA\_Chx\_LINK register. After loading a linked descriptor, the descriptor registers will reflect the content of the loaded descriptor. Note that the linked descriptor must be word aligned in memory. The two least significant bits of the LDMA\_CHx\_LINK register are used by the LINK and LINKMODE bits. The two least significant bits of the link address are always zero.

### 9.3.1.7 Addressing Modes

The DMA descriptors support absolute addressing or relative addressing. When using relative addressing, the offset is relative to the current contents of the respective address registers. Regardless of the descriptor addressing modes, the address registers always indicate the absolute address. For example, when loading a descriptor using relative SRC addressing, the LDMA will add the descriptor source address (offset) to the contents of the SRCADDR register (base address). After loading, the SRCADDR register will indicate the absolute address of the loaded descriptor.

The initial descriptor must use absolute addressing. The LDMA will ignore the DSTMODE, SRCMODE, and LINKMODE bits for the initial descriptor and interpret the addresses as an absolute addresses.

Relative addressing is most useful for the link address. The initial descriptor will indicate the absolute address of the linked descriptors in memory. The linked descriptors might be an array of structures. In this case the offset between descriptors is constant and is always 16 bytes. The LINK address is not incremented or decremented after each transfer. Thus, a relative offset of 0x10 may be used for all linked descriptors.

The source and destination addresses also support relative addressing. When using relative addressing with the source or destination address registers, the LDMA adds the relative offset to the current contents of the respective address register. Since the source and destination addresses are normally incremented after each transfer, the final address will point to one unit past the last transfer. Thus, an offset of zero will give the next sequential data address.

See the example [9.4.6 2D Copy](#) for an common use of relative addressing.

9.3.1.8 Byte Swap

Enabling byte swap reverses the endianness of the incoming source data read into the LDMA's FIFO. Byte swap is only valid for transfer sizes of word and half-word. Note that linked structure reads are not byte swapped.

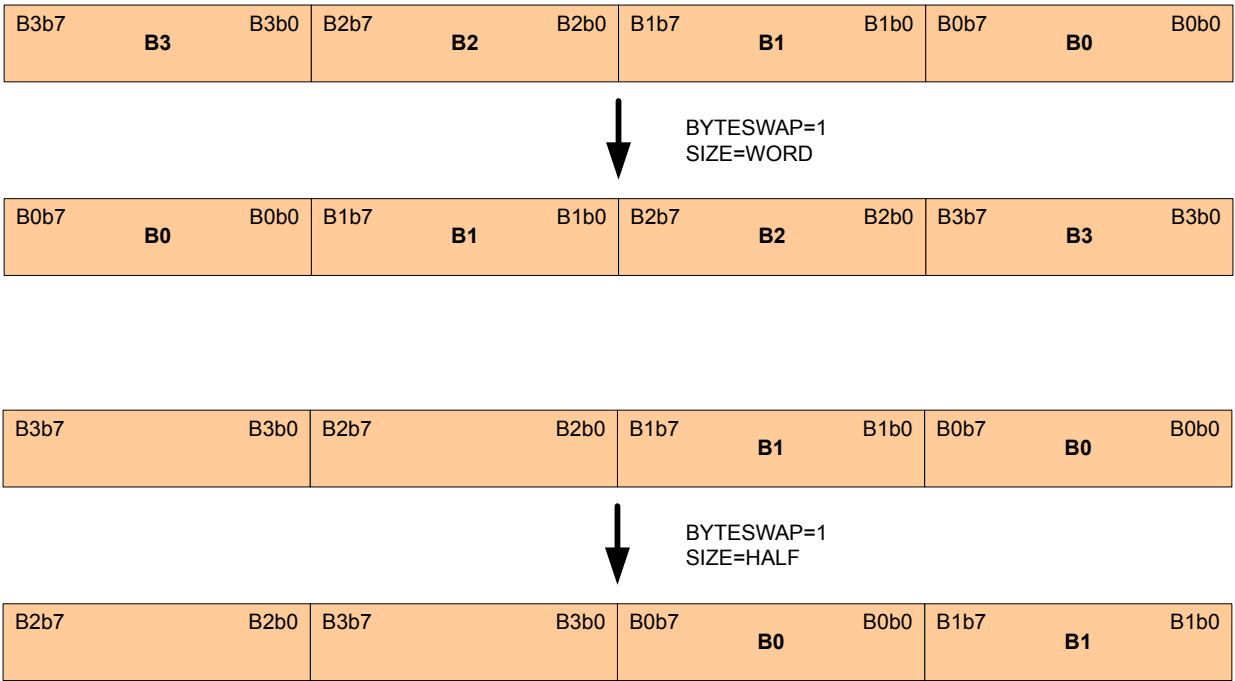

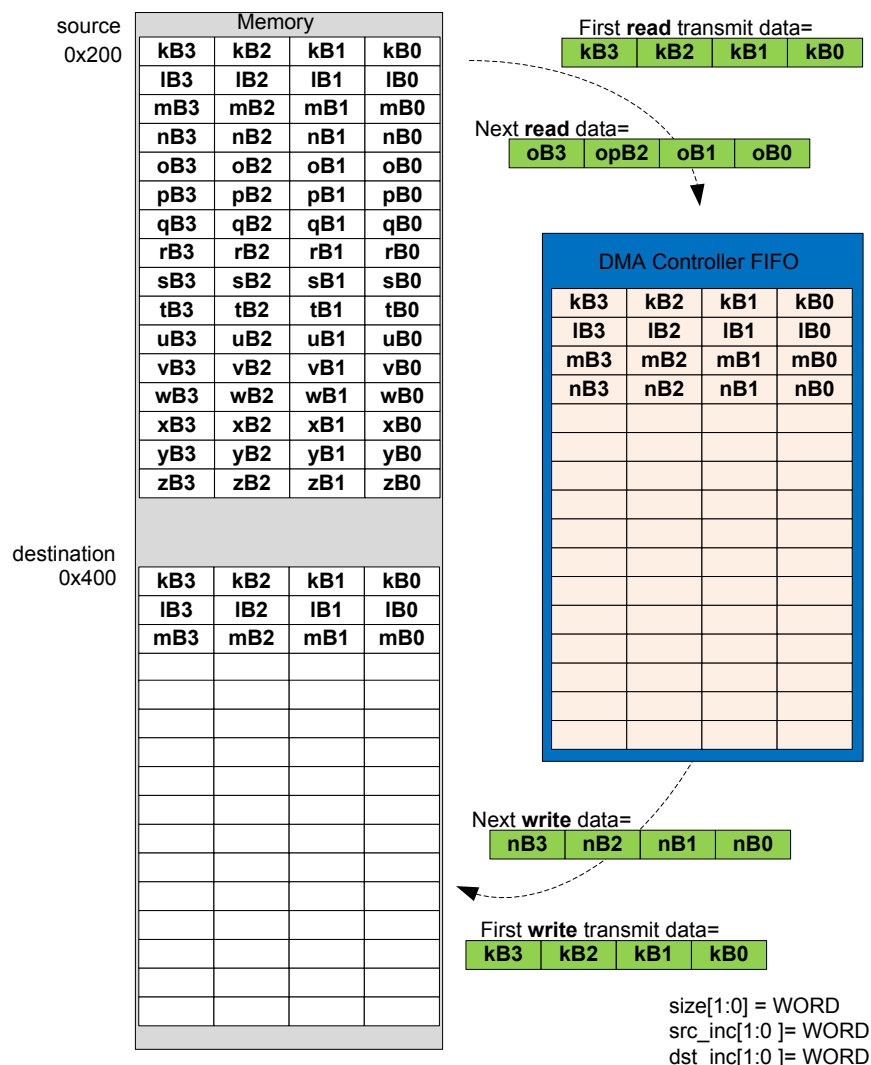

Figure 9.2. Word and Half-Word Endian Byte Swap Examples

The DMA channels' SIZE, SRCINC, and DSTINC bit-fields are programmed to best utilize memory resources. They provide a means for memory packing and unpacking, as well as for matching the size of data being transmitted to or received from an IO peripheral. The following figure shows how 32-bit words of data are read from a memory source into the DMA's internal transfer FIFO, and then written out to the memory destination. The memory organization in bytes is shown as well as the first read to and write from the DMA's FIFO.

### Figure 9.3. Memory-to-Memory Transfer WORD Size Example

The next example shows four variations of half-word sized transfers, with all possible combinations of half- and full-word source and destination increments. Note that when the size and source/destination increments are all configured for half-word, the resulting DMA transfer organization is equivalent to the full-word sized transfer in the previous example. The difference is that the half-word configuration requires twice as many DMA transfers.

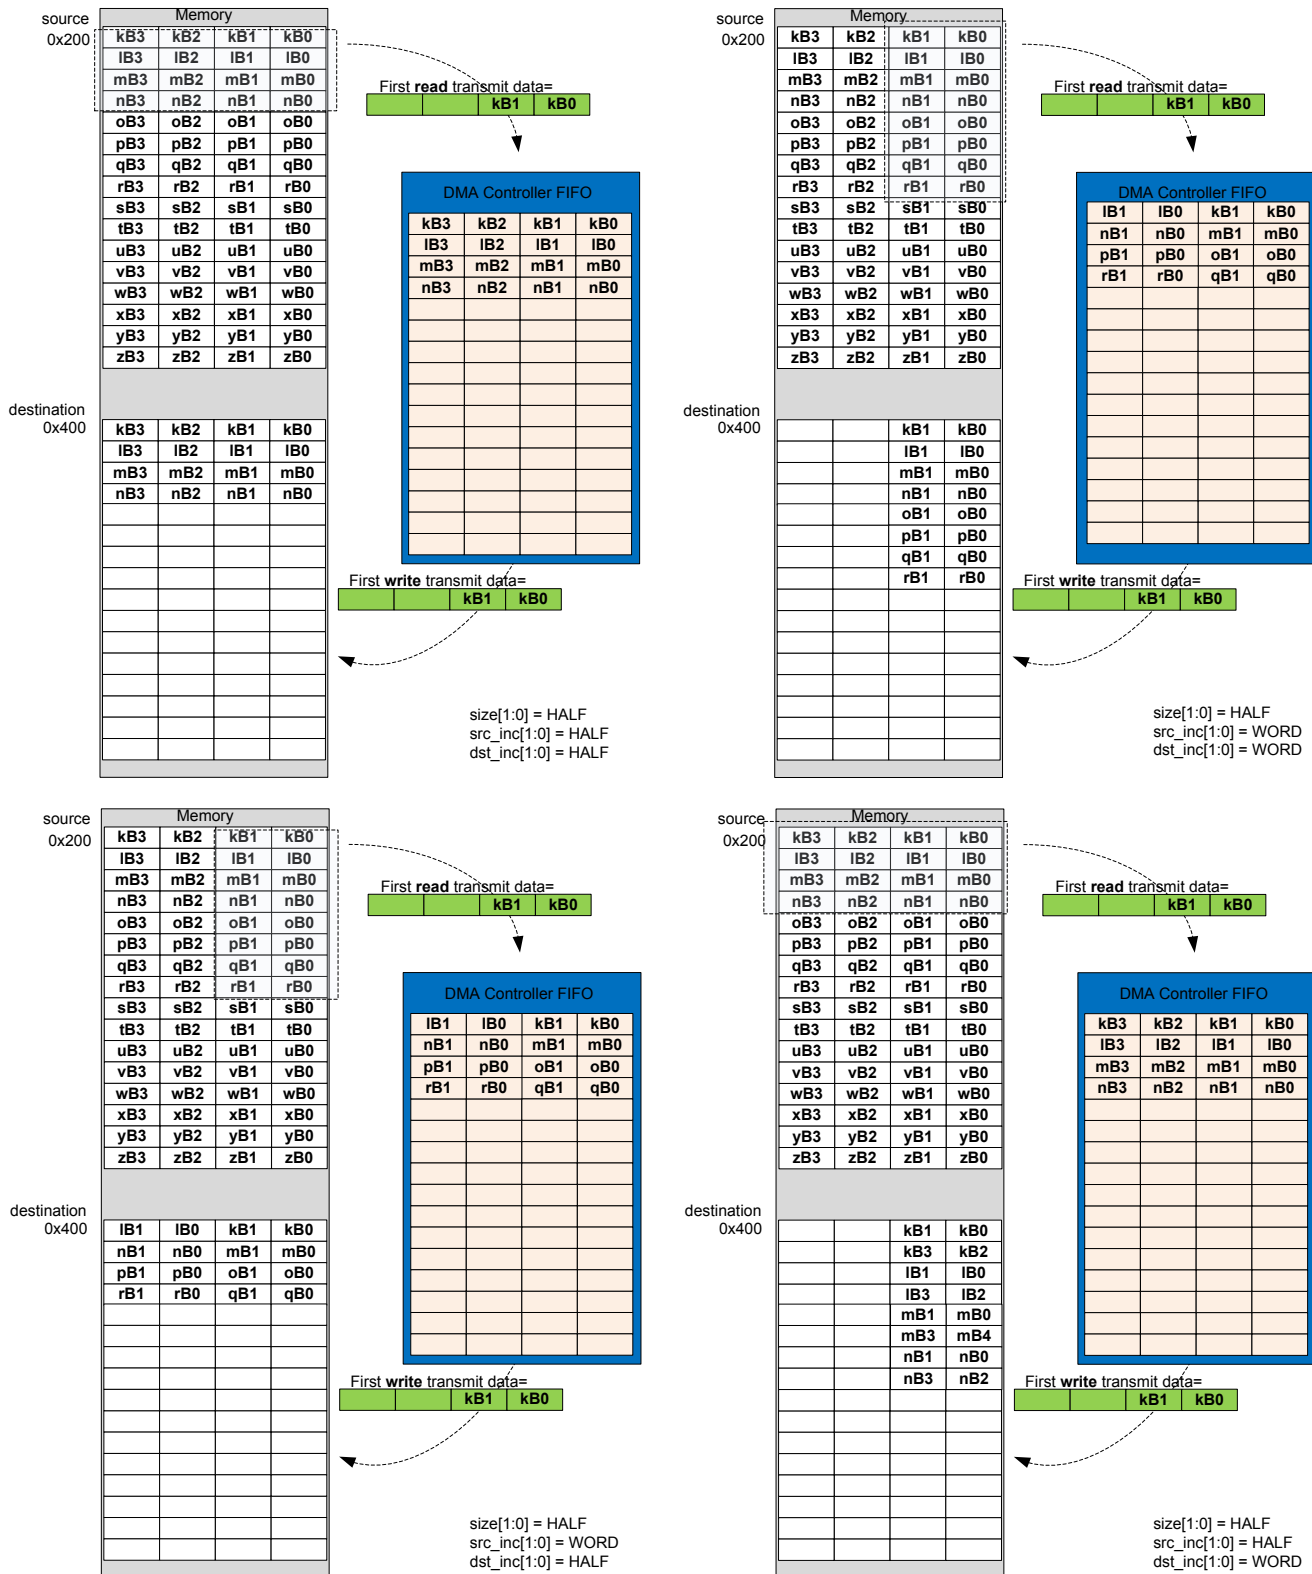

Figure 9.4. Memory-to-Memory Transfer HALF Size Examples

Fields SRCINCSIGN and DSTINCSIGN allow for address decrement. These can be used to mirror an image, for example, in the pixel copy application.

### 9.3.2 Channel Configuration

Each DMA channel has associated configuration and loop counter registers for controlling direction of address increment, arbitration slots, and descriptor looping.

#### 9.3.2.1 Address Increment/Decrement

Normally DMA transfers increment the source and destination addresses after each DMA transfer. Each channel is also capable of decrementing the source and/or destination addresses after each DMA transfer. This may be useful for flipping an array or copying data from tail to head. For example, a data packet might be prepared as an array of data with increasing addresses and then transmitted from the highest address to the lowest address, from tail to head.

After reset the SRCINCSIGN and DSTINCSIGN bits in the LDMA\_CHx\_CFG register are cleared causing the source and destination addresses to increment after each transfer. If the SRCINCSIGN bit is set, the DMA will decrement the source address after each transfer. If the DSTINCSIGN bit in the LDMA\_CHx\_CFG register is set, the DMA will decrement the destination address after each transfer. Setting only one of these bits will flip the data. Setting both bits will copy from tail to head, but will not flip the data.

The SRCINCSIGN and DSTINCSIGN bits apply to all descriptors used by that channel. Software should take care to set the starting source and/or destination address to the highest data address when decrementing.

#### 9.3.2.2 Loop Counter

Each channel has a LDMA\_CHx\_LOOP register that includes a loop counter field. To use looping, software should initialize the loop counter with the desired number of repetitions before enabling the transfer. A descriptor with the DECLOOPCNT bit set to TRUE will repeat the loop and decrement the loop counter until LOOPCNT = 0.

For a looping descriptor, with DECLOOPCNT=1, the LINK address in the LDMA\_CHx\_LINK register is used as the loop address. While LOOPCNT is greater than zero, the descriptor will execute and then the LDMA will load the next descriptor using the address specified in the LDMA\_CHx\_LINK register. This feature enables looping of multiple descriptors. To repeat a single descriptor, the LINK address of the descriptor should point to itself.

After LOOPCNT reaches zero, if the LINK bit in the descriptor LINK word is clear the transfer stops. If the LINK bit is set, the LDMA will load the next sequential descriptor located immediately following the looping descriptor. The behavior of the LINK bit is different for a looping descriptor. This is necessary because the LINK address is re-purposed as the loop address for a looping descriptor.

Note that LOOPCNT sets the number of repeats, not the number of iterations. The total number of loop iterations will be LOOPCNT plus 1. Normally, the LOOPCNT should be set to one or more repeats.

Also note that because there is only one LOOPCNT per channel, software intervention is required to update the LOOPCNT if a sequence of transfers contains multiple loops. It is also possible to use a write immediate DMA data transfer to update the LDMA\_CHx\_LOOP register.

### 9.3.3 Channel Select Configuration

The channel select block determines which peripheral request signal connects to each DMA channel.

This configuration is done by software through the SOURCESEL and SIGSEL fields of the LDMA\_CHn\_REQSEL register. SOURCESEL selects the peripheral and SIGSEL picks which DMA request signals to use from the selected peripheral.

#### 9.3.4 Starting a transfer

A transfer may be started by software, a peripheral request, or a descriptor load.

Software may initiate a transfer by setting the bit for the desired channel in the LDMA\_SREQ register. In this case the channel should set SOURCESEL to NONE to prevent unintentional triggering of the channel by a peripheral.

A peripheral may trigger the channel by configuring the peripheral source and signal as described in [9.3.3 Channel Select Configuration](#)

The LDMA may also be configured to begin a transfer immediately after a new descriptor is loaded by setting the STRUCTREQ field of the LDMA\_CHx\_CTRL register or descriptor word.

This configuration is done by software through the SOURCESEL and SIGSEL fields of the LDMA\_CHn\_REQSEL register. SOURCESEL selects the peripheral and SIGSEL picks which DMA request signals to use from the selected peripheral.

### 9.3.4.1 Peripheral Transfer Requests

By default peripherals issue a Single Request (SREQ) when any data is present. For peripherals with a data buffer or FIFO this occurs any time the FIFO is not empty. Upon receiving an SREQ the LDMA will perform one DMA transfer and stop till another request is made.

It is generally more efficient to wait for a peripheral to accumulate data and transfer in a burst. This both reduces overhead of the DMA engine and allows EM2 peripherals to save power by using the LDMA less often. To enable this set the IGNORESREQ bit in the LDMA\_CHx\_CTRL register (or descriptor) which will cause the LDMA to ignore SREQ's and wait for a full Request (REQ) signal. When the REQ is received the entire descriptor will be executed. For most peripherals with a FIFO the REQ signal is set when the FIFO is full, or a predetermined threshold has been reached. See the individual peripheral chapters for more information.

### 9.3.5 Managing Transfer Errors

LDMA transfer errors are normally managed using interrupts. Software should clear the ERROR flag in the bit in the LDMA\_IF register and enable error interrupts by setting the ERROR bit in the LDMA\_IEN register before initiating a DMA transfer

The LDMA interrupt handler should check the ERROR flag bit in the LDMA\_IF register. If the ERROR flag bit is set, it should then read the CHERROR field in the LDMA\_STATUS register to determine the errant channel. The interrupt handler should reset the channel and clear the ERROR flag bit in the LDMA\_IF register before returning.

### 9.3.6 Arbitration

While multiple channels are configured simultaneously the LDMA engine can only be actively copying data for one channel at a time. Arbitration determines which channel is being serviced at any point in time. The LDMA will choose a channel through arbitration, transfer BLOCK\_SIZE elements of that channel and then arbitrate again choosing another channel to service. This allows high priority channels to be serviced while lower priority channels are in the middle of a transfer.

#### 9.3.6.1 Arbitration Priority

There are two modes in determining priority when the controller arbitrates: fixed priority and round robin priority.

In fixed priority mode, channel 0 has the highest priority. As the channel number increases, the priority decreases. When the LDMA controller is idle or when a transfer completes, the highest priority channel with an active request is granted the transfer. This mode guarantees smallest latency for the highest priority requesters. It is best suited for systems where peak bandwidth is well below LDMA controller's maximum ability to serve. The drawback of this mode is the possibility of starvation for lowest priority requesters.

In the round robin priority mode, each active requesting channel is serviced in the order of priority. A late arriving request on a higher priority channel will not get serviced until the next round. This mode minimizes the risk of starving low-priority latency-tolerant requesters. The drawback of this mode is higher risk of starving low-latency requesters.

The NUMFIXED field in the LDMA\_CTRL register determines which channels are fixed priority and which are round robin. Channels lower than NUMFIXED are fixed priority while those above it are round robin. A value of 0x0 implies all channels are round robin. A value of 0x4 implies channels 0 through 3 are fixed priority and 4 through 7 are round robin. A value of 7 implies that channels 0 through 6 are fixed and channel 7 is round robin. This is functionally equivalent to having 8 fixed priority channels.

Fixed priority channels always take priority over round robin. As long as NUMFIXED is greater than 0, there is a possibility that a higher priority channel can starve the remaining channels.

To address the drawbacks of using fixed priority or round robin priority the LDMA implements the concept of arbitration slots. This allows for channels to have high bandwidth and low latency while preventing starvation of latency tolerant low priority channels.

Each channel has a two bit ARBSLOT field in its LDM\_CHx\_CFG register. This field only applies to channels marked as round robin (determined by NUMFIXED). The channels in the same arbitration slot are treated equally with round robin scheduling. Channels marked with a higher arbitration slot will get serviced more frequently. By default all channels are placed in arbitration slot 1.

Every time the channels in slot 1 get serviced the channels in slot 2 get serviced twice, those in slot 4 get serviced 4 times, and those in slot 8 get serviced 7 times. The specific arbitration allocation can be seen by the following table. The highest arbitration slot is serviced every other arbitration cycle, allowing for low latency response. If there are no requests from channels in arbitration slot then that slot is immediately skipped.

Table 9.1. Arbitration Slot Order

Arb-slot order	8	4	8	2	8	4	8	1	8	4	8	2	8	4
Arb-slot1								1						
Arb-slot2				1								1		
Arb-slot4		1				1				1				1
Arb-slot8	1		1		1		1		1		1		1	

The top row shows the order at which the arbitration slots are executed. The remaining part of the table shows a more visual interpretation of the arbitration order.

For example, if we have one low latency channel (CHNL0) and two latency tolerant channels (CHNL1 and CHNL2). We could use the following settings.

LDMA\_CTRL.NUMFIXED = 0; set round robbin for all channels.

CHNL0\_CFG.ARBSLOTS = TWO;

CHNL1\_CFG.ARBSLOTS = ONE;

CHNL2\_CFG.ARBSLOTS = ONE;

If all channels are constantly requesting transfers, then the arbitration order is: CHNL0, CHNL1, CHNL0, CHNL2, CHNL0, CHNL1, CHNL0, CHNL2, CHNL0, etc

Note, there are no channels assigned to arbitration slot four or eight in this exampl, so thoes slots are skipped and the final sequence is ARBSLOT2, ARBSLOT1, ARBSLOT2, ARBSLOT1, etc...

Channel 1 and Channel 2 are selected in round robin order when arbitration slot 1 is executed.

If we replace the ARBSLOTS value for channel 0 with EIGHT, then the sequence would look like the following:

CHNL0, CHNL0, CHNL0, CHNL0, CHNL1, CHNL0, CHNL0, CHNL0, CHNL2, CHNL0, CHNL0, CHNL0, CHNL0, CHNL1, etc.

### 9.3.6.2 DMA Transfer Arbitration

In addition to the inter channel arbitration, software can configure when the controller arbitrates during a DMA transfer. This provides reduced latency to higher priority channels when configuring low priority transfers with more arbitration cycles.

The LDMA provides four bits that configure how many DMA transfers occur before it re-arbitrates. These bits are known as the BLOCKSIZE bits and they map to the arbitration rate as shown below. For example, if BLOCKSIZE = 4 then the arbitration rate is 6, that is, the controller arbitrates every 6 DMA transfers.

[Table 9.2 AHB bus transfer arbitration interval on page 135](#) lists the arbitration rates.

**Table 9.2. AHB bus transfer arbitration interval**

BLOCKSIZE	Arbitrate after x DMA transfers
0	x = 1
1	x = 2
2	x = 3
3	x = 4
4	x = 6
5	x = 8
6	x = 12
7	x = 16
8	x = 24
9	x = 32
10	x = 64
11	x = 128
12	x = 256
13	x = 512
14	x = 1024
15	x = lock

**Note:**

Software must take care not to assign a low-priority channel with a large BLOCKSIZE because this prevents the controller from servicing high-priority requests, until it re-arbitrates.

The number of DMA transfers that need to be done is specified by the user in XFERCNT. When XFERCNT > BLOCKSIZE and is not an integer multiple of BLOCKSIZE then the controller always performs sequences of BLOCKSIZE transfers until XFERCNT < BLOCKSIZE remain to be transferred. The controller performs the remaining XFERCNT transfers at the end of the DMA cycle.

Software must store the value of the BLOCKSIZE bits in the channel control data structure. See [9.3.7.1 XFER descriptor structure](#) for more information about the location of the BLOCKSIZE bits in the data structure.

### 9.3.7 Channel descriptor data structure

Each channel descriptor consists of four 32-bit words:

- CTRL - control word contains information like transfer count and block size.
- SRC - source address points to where to copy data from
- DST - destination address points to where to copy data to
- LINK - link address points to where to load the next linked descriptor

These words map directly to the LDMA\_CHx\_CTRL, LDMA\_CHx\_SRC, LDMA\_CHx\_DST, and LDMA\_CHx\_LINK registers. The usage of the SRC and DST fields may differ depending on the structure type

There are three different types of descriptor data structures: **XFER**, **SYNC**, and **WRI**

#### 9.3.7.1 XFER descriptor structure

This descriptor defines a typical data transfer which may be a Normal, Link, or Loop transfer.

Only this structure type can be written directly into LDMA's registers by the CPU. All descriptors may be linked to. Please refer to the register descriptions for additional information.

For specifying XFER structure type, set STRUCTTYPE to 0. Please see the peripheral register descriptions for information on the fields in this structure.

Name	Bit Position																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTRL	DSTMODE	SRCMODE	DSTINC		SIZE		SRCINC		IGNORESREQ	DECLOOPCNT	REQMODE	DONEIFSEN	BLOCKSIZE			BYTESWAP	XFERCNT											STRUCTREQ			STRUCTTYPE	
SRC	SRCADDR																															
DST	DSTADDR																															
LINK	LINKADDR																															
LINKMODE																																

### 9.3.7.2 SYNC descriptor structure

This descriptor defines an intra-channel synchronizing structure. It allows the channel to wait for some external stimulus before continuing on to the next descriptor. This structure is also used to provide stimulus to another channel to indicate that it may continue.

For example channel 1 may be configured to transfer a header into a buffer while channel 2 is simultaneously transferring data into the same structure. When channel 1 has completed it can wait for a sync signal from channel 2 before transferring the now complete buffer to a peripheral.

Sync descriptors do nothing until a condition is met. The condition is formed by the SYNCTRIG field in the LDMA\_SYNC register and the MATCHEN and MATCHVAL fields of the descriptor. When  $(\text{SYNCTRIG} \& \text{MATCHEN}) == (\text{MATCHVAL} \& \text{MATCHEN})$  the next descriptor is loaded. In addition to waiting for the condition a Link descriptor can set or clear bits in SYNCTRIG to meet the conditions of another channel and cause it to continue. The CPU also has the ability to set and clear the SYNCTRIG bits from software.

This structure type can only be linked in from memory.

For specifying SYNC structure type, set STRUCTTYPE to 1.

Name	Bit Position																																	
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
CTRL												DONEIFSEN																			STRUCTTYPE			
SRC																	SYNCCLR								SYNCSET									
DST																	MATCHEN								MATCHVAL									
LINK	LINKADDR																														LINK		LINKMODE	

Bit	Name	Description
1:0	STRUCTTYPE	<b>Descriptor Type</b> This field indicates which type of descriptor this is. It must be 1 for a SYNC descriptor.
20	DONEIFSEN	<b>Done if Set indicator</b> If set the interrupt flag will be set descriptor completes.
7:0	SYNCCLR	<b>Sync Trigger Clear</b> This bit-field is used to clear corresponding bits within the SYNCTRIG field of the SYNC LDMA_SYNC register. To clear a given bit, a one should be loaded to the corresponding bit. Set is given priority over clear if both corresponding bits are loaded with a one. The sync trigger clear function can only be used when loaded from a linked structure. Alternately, the user can directly write the SYNCTRIG bit-field if required.
7:0	SYNCSET	<b>Sync Trigger Set</b> This bit-field is used to set corresponding bits within the SYNCTRIG bit-field. To set a given bit, a one should be loaded to the corresponding bit. Set is given priority over clear if both corresponding bits are loaded with a one. The sync trigger set function can only be used when loaded from a linked structure. Alternately, the user can directly write the SYNCTRIG bit-field if required.
7:0	MATCHEN	<b>Sync Trigger Match Enable</b> This bit-field serves as the SYNCTRIG match enable. A sync match triggers the load of the next linked DMA structure as specified by link_mode, when: $(\text{SYNCTRIG} \& \text{MATCHEN}) == (\text{MATCHVAL} \& \text{MATCHEN})$ .
7:0	MATCHVAL	<b>Sync Trigger Match Value</b>

Bit	Name	Description
		This bit-field serves as the SYNCTRIG match value. A sync match triggers the load of the next linked DMA structure as specified by link_mode, when: (SYNCTRIG & MATCHEN) == (MATCHVAL & MATCHEN).

### 9.3.7.3 WRI descriptor structure

This descriptor defines a write-immediate structure. This allows a list of descriptors to write a value to a register or memory location. For example, if a channel wishes to perform two loops in a descriptor sequence a WRI may be used to program the loop count for the second loop.

This structure type can only be linked in from memory.

For specifying WRI structure type, set STRUCTTYPE to 2.

Name	Bit Position																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INTC												DONEIFSEN															STRUCTTYPE					
SRC	IMMVAL																															
DST	DSTADDR																															
LINK	LINKADDR																											LINK		LINKMODE		
Bit	Name		Description																													
1:0	STRUCTTYPE		<b>Descriptor Type</b> This field indicates which type of descriptor this is. It must be 2 for a WRI descriptor.																													
20	DONEIFSEN		<b>Done if Set indicator</b> If set the interrupt flag will be set descriptor completes.																													
31:0	IMMVAL		<b>Immediate Value for Write</b> This bit-field specifies the immediate data value that is to be written to the address pointed to by DSTADDR. Only one write occurs for WRI structures.																													
31:0	DSTADDR		<b>Address to write</b> This bit-field specifies the address the immediate data should be written to.																													

### 9.3.8 Interaction with the EMU

The LDMA interacts with the Energy Management Unit (EMU) to allow transfers from a low energy peripheral while in EM2 DeepSleep. For example, when using the LEUART in EM2 DeepSleep the EMU can wake up the LDMA sufficiently long to allow data transfers to occur. See section "DMA Support" in the LEUART documentation.

### 9.3.9 Interrupts

The LDMA\_IF Interrupt flag register contains one DONE bit for each channel and one combined ERROR bit. When enabled, these interrupts are available as interrupts to the Cortex-M4 core. They are combined into one interrupt vector, DMA\_INT. If the interrupt for the DMA is enabled in the ARM Cortex-M4 core, an interrupt will be made if one or more of the interrupt flags in LDMA\_IF and their corresponding bits in LDMA\_IEN are set.

When a descriptor finishes execution the interrupt flag for that channel will be set if the DONEIFSEN field of the LDMA\_CHx\_LOOP register is set. If LINK and DONEIFSEN are both set when the descriptor completes the interrupt and the linked descriptor will be immediately loaded. When the final descriptor in a linked list (LINK = 0) is finished the interrupt flag is always set regardless of the state of DONEIFSEN.

### 9.3.10 Debugging

For a peripheral request DMA transfer, if software sets a bit for a channel in the LDMA\_DBGHALT register then the DMA will halt during a debug halt and the SRC and DST registers in the debug window will show the transfer in progress. Otherwise, during debug halt the DMA will continue to run and complete the entire transfer causing the descriptor registers to indicate the transfer has completed.

## 9.4 Examples

This section provides examples of common LDMA usage. All examples assume the LDMA is in the reset state with the channel being configured disabled and LDMA\_CHx\_CFG, LDMA\_CHx\_LOOP, and LDMA\_CHx\_LINK cleared.

### 9.4.1 Single Direct Register DMA Transfer

This simple example uses only the Channel Descriptor registers directly and does not use linking. Software writes directly to the LDMA channel registers. This example does not use a memory based descriptor list.

This example is suitable for most simple transfers that are limited to transferring one block of data. It supports anything that can be done using a single descriptor. This includes endian conversion and packing/unpacking data. Channel 0 is used for this example.

The LDMA will be used to copy 127 contiguous half words (254 bytes) from 0x0 to 0x1000. It will allow arbitration every 4 transfers and is triggered by a CPU write to the LDMA\_SWREQ register. The CH0 interrupt flag will be set when the transfer completes since the descriptor does not link to another descriptor.

- Configure LDMA\_CH0\_CTRL
  - DSTMODE = 0 (absolute)
  - SRCMODE = 0 (absolute)
  - SIZE = HALFWORD (16 bits)
  - DSTINC = 0 (1 half-word)
  - SRCINC = 0 (1 half-word)
  - DECLOOPCNT=0 (unused)
  - REQMODE = 1 (one request transfers all data)
  - BLOCKSIZE = 3 (4 transfers)
  - BYTESWAP=0 (no byte swap)
  - XFERCNT=127 (transfer 127 half words)
  - STRUCTTPYE=0 (TRANSFER)
- Write source address to LDMA\_CH0\_SRC register
- Write destination address to LDMA\_CH0\_DST register
- Configure the LDMA\_CH0REQSEL register for the desired peripheral or select none for a memory-to-memory transfer
- Clear and enable interrupts.
  - Write a 1 to bit 0 of the LDMA\_IFC register to clear the CH0 DONE flag
  - Write a 1 to bit 0 of the LDMA\_IEN register to enable the CH0 interrupt
- Write a 1 to bit 0 of the LDMA\_CHEN register to enable CH0

The REQMODE field is normally cleared to zero for a peripheral request transfer and will transfer the specified block size for each peripheral request. The REQMODE may be set to 1 for a memory-to-memory transfer or any time it is desired for a single DMA request to initiate complete transfer.

### 9.4.2 Descriptor Linked List

This example shows how to use a Linked List of descriptors. Each descriptor has a link address which points to the next descriptor in the list. A descriptor may be removed from the Linked list by altering the Link address of the one before it to point to the one after it. Descriptor Linked lists are useful when handling an array of buffers for communication data. For example, a bad packet can be removed from a receiver queue by simply removing the descriptor from the linked list.

Software loads the first descriptor into the DMA by writing the descriptor address to LDMA\_CHx\_LINK and setting the bit for that channel in the LDMA\_LINKLOAD register. This method is preferred when using a linked list in memory since it treats the first descriptor just like all the others. However, it is also allowed acceptable for software to write the first descriptor directly to the LDMA registers.

In this example 4 descriptors are executed in series. the interrupt flag is set after the 2nd and 4th (last) descriptors have completed.

- Prepare a list of descriptors using the XFER structure type in RAM
- Initialize the CTRL, SRC, and DST members as desired
  - Setting STRUCTREQ in the CTRL word for descriptors 2-4 will cause them to begin transferring data as soon as they are loaded.
- Write 0x00000013 to the LINK member of all but the last descriptor
  - LINKMODE = 1 (relative addressing)
  - LINK = 1 (Link to the next descriptor)
  - LINKADDR = 0x00000010 (size of descriptor)
- Set the DONEIFSEN bit in the CTRL member of the 2nd structure so that the interrupt flag will be set when it completes
- Write 0x00000000 to the LINK member of the last descriptor
  - LINK = 0 (Do not link to the next descriptor)
  - LINKMODE = 0 (don't care)
  - LINKADDR = 0x00000000 (don't care)

Each descriptor now points to the start of the next descriptor as shown on the left in [Figure 9.5 Descriptor Linked List on page 140](#). To remove a descriptor from the linked list modify the LINK address of the descriptor of the one before to point to the one after. For example to remove the third descriptor, add 0x00000010 to the LINK register of the second descriptor. The second descriptor will now point to the forth descriptor and skip over the third descriptor as shown on the right in [Figure 9.5 Descriptor Linked List on page 140](#).

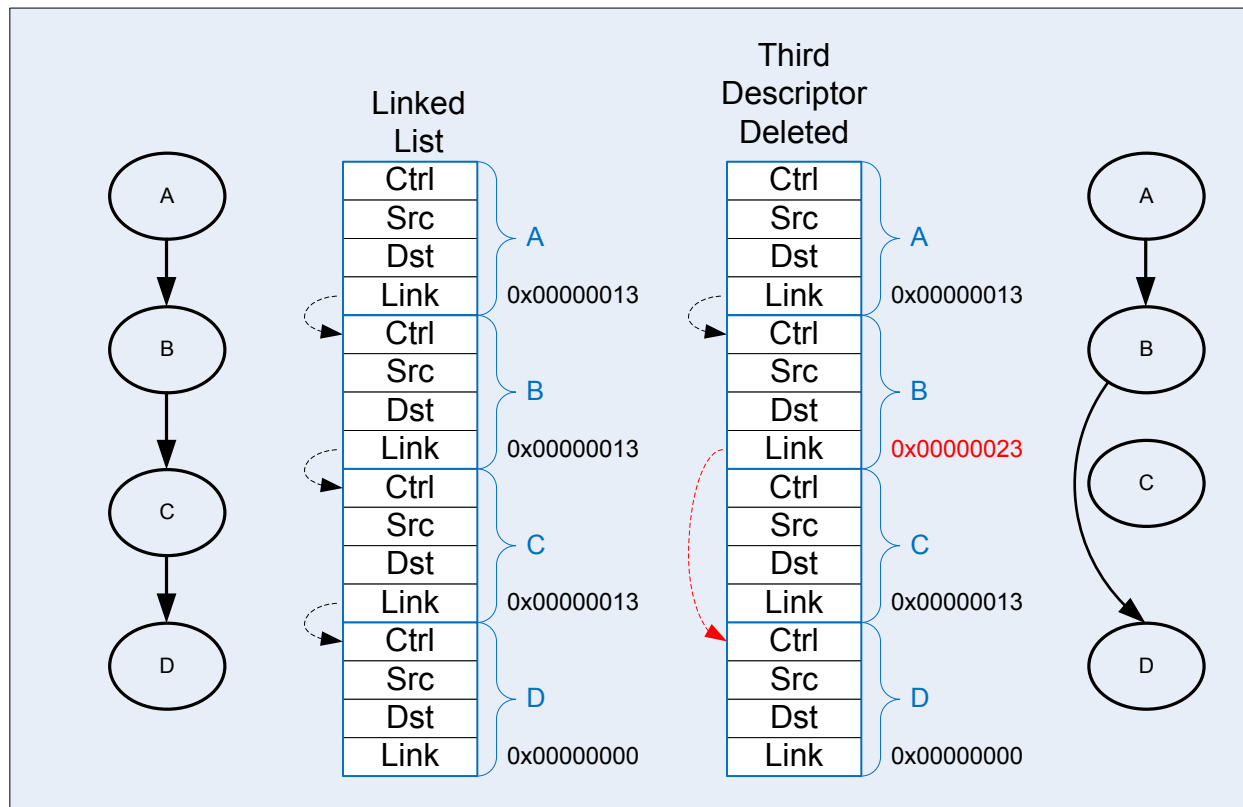

Figure 9.5. Descriptor Linked List

To start execution of the linked list of descriptors:

- Write the absolute address of the first descriptor to the LINKADR field of the LDMA\_CH0\_LINK register
- Set the LINK bit of the LDMA\_CH0\_LINK register.
- Configure the LDMA\_CH0REQSEL register for the desired peripheral or select none for memory-to-memory
- Clear and enable interrupts as desired
- Set bit 0 in the LDMA\_LINKLOAD register to initiate loading and execution of the first descriptor

Alternatively, software can manually copy the first descriptor contents to the LDMA\_CH0\_CTRL, LDMA\_CH0\_SRC, LDMA\_CH0\_DST, and LDMA\_CH0\_LINK registers and then enable the channel in the LDMA\_CHEN register.

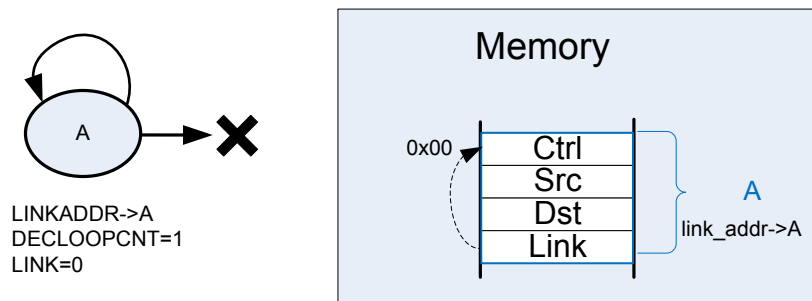

### 9.4.3 Single Descriptor Looped Transfer

This example demonstrates how to use looping using a single descriptor. This method allows a single DMA transfer to be repeated a specified number of times. The looping descriptor is stored in memory and reloaded by hardware. After a specified number of iterations, the transfer stops.

CH0 is setup to copy 4 words from the ADC FIFO into a 15 word buffer at 0x1000. It repeats 4 times to fill the entire 16 word buffer. An interrupt will fire when the entire 16 words have been transferred.

Initialize the Linked descriptor in memory as follows:

- Configure CTRL member
  - DSTMODE = 0 (absolute)
  - SRCMODE = 0 (absolute)
  - SIZE = WORD
  - DSTINC = 0 (1 WORD)
  - SRCINC = 3 (0 WORDS)
  - DECLOOPCNT=1 (decrement loop count)
  - REQMODE=1 (Use XFERCNT)
  - BLOCKSIZE = 4 (4 words)
  - BYTESWAP=0 (no swap)
  - XFERCNT= 4 (4 words)
  - STRUCTTYPE=0 (TRANSFER)
  - IGNORESREQ=1 (ignore single requests)
- Write the address ADC0\_SINGLEDATA register to the SRC member
- Write 0x1000 address to DST member
- Configure the LINK member
  - LINK = 0 (stop after loop)
  - MODE = 1 (relative link address)
  - LINKADDR = 0 (point to ourself)
- Configure the Channel
  - Write the desired number of repeats to the LDMA\_CH0\_LOOP register
  - SOURCESEL in LDMA\_CH0REQSEL = ADC0 (select the ADC)
  - SIG in LDMA\_CH0REQSEL = ADC0SCAN (select the single conversion request)
- Clear and enable interrupts
- Load the descriptor using LINKLOAD as described in [9.4.2 Descriptor Linked List](#)

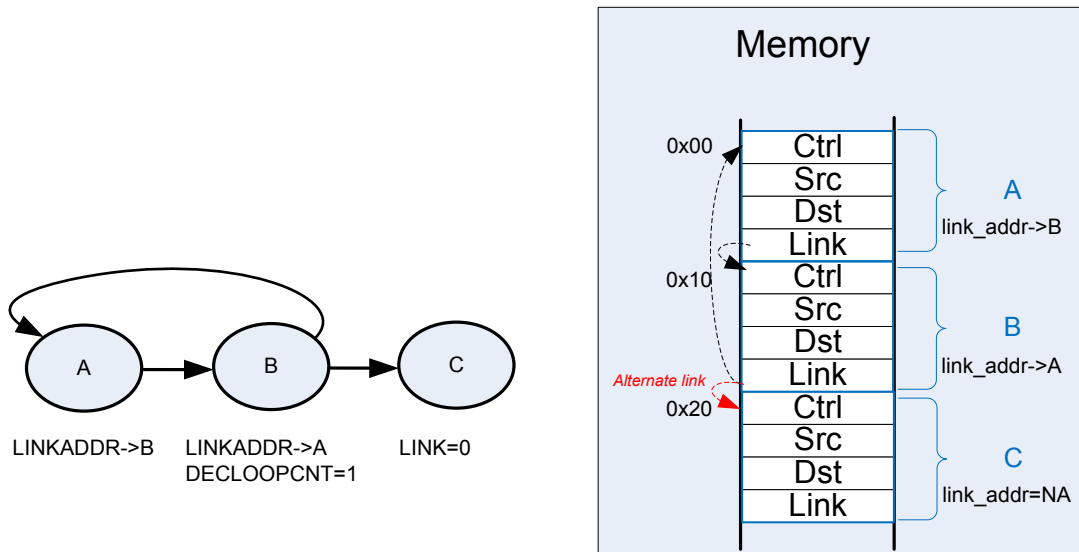

**Figure 9.6. Single Descriptor Looped Transfer**

Note that the looping descriptor must be stored in memory, because it must load itself from the link address in memory on each iteration.

#### 9.4.4 Descriptor List with Looping

This example uses a descriptor list in memory with looping over multiple descriptors. This example also uses the looping feature and continues on with the next sequential descriptor after looping completes.

The descriptor list in memory is shown in figure [Figure 9.7 Descriptor List with Looping on page 143](#). Descriptor A links to descriptor B. Descriptor B has the DECLOOPCNT bit enabled and loops back to the start of descriptor A. The LINK address of descriptor B is used for the loop address. The LINK bit is set to indicate that execution will continue after completion of looping. Once the LOOPCNT reaches zero, the LDMA will load descriptor C. Descriptor C must be located immediately following descriptor B.

**Figure 9.7. Descriptor List with Looping**

Initialization is similar to the single looping descriptor with the following modifications.

- Set the LINK bit in descriptors A and B
- write the address of descriptor A into the LIKADDRESS of descriptor B
- write the address of descriptor B into the LIKADDRESS of descriptor A
- Descriptor C must be located immediately after descriptor B in memory

### 9.4.5 Simple Inter-Channel Synchronization

The LDMA controller features synchronization structures which allow differing channels and/or hardware events to pause a DMA sequence, and wait for a synchronizing event to restart it.

In this example DMA channel 0 and 1 are tasked with the transfer of different sets of data. Channel 0 has two transfer structures, and channel 1 just one, but channel 0 must wait until channel 1 has completed its transfer before it starts its second transfer structure.

Pausing channel 0 is accomplished by inserting a sync wait structure between the two transfer structures. This sync structure waits on SYNCTRIG[7] to be set by a sync set/clear structure which is controlled by channel 1. Sync structures do not transfer data, they can only set, clear, or wait to match the SYNCTRIG[7:0] bits. Note that sync structures cannot decrement loop counter.

```
LDMA_SYNC
  SYNCTRIG=0x0 (at time 0)

LDMA_CH0

  Structure A @ 0x00          Structure B @ 0x10          Structure C @ 0x20
  CTRL                      CTRL                      CTRL
    STRUCTTYPE=XFER          STRUCTTYPE=SYNC          STRUCTTYPE=XFER
  LINK                      LINK                      LINK
    LINKADDR[29:0]=0x00000004 LINKADDR[29:0]=0x00000008 LINKADDR[29:0]=NA
    LINK=1                  LINK=1                  LINK=0

                                DST
                                MATCHEN=0x80
                                MATCHVAL=0x80 (waits for SYNCTRIG[7]=1)

LDMA_CH1

  Structure Y @ 0x30          Structure Z @ 0x40
  CTRL                      CTRL
    STRUCTTYPE=XFER          STRUCTTYPE=SYNC
  LINK                      LINK
    LINKADDR[29:0]=0x00000010 LINKADDR=NA
    LINK=1                  LINK=0

                                SRC
                                SRCCLR=0x0
                                SRCSET=0x80 (sets SYNCTRIG[7])
```

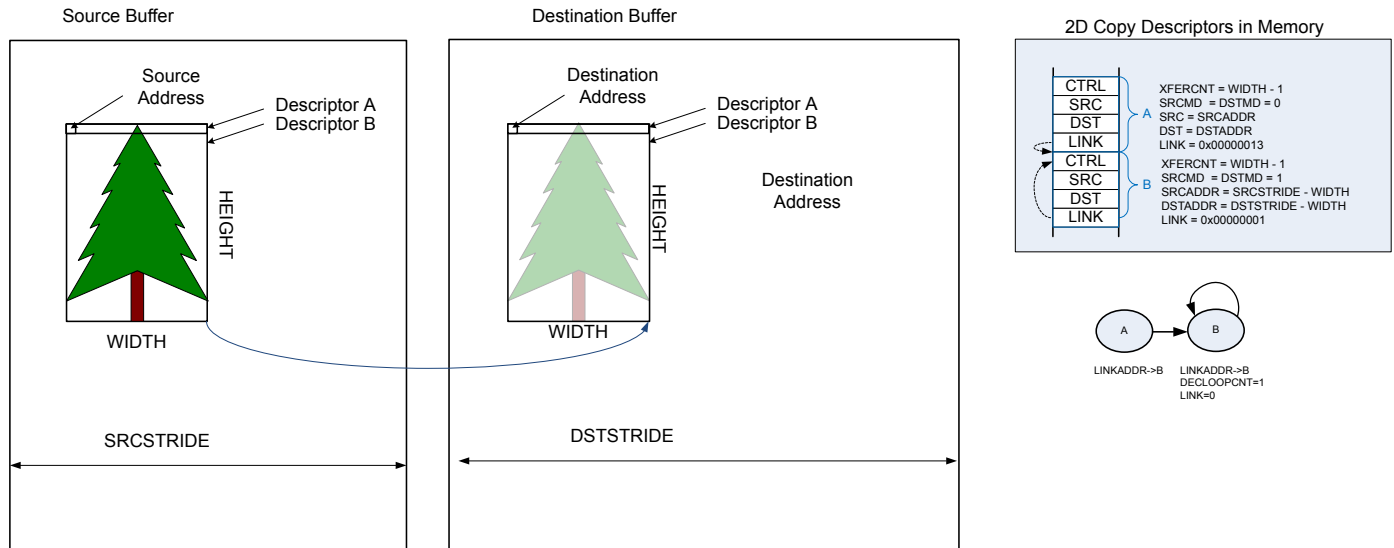

**Figure 9.8. Simple Intra-channel Synchronization Example**

Both A and Y effectively start at the same time. A finishes earlier, then it links to B, which waits for the SYNC[7] bit to be set before loading C. Y finishes after B is loaded, and it links to sync structure Z, which sets the SYNC[7] bit. Channel 0 responds to the trigger set by loading C for the final data transfer.

### 9.4.6 2D Copy

The LDMA can easily perform a 2D copy using a descriptor list with looping. This set up is visualized in [Figure 9.9 2D copy on page 146](#).

For an application working with graphics, this would mean the ability to copy a rectangle of a given width and height from one picture to another.

**Figure 9.9. 2D copy**

The first descriptor will use absolute addressing mode and the source and destination addresses should point to the desired target addresses. The first descriptor will copy only the first row. The **XFERCNT** of the first descriptor is set to the desired width minus one.

- **CTRL**
  - **XFERCNT** =  $WIDTH - 1$
  - **SRCMD** = 0 (absolute)
  - **DSTMD** = 0 (absolute)
- **SRCADDR** = target source address
- **DSTADDR** = target destination address
- **LINK** = 0x00000013
  - **LINK**=1
  - **LINKMD**=1
  - **LINKADDR**=0x00000010 (point to next descriptor)

The second descriptor will use relative addressing and the source and destination addresses are set to the desired offset. After the completion of the first descriptor, the address registers will point to the last address transferred. Thus, the width must be subtracted from the stride to get the offset. The second descriptor uses looping and the link register has not offset.

- **CTRL**
  - **XFERCNT** =  $WIDTH - 1$
  - **SRCMD** = 1 (relative)
  - **DSTMD** = 1 (relative)
  - **DECLOOPCNT** = 1
- **SRCADDR** = desired source offset ( $SRCSTRIDE - WIDTH$ )
- **DSTADDR** = desired destination offset ( $DSTSTRIDE - WIDTH$ )
- **LINK** = 0x00000001
  - **LINK**=0
  - **LINKMD**=1 (relative)
  - **LINKADDR**=0x00000000 (no offset)

Because the first descriptor already transferred one row, the number of looping repeats should be the desired height minus two. Therefore, LOOPCNT should be set to HEIGHT minus two before initiating the transfer.

This same method is easily extended to copy multiple rectangles by linking descriptors together. To initialize the LDMA\_CHx\_LOOP register, precede each descriptor pair described above with a write immediate descriptor which writes the desired value to the LOOPCNT field of the LDMA\_CHx\_LOOP register.

### 9.4.7 Ping-Pong

Communication peripherals often use ping-pong buffers. Ping-pong buffers allow the CPU to process data in one buffer while a peripheral transmits or receives data in the other buffer.

Both transmit and receive ping-pong buffers are easily implemented using the LDMA. In either case, this requires two descriptors as shown in [Figure 9.10 Infinite Ping-Pong Example on page 148](#). The LINKADDR field of the LINK member should point to the other descriptor. Using two adjacent descriptors and relative link addressing ensures the descriptors are easily reloadable.

**Figure 9.10. Infinite Ping-Pong Example**

A **receiver** ping-pong buffer controller consists of two buffers and two descriptors stored in memory that point to the two buffers. Once initialized, as the peripheral receives data, it will fill the first buffer. Once the first buffer is full, it will link automatically to the second buffer and generate an interrupt. Software will then process the data in the first buffer while the LDMA is transferring data to the second buffer. For a receiver ping-pong buffer each descriptor should link to the other descriptor. The link bit should be set to provide infinite ping pong between the two buffers. The DONEIFS bit in each descriptor should be set to generate an interrupt on the completion of each descriptor.

- Descriptor A
  - CTRL
    - DONEIFS = 1
    - other settings as desired
  - SRCADDR = peripheral source address
  - DSTADDR = memory destination address
  - LINK = 0x00000013
    - LINKADDR = 0x00000010 (next descriptor)
    - LINK = 1 (link to next descriptor)
    - LINKMD = 1 (relative addressing)
- Descriptor B
  - CTRL
    - DONEIFS = 1
    - other settings as desired
  - SRCADDR = peripheral source address
  - DSTADDR = memory destination address
  - LINK = 0xFFFFFFFF3
    - LINKADDR = 0xFFFFFFFF0 (previous descriptor)
    - LINK = 1 (link to previous descriptor)
    - LINKMD = 1 (relative addressing)

For **transmitter** ping-pong buffer, software will fill the first buffer and then initiate the DMA transfer. The LDMA will transmit the first buffer data while software is filling the second buffer. In this case, the two descriptors should point to each other, but not automatically continue to the second buffer. The LINK bit should be cleared to zero. Once software has loaded the first buffer, it will use the

LINKLOAD bit to load the first descriptor and transmit the data. The DONEIFS need not be set in each descriptor. The DMA will stop and then generate an interrupt at the completion of each descriptor.

- Descriptor A
  - CTRL
    - DONEIFS = 0
    - other settings as desired
  - SRCADDR = memory source address
  - DSTADDR = peripheral destination address
  - LINK = 0x00000013
    - LINKADDR = 0x00000010 (next descriptor)
    - LINK = 0 (link to next descriptor)
    - LINKMD = 1 (relative addressing)
- Descriptor B
  - CTRL
    - DONEIFS = 0
    - other settings as desired
  - SRCADDR = memory source address
  - DSTADDR = peripheral destination address
  - LINK = 0xFFFFFFFF3
    - LINKADDR = 0xFFFFFFFF0 (previous descriptor)
    - LINK = 0 (link to previous descriptor)
    - LINKMD = 1 (relative addressing)

#### 9.4.8 Scatter-Gather

Scatter-Gather in general refers to a process that copies data from multiple locations scattered in memory and gathers the data to a single location in memory, or vice versa. A simple descriptor list allows data gathering. For example, data from a discontinuous list of buffers might be copied to a contiguous sequential array of buffers. The inverse is also possible when a sequential array of buffers is scattered to a discontinuous list of available buffers. See section [9.4.2 Descriptor Linked List](#).

Some DMAs which only have two descriptors implement scatter-gather by using one descriptor to modify the other descriptor. While it is possible to implement this same behavior using the LDMA, it is much more straight-forward to just use a simple descriptor list.

## 9.5 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	LDMA_CTRL	RW	DMA Control Register
0x004	LDMA_STATUS	R	DMA Status Register
0x008	LDMA_SYNC	RWH	DMA Synchronization Trigger Register (Single-Cycle RMW)
0x020	LDMA_CHEN	RWH	DMA Channel Enable Register (Single-Cycle RMW)
0x024	LDMA_CHBUSY	R	DMA Channel Busy Register
0x028	LDMA_CHDONE	RWH	DMA Channel Linking Done Register (Single-Cycle RMW)
0x02C	LDMA_DBGHALT	RW	DMA Channel Debug Halt Register

## 9.6 Register Description

### 9.6.1 LDMA\_CTRL - DMA Control Register

Offset	Bit Position																															
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset						0x7										0x00																
Access						RW										RW																
Name						NUMFIXED										SYNCPRSCLEN																

Bit	Name	Reset	Access	Description
31:27	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
26:24	NUMFIXED	0x7	RW	<b>Number of Fixed Priority Channels</b>  This field defines the number of Fixed Priority Arbitration channels. Channels CH0 through CH(n-1) are fixed, and channels CH(n) through CH7 are round robin, where n is the field value. The reset value will give all fixed channels.
23:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:8	SYNCPRSCLEN	0x00	RW	<b>Synchronization PRS Clear Enable</b>  Setting a bit in this field will enable the corresponding PRS input to clear the respective bit in the SYNCTRIG field of the LDMA_SYNC register. Refer to the PRS section for a list of the PRS inputs.
7:0	SYNCPRSETEN	0x00	RW	<b>Synchronization PRS Set Enable</b>  Setting a bit in this field will enable the corresponding PRS input to set the respective bit in the SYNCTRIG field of the LDMA_SYNC register. Refer to the PRS section for a list of the PRS inputs.

## 9.6.2 LDMA\_STATUS - DMA Status Register

Offset	Bit Position																																		
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reset				0x08								0x10								0x0								0x0						0	0
Access				R								R								R								R						R	R
Name				CHNUM								FIFOLEVEL								CHERROR								CHGRANT						ANYREQ	ANYBUSY

**9.6.3 LDMA\_SYNC - DMA Synchronization Trigger Register (Single-Cycle RMW)**

Offset	Bit Position																															
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									RWH							
Name																									SYNCTRIG							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	SYNCTRIG	0x00	RWH	<b>Synchronization Trigger</b>  The SYNC trigger field allows a transfer to pause until a specified trigger bit is set or cleared. The SYNC trigger bits may be set and cleared by a SYNC descriptor, PRS signal, or software. Note: software requires to use single-cycle read-modify-write, detailed in

**9.6.4 LDMA\_CHEN - DMA Channel Enable Register (Single-Cycle RMW)**

Offset	Bit Position																															
0x020	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									RWH							
Name																									CHEN							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	CHEN	0x00	RWH	<b>Channel Enables</b>  Setting one of these bits will enable the respective DMA channel. If cleared while a transfer is in progress, the current transfer block will complete. The remaining blocks will pause until resumed later by setting this bit again. Note: software requires to use single-cycle read-modify-write, detailed in

**9.6.5 LDMA\_CHBUSY - DMA Channel Busy Register**

Offset	Bit Position																															
0x024	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																													0x00			
Access																													R			
Name																													BUSY			

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	BUSY	0x00	R	<b>Channels Busy</b> The bits of this field read 1 when the corresponding channel is busy.

**9.6.6 LDMA\_CHDONE - DMA Channel Linking Done Register (Single-Cycle RMW)**

Offset	Bit Position																															
0x028	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									RWH							
Name																									CHDONE							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	CHDONE	0x00	RWH	<b>DMA Channel Linking or Done</b> Each DMA channel sets the corresponding bit in this register when the entire transfer is done. The interrupt service routine should clear these bits. Enabling a DMA channel will also clear the corresponding LINKDONE bit. Note: software requires to use single-cycle read-modify-write, detailed in <a href="#">4.2.2 Peripheral Bit Set and Clear</a>

**9.6.7 LDMA\_DBGHALT - DMA Channel Debug Halt Register**

Offset	Bit Position																															
0x02C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									RW							
Name																									DBGHALT							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DBGHALT	0x00	RW	<b>DMA Debug Halt</b>
Setting one of these bits will mask the corresponding DMA channel's peripheral request when debugging and the CPU is halted. This may be useful for debugging DMA software.				

**9.6.8 LDMA\_SWREQ - DMA Channel Software Transfer Request Register**

Offset	Bit Position																															
0x030	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									W1							
Name																									SWREQ							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	SWREQ	0x00	W1	<b>Software Transfer Requests</b>
Setting one of these bits will trigger a DMA transfer for the corresponding channel. Writing zeros has no effect.				

**9.6.9 LDMA\_REQDIS - DMA Channel Request Disable Register**

Offset	Bit Position																															
0x034	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									RW							
Name																									REQDIS							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	REQDIS	0x00	RW	<b>DMA Request Disables</b>
Setting one of these bits will disable peripheral requests for the corresponding channel. When cleared any pending peripheral requests will be serviced.				

**9.6.10 LDMA\_REQPEND - DMA Channel Requests Pending Register**

Offset	Bit Position																															
0x038	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									R							
Name																									REQPEND							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	REQPEND	0x00	R	<b>DMA Requests Pending</b>
When a DMA channel has a pending peripheral request the corresponding REQPEND bit will read 1.				

## 9.6.11 LDMA\_LINKLOAD - DMA Channel Link Load Register

Offset	Bit Position																															
0x03C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									W1							
Name																									LINKLOAD							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	LINKLOAD	0x00	W1	<b>DMA Link Loads</b>
Setting one of these bits will force the corresponding DMA channel to load the next DMA structure and enable the channel. This empowers software to step through a sequence of descriptors.				

## 9.6.12 LDMA\_REQCLEAR - DMA Channel Request Clear Register

Offset	Bit Position																															
0x040	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									W1							
Name																									REQCLEAR							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	REQCLEAR	0x00	W1	<b>DMA Request Clear</b>
Setting one of these bits will clear any internally registered transfer requests for the corresponding channel.				

## 9.6.13 LDMA\_IF - Interrupt Flag Register

Offset	Bit Position																																
0x060	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset	0																									0x00							
Access	R																									R							
Name	ERROR																									DONE							

Bit	Name	Reset	Access	Description
31	ERROR	0	R	<b>Transfer Error Interrupt Flag</b> The ERRORIF flag is set when a read or write error occurs. The CHERROR field in the LDMA_STATUS register reflects the number of the channel which had the last error.
30:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DONE	0x00	R	<b>DMA Structure Operation Done Interrupt Flag</b> When a channel completes a transfer or sync operation, the corresponding DONE bit is set in the LDMA_IF register.

## 9.6.14 LDMA\_IFS - Interrupt Flag Set Register

Offset	Bit Position																																
0x064	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset	0																									0x00							
Access	W1																									W1							
Name	ERROR																									DONE							

Bit	Name	Reset	Access	Description
31	ERROR	0	W1	<b>Set ERROR Interrupt Flag</b> Write 1 to set the ERROR interrupt flag
30:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DONE	0x00	W1	<b>Set DONE Interrupt Flag</b> Write 1 to set the DONE interrupt flag

## 9.6.15 LDMA\_IFC - Interrupt Flag Clear Register

Offset	Bit Position																																
0x068	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset	0																									0x00							
Access	(R)W1																									(R)W1							
Name	ERROR																									DONE							

Bit	Name	Reset	Access	Description
31	ERROR	0	(R)W1	<b>Clear ERROR Interrupt Flag</b>  Write 1 to clear the ERROR interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).
30:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DONE	0x00	(R)W1	<b>Clear DONE Interrupt Flag</b>  Write 1 to clear the DONE interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).

## 9.6.16 LDMA\_IEN - Interrupt Enable register

Offset	Bit Position																																
0x06C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset	0																									0x00							
Access	RW																									RW							
Name	ERROR																									DONE							

Bit	Name	Reset	Access	Description
31	ERROR	0	RW	<b>ERROR Interrupt Enable</b>  Enable/disable the ERROR interrupt
30:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DONE	0x00	RW	<b>DONE Interrupt Enable</b>  Enable/disable the DONE interrupt

9.6.17 LDMA\_CHx\_REQSEL - Channel Peripheral Request Select Register

Offset	Bit Position																															
0x080	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset												0x00																0x0				
Access												RW																RW				
Name												SOURCESEL																SIGSEL				

Bit	Name	Reset	Access	Description
31:22	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
21:16	SOURCESEL	0x00	RW	<b>Source Select</b> Select input source to DMA channel.
	Value	Mode		Description
	0b000000	NONE		No source selected
	0b000001	PRS		Peripheral Reflex System
	0b001000	ADC0		Analog to Digital Converter 0
	0b001100	USART0		Universal Synchronous/Asynchronous Receiver/Transmitter 0
	0b001101	USART1		Universal Synchronous/Asynchronous Receiver/Transmitter 1
	0b010000	LEUART0		Low Energy UART 0
	0b010100	I2C0		I2C 0
	0b011000	TIMER0		Timer 0
	0b011001	TIMER1		Timer 1
	0b110000	MSC		Memory System Controller
	0b110001	CRYPTO		Advanced Encryption Standard Accelerator
15:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3:0	SIGSEL	0x0	RW	<b>Signal Select</b> Select input signal to DMA channel.
	Value	Mode		Description
	SOURCESEL = 0b000000 (NONE)			
	0bxxxx	OFF		Channel input selection is turned off
	SOURCESEL = 0b000001 (PRS)			
	0b0000	PRSREQ0		PRSREQ0
	0b0001	PRSREQ1		PRSREQ1
	SOURCESEL = 0b001000 (ADC0)

Name	DSTMODE	SRCMODE	DSTINC		SIZE		SRCINC		IGNORESREQ	DECLOOCPNT	REQMODE	DONEIFSEN		BLOCKSIZE		BYTESWAP		XFERCNT								STRUCTREQ			STRUCTTYPE			

Bit	Name	Reset	Access	Description															
31	DSTMODE	0	R	<b>Destination Addressing Mode</b>  This field specifies the destination addressing mode of linked descriptors. After loading a linked descriptor, reading this field will indicate the destination addressing mode of the linked descriptor. Note that the first descriptor always uses absolute addressing mode. <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>0</td><td>ABSOLUTE</td><td>The DSTADDR field of LDMA_CHx_DST contains the absolute address of the destination data.</td></tr><tr><td>1</td><td>RELATIVE</td><td>The DSTADDR field of LDMA_CHx_DST contains the relative offset of the destination data.</td></tr></table>	Value	Mode	Description	0	ABSOLUTE	The DSTADDR field of LDMA_CHx_DST contains the absolute address of the destination data.	1	RELATIVE	The DSTADDR field of LDMA_CHx_DST contains the relative offset of the destination data.						
Value	Mode	Description																	
0	ABSOLUTE	The DSTADDR field of LDMA_CHx_DST contains the absolute address of the destination data.																	
1	RELATIVE	The DSTADDR field of LDMA_CHx_DST contains the relative offset of the destination data.																	
30	SRCMODE	0	R	<b>Source Addressing Mode</b>  This field specifies the source addressing mode of linked descriptors. After loading a linked descriptor, reading this field will indicate the source addressing mode of the linked descriptor. Note that the first descriptor always uses absolute addressing mode. <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>0</td><td>ABSOLUTE</td><td>The SRCADDR field of LDMA_CHx_SRC contains the absolute address of the source data.</td></tr><tr><td>1</td><td>RELATIVE</td><td>The SRCADDR field of LDMA_CHx_SRC contains the relative offset of the source data.</td></tr></table>	Value	Mode	Description	0	ABSOLUTE	The SRCADDR field of LDMA_CHx_SRC contains the absolute address of the source data.	1	RELATIVE	The SRCADDR field of LDMA_CHx_SRC contains the relative offset of the source data.						
Value	Mode	Description																	
0	ABSOLUTE	The SRCADDR field of LDMA_CHx_SRC contains the absolute address of the source data.																	
1	RELATIVE	The SRCADDR field of LDMA_CHx_SRC contains the relative offset of the source data.																	
29:28	DSTINC	0x0	RWH	<b>Destination Address Increment Size</b>  This bit-field specifies the stride or number of unit data addresses to increment the destination address after each unit of data is transferred. The unit data width is controlled by the SIZE bit-field and can be a byte, half-word or word. <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>0</td><td>ONE</td><td>Increment destination address by one unit data size after each write</td></tr><tr><td>1</td><td>TWO</td><td>Increment destination address by two unit data sizes after each write</td></tr><tr><td>2</td><td>FOUR</td><td>Increment destination address by four unit data sizes after each write</td></tr><tr><td>3</td><td>NONE</td><td>Do not increment the destination address. Writes are made to a fixed destination address, for example writing to a FIFO.</td></tr></table>	Value	Mode	Description	0	ONE	Increment destination address by one unit data size after each write	1	TWO	Increment destination address by two unit data sizes after each write	2	FOUR	Increment destination address by four unit data sizes after each write	3	NONE	Do not increment the destination address. Writes are made to a fixed destination address, for example writing to a FIFO.
Value	Mode	Description																	
0	ONE	Increment destination address by one unit data size after each write																	
1	TWO	Increment destination address by two unit data sizes after each write																	
2	FOUR	Increment destination address by four unit data sizes after each write																	
3	NONE	Do not increment the destination address. Writes are made to a fixed destination address, for example writing to a FIFO.																	
27:26	SIZE	0x0	RWH	<b>Unit Data Transfer Size</b>  This field specifies the size of data transferred. <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>0</td><td>BYTE</td><td>Each unit transfer is a byte</td></tr><tr><td>1</td><td>HALFWORD</td><td>Each unit transfer is a half-word</td></tr><tr><td>2</td><td>WORD</td><td>Each unit transfer is a word</td></tr></table>	Value	Mode	Description	0	BYTE	Each unit transfer is a byte	1	HALFWORD	Each unit transfer is a half-word	2	WORD	Each unit transfer is a word			
Value	Mode	Description																	
0	BYTE	Each unit transfer is a byte																	
1	HALFWORD	Each unit transfer is a half-word																	
2	WORD	Each unit transfer is a word																	
25:24	SRCINC	0x0	RWH	<b>Source Address Increment Size</b>  This bit-field specifies the stride or number of unit data addresses to increment the source address after each unit of data is transferred. The unit data width is controlled by the SIZE bit-field and can be a byte, half-word or word. <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>0</td><td>ONE</td><td>Increment source address by one unit data size after each read</td></tr><tr><td>1</td><td>TWO</td><td>Increment source address by two unit data sizes after each read</td></tr></table>	Value	Mode	Description	0	ONE	Increment source address by one unit data size after each read	1	TWO	Increment source address by two unit data sizes after each read						
Value	Mode	Description																	
0	ONE	Increment source address by one unit data size after each read																	
1	TWO	Increment source address by two unit data sizes after each read																	

Bit	Name	Reset	Access	Description
	2	FOUR		Increment source address by four unit data sizes after each read
	3	NONE		Do not increment the source address. In this mode reads are made from a fixed source address, for example reading FIFO.
23	IGNORESREQ	0	RWH	<b>Ignore Sreq</b> The channel arbiter will ignore single requests (SREQ) and only respond to multiple requests (REQ) when this bit is set.
22	DECLOOPCNT	0	RWH	<b>Decrement Loop Count</b> When using looping, setting this bit will decrement the LOOPCNT field in the LDMA_CHx_LOOP register after each descriptor execution.
21	REQMODE	0	RWH	<b>DMA Request Transfer Mode Select</b>
	Value	Mode		Description
	0	BLOCK		The LDMA transfers one BLOCKSIZE per transfer request.
	1	ALL		One transfer request transfers all units as defined by the XFRCNT field.
20	DONEIFSEN	0	RWH	<b>DMA Operation Done Interrupt Flag Set Enable</b> Setting this bit will set the interrupt flag when the transfer is done, or linked in the case where the LINK bit is set, or synchronized in the case of a SYNC transfer.
19:16	BLOCKSIZE	0x0	RWH	<b>Block Transfer Size</b> This bit-field controls the number of unit data transfers per arbitration cycle
	Value	Mode		Description
	0	UNIT1		One unit transfer per arbitration
	1	UNIT2		Two unit transfers per arbitration
	2	UNIT3		Three unit transfers per arbitration
	3	UNIT4		Four unit transfers per arbitration
	4	UNIT6		Six unit transfers per arbitration
	5	UNIT8		Eight unit transfers per arbitration
	7	UNIT16		Sixteen unit transfers per arbitration
	9	UNIT32		32 unit transfers per arbitration
	10	UNIT64		64 unit transfers per arbitration
	11	UNIT128		128 unit transfers per arbitration
	12	UNIT256		256 unit transfers per arbitration
	13	UNIT512		512 unit transfers per arbitration
	14	UNIT1024		1024 unit transfers per arbitration
	15	ALL		Transfer all units as specified by the XFRCNT field
15	BYTESWAP	0	RWH	<b>Endian Byte Swap</b> For word and half-word transfers, setting this bit will swap all bytes of each word or half-word.
14:4	XFERCNT	0x000	RWH	<b>DMA Unit Data Transfer Count</b>

Bit	Name	Reset	Access	Description
	Specifies number of unit data (words, half-words, or bytes) to transfer, as determined by the SIZE field. The value written should be one less than the desired transfer count.			
3	STRUCTREQ	0	W1	<b>Structure DMA Transfer Request</b> When a linked descriptor is loaded with this bit set, it will immediately trigger a transfer.
2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1:0	STRUCTTYPE	0x0	R	<b>DMA Structure Type</b>
	Value	Mode	Description	
	0	TRANSFER	DMA transfer structure type selected.	
	1	SYNCHRONIZE	Synchronization structure type selected.	
	2	WRITE	Write immediate value structure type selected.	

### 9.6.21 LDMA\_CHx\_SRC - Channel Descriptor Source Data Address Register

Offset	Bit Position																															
0x090	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	RWH															
Name																	SRCADDR															

Bit	Name	Reset	Access	Description
31:0	SRCADDR	0x00000000	RWH	<b>Source Data Address</b> Writing to this register sets the source address. Reading from this register during a DMA transfer will indicate the next source read address. The value of this register is incremented or decremented with each source read.

9.6.22 LDMA\_CHx\_DST - Channel Descriptor Destination Data Address Register

Offset	Bit Position																															
0x094	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	RWH															
Name																	DSTADDR															

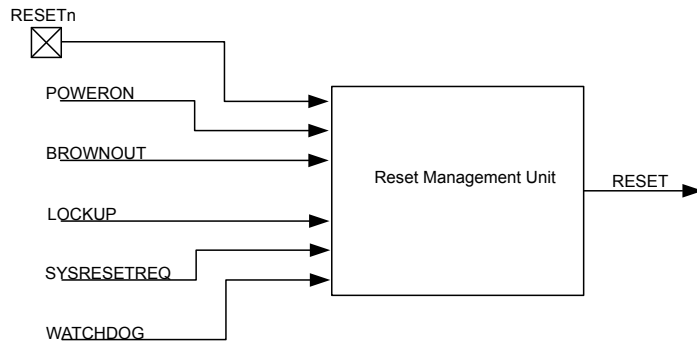

Bit	Name	Reset	Access	Description
31:0	DSTADDR	0x00000000	RWH	<b>Destination Data Address</b>
				Writing to this register sets the destination address. Reading from this register during a DMA transfer will indicate the next destination write address. This value of this register is incremented or decremented with each destination write.

## 9.6.23 LDMA\_CHx\_LINK - Channel Descriptor Link Structure Address Register

Offset	Bit Position																																	
0x098	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset	0x00000000																														0	0		
Access	RWH																														RWH	R		
Name	LINKADDR																														LINK	LINKMODE		

Bit	Name	Reset	Access	Description
31:2	LINKADDR	0x00000000	RWH	<b>Link Structure Address</b>  To use linking, write the address of the the first linked descriptor to this register. When a linked descriptor is loaded, it may also be linked to another descriptor. Reading this register will reflect the address of the next linked descriptor.
1	LINK	0	RWH	<b>Link Next Structure</b>  After completing the initial transfer, if this bit is set, the DMA will load the next linked descriptor. If the next linked descriptor also has this bit set, the DMA will load the next linked descriptor.
0	LINKMODE	0	R	<b>Link Structure Addressing Mode</b>  This field specifies the addressing mode of linked descriptors. After loading a linked descriptor, reading this field will indicate the addressing mode of the loaded linked descriptor. Note that the first descriptor always uses absolute addressing mode.
Value				Mode
0				ABSOLUTE
1				RELATIVE
				Description
				The LINKADDR field of LDMA_CHx_LINK contains the absolute address of the linked descriptor.
				The LINKADDR field of LDMA_CHx_LINK contains the relative offset of the linked descriptor.

## 10. RMU - Reset Management Unit

### Quick Facts

#### What?

The RMU ensures correct reset operation. It is responsible for connecting the different reset sources to the reset lines of the EFR32.

#### Why?

A correct reset sequence is needed to ensure safe and synchronous startup of the EFR32. In the case of error situations such as power supply glitches or software crash, the RMU provides proper reset and startup of the EFR32.

#### How?

The Power-on Reset and Brown-out Detector of the EFR32 provides power line monitoring with exceptionally low power consumption. The cause of the reset may be read from a register, thus providing software with information about the cause of the reset.

### 10.1 Introduction

The RMU is responsible for handling the reset functionality of the EFR32.

### 10.2 Features

- Reset sources
  - Power-on Reset (POR)
  - Brown-out Detection (BOD) on the following power domains:
    - Analog Unregulated Power Domain AVDD
    - Digital Unregulated Power Domain DVDD
    - Regulated Digital Domain DECOUPLE (DEC)
  - RESETn pin reset
  - Watchdog reset
  - EM4 Hibernate/Shutoff wakeup reset from GPIO pin
  - Software triggered reset (SYSRESETREQ)
  - Core LOCKUP condition
- EM4 Hibernate/Shutoff Detection
- Configurable reset levels
- A software readable register indicates the cause of the last reset

### 10.3 Functional Description

The RMU monitors each of the reset sources of the EFR32. If one or more reset sources go active, the RMU applies reset to the EFR32. When the reset sources go inactive the EFR32 starts up. At startup the EFR32 loads the stack pointer and program entry point from memory, and starts execution. [Figure 10.1 RMU Reset Input Sources and Connections on page 172](#) shows an overview of the reset system on EFR32.

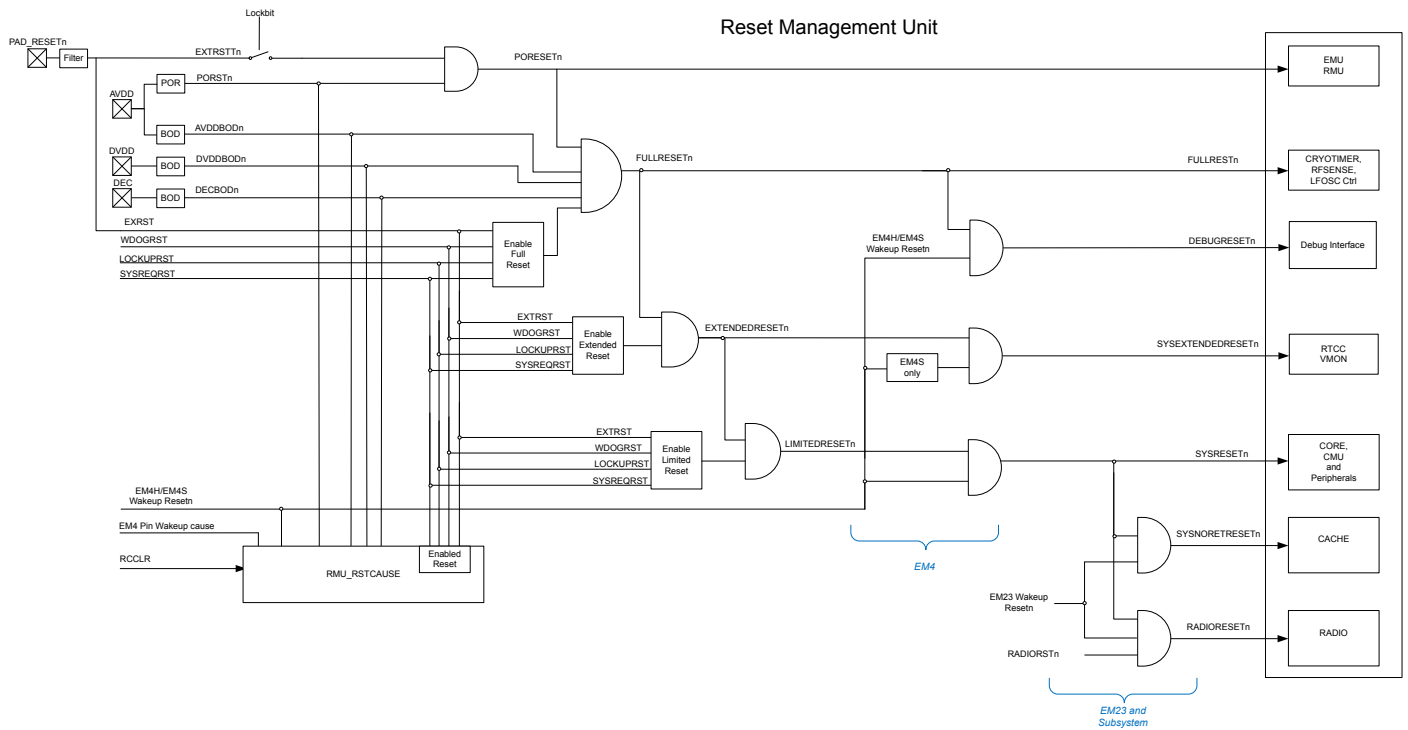

Figure 10.1. RMU Reset Input Sources and Connections

### 10.3.1 Reset levels

The reset sources on EFR32 can be divided in two main groups; Hard resets and Soft resets.

The soft resets can be configured to be either DISABLED, LIMITED, EXTENDED or FULL. The reset level for soft reset sources is configured in the xxxRMODE bitfields in RMU\_CTRL.

**Table 10.1. Reset levels**

RMU_CTRL_xxxRMODE	Parts of system reset
DISABLED	Nothing is reset, request will not be registered in RMU_RSTCAUSE
LIMITED	Everything reset, with exception of CRYOTIMER, RFSENSE, DE-BUGGER, RTCC, VMON and parts of CMU, RMU and EMU.
EXTENDED	Everything reset, with exception of CRYOTIMER, RFSENSE, DE-BUGGER, and parts of CMU, RMU and EMU.
FULL	Everything reset, with exception of some registers in RMU and EMU.

The reset sources resulting in a soft reset are:

- Watchdog reset
- Lockup reset
- System reset request
- Pin reset<sup>1</sup>

1 Pin reset can be configured to be either a soft or a hard reset, see [10.3.5 RESETn pin Reset](#) for details

**Note:** LIMITED and EXTENDED resets are synchronized to HFSRCCLK. If HFSRCCLK is slow, there will be latency on reset assertion. If HFSRCCLK is not running, reset will be asserted after a timeout.

Hard resets will reset the entire chip, the reset sources resulting in a hard reset are:

- Power-on reset
- Brown-out reset
- Pin reset<sup>1</sup>

### 10.3.2 RMU\_RSTCAUSE Register

Whenever a reset source is active, the corresponding bit in the RMU\_RSTCAUSE register is set. At startup the program code may investigate this register in order to determine the cause of the reset. The register is cleared upon POR and software write to RMU\_CMD\_RCCLR. The register should be cleared after the value has been read at startup, otherwise the register may indicate multiple causes for the reset at next startup.

RMU\_RSTCAUSE should be interpreted according to [Table 10.2 RMU Reset Cause Register Interpretation on page 174](#). In [Table 10.2 RMU Reset Cause Register Interpretation on page 174](#), the reset causes are ordered by severity from right to left. A reset cause bit is invalidated (i.e. can not be trusted) one of the bits to the right of it does not match the table. X bits are don't care.

#### Note:

Notice that it is possible to have multiple reset causes. For example, an external reset and a watchdog reset may happen simultaneously.

**Table 10.2. RMU Reset Cause Register Interpretation**

RMU_RSTCAUSE									Reset cause
EM4RST	WDOG RST	SYS-REQ RST	LOCK-UP RST	EXTRST	DEC-BOD	DVDD BOD	AVDD-BOD	PORS T	
X	X	X	X	X	X	X	X	1	Power on reset
X	X	X	X	X	X	X	1	0	Brown-out on AVDD power
X	X	X	X	X	X	1	X	0	Brown-out on DVDD power
X	X	X	X	X	1	X	X	0	Brown-out on DEC power
X	X	X	X	1	X	X	X	0	Pin reset
X	X	X	1	0/X <sup>1</sup>	0	0	0	0	Lockup reset
X	X	1	X	0/X <sup>1</sup>	0	0	0	0	System reset request
X	1	X	X	0/X <sup>1</sup>	0	0	0	0	Watchdog reset
1	X	X	X	0/X <sup>1</sup>	0	0	0	0	System has been in EM4

1 Pin reset configured as hard/soft

### 10.3.3 Power-On Reset (POR)

The POR ensures that the EFR32 does not start up before the supply voltage  $V_{DD}$  has reached the threshold voltage  $V_{PORthr}$  (see Device Datasheet Electrical Characteristics for details). Before the threshold voltage is reached, the EFR32 is kept in reset state. The operation of the POR is illustrated in [Figure 10.2 RMU Power-on Reset Operation on page 175](#), with the active low  $POWERONn$  reset signal. The reason for the “unknown” region is that the corresponding supply voltage is too low for any reliable operation.

Figure 10.2. RMU Power-on Reset Operation

### 10.3.4 Brown-Out Detector (BOD)

The EFR32 The BODs also include hysteresis, which prevents instability in the corresponding  $BROWNOUTn$  line when the supply is crossing the  $VBODthr$  limit or the  $AVDD$  bods drops below decouple pin (DEC). The operation of the BOD is illustrated in [Figure 10.3 RMU Brown-out Detector Operation on page 175](#). The “unknown” regions are handled by the POR module.

Figure 10.3. RMU Brown-out Detector Operation

### 10.3.5 RESETh pin Reset

The pin reset on EFR32 can be configured to be either hard or soft. By default, pin reset is configured as a soft reset source. To configure it as a hard reset, clear the PINRESETSOFT bit in CLW0 in the Lock bit page, see [8.3.2 Lock Bits \(LB\) Page Description](#) for details. Forcing the RESETh pin low generates a reset of the EFR32. The RESETh pin includes an on-chip pull-up resistor, and can therefore be left unconnected if no external reset source is needed. Also connected to the RESETh line is a filter which prevents glitches from resetting the EFR32.

### 10.3.6 Watchdog Reset

The Watchdog circuit is a timer which (when enabled) must be cleared by software regularly. If software does not clear it, a Watchdog reset is activated. This functionality provides recovery from a software stalemate. Refer to the Watchdog section for specifications and description. The Watchdog reset can be configured to cause different levels of reset as determined by WDOGRMODE in the RMU\_CTRL register.

### 10.3.7 Lockup Reset

A Cortex-M4 lockup is the result of the core being locked up because of an unrecoverable exception following the activation of the processor's built-in system state protection hardware.

A Cortex-M4 lockup gives immediate indication of seriously errant kernel software. This is the result of the core being locked up due to an unrecoverable exception following the activation of the processor's built in system state protection hardware. For more information about the Cortex-M4 lockup conditions see the ARMv7-M Architecture Reference Manual. The Lockup reset does not reset the Debug Interface, unless configured as a FULL reset. The Lockup reset can be configured to cause different levels of reset as determined by the LOCKUPRMODE bits in the RMU\_CTRL register. This includes disabling the reset.

### 10.3.8 System Reset Request

Software may initiate a reset (e.g. if it finds itself in a non-recoverable state). By asserting the SYSRESETREQ in the Application Interrupt and Reset Control Register, a reset is issued. The SYSRESETREQ does not reset the Debug Interface, unless configured as a FULL reset. The SYSRESETREQ reset can be configured to cause different levels of reset as determined by SYSRESETRMODE bits in the RMU\_CTRL register. This includes disabling the reset.

### 10.3.9 Radio Reset

The Radio subsystem can reset with the RADIORST bit in the RMU\_RST register. To reset the Radio subsystem in a safe manner, all clocks in CMU\_HFRADIOCLKEN0 have to be stopped. The sequence is:

1. Clear all bits in CMU\_HFRADIOCLKEN0
2. Set RMU\_RST\_RADIORST
3. Clear RMU\_RST\_RADIORST
4. Re-initialize Radio subsystem

### 10.3.10 Reset state

The RESETSTATE bitfield in RMU\_CTRL is a read-write register intended for software use only, and can be used to keep track of state throughout a reset. This bitfield is only reset by POR and hard pin reset.

### 10.3.11 Registers with alternate reset

[Figure 10.1 RMU Reset Input Sources and Connections on page 172](#) shows an overview of how the different parts of the design are affected by the different levels of reset. For RMU, EMU and CMU there are some exceptions. These are given in the following tables.

## 10.4 Registers with alternate reset

### Alternate reset for registers in RMU

RMU reset levels	
POR and hard pin reset	RMU_CTRL_WDOGRMODE RMU_CTRL_LOCKUPRMODE RMU_CTRL_SYSRMODE RMU_CTRL_PINRMODE RMU_CTRL_RESETSTATE

### Alternate reset for registers in CMU

CMU reset levels	
FULL reset	CMU_LFRCCOCTRL CMU_LFXOCTRL
EXTENDED reset	CMU_LFECLKSEL CMU_LFECLKEN0 CMU_LFEPRESC0

### Alternate reset for registers in EMU

EMU reset levels	
POR, BOD, and hard pin reset	EMU_DCDCLNVCTRL
POR, BOD, and hard pin reset	EMU_PWRCTRL EMU_DCDCCTRL EMU_DCDCMISCCTRL EMU_DCDCZDETCTRL EMU_DCDCCLIMCTRL EMU_DCDCTIMING EMU_DCDCLPVCTRL EMU_DCDCLPCTRL EMU_DCDCLNFREQCTRL
EXTENDED reset	EMU_VMONAVDDCTRL EMU_VMONALTAVDDCTRL EMU_VMONDVDDCTRL EMU_VMONIO0CTRL EMU_VMONPAVDDCTRL
FULL reset	EMU_EM4CTRL

## 10.5 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	RMU_CTRL	RW	Control Register
0x004	RMU_RSTCAUSE	R	Reset Cause Register
0x008	RMU_CMD	W1	Command Register
0x00C	RMU_RST	RW	Reset Control Register
0x010	RMU_LOCK	RWH	Configuration Lock Register

10.6 Register Description

10.6.1 RMU\_CTRL - Control Register

Offset	Bit Position																															
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset							0x0											0x4			0x2			0x2			0x4					
Access							RW											RW			RW			RW			RW					
Name							RESETSTATE											PINRMODE			SYSRMODE			LOCKUPRMODE			WDOGRMODE					

Bit	Name	Reset	Access	Description
31:26	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
25:24	RESETSTATE	0x0	RW	<b>System Software Reset State</b> Bit-field for software use only. This field has no effect on the RMU and is reset by power-on reset and hard pin reset only.
23:15	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
14:12	PINRMODE	0x4	RW	<b>PIN Reset Mode</b> Controls the reset level for Pin reset request. These settings only apply when PINRESETSOFT in CLW0 in the Lock bit page is set.
	Value	Mode	Description	
	0	DISABLED	Reset request is blocked.	
	1	LIMITED	The CRYOTIMER, DEBUGGER, RTCC, are not reset.	
	2	EXTENDED	The CRYOTIMER, DEBUGGER are not reset. RTCC is reset.	
	4	FULL	The entire device is reset except some EMU and RMU registers.	
11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
10:8	SYSRMODE	0x2	RW	<b>Core Sysreset Reset Mode</b> Controls the reset level for Core SYSREST reset request.
	Value	Mode	Description	
	0	DISABLED	Reset request is blocked.	
	1	LIMITED	The CRYOTIMER, DEBUGGER, RTCC, are not reset.	
	2	EXTENDED	The CRYOTIMER, DEBUGGER are not reset. RTCC is reset.	
	4	FULL	The entire device is reset except some EMU and RMU registers.	
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:4	LOCKUPRMODE	0x2	RW	<b>Core LOCKUP Reset Mode</b> Controls the reset level for Core LOCKUP reset request.
	Value	Mode	Description	
	0	DISABLED	Reset request is blocked.	
	1	LIMITED	The CRYOTIMER, DEBUGGER, RTCC, are not reset.	
	2	EXTENDED	The CRYOTIMER, DEBUGGER are not reset. RTCC is reset.	
	4	FULL	The entire device is reset except some EMU and RMU registers.	
3	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
2:0	WDOGRMODE	0x4	RW	<b>WDOG Reset Mode</b> Controls the reset level for WDOG reset request.
	Value	Mode	Description	

Bit	Name	Reset	Access	Description
	0	DISABLED		Reset request is blocked. This disable bit is redundant with enable/disable bit in WDOG
	1	LIMITED		The CRYOTIMER, DEBUGGER, RTCC, are not reset.
	2	EXTENDED		The CRYOTIMER, DEBUGGER are not reset. RTCC is reset.
	4	FULL		The entire device is reset except some EMU and RMU registers.

10.6.2 RMU\_RSTCAUSE - Reset Cause Register

Offset	Bit Position																			
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12

15:0	LOCKKEY	0x0000	RWH	<b>Configuration Lock Key</b>  Write any other value than the unlock code to lock RMU_CTRL and RMU_RST from editing. Write the unlock code to unlock. When reading the register, bit 0 is set when the lock is enabled.
Mode		Value	Description	
Read Operation				
UNLOCKED		0	RMU registers are unlocked	
LOCKED		1	RMU registers are locked	
Write Operation				
LOCK		0	Lock RMU registers	
UNLOCK		0xE084	Unlock RMU registers	

## 11. EMU - Energy Management Unit

### Quick Facts

#### What?

The EMU (Energy Management Unit) handles the different low energy modes in EFR32

#### Why?

The need for performance and peripheral functions varies over time in most applications. By efficiently scaling the available resources in real-time to match the demands of the application, the energy consumption can be kept at a minimum.

#### How?

With a broad selection of energy modes, a high number of low-energy peripherals available even in EM2 DeepSleep, and short wake-up time (2  $\mu$ s from EM2 DeepSleep and EM3 Stop), applications can dynamically minimize energy consumption during program execution.

### 11.1 Introduction

The Energy Management Unit (EMU) manages all the low energy modes (EM) in EFR32. Each energy mode manages if the CPU and the various peripherals are available. The energy modes range from EM0 Active to EM4 Shutoff. EM0 Active mode provides the highest amount of features, enabling the CPU, Radio, and peripherals with the highest clock frequency. EM4 Shutoff Mode provides the lowest power state, allowing the part to return to EM0 Active on a wakeup condition. The EMU also controls the various power routing configurations, internal regulators settings, and voltage monitoring needed for optimal power configuration and protection.

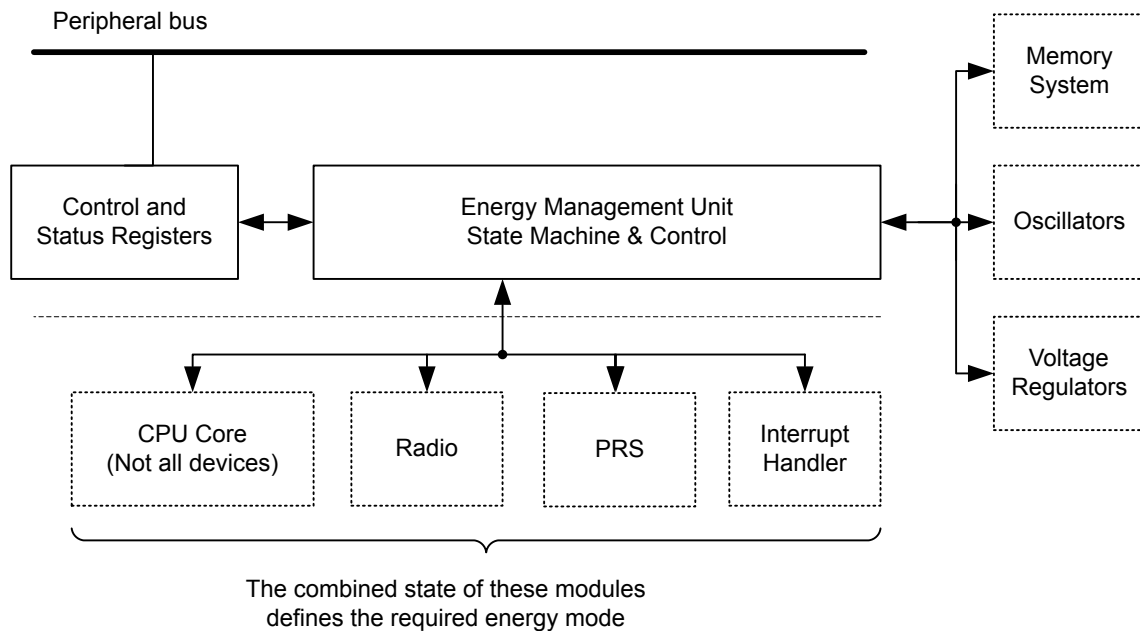

### 11.2 Features

The primary features of the EMU are listed below:

- Energy Modes control
  - Entry into EM4 Hibernate or EM4 Shutoff
  - Configuration of regulators and clocks for each Energy Mode
  - Configuration of various EM4 Hibernate/Shutoff wakeup conditions
  - Configuration of RAM power and retention settings
  - Configuration of GPIO retention settings
- Power routing configurations
  - DCDC control
  - Internal power switches allowing for extensible system power architecture
- Temperature measurement control and status
- Brown Out Detection
- Voltage Monitoring
  - Four dedicated continuous monitor channels
  - Optional monitor features include interrupt generation, low power mode wakeup, and EM4 Entry
- State Retention

### 11.3 Functional Description

The EMU is responsible for managing the wide range of energy modes available in EFR32. The block works in harmony with the entire platform to easily transition between energy modes in the most efficient manner possible. The following diagram [Figure 11.1 EMU Overview on page 187](#), shows the relative connectivity to the various blocks in the system.

**Figure 11.1. EMU Overview**

The EMU is available on the peripheral bus. The energy management state machine controls the internal voltage regulators, oscillators, memories, and interrupt system. Events, interrupts, and resets can trigger the energy management state machine to return to the active state. This is further described in the following sections.

The power architecture is highly configurable to meet system power performance needs. Several external power configurations are supported. The EMU allows flexible control of internal DCDC, Digital LDO Regulator, and internal power switching.

### 11.3.1 Energy Modes

EFR32 features six main energy modes, referred to as Energy Mode 0 (EM0 Active) through Energy Mode 4 (EM4 Shutoff). The Cortex-M4 is only available for program execution in EM0 Active. In EM0 Active/EM1 Sleep any peripheral function can be enabled. EM2 DeepSleep through EM4 Shutoff, also referred to as low energy modes, provide a significantly reduced energy consumption while still allowing a rich set of peripheral functionality. The following [Table 11.1 table on page 188](#) shows the possible transitions between different energy modes.

**Table 11.1. Energy Mode Transitions**

Current Mode	EM Transition Action					
	Enter EM0 Active	Enter EM1 Sleep	Enter EM2 DeepSleep	Enter EM3 Stop	Enter EM4 Hibernate	Enter EM4 Shutoff
EM0 Active		Sleep (WFI, WFE)	Deep Sleep (WFI, WFE)	Deep Sleep (WFI, WFE)	EM4 Entry	EM4 Entry
EM1 Sleep	IRQ		Peripheral wake up done <sup>1</sup>	Peripheral wake up done <sup>1</sup>		
EM2 DeepSleep	IRQ	Peripheral wake up req <sup>1</sup>				
EM3 Stop	IRQ	Peripheral wake up req <sup>1</sup>				
EM4 Hibernate	Wake Up					
EM4 Shutoff	Wake Up					

<sup>1</sup> Peripheral wakeup from EM2/3 to EM1 and then automatically back to EM2/3 when done.

The RAC, ADC, and LEUART have the ability to temporarily wake up the part from either EM2 DeepSleep or EM3 Stop to EM1 Sleep in order to transfer data. Once completed, the part is automatically placed back into the EM2 DeepSleep or EM3 Stop mode.

The Core can always request to go to EM1 Sleep with the WFI or WFE command during EM0 Active. The core will be prevented from entering EM2 DeepSleep, EM3 Stop, EM4 Hibernate, or EM4 Shutoff if the RAC is transferring data or if Flash is programming or erasing.

An overview of supported energy modes and available functionality is shown in [Table 11.2 Table 2. EMU Energy Mode Overview on page 188](#). By default, the system is configured in the lowest configuration within each energy mode. Functionality may be selectively enabled.

**Table 11.2. EMU Energy Mode Overview**

	EM0 Active	EM1 Sleep	EM2 Deep-Sleep	EM3 Stop	EM4 Hibernate	EM4 Shutoff
Wakeup time to EM0 Active/EM1 Sleep	-	-	2 $\mu$ s <sup>1</sup>	2 $\mu$ s <sup>1</sup>	160 $\mu$ s <sup>1</sup>	160 $\mu$ s <sup>1</sup>

- 1 approximate time. refer to datasheet
- 2 HFXO can be kept running in EM2 DeepSleep
- 3 I2C functionality limited to receive address recognition
- 4 ACMP functionality limited to edge interrupt
- 5 Must be using ULFRCO
- 6 Pin wakeup from selected pins.

The different Energy Modes are summarized in the following sections.

#### 11.3.1.1 EM0 Active

EM0 Active provides all system features.

- Cortex-M4 is executing code
- Radio functionality is available
- High and low frequency clock trees are active
- All peripheral functionality is available

#### 11.3.1.2 EM1 Sleep

EM1 Sleep disables the core but leaves the remaining system fully available.

- Cortex-M4 is in sleep mode. Clocks to the core are off
- Radio functionality is available
- High and low frequency clock trees are active
- All peripheral functionality is available

### 11.3.1.3 EM2 DeepSleep

This is the first level into the low power energy modes. Most of the high frequency peripherals are disabled or have reduced functionality. Memory and registers retain their values.

- Cortex-M4 is in sleep mode. Clocks to the core are off.
- RFSense available. Radio inactive
- High frequency clock tree is inactive
  - High frequency oscillator may still be enabled for fast startup
- Low frequency clock tree is active
- The following low frequency peripherals are available
  - RTCC, WDOG, LEUART, LETIMER, PCNT, CRYOTIMER
- Wakeup to EM0 Active through
  - Peripheral interrupt, reset pin, power on reset, asynchronous pin interrupt, I2C address recognition, or ACMP edge interrupt
- Wakeup to EM1 Sleep through
  - RAC data transfer request
  - Part returns to EM2 DeepSleep when transfers are complete
- RAM and register values are preserved
- Options
  - Ability to have Digital LDO Regulator in full power mode for fast wakeup
  - Selectively pick which RAM areas to retain

### 11.3.1.4 EM3 Stop

This low energy mode has both high frequency and low frequency clocks stopped. Most peripherals are disabled or have reduced functionality. Memory and registers retain their values.

- Cortex-M4 is in sleep mode. Clocks to the core are off.
- RFSense available. Radio inactive
- High frequency clock tree is inactive
  - High frequency oscillator may still be enabled for fast startup
- Low frequency clock tree is inactive
- The following low frequency peripherals are available if clocked by the ULFRCO
  - RTCC, WDOG, CRYOTIMER
- Wakeup to EM0 Active through
  - Peripheral interrupt, reset pin, power on reset, asynchronous pin interrupt, I2C address recognition, or ACMP edge interrupt
- Wakeup to EM1 Sleep through
  - RAC data transfer request
  - Part returns to EM3 Stop when transfers are complete
- RAM and register values are preserved
- Options
  - Ability to have Digital LDO Regulator in full power mode for fast wakeup
  - Selectively pick which RAM areas to retain

### 11.3.1.5 EM4 Hibernate

The majority of peripherals are shutoff to reduce leakage power. A few selected peripherals are available. System memory and registers do not retain values. GPIO PAD state and RTCC RAM are retained. Wakeup from EM4 Hibernate requires a reset to the system, returning it back to EM0 Active

- Cortex-M4 is off
- RFSense available. Radio is off.
- High frequency clock tree is off
- Low frequency clock tree may be active
- The following low frequency peripherals are available
  - RTCC, CRYOTIMER
- Wakeup to EM0 Active through
  - VMON, TEMPCHANGE, RTCC, RFSense, CRYOTIMER, reset pin, power on reset, asynchronous pin interrupt
- GPIO PAD state retention
- RTCC RAM retained

### 11.3.1.6 EM4 Shutoff

EM4 Shutoff is the lowest energy mode of the part. There is no retention except for GPIO PAD state. Wakeup from EM4 Shutoff requires a reset to the system, returning it back to EM0 Active

- Cortex-M4 is off
- RFSense available. Radio is off.
- High frequency clock tree is off
- Low frequency clock tree may be active
- The following low frequency peripherals are available
  - CRYOTIMER
- Wakeup to EM0 Active through
  - RFSense, CRYOTIMER, reset pin, power on reset, asynchronous pin interrupt
- GPIO PAD state retention

## 11.3.2 Entering Low Energy Modes

The following sections describe the requirements for entering the various Energy Modes.

### 11.3.2.1 Entry into EM1 Sleep

Energy mode EM1 Sleep is entered when the Cortex-M4 executes the Wait For Interrupt (WFI) or Wait For Event (WFE) instruction while the SLEEPDEEP bit the Cortex-M4 System Control Register is cleared. The MCU can re-enter sleep automatically out of an Interrupt Service Routine (ISR) if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set. Refer to ARM documentation on entering Sleep modes.

Alternately, EM1 Sleep can be entered from either EM2 DeepSleep or EM3 Stop from a Peripheral Wakeup Request allowing transfers from the Peripheral to System RAM. On EFR32, the RAC, ADC, or LEUART peripherals can request this wakeup event. Please refer to their respective register specification to enable this option. The system will return back to EM2 DeepSleep or EM3 Stop once the RAC, ADC, or LEUART have completed its transfers and processing.

During Peripheral Wakeup Request, additional system resources such as FLASH and other Peripherals can be enabled for access. Refer to EMU\_PERWUCONF for more details into system options.

### 11.3.2.2 Entry into EM2 DeepSleep or EM3 Stop

Energy mode EM2 DeepSleep or EM3 Stop may be entered when **all** of the following conditions are true:

- Radio RAC state machine is in OFF state
- IDAC is currently not updating output.
- Cortex-M4 (if present) is in DEEPSLEEP state
- Flash Program/Erase Inactive
- DMA done with all current requests

Entry into EM2 DeepSleep and EM3 Stop can be blocked by setting the EMU\_CTRL->EM2BLOCK bit.

**Note:** When EM2 DeepSleep or EM3 Stop entry is blocked, the part is not able to enter a lower energy state. The core will be in a sleep state, similar to EM1, where it is waiting for a proper interrupt of other valid wakeup event. Once the blocking conditions are removed, then the part will automatically enter a lower energy state.

Energy mode EM2 DeepSleep is entered from EM0 Active when the Cortex-M4 executes the Wait For Interrupt (WFI) or Wait For Event (WFE) instruction while the SLEEPDEEP bit in the Cortex-M4 System Control Register is set. The MCU can re-enter DeepSleep automatically out of an Interrupt Service Routine (ISR) if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set. Refer to ARM documentation on entering Sleep modes.

Alternately, EM2 DeepSleep or EM3 Stop is entered from EM1 Sleep upon the completion of a Peripheral Wakeup Request from the RAC if no EM0 Active wakeup happens in the meantime.

### 11.3.2.3 Entry into EM4 Hibernate

Energy mode EM4 Hibernate and EM4 Shutoff is entered through register access.

Software must ensure no modules are active, such as RAC, when entering EM4 Hibernate/Shutoff. EM4CTRL->EM4STATE field must be configured to select either Hibernate (EM4H) or Shutoff (EM4S) mode prior to entering EM4.

Software may enter EM4 Hibernate/Shutoff from EM0 Active by writing the sequence 2-3-2-3 to EM4CTRL->EM4ENTRY bit field. If the EM4BLOCK bit in WDOGn\_CTRL is set, the CPU will be prevented from entering EM4 Hibernate/Shutoff by software request.

### 11.3.3 Exiting a Low Energy Mode

A system in EM2 DeepSleep and EM3 Stop can be woken up to EM0 Active through regular interrupt requests from active peripherals. Since state and RAM retention is available, the EFR32 is fully restored and can continue to operate as before it went into the Low Energy Mode.

Wakeup from EM4 Hibernate or EM4 Shutoff is performed through reset. Wakeup from a specific module must be enabled in EMU\_EM4WUCONF.

Enabled interrupts that can cause wakeup from a low energy mode are shown in [Table 11.3 EMU Wakeup Triggers from Low Energy Modes on page 193](#). The wakeup triggers always return the EFR32 to EM0 Active/EM1 Sleep. Additionally, any reset source will return to EM0 Active.

**Table 11.3. EMU Wakeup Triggers from Low Energy Modes**

Peripheral	Wakeup Trigger	EM2 Deep-Sleep	EM3 Stop	EM4 Hibernate	EM4 Shutoff
LEUART (Low Energy Uart)	Receive / transmit	Yes	-	-	-
LETIMER	Any enabled interrupt	Yes	-	-	-
I <sup>2</sup> C	Receive address recognition	Yes	Yes	-	-
ACMP	Any enabled edge interrupt	Yes	Yes	-	-
PCNT	Any enabled interrupt	Yes	Yes <sup>1</sup>	-	-
RTCC	Any enabled interrupt	Yes	Yes	Yes <sup>2</sup>	
VMON	Rising or falling edge on any monitored power	Yes	Yes	Yes <sup>2</sup>	-
TEMPCHANGE	Measured temperature outside the defined limits	Yes	Yes	Yes <sup>2</sup>	-
CRYOTIMER	Timeout	Yes	Yes	Yes <sup>2</sup>	Yes <sup>2</sup>
Pin Interrupts	Transition	Yes	Yes	Yes <sup>23</sup>	Yes <sup>23</sup>
RFSENSE	RF signal detected	Yes	Yes	Yes <sup>2</sup>	Yes <sup>2</sup>
Reset Pin	Assertion	Yes	Yes	Yes	Yes
Power	Cycle Off/On	Yes	Yes	Yes	Yes

<sup>1</sup> When using an external clock

<sup>2</sup> Corresponding bit in EMU\_WUEN must be set.

<sup>3</sup> Only available on a subset of the pins. Please refer to the Data Sheet for details.

### 11.3.4 Power Configurations

The EFR32 allows several power configurations with additional options giving flexible power architecture selection.

In order to provide the lowest power consuming radio solutions, the EFR32 comes with a DC-DC module to power internal circuits. The DC-DC requires an external inductor and capacitor (please refer to the Data Sheet for preferred values).

The EFR32 has multiple internal power domains: IO Supply (IOVDD), Analog & Flash (AVDD), RF Analog Supply (RFVDD), RF Power Amplifier Supply (PAVDD), Input to Digital LDO (DVDD), and Low Voltage Digital Supply (DECOUPLE). Additional detail for each configuration and option is given in the following sections.

When assigning supply sources, the following requirement must be adhered to:

- VREGVDD = AVDD (Must be the highest voltage in the system)
- VREGVDD >= DVDD
- VREGVDD >= PAVDD
- VREGVDD >= RFVDD
- VREGVDD >= IOVDD
- DVDD >= DECOUPLE

The system boots up into a safe power state, but must be immediately programmed to the desired configuration by writing to the EMU\_PWRCFG->PWRCFG bitfield. Out of POR, the PWRCFG is set to STARTUP, locking access to various power control registers. Once written, the PWRCFG cannot be changed.

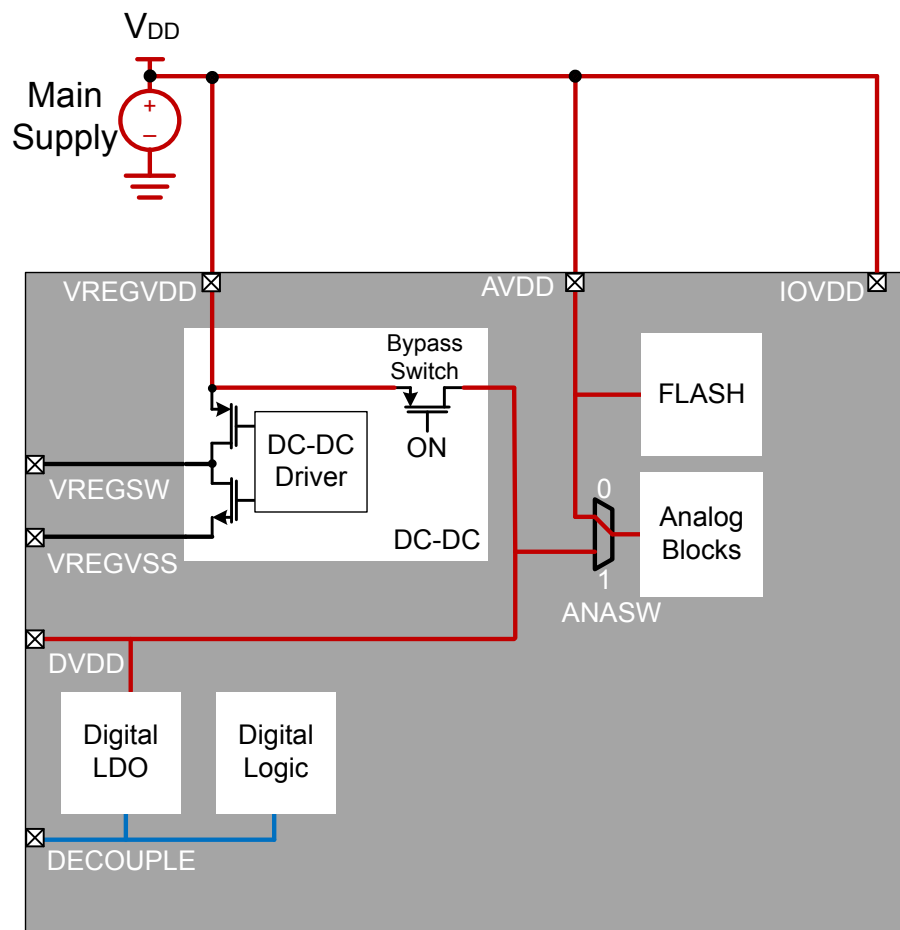

#### 11.3.4.1 Power Configuration 0: STARTUP

During power-on reset (POR), the system boots up in a safe Startup Configuration that supports all of the available Power Configurations. The Startup Configuration is shown in the simplified diagram below.

In the Startup Configuration:

- The DC-DC converter's Bypass switch is On (i.e., the VREGVDD pin is shorted internally to the DVDD pin).
- The analog blocks are powered from the AVDD supply pin (i.e., ANASW=0).

After power on, firmware can configure the device based on the external hardware configuration. Note that the PWRCFG register can only be written once to a valid value and is then locked. This should be done immediately out of boot to select the proper power configuration. The DCDC and PWRCTRL registers will be locked until the PWRCFG register is configured.

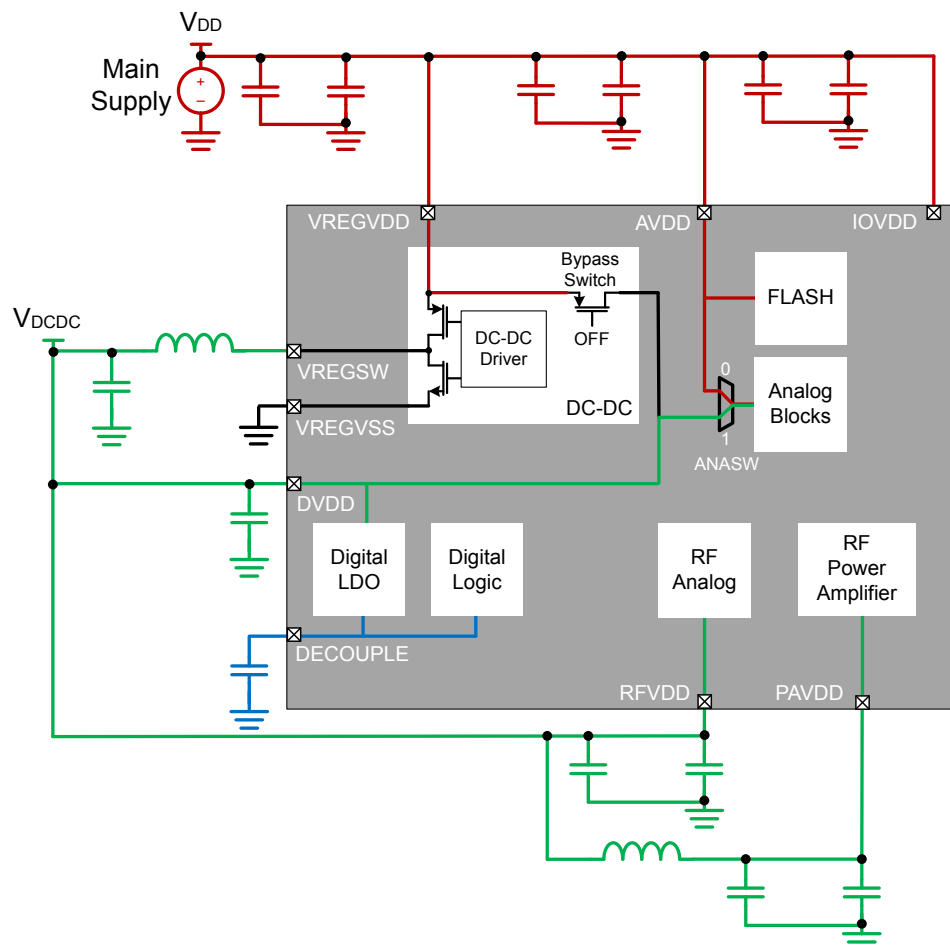

In Power Configuration 1, the DC-DC converter is programmed in Off mode and the Bypass switch is Off. The DVDD pin must be powered externally - typically, DVDD is connected to the main supply. IOVDD and AVDD are powered from the main supply as well. RFVDD and PAVDD, which power the radio, are shorted to the main supply as well.

### 11.3.4.3 Power Configuration 2: DC-DC

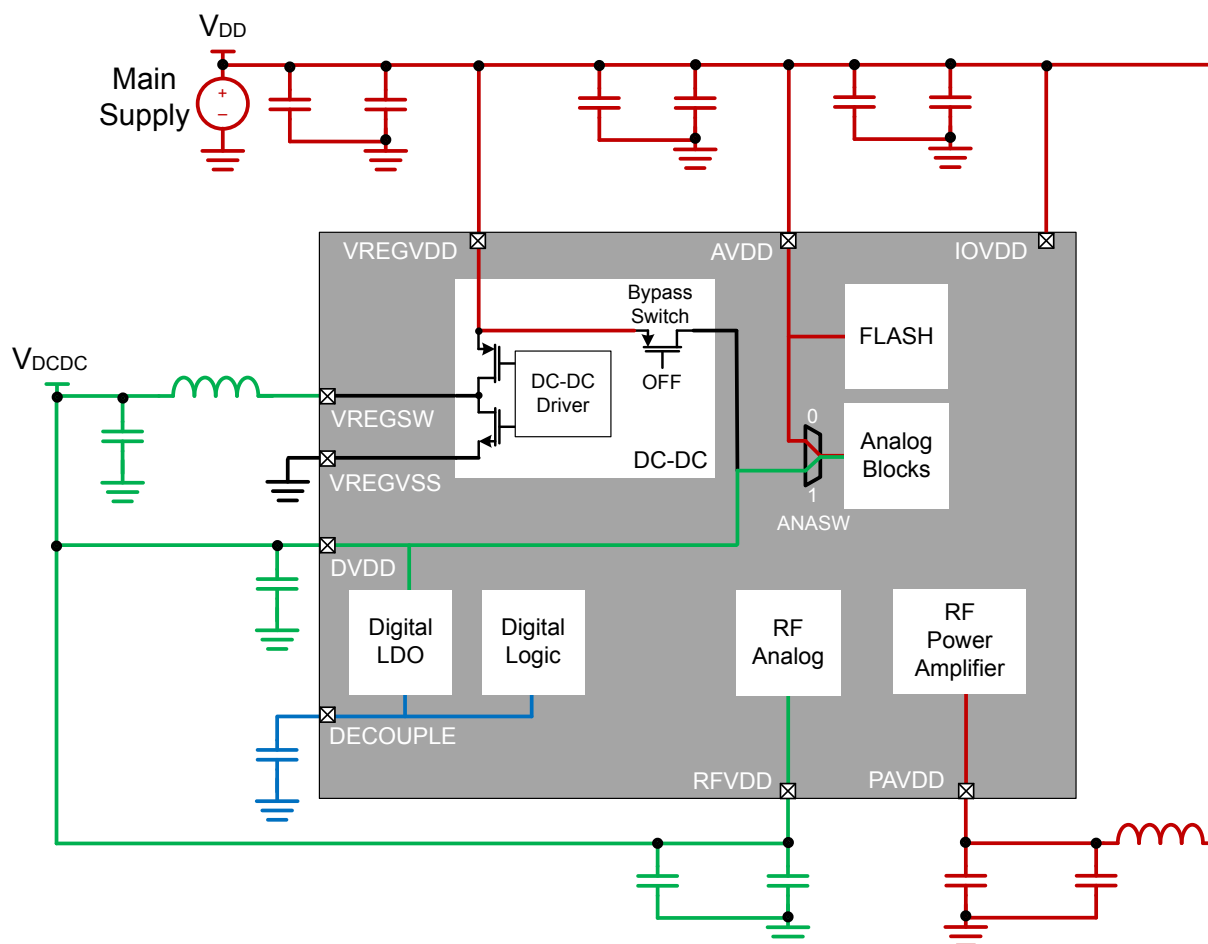

For the lowest power applications, the DC-DC converter can be used to power the DVDD supply, as well as RFVDD and PAVDD.

In Power Configuration 2, the DC-DC Output ( $V_{DCDC}$ ) is connected to DVDD. DVDD powers the internal Digital LDO which powers the digital circuits. AVDD is connected to the main supply voltage. The internal analog blocks may be powered from AVDD or DVDD, depending on the ANASW configuration. IOVDD could be connected to either the main supply (as shown below) or to  $V_{DCDC}$ , depending on the system IO requirements. RFVDD and PAVDD are powered from  $V_{DCDC}$  as well.

As the Main Supply voltage approaches the DC-DC output voltage, it eventually reaches a point where becomes inefficient (or impossible) for the DC-DC module to regulate  $V_{DCDC}$ . At this point, the system can be dynamically switched into DC-DC bypass mode, which effectively disables the DC-DC and shorts the Main Supply voltage directly to the DC-DC output. If and when sufficient voltage margin on the Main Supply returns, the system can be switched back into DC-DC regulation mode.

An alternate "High RF Power" DC-DC configuration has the external Main Supply connected directly to the PAVDD. This configuration supports a higher transmit power (e.g., >13 dBm) required for some radio protocol specifications. No additional software setting is required for this mode. The following diagram shows an example of connecting PAVDD to the Main Supply while DVDD and RFVDD are connected to the filtered  $V_{DCDC}$ .

### 11.3.5 DC-to-DC Interface

The low power (LP) controller contains a ring oscillator which gets turned on once the feed-back voltage drops below the internal reference. The pulse train charges up the external capacitor and once the feed-back voltage is at the expected level, the oscillator turns off. The mode uses a comparator with hysteresis. The LP controller supports load current up to approximately 10mA.

The EFR32 features a DC-to-DC buck converter which requires a single external inductor and a single external capacitor. The converter takes the VREGVDD input voltage and converts it down to an output voltage between VREGVDD and 1.8 V with a peak efficiency of approximately 90% in Low Noise (LN) mode and 85% in Low Power (LP) mode. Refer to datasheet for full DC-DC specifications.

The DC-DC converter operates in either Low Noise (LN) or Low Power (LP) mode. LN mode is intended for higher current operation (e.g., EM0), whereas LP mode is intended for very low current operation (e.g., EM2 and below). The DC-DC may be configured to automatically transition from LN mode in EM0/EM1 to LP mode in EM2, EM3, or EM4.

In addition, the DC-DC converter supports an unregulated Bypass mode, in which the input voltage is directly shorted to the DC-DC output.

#### 11.3.5.1 Bypass Mode

In Bypass mode, the VREGVDD input voltage is directly shorted to the DC-DC converter output through an internal switch. Out of reset, the DC-DC converter defaults to Bypass mode.

Consult the datasheet for the Bypass switch impedance specification.

### 11.3.5.2 Low Power (LP) Mode

The Low Power (LP) controller operates in a hysteretic mode to keep the output voltage within a defined voltage band. Once the DC-DC output voltage drops below a programmable internal reference, the LP controller generates a pulse train to control the powertrain PFET switch, which charges up the DC-DC output capacitor. When the output voltage is at the programmed upper level, the powertrain PFET is turned off. The output ripple voltage may be quite large (>100 mV) in LP mode.

The LP controller supports load currents up to approximately 10 mA, making it suitable for EM2, EM3, or EM4 low energy modes.

### 11.3.5.3 Low Noise (LN) Mode

The Low Noise (LN) controller continuously switches the powertrain NFET and PFET switches to maintain a constant programmed voltage at the DVDD pin. The LN controller supports load current from sub-mA up to 200 mA.

The LN controller switching frequency is programmable using the RCOBAND bitfield in the EMU\_DCDCCLNFREQCTRL register. See below for recommended RCOBAND settings for each mode.

The DC-DC Low Noise controller operates in one of two modes:

1. Continuous Conduction Mode (CCM)
2. Discontinuous Conduction Mode (DCM)

#### 11.3.5.3.1 Low Noise (LN) Continuous Conduction Mode (CCM)

CCM operation is configured by setting the LNFORCECCM bit in the EMU\_DCDCMISCCTRL register. CCM can be used to improve the DC-DC converter's output transient response time to quick load current changes, which minimizes voltage transients on the DC-DC output.

Note that all references to CCM in the documentation actually refer to Forced Continuous Conduction Mode (FCCM) - that is, if the LNFORCECCM bit is set and the output load current is very low, the DC-DC will be forced to operate in CCM. In this case, the current through the inductor may be negative and current may flow back into the battery.

CCM is required for radio or Wireless Gecko systems because, unlike DCM, it allows use of the radio's interference minimization features. In CCM, the recommended DC-DC converter switching frequency is 6.4 MHz (RCOBAND = 4). Note that when the radio's interference minimization features are enabled, RCOBAND = 4 corresponds to a DC-DC converter switching frequency of 7 MHz.

#### 11.3.5.3.2 Low Noise (LN) Discontinuous Conduction Mode (DCM)

To enable DCM, the LNFORCECCM bit in EMU\_DCDCMISCCTRL must be cleared before entering LN. Typically, this configuration would occur while the part was in Bypass mode. Once DCM is enabled, the DC-DC should operate in DCM at light load currents. However, as the load current increases, the DC-DC will automatically transition into CCM without software intervention.

The advantage of DCM is improved efficiency for light load currents. However, in DCM the DC-DC has poorer dynamic response to changes in load current, leading to potentially larger changes in the regulated output voltage. In addition, DCM increases the potential RF switching interference, because in DCM the DC-DC switching events are load dependent and can no longer be synchronized with radio operation. For these reasons, DCM is not recommended for radio applications or for non-radio applications that expect large instantaneous load current steps. For example, if the DC-DC is in DCM, firmware may need to increment the core clock frequency in small steps to prevent a large sudden load increase.

In DCM, the recommended DC-DC converter switching frequency is 3 MHz (RCOBAND = 0).

### 11.3.5.4 Analog Peripheral Power Selection

The analog peripherals (e.g., ULFRCO, LFRCO, LFXO, HFRCO, AUXHFRCO, VMON, IDAC, ADC) may be powered from one of two supply pins, depending on the configuration of the ANASW bit in the EMU\_PWRCTRL register: Changes to the ANASW setting should be made immediately out of reset (i.e., in the Startup Configuration) before all clocks (with the exception of HFRCO and ULFRCO) are enabled. Once ANASW is configured it should not be changed. Note that the flash is always powered from the AVDD pin, regardless of the state of the ANASW bit.

**Table 11.4. Analog Peripheral Power Configuration**

ANASW	Analog Peripheral Power Source	Comments
0 (default)	AVDD pin	This configuration may provide a quieter supply to the analog modules, but is less efficient as AVDD is typically at a higher voltage than DVDD.
1	DVDD pin	This configuration may provide a noisier supply to the analog modules, but is more efficient.

### 11.3.5.5 IOVDD Connection

The IOVDD can be connected to either the DCDC Output ( $V_{DCDC}$ ) or the main supply.

Note that when IOVDD is powered from the  $V_{DCDC}$ , any circuit attached to IOVDD must be capable of withstanding the main supply voltage momentarily. This is because at startup, the bypass switch is on, shorting the main supply to  $V_{DCDC}$ . In addition, the system must take into consideration the maximum allowable DCDC load current. Refer to datasheet for DCDC specification.

IOVDD must be less than or equal to AVDD.

### 11.3.5.6 DC-to-DC Programming Guidelines

**Note:** Refer to Application Note AN0948: "Power Configurations and DC-DC" for detailed information on programming the DC-DC. Application Notes can be found on the Silicon Labs website ([www.silabs.com/32bit-appnotes](http://www.silabs.com/32bit-appnotes)) or using the **[Application Notes]** tile in Simplicity Studio.

## 11.3.6 Brown Out Detector (BOD)

### 11.3.6.1 AVDD BOD

The EFR32 has a fast response Brown Out Detector (BOD) on AVDD that is always active. This BOD ensures the minimal supply is provided to the AVDD supply (typically also connected to VREGVDD). Once triggered, the BOD will cause the system to reset.

**Note:** In EM4 Hibernate/Shutoff a low power version of the AVDD BOD, called EM4BOD, is available to trigger a reset at level lower than in other energy modes. All other BOD's are disabled during EM4 Hibernate/Shutoff

### 11.3.6.2 DVDD and DECOUPLE BOD

Additional BODs will monitor DVDD and DECOUPLE during EM0 Active through EM3 Stop. This can cause a reset to the internal logic, but will not cause a power-on reset or reset the EMU or RTCC.

### 11.3.7 Voltage Monitor (VMON)

The EFR32 features an extremely low energy Voltage Monitor (VMON) capable of running down to EM4 Hibernate. Trigger points are preloaded but may be reconfigured.

- AVDD X 2
- DVDD
- IOVDD0

**Table 11.5. VMON Events**

Feature	Condition	AVDD	DVDD	DEC	IOVDD
Hysteresis (separate rise and fall triggers)	-	Yes	-	-	-
Interrupt	Fall or Rise	Yes	Yes	Yes	Yes
Wakeup from EM4 Hibernate	Fall or Rise	Yes	Yes	Yes	Yes

The status of the VMON is reflected in the EMU\_STATUS register.

The status of the sticky interrupt can be found at EMU\_IF.

### 11.3.8 Powering off SRAM blocks

SRAM blocks may be powered off using the EMU->RAM0CTRL POWERDOWN fields. One SRAM block will always be powered on for proper system functionality. The stack must be located in retained memory.

### 11.3.9 Temperature Sensor Status

EMU provides low energy periodic temperature measurement. Temperature measurement is taken every 250 ms with the 8-bit result stored in EMU->TEMP register.

**Note:** EMU temperature sensor is always running (except in EM4 Shutoff) and is independent from ADC temperature sensor.

The EMU provides the following features around temperature changes

- Wakeup from EM4 Hibernate on Temperature Change
- Interrupt from High Level Trip
- Interrupt from Low Level Trip

### 11.3.10 Registers latched in EM4

The following registers will be latched when entering EM4. After wakeup from EM4, these registers will be reset and require reprogramming prior to writing the EMU\_CMD\_EM4UNLATCH command.

- CMU\_LFEPRESC0

### 11.3.11 Register Resets

Each EMU register requires retaining state in various energy modes and power transitions and will consequently need to be reset with a different condition. The following reset conditions will apply to the appropriate set of registers as marked in the Register Description table.

- Reset with POR or Hard Pin Reset
- Reset with POR, Hard Pin Reset, or any BOD reset
- Reset with SYSEXTENDEDRESETn
- Reset with FULLRESETn (default)

If a register field is not marked with a specific reset condition then it is assumed to be reset with FULLRESETn.

## 11.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	EMU_CTRL	RW	Control Register
0x004	EMU_STATUS	R	Status Register
0x008	EMU_LOCK	RWH	Configuration Lock Register
0x00C	EMU_RAM0CTRL	RW	Memory Control Register
0x010	EMU_CMD	W1	Command Register
0x018	EMU_EM4CTRL	RW	EM4 Control Register
0x01C	EMU_TEMPLIMITS	RW	Temperature limits for interrupt generation
0x020	EMU_TEMP	R	Value of last temperature measurement
0x024	EMU_IF	R	Interrupt Flag Register
0x028	EMU_IFS	W1	Interrupt Flag Set Register
0x02C	EMU_IFC	(R)W1	Interrupt Flag Clear Register
0x030	EMU_IEN	RW	Interrupt Enable Register
0x034	EMU_PWRLOCK	RW	Regulator and Supply Lock Register
0x038	EMU_PWRCFG	RW	Power Configuration Register. This is no longer used
0x03C	EMU_PWRCTRL	RW	Power Control Register.
0x040	EMU_DCDCCTRL	RW	DCDC Control
0x04C	EMU_DCDCMISCCTRL	RW	DCDC Miscellaneous Control Register
0x050	EMU_DCDCZDETCTRL	RW	DCDC Power Train NFET Zero Current Detector Control Register
0x054	EMU_DCDCCLIMCTRL	RW	DCDC Power Train PFET Current Limiter Control Register
0x05C	EMU_DCDCLNVCTRL	RWH	DCDC Low Noise Voltage Register
0x060	EMU_DCDCTIMING	RW	DCDC Controller Timing Value Register
0x064	EMU_DCDCLPVCTRL	RW	DCDC Low Power Voltage Register
0x06C	EMU_DCDCLPCTRL	RW	DCDC Low Power Control Register
0x070	EMU_DCDCLNFREQCTRL	RW	DCDC Low Noise Controller Frequency Control
0x078	EMU_DCDCSYNC	R	DCDC Read Status Register
0x090	EMU_VMONAVDDCTRL	RW	VMON AVDD Channel Control
0x094	EMU_VMONALTAVDDCTRL	RW	Alternate VMON AVDD Channel Control
0x098	EMU_VMONDVDDCTRL	RW	VMON DVDD Channel Control
0x09C	EMU_VMONIO0CTRL	RW	VMON IOVDD0 Channel Control
0x0A8	EMU_VMONPAVDDCTRL	RW	VMON PAVDD Channel Control

## 11.5 Register Description

### 11.5.1 EMU\_CTRL - Control Register

Offset	Bit Position																															
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																																
Access																																
Name																																

Bit	Name	Reset	Access	Description
31:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	EM2BLOCK	0	RW	<b>Energy Mode 2 Block</b> This bit is used to prevent the MCU from entering Energy Mode 2 or 3.
0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

11.5.2 EMU\_STATUS - Status Register

Offset	Bit Position																																				
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
Reset							0						0																	0	0		0	0	0	0	
Access							R						R																	R	R		R	R	R	R	
Name							RACTIVE						EM4IORET																	VMONFVDD	VMONPAVDD		VMONIO0	VMONDVDD	VMONALTAVDD	VMONAVDD	VMONRDY

Bit	Name	Reset	Access	Description
31:26	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
25	RACACTIVE	0	R	<b>Radio Controller Active</b>  This bit indicates the status of the RAC state machine. System can not enter EM2 or lower if set.
Value		Description		
0		RAC is in OFF state		
1		RAC is not in OFF state		
24:21	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
20	EM4IORET	0	R	<b>IO Retention Status</b>  The status of IO retention. Will be set upon EM4 entry based on EM4IORETMODE in EMU_EM4CTRL. Cleared by setting EM4UNLATCH in EMU_CMD, and can also be cleared in EM4H by the VMON.
Value		Mode	Description	
0		DISABLED	IO retention is disabled.	
1		ENABLED	IO retention is enabled.	
19:9	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
8	VMONFVDD	0	R	<b>VMON VDDFLASH Channel.</b>  Indicates the status of the VDDFLASH channel of the VMON.
7	VMONPAVDD	0	R	<b>VMON PAVDD Channel.</b>  Indicates the status of the PAVDD channel of the VMON.
6:5	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
4	VMONIO0	0	R	<b>VMON IOVDD0 Channel.</b>  Indicates the status of the IOVDD0 channel of the VMON.
3	VMONDVDD	0	R	<b>VMON DVDD Channel.</b>  Indicates the status of the DVDD channel of the VMON.
2	VMONALTAVDD	0	R	<b>Alternate VMON AVDD Channel.</b>  Indicates the status of the Alternate AVDD channel of the VMON.
1	VMONAVDD	0	R	<b>VMON AVDD Channel.</b>  Indicates the status of the AVDD channel of the VMON.
0	VMONRDY	0	R	<b>VMON ready</b>  VMON status. When high, this bit indicates that all the enabled channels are ready. When low, it indicates that one or more of the enabled channels are not ready.

### 11.5.3 EMU\_LOCK - Configuration Lock Register

Offset	Bit Position																																					
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset																																	0x0000					
Access																																	RWH					
Name																																	LOCKKEY					

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:0	LOCKKEY	0x0000	RWH	<b>Configuration Lock Key</b>  Write any other value than the unlock code to lock all EMU registers, except the interrupt registers and regulator control registers, from editing. Write the unlock code to unlock. When reading the register, bit 0 is set when the lock is enabled.
Mode		Value	Description	
Read Operation				
UNLOCKED		0	EMU registers are unlocked	
LOCKED		1	EMU registers are locked	
Write Operation				
LOCK		0	Lock EMU registers	
UNLOCK		0xADE8	Unlock EMU registers	

### 11.5.4 EMU\_RAM0CTRL - Memory Control Register

Offset	Bit Position																															
0x00C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																								0					0x0			
Access																								RW					RW			
Name																								RAMHPOWERDOWN					RAMPOWERDOWN			

Bit	Name	Reset	Access	Description
31:9	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
8	RAMHPOWER-DOWN	0	RW	<b>RAMH power-down</b>  RAMH power-down. When it is powered down, it cannot be powered up again. The block will be powered up after the reset.
	Value	Mode		Description
	0	NONE		RAMH not powered down
	1	RAMHBLK		Power down RAMH (address range 0x20007C00-0x20007FFF)
7:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3:0	RAMPOWERDOWN	0x0	RW	<b>RAM0 blockset power-down</b>  RAM blockset power-down in EM23 with full access in EM01. Block 0 (address range 0x20000000-0x20003FFF) may never be powered down.
	Value	Mode		Description
	0	NONE		None of the RAM blocks powered down
	8	BLK4		Power down RAM blocks 4 and above (address range 0x20006000-0x20007BFF)
	12	BLK3TO4		Power down RAM blocks 3 and above (address range 0x20004000-0x20007BFF)
	14	BLK2TO4		Power down RAM blocks 2 and above (address range 0x20002000-0x20007BFF)
	15	BLK1TO4		Power down RAM blocks 1 and above (address range 0x20001000-0x20007BFF)

11.5.5 EMU\_CMD - Command Register

Offset	Bit Position																																
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																																	0
Access																																	W1
Name																																	EM4UNLATCH

Bit	Name	Reset	Access	Description
31:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	EM4UNLATCH	0	W1	<b>EM4 Unlatch</b>  When entering EM4, several registers will be latched in order to maintain constant functionality throughout EM4. Upon wakeup, these registers will be reset and can have contradictory values to the latched values. To ensure a seamless transition from EM4 to EM0, the unlatch command should be given after properly reconfiguring these latched registers. The unlatch command can be executed after any reset condition but is only needed after EM4 wakeup.

## 11.5.6 EMU\_EM4CTRL - EM4 Control Register

Offset	Bit Position																															
0x018	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset															0x0													0x0	0	0	0	0
Access															W1													RW	RW	RW	RW	RW
Name															EM4ENTRY													EM4IORETMODE	RETAINULFRCO	RETAINLFXO	RETAINLFRCO	EM4STATE

Bit	Name	Reset	Access	Description
31:18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17:16	EM4ENTRY	0x0	W1	<b>Energy Mode 4 Entry</b>  This register is used to enter the Energy Mode 4 sequence. Writing the sequence 2,3,2,3,2,3,2 will enter the part into Energy Mode 4.
15:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5:4	EM4IORETMODE	0x0	RW	<b>EM4 IO Retention Disable</b>  Determine when IO retention will be applied and removed.
	Value	Mode	Description	
	0	DISABLE	No Retention: Pads enter reset state when entering EM4	
	1	EM4EXIT	Retention through EM4: Pads enter reset state when exiting EM4	
	2	SWUNLATCH	Retention through EM4 and Wakeup: software writes UNLATCH register to remove retention	
3	RETAINULFRCO	0	RW	<b>ULFRCO Retain during EM4S</b>  Retain the ULFRCO upon EM4S entry. If set to 1, an already running ULFRCO will be retained in its running state in EM4. ULFRCO will always be retained if EM4STATE is in EM4H.
2	RETAINLFXO	0	RW	<b>LFXO Retain during EM4</b>  Retain the LFXO upon EM4(SH/H) entry. If set to 1, an already running LFXO will be retained in its running state in EM4.
1	RETAINLFRCO	0	RW	<b>LFRCO Retain during EM4</b>  Retain the LFRCO upon EM4(S/H) entry. If set to 1, an already running LFRCO will be retained in its running state in EM4.
0	EM4STATE	0	RW	<b>Energy Mode 4 State</b>  When set, the system will enter Hibernate state (EM4H) when entering EM4. In EM4H, the regulator will be on in reduced mode allowing for RTCC. Otherwise, when entering in EM4, the regulator will be disabled allowing for lowest power mode, Shutoff state (EM4S).
	Value	Mode	Description	
	0	EM4S	EM4S Shutoff state	
	1	EM4H	EM4H Hibernate state	

## 11.5.7 EMU\_TEMPLIMITS - Temperature limits for interrupt generation

Offset	Bit Position																																
0x01C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0	0xFF								0x00							
Access																	RW	RW								RW							
Name																	EM4WUEN	TEMPHIGH								TEMPLOW							

Bit	Name	Reset	Access	Description
31:17	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
16	EM4WUEN	0	RW	<b>Enable EM4 Wakeup due to low/high temperature</b> Enable EM4 wakeup from low or high temperature from EM4H
15:8	TEMPHIGH	0xFF	RW	<b>Temperature High Limit</b> The TEMPHIGH interrupt flag is set when a periodic temperature measurement is equal to or higher than this value. If the high limit is changed during a temperature measurement (TEMPACTIVE=1), the limit update will be delayed until the end of the temperature measurement.
7:0	TEMPLOW	0x00	RW	<b>Temperature Low Limit</b> The TEMPLOW interrupt flag is set when a periodic temperature measurement is equal to or lower than this value. If the low limit is changed during a temperature measurement (TEMPACTIVE=1), the limit update will be delayed until the end of the temperature measurement.

## 11.5.8 EMU\_TEMP - Value of last temperature measurement

Offset	Bit Position																															
0x020	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xxx							
Access																									R							
Name																									TEMP							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	TEMP	0xFF	R	<b>Temperature Measurement</b> Value of last periodic temperature measurement. Value is asynchronously updated. Value is stable for 250 ms after a temperature-based interrupt (TEMPHIGH, TEMPLOW, or TEMP) and can be read with a single read operation. If register is read not in response to a temperature-based interrupt, multiple readings should be taken until two consecutive values are the same.

### 11.5.9 EMU\_IF - Interrupt Flag Register

Offset	Bit Position																																		
0x024	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VMONDVDDFALL																																			
VMONALTAVDDRISE																																			
VMONALTAVDDFALL																																			
VMONAVDDRISE																																			
VMONAVDDFALL																																			

Bit	Name	Reset	Access	Description
31	TEMPHIGH	0	R	<b>Temperature High Limit Reached</b> Set when the value of a periodic temperature measurement is higher or equal than TEMPHIGH in EMU_TEMPLIMITS
30	TEMPLOW	0	R	<b>Temperature Low Limit Reached</b> Set when the value of a periodic temperature measurement is lower or equal than TEMPHIGH in EMU_TEMPLIMITS
29	TEMP	0	R	<b>New Temperature Measurement Valid</b> Set when a new periodic temperature measurement is available
28:25	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
24	EM23WAKEUP	0	R	<b>Wakeup IRQ from EM2 and EM3</b> Will be set when the system wakes up from EM2 and EM3. This interrupt can be used to run initialization code need to reconfigure the system when returning from EM2 and EM3.
23:21	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
20	DCDCINBYPASS	0	R	<b>DCDC is in bypass</b> DCDC is in bypass
19	DCDCLNRUNNING	0	R	<b>LN mode is running</b> This flag is set once the DCDC regulator has started to run in LN mode
18	DCDCLPRUNNING	0	R	<b>LP mode is running</b> This flag is set once the DCDC regulator has started to run in LP mode
17	NFETOVERCURRENTLIMIT	0	R	<b>NFET current limit hit</b> Reserved for internal use.
16	PFETOVERCURRENTLIMIT	0	R	<b>PFET current limit hit</b> Reserved for internal use.
15	VMONFVDDRISE	0	R	<b>VMON VDDFLASH Channel Rise</b> A rising edge on VMON VDDFLASH channel has been detected.
14	VMONFVDDFALL	0	R	<b>VMON VDDFLASH Channel Fall</b> A falling edge on VMON VDDFLASH channel has been detected.
13	VMONPAVDDRISE	0	R	<b>VMON PAVDD Channel Rise</b> A rising edge on VMON PAVDD channel has been detected.
12	VMONPAVDDFALL	0	R	<b>VMON PAVDD Channel Fall</b> A falling edge on VMON PAVDD channel has been detected.
11:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7	VMONIO0RISE	0	R	<b>VMON IOVDD0 Channel Rise</b> A rising edge on VMON IOVDD0 channel has been detected.
6	VMONIO0FALL	0	R	<b>VMON IOVDD0 Channel Fall</b> A falling edge on VMON IOVDD0 channel has been detected.
5	VMONDVDDRISE	0	R	<b>VMON DVDD Channel Rise</b>

Bit	Name	Reset	Access	Description
				A rising edge on VMON DVDD channel has been detected.
4	VMONDVDDFALL	0	R	<b>VMON DVDD Channel Fall</b> A falling edge on VMON DVDD channel has been detected.
3	VMONALTAVDDRISE	0	R	<b>Alternate VMON AVDD Channel Rise</b> A rising edge on Alternate VMON AVDD channel has been detected.
2	VMONALTAVDDFALL	0	R	<b>Alternate VMON AVDD Channel Fall</b> A falling edge on Alternate VMON AVDD channel has been detected.
1	VMONAVDDRISE	0	R	<b>VMON AVDD Channel Rise</b> A rising edge on VMON AVDD channel has been detected.
0	VMONAVDDFALL	0	R	<b>VMON AVDD Channel Fall</b> A falling edge on VMON AVDD channel has been detected.

Reset																									1	1					0x0	
Access																									RW	RW					RW	
Name																									DCDCMODEEM4	DCDCMODEEM23			DCDCMODE			

Bit	Name	Reset	Access	Description
31:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5	DCDCMODEEM4	1	RW	<b>DCDC Mode EM4H</b>  Determines the DCDC mode in EM4H. When the DCDCMODE field is set to OFF, this bit must be cleared so that the DCDC remains off. Reset with POR, Hard Pin Reset, or BOD Reset.
	Value	Mode	Description	
	0	EM4SW	DCDC mode is according to DCDCMODE field.	
	1	EM4LOWPOWER	DCDC mode is low power.	
4	DCDCMODEEM23	1	RW	<b>DCDC Mode EM23</b>  Determines the DCDC mode in EM2 and EM3. When the DCDCMODE field is set to OFF, this bit must be cleared so that the DCDC remains off. Reset with POR, Hard Pin Reset, or BOD Reset.
	Value	Mode	Description	
	0	EM23SW	DCDC mode is according to DCDCMODE field.	
	1	EM23LOWPOWER	DCDC mode is low power.	
3:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1:0	DCDCMODE	0x0	RW	<b>Regulator Mode</b>  Determines the operating mode of the DCDC regulator. When the DCDCMODE is set of OFF, DCDCMODEEM23 and DCDCMODEEM4 must be cleared. Reset with POR, Hard Pin Reset, or BOD Reset.
	Value	Mode	Description	
	0	BYPASS	DCDC regulator is operating in bypass mode.	
	1	LOWNOISE	DCDC regulator is operating in low noise mode.	
	2	LOWPOWER	DCDC regulator is operating in low power mode.	
	3	OFF	DCDC regulator is off. Note: DVDD must be supplied externally	

11.5.17 EMU\_DCDCMISCCTRL - DCDC Miscellaneous Control Register

Offset	Bit Position

Reset			0x3			0x3				0x3			0x0			0x7			0x7									0				
Access			RW			RW				RW			RW			RW			RW									RW				
Name			LPCMPBIAS			LNCLIMILIMSEL				LPCLIMILIMSEL			BYPLIMSEL			NFETCNT			PFETCNT									LNFORCECCM				

Bit	Name	Reset	Access	Description
31:30	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
29:28	LPCMPBIAS	0x3	RW	<b>LP mode comparator bias selection</b>  LP mode comparator bias selection. Reset with POR, Hard Pin Reset, or BOD Reset.
	Value	Mode		Description
	0	BIAS0		Maximum load current less than 75uA.
	1	BIAS1		Maximum load current less than 500uA.
	2	BIAS2		Maximum load current less than 2.5mA.
	3	BIAS3		Maximum load current less than 10mA.
27	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
26:24	LNCLIMILIMSEL	0x3	RW	<b>Current limit level selection for current limiter in LN mode</b>  High-side current limiter's current limit level selection in low noise mode. The recommended setting is calculated by $LNCLIMILIMSEL = (I\_MAX + 40mA) * 1.5 / (5mA * (PFETCNT + 1)) - 1$ , where $I\_MAX$ is the maximum average current allowed to the load, and 40mA represents the current ripple with some margin, and the factor of 1.5 accounts for detecting error and other variations. For strong battery, it is recommended to have $I\_MAX = 200mA$ . It should never have $I\_MAX$ higher than 200mA to avoid reliability issues. Reset with POR, Hard Pin Reset, or BOD reset.
23	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
22:20	LPCLIMILIMSEL	0x3	RW	<b>Current limit level selection for current limiter in LP mode</b>  High-side current limiter's current limit level selection in low power mode. It is calculated by $LPCLIMILIMSEL = (I\_MAX + 40mA) * 1.5 / (5mA * (PFETCNT + 1)) - 1$ . To optimize the power efficiency, it is recommended to have $PFETCNT = 7$ and $(I\_MAX + 40mA) * 1.5 = 80mA$ , and consequently calculated $LPCLIMILIMSEL = 1$ . Reset with POR, Hard Pin Reset, or BOD reset.
19:16	BYPLIMSEL	0x0	RW	<b>Current Limit In Bypass Mode</b>  Set current limit in bypass mode when BYPLIMEN equals one. The limit is from 20mA to 320mA, with 20mA/step. Reset with POR, Hard Pin Reset, or BOD Reset.
15:12	NFETCNT	0x7	RW	<b>NFET switch number selection</b>  NFET power switch count number. The selected number of switches are $NFETCNT + 1$ . This value applies to both LN and LP mode. Because of this, when transitioning from LN to LP mode, software may need to update the NFETCNT setting desired for LP mode while still in LN mode. This may cause a very momentary efficiency hit. Reset with POR, Hard Pin Reset, or BOD Reset.
11:8	PFETCNT	0x7	RW	<b>PFET switch number selection</b>  PFET power switch count number. The selected number of switches are $PFETCNT + 1$ . This value applies to both LN and LP mode. Because of this, when transitioning from LN to LP mode, software may need to update the PFETCNT setting desired for LP mode while still in LN mode. This may cause a very momentary efficiency hit. Reset with POR, Hard Pin Reset, or BOD Reset.
7:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	LNFORCECCM	0	RW	<b>Force DCDC into CCM mode in low noise operation</b>  When this bit is set to 1 in low noise mode, the zero detector is configured as zero-crossing detector and the DCDC will be in forced CCM mode. The threshold set by ZDETILIMSEL will be ignored. When this bit is set to 0 in low noise mode, the zero detector is configured as reverse-current limiter and the DCDC will be in DCM mode. The reverse current limit level is set by ZDETILIMSEL. In low power mode, the zero detector is always configured as zero-crossing detector. Reset with POR, Hard Pin Reset, or BOD reset.

## 11.5.18 EMU\_DCDCZDETCTRL - DCDC Power Train NFET Zero Current Detector Control Register

Offset	Bit Position																																	
0x050	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset																							0x1			0x3								
Access																							RW			RW								
Name																							ZDETBLANKDLY			ZDETILIMSEL								

Bit	Name	Reset	Access	Description
31:10	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
9:8	ZDETBLANKDLY	0x1	RW	<b>Reserved for internal use. Do not change.</b> Reserved for internal use. Do not change.
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:4	ZDETILIMSEL	0x3	RW	<b>Reverse current limit level selection for zero detector</b>  Zero detector is reconfigured as low-side reverse current limiter when LNFORCECCM=1 in LN mode. The configuration of this register is calculated by the allowed average reverse current I_RMAX through the equation: $ZDETILIMSEL = (I\_RMAX + 40mA) * 1.5 / (2.5mA * (NFETCNT + 1))$ , where 40mA represents the current ripple with some margin, and the factor of 1.5 accounts for detecting error and other variations. When the battery is tolerable with large reverse current, it is recommended to have I_RMAX=160mA to maximize ZDETILIMSEL to 7 with NFETCNT=15. Please be noticed that when LNFORCECCM=1 but ZDETILIMSEL=0, the DCDC's behavior will be very similar to when LNFORCECCM=0. In another words, the DCDC is in DCM mode. When LNFORCECCM=0, zero detector only detect zero-crossing and this register is ignored. Reset with POR, Hard Pin Reset, or BOD reset.
3:0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

### 11.5.19 EMU\_DCDCCLIMCTRL - DCDC Power Train PFET Current Limiter Control Register

## 12. CMU - Clock Management Unit

### Quick Facts

#### What?

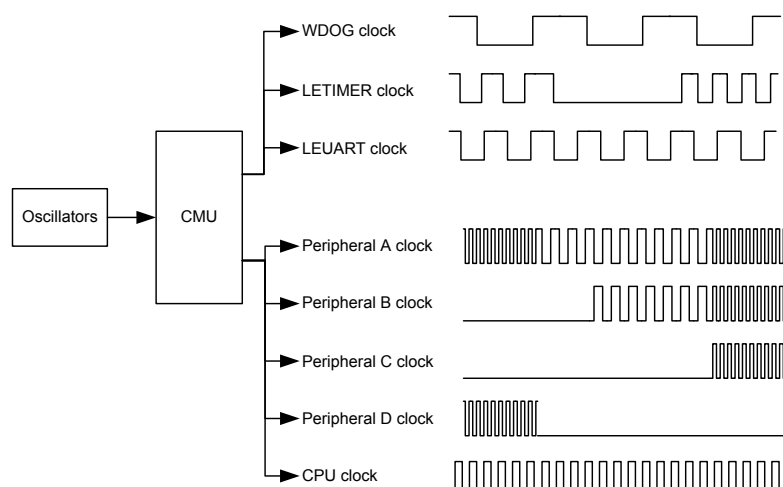

The CMU controls oscillators and clocks. EFR32 supports 6 different oscillators with minimized power consumption and short start-up time. The CMU has HW support for calibration of RC oscillators.

#### Why?

Oscillators and clocks contribute significantly to the power consumption of the MCU. With the low power oscillators combined with the flexible clock control scheme, it is possible to minimize the energy consumption in any given application.

#### How?

The CMU can configure different clock sources, enable/disable clocks to peripherals on an individual basis and set the prescaler for the different clocks. The short oscillator start-up times makes duty-cycling between active mode and the different low energy modes (EM2 DeepSleep, EM3 Stop, and EM4 Hibernate/Shutoff) very efficient. The calibration feature ensures high accuracy RC oscillators. Several interrupts are available to avoid CPU polling of flags.

### 12.1 Introduction

The Clock Management Unit (CMU) is responsible for controlling the oscillators and clocks in the EFR32. The CMU provides the capability to turn on and off the clock on an individual basis to all peripheral modules in addition to enable/disable and configure the available oscillators. The high degree of flexibility enables software to minimize energy consumption in any specific application by not wasting power on peripherals and oscillators that do not need to be active.

### 12.2 Features

- Multiple clock sources available:
  - 38 MHz - 40 MHz High Frequency Crystal Oscillator (HFXO)
  - 1 MHz - 38 MHz High Frequency RC Oscillator (HFRCO)
  - 1 MHz - 38 MHz Auxiliary High Frequency RC Oscillator (AUXHFRCO)
  - 32768 Hz Low Frequency Crystal Oscillator (LFXO)
  - 32768 Hz Low Frequency RC Oscillator (LFRCO)
  - 1000 Hz Ultra Low Frequency RC Oscillator (ULFRCO)
- Low power oscillators.
- Low start-up times.
- Separate prescalers for High Frequency Core Clocks (HFCORECLK), Radio Clocks (HFRADIOCLK), and Peripheral Clocks (HFPERCLK).
- Individual clock prescaler selection for each Low Energy Peripheral.
- Clock gating on an individual basis to core modules and all peripherals.
- Selectable clocks can be output to external pins and/or PRS.
- Wakeup interrupt based on LFRCO or LFXO ready, allowing to wait for low frequency oscillator startup while being in EM2 DeepSleep avoiding the need for polling.
- Auxiliary 1 MHz - 38 MHz RC oscillator (AUXHFRCO), which is asynchronous to the HFSRCCLK system clock, can be selected for ADC operation and debug trace.

### 12.3 Functional Description

An overview of the CMU is shown in [Figure 12.1 CMU Overview on page 241](#). This figure shows the CMU for the largest device in the EFR32 family. Please refer to the Configuration Summary in the Device Datasheet to see which core, radio, and peripheral modules, and therefore clock connections, are present in a specific device.

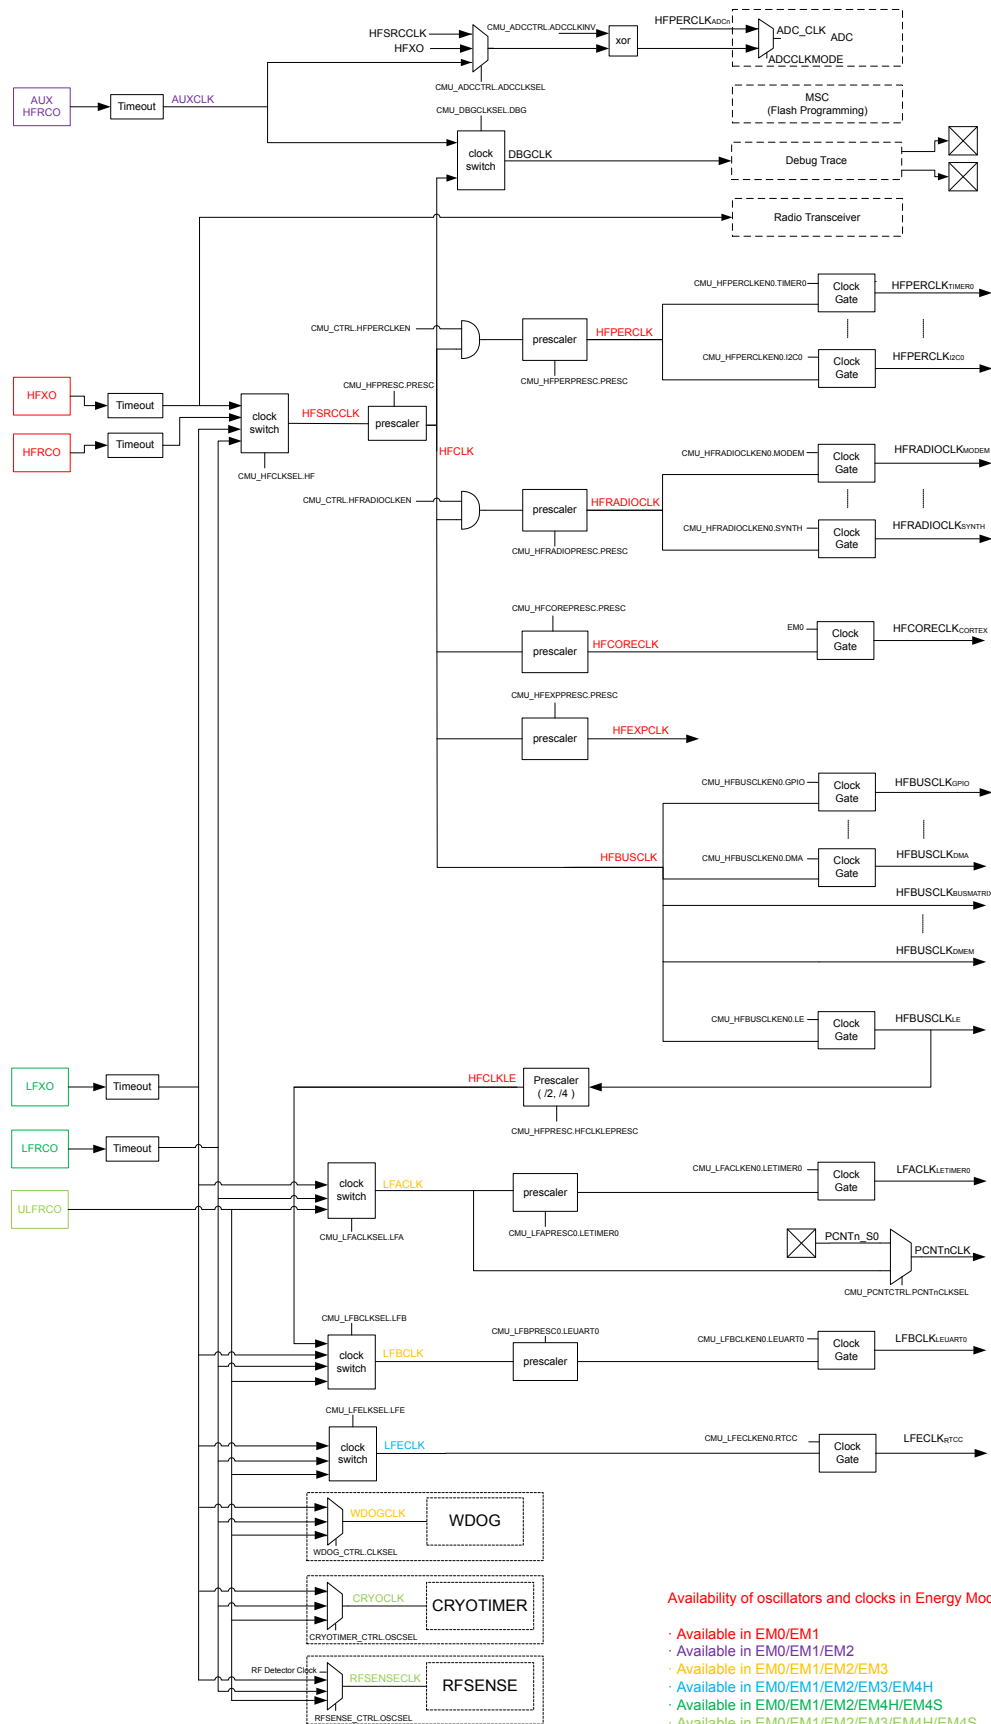

Figure 12.1. CMU Overview

## 12.3.1 System Clocks

### 12.3.1.1 HFCLK - High Frequency Clock

HFSRCCLK is the selected High Frequency Source Clock. HFCLK is an optionally prescaled version of HFSRCCLK. The HFSRCCLK, and therefore HFCLK, can be driven by a high-frequency oscillator (HFRCO or HFXO or HFRCODIV2 see ) or one of the low-frequency oscillators (LFRCO or LFXO). Additionally, HFSRCCLK can also be driven from a pin (CLKIN) described in [12.3.6 Clock Input from a Pin](#). By default the HFRCO is selected. In most applications, one of the high frequency oscillators will be the preferred choice. To change the selected clock source, write to the HF bitfield in CMU\_HFCLKSEL. The high frequency clock source can also be changed automatically by hardware as explained in [12.3.2.9 Automatic HFXO Start](#). The currently selected source for HFSRCCLK and HFCLK can be read from CMU\_HFCLKSTATUS. The HFSRCCLK is running in EM0 Active and EM1 Sleep and is automatically stopped in EM2 DeepSleep.

#### Note:

If a low frequency clock (i.e. LFRCO or LFXO) is selected as source clock for HFSRCCLK via the HF bitfield in CMU\_HFCLKSEL, then no register reads should be performed from Low Energy Peripherals for registers which can change value every clock cycle (e.g. a counter register). In addition to the peripherals on LFACLK, LFBCLK and LFECLK, this restriction applies in general to any low frequency peripheral, which is not directly or indirectly clocked from HFSRCCLK (e.g. the WDOG).

HFCLK can optionally be prescaled by setting PRESC in CMU\_HFPRESC to a non-zero value. This prescales HFCLK to all high frequency components and is typically used to save energy in applications where the system is not required to run at the highest frequency. The prescaler setting can be changed dynamically and the new setting takes effect immediately. HFCLK is used by the CMU and drives the prescalers that generate HFCORECLK, HFRADIOCLK, and HPPERCLK allowing for flexible clock prescaling. The HFBUSCLK, used, for example, in the bus and memory system, is equal to HFCLK.

The HFXO clock is fed directly to the Radio Transceiver. The clock received by the Radio Transceiver is therefore not affected by the selected clock source for HFSRCCLK nor by any clock prescaler.

### 12.3.1.2 HFCORECLK - High Frequency Core Clock

HFCORECLK is a prescaled version of HFCLK. This clock drives the Core Modules, which consists of the CPU and modules that are tightly coupled to the CPU, e.g. the cache. The prescale factor for prescaling HFCLK into HFCORECLK is set using the CMU\_HFCOREPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

#### Note:

Note that if HPPERCLK or HFRADIOCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to (radio) peripheral modules will increase with the ratio between the clocks. Please refer to [4.2.4 Bus Matrix](#) for more details.

### 12.3.1.3 HFBUSCLK - High Frequency Bus Clock

HFBUSCLK is equal to HFCLK. This clock drives Bus and Memory System Modules as for example the Bus Matrix, MSC, RAM, DMA, CRYPTO and GPIO. HFBUSCLK is also used to drive the bus interface to the Low Energy Peripherals as described further in [12.3.1.6 LFACLK - Low Frequency A Clock](#), [12.3.1.7 LFBCLK - Low Frequency B Clock](#) and [12.3.1.8 LFECLK - Low Frequency E Clock](#). Some of the modules that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific module in CMU\_HFBUSCLKEN0. The frequency of HFBUSCLK is equal to the frequency of HFCLK and can therefore only be prescaled by using the PRESC bitfield in CMU\_HFPRESC.

### 12.3.1.4 HPPERCLK - High Frequency Peripheral Clock

Like HFCORECLK, HPPERCLK also is a prescaled version of HFCLK. This clock drives the High-Frequency Peripherals. All the peripherals that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific peripheral in CMU\_HPPERCLKEN0. The peripherals can also be gated simultaneously by clearing the HPPERCLKEN bit in the CMU\_CTRL register. The prescale factor for prescaling HFCLK into HPPERCLK is set using the CMU\_HPPERPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

#### Note:

Note that if HPPERCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to peripheral modules will increase with the ratio between the clocks. E.g. if a bus-access normally takes three cycles, it will take 9 cycles if HPPERCLK runs three times as fast as the HFCORECLK.

### 12.3.1.5 HFRADIOCLK - High Frequency Radio Clock

HFRADIOCLK is a prescaled version of HFCLK which drives the High-Frequency Radio Peripherals. All the radio peripherals that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific peripheral in CMU\_HFRADIOCLKEN0. The radio peripherals can also be gated simultaneously by clearing the HFRADIOCLKEN bit in the CMU\_CTRL register. The prescale factor for prescaling HFCLK into HFRADIOCLK is set using the CMU\_HFRADIOPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:**

Note that if HFRADIOCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to radio peripheral modules will increase with the ratio between the clocks. E.g. if a bus-access normally takes three cycles, it will take 9 cycles if HFRADIOCLK runs three times as fast as the HFCORECLK.

### 12.3.1.6 LFACLK - Low Frequency A Clock

LFACLK is the selected clock for the Low Energy A Peripherals. There are three selectable sources for LFACLK: LFRCO, LFXO and ULFRCO. In addition, the LFACLK can be disabled, which is the default setting. The selection is configured using the LFA field in CMU\_LFACKSEL.

The bus interface to the Low Energy A Peripherals is clocked by HFBUSCLK<sub>LE</sub> and this clock therefore needs to be enabled when programming a Low Energy (LE) peripheral.

Each Low Energy Peripheral that is clocked by LFACLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFAPRESC0 and the clock enable bits can be found in CMU\_LFACKEN0.

When operating in oversampling mode, the pulse counters are clocked by LFACLK. This is configured for each pulse counter (n) individually by setting PCNTnCLKSEL in CMU\_PCNTCTRL.

### 12.3.1.7 LFBCLK - Low Frequency B Clock

LFBCLK is the selected clock for the Low Energy B Peripherals. There are four selectable sources for LFBCLK: LFRCO, LFXO, HFCLKLE and ULFRCO. In addition, the LFBCLK can be disabled, which is the default setting. The selection is configured using the LFB field in CMU\_LFBCLKSEL. The HFCLKLE setting allows the Low Energy B Peripherals to be used as high-frequency peripherals.

The bus interface to the Low Energy B Peripherals is clocked by HFBUSCLK<sub>LE</sub> and this clock therefore needs to be enabled when programming a LE peripheral.

**Note:**

If HFCLKLE is selected as LFBCLK, the clock will stop in EM2 DeepSleep and EM3 Stop.

Each Low Energy Peripheral that is clocked by LFBCLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFBPRESC0 and the clock enable bits can be found in CMU\_LFBCLKEN0.

### 12.3.1.8 LFECLK - Low Frequency E Clock

LFECLK is the selected clock for the Low Energy E Peripherals. There are three selectable sources for LFECLK: LFRCO, LFXO and ULFRCO. In addition, the LFECLK can be disabled, which is the default setting. The selection is configured using the LFE field in CMU\_LFECLKSEL.

The bus interface to the Low Energy E Peripherals is clocked by HFBUSCLK<sub>LE</sub> and this clock therefore needs to be enabled when programming a LE peripheral.

**Note:**

LFECLK is in a different power domain than LFACLK and LFBCLK, which makes it available all the way down to EM4 Hibernate.

Each Low Energy Peripheral that is clocked by LFECLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFEPRESC0 and the clock enable bits can be found in CMU\_LFECLKEN0.

### 12.3.1.9 PCNTnCLK - Pulse Counter n Clock

Each available pulse counter is driven by its own clock, PCNTnCLK where n is the pulse counter instance number. Each pulse counter can be configured to use an external pin (PCNTn\_S0) or LFACLK as PCNTnCLK.

### 12.3.1.10 WDOGCLK - Watchdog Timer Clock

The Watchdog Timer (WDOG) can be configured to use one of three different clock sources: LFRCO, LFXO or ULFRCO.

### 12.3.1.11 CRYOCLK - Cryotimer Clock

The Cryotimer clock can be configured to use one of three different clock sources: LFRCO, LFXO or ULFRCO. The Cryotimer can also run in EM4 Hibernate/Shutoff provided that its selected clock is kept enabled as configured in EMU\_EM4CTRL.

### 12.3.1.12 RFSENSECLK - RFSENSE Clock

The RFSENSE clock can be configured to use one of four different clock sources: LFRCO, LFXO, ULFRCO or the RF Detector Clock. The RFSENSE module can also run in EM4 Hibernate/Shutoff provided that its selected clock is kept enabled as configured in EMU\_EM4CTRL.

### 12.3.1.13 AUXCLK - Auxiliary Clock

AUXCLK is a 1 MHz - 38 MHz clock driven by a separate RC oscillator, the AUXHFRCO. This clock can be used for ADC operation and Serial Wire Output (SWO). When the AUXHFRCO is selected as the ADC clock via the ADC0CLKSEL bitfield in the CMU\_ADCCTRL register this clock will become active automatically when needed. Even if the AUXHFRCO has not been enabled explicitly by software, the ADC can automatically start and stop it. The AUXHFRCO is explicitly enabled by writing a 1 to AUXHFRCOEN in CMU\_OS-CENCMD. This explicit enabling is required when using the selecting AUXCLK for SWO operation.

### 12.3.1.14 Debug Trace Clock

The CMU selects the clock used for debug trace via the DBGCLKSEL register. The user can use the AUXHFRCO or the HFCLK. The selected debug trace clock will be used to run the Cortex-M4 trace logic.

**Note:**

When using AUXHFRCO as the debug trace clock, it must be stopped before entering EM2 or EM3.

## 12.3.2 Oscillators

### 12.3.2.1 Enabling and Disabling

The different oscillators can typically be enabled and disabled via both hardware and software mechanisms. Enabling via software is done by setting the corresponding enable bit in the CMU\_OSCENCMD register. Disabling via software is done by setting the corresponding disable bit in CMU\_OSCENCMD. Enabling via hardware can be performed by various peripherals and varies per oscillator. Disabling via hardware is typically performed on entry of low energy modes. The enable and disable mechanisms for each of the oscillators are summarized in [Table 12.1 Software based and Hardware based Enabling and Disabling of Oscillators on page 245](#) and described in more detail below.

**Table 12.1. Software based and Hardware based Enabling and Disabling of Oscillators**

Oscillator	SW Enable	SW Disable	HW Enable	HW Disable
ULFRCO	-	-	Enabled when in EM0/EM1/EM2/EM3/EM4H.	EM4S entry depending on configuration in EMU_EM4CTRL.
LFRCO	Via LFRCOEN in CMU_OSCENCMD.	Via LFRCODIS in CMU_OSCENCMD.	Via the WDOG if it is configured to use LFRCO as its clock source via the CLKSEL bitfield in WDOG_CTRL while SWOSCBLOCK is set.	EM3 entry. EM4 entry depending on configuration in EMU_EM4CTRL.
LFXO	Via LFXOEN in CMU_OSCENCMD.	Via LFXODIS in CMU_OSCENCMD.	Via the WDOG if it is configured to use LFXO as its clock source via the CLKSEL bitfield in WDOG_CTRL while SWOSCBLOCK is set.	EM3 entry. EM4 entry depending on configuration in EMU_EM4CTRL.
HFRCO	Via HFRCOEN in CMU_OSCENCMD.	Via HFRCODIS in CMU_OSCENCMD.	Reset exit. EM2/EM3 exit. Automatic control by LEUART RX/TX DMA wake-up as configured in LEUARTn_CTRL.	EM2/EM3/EM4 entry. Automatic control by LEUART RX/TX DMA wake-up as configured in LEUARTn_CTRL. Automatic start and selection of HFXO causes HFRCO disable.
AUXHFRCO	Via AUXHFRCOEN in CMU_OSCENCMD.	Via AUXHFRCODIS in CMU_OSCENCMD.	Automatic control by ADC.	EM2/EM3/EM4 entry. Automatic control by ADC even in EM2/EM3.
HFXO	Via HFXOEN in CMU_OSCENCMD.	Via HFXODIS in CMU_OSCENCMD.	Automatic start by Radio Controller (RAC) or EM0/EM1 entry as configured in CMU_HFXOCTRL.	EM2/EM3/EM4 entry.

### 12.3.2.1.1 LFRCO and LFXO

The LFXO and LFRCO can be enabled and disabled by software via the CMU\_OSCENCMD register. The WDOG can be configured to force the LFXO or LFRCO to become (and remain) enabled when such an oscillator is selected as its clock source via the CLKSEL bitfield in the WDOG\_CTRL register while SWOSCBLOCK is set. In that case LFXODIS and LFRCODIS commands are blocked. They are automatically disabled when entering EM3. Upon EM4 entry they are default turned off, but they can optionally be retained depending on the EMU\_EM4CTRL configuration. Retaining of the LFXO or LFRCO in EM4 is needed if such an oscillator is required by a specific peripheral in EM4. Retaining can also be used to guarantee quick oscillator availability after EM4 exit.

**Note:**

In order to support usage of LFRCO and LFXO in EM4, their settings are automatically latched upon EM4 entry. These settings remain latched upon wake-up from EM4 to EM0 although the related registers (CMU\_LFRCOCTRL, CMU\_LFXOCTRL, CMU\_LFECLKSEL, CMU\_LFECLKEN0 and CMU\_LEEPPRESCO) will have been reset. The registers can be rewritten by software, but they will only affect the LFRCO and LFXO after unlatching their settings by setting EM4UNLATCH in the EMU\_CMD register.

**Note:**

Turning off the LFRCO and LFXO upon EM4 Hibernate/Shutoff entry is most easily done by using the RETAINLFRCO and RETAINLFXO bitfields from the EMU\_EM4CTRL register, which are default such that the LFRCO and LFXO are turned off automatically upon EM4 Hibernate/Shutoff entry. Alternatively the LFRCO and LFXO can be disabled via the CMU\_OSCENCMD register, in which case software should wait for the oscillators to be properly disabled before executing the EM4 Hibernate/Shutoff entry routine.

After enabling the LFRCO (or LFXO), it should not be disabled before it has been signaled to be ready. Similarly, after disabling the LFRCO (or LFXO), it should not be re-enabled before it has been signaled to be non-ready. Before entering EM4, software should check that the LFRCO (or LFXO) is signaled to be ready before allowing or initiating the EM4 entry if that oscillator is required in EM4. Also, to guarantee latching the latest settings, no control write should be ongoing upon EM4 entry as can be checked via the CMU\_SYNCBUSY register. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_LFRCOEN;
while ((CMU->STATUS & CMU_STATUS_LFRCORDY) != CMU_STATUS_LFRCORDY);

CMU->OSCENCMD = CMU_OSCENCMD_LFRCODIS;
while ((CMU->STATUS & CMU_STATUS_LFRCORDY) == CMU_STATUS_LFRCORDY);
```

When the LFXO is disabled, the interface to the LFXTAL\_N and LFXTAL\_P pins are set in a high-Z state. The XTAL oscillations will not stop immediately when LFXO is disabled, but typically die out gradually over some 100 ms. If the LFXO is enabled before XTAL oscillations have had time to reach zero amplitude, startup time can be significantly shorter.

**Note:**

The LFRCORDY and LFXORDY interrupts can be used to wake up the system from EM2 DeepSleep. In this way busy waiting for the LFRCO or LFXO to become ready can be avoided by going into EM2 after enabling these oscillators and sleeping until the interrupt causes a wakeup.

### 12.3.2.1.2 ULFRCO

The ULFRCO is automatically enabled in EM0, EM1, EM2, EM3, and EM4H and cannot be controlled via CMU\_OSCENCMD. It is automatically disabled upon entering EM4S unless prevented by the configuration in EMU\_EM4CTRL.

### 12.3.2.1.3 HFRCO

The HFRCO can be enabled and disabled by software via the CMU\_OSCENCMD register. The HFRCO is disabled automatically when entering EM2, EM3, or EM4. Further hardware based enabling and disabling can be performed by the LEUART when using automatic RX/TX DMA wakeup as controlled by the RXDMAWU and TXDMAWU bits in the LEUARTn\_CTRL register. An automatic start and selection of the HFXO will lead to an automatic HFRCO disabling.

#### 12.3.2.1.4 HFXO

The HFXO can be enabled and disabled by software via the CMU\_OSCENCMD register. The HFXO is disabled automatically when entering EM2, EM3, or EM4. Hardware based HFXO enabling can be initiated by various peripherals as configured via the AUTOSTARTEM0EM1, AUTOSTARTSELEM0EM1, AUTOSTARTRDYSELRACT bits in the CMU\_HFXOCTRL register. The interaction between hardware based and software based control of the HFXO is further explained in [12.3.2.9 Automatic HFXO Start](#).

After enabling the HFXO, it should not be disabled before it has been signaled to be enabled. Similarly, after disabling the HFXO it should not be re-enabled before it has been signaled to be non-enabled. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_HFXOEN;
while ((CMU->STATUS & CMU_STATUS_HFXOENS) != CMU_STATUS_HFXOENS);

CMU->OSCENCMD = CMU_OSCENCMD_HFXODIS;
while ((CMU->STATUS & CMU_STATUS_HFXOENS) == CMU_STATUS_HFXOENS);
```

### 12.3.2.2 Oscillator Start-up Time and Time-out

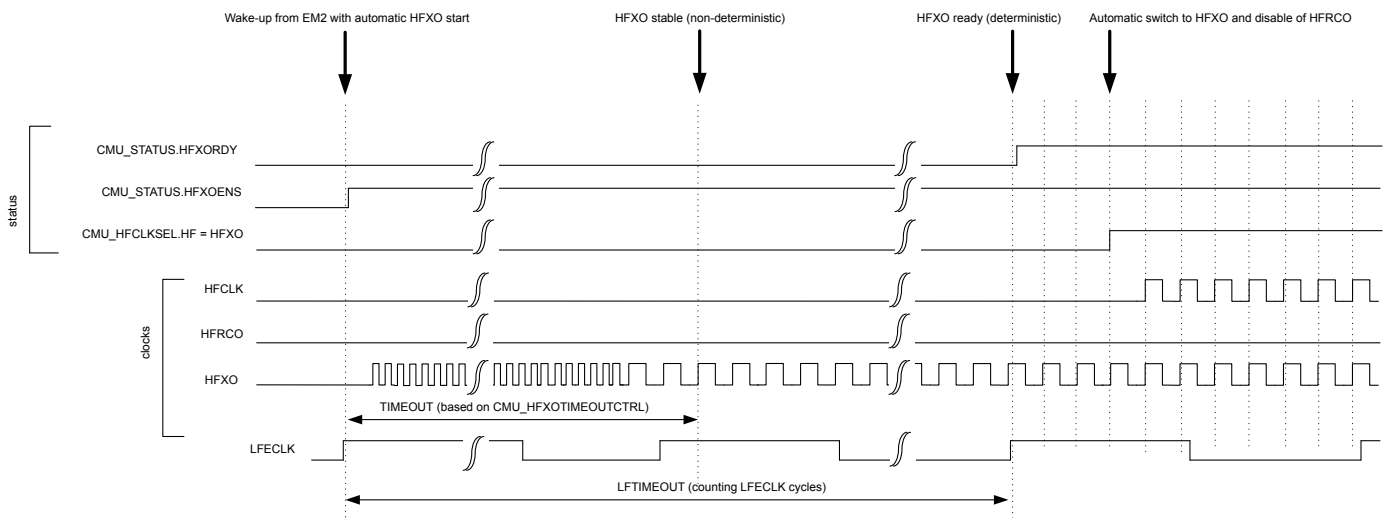

The start-up time differs per oscillator and the usage of an oscillator clock can further be delayed by a time-out. The LFRCO, LFXO and the HFXO have a configurable time-out which is set by software in the (various) TIMEOUT bitfields of the CMU\_LFRCTRL, CMU\_LFXOCTRL and CMU\_HFXOCTRL registers respectively. The time-out delays the assertion of the READY signal for LFRCO, LFXO and HFXO and should allow for enough time for the oscillator to stabilize. The time-out can be optimized for the chosen crystal (for LFXO and HFXO) used in the application. In case LFRCO and/or LFXO has been retained throughout EM4 Hibernate/Shut-off, such retained oscillators can be quickly restarted for use as LFACLK, LFBCLK or LFECLK by using the minimum TIMEOUT settings for them. For the other RC oscillators (HFRCO, AUXHFRCO, and ULFRCO), the start-up time is known and a fixed time-out is used.

There are individual bits in the CMU\_STATUS register for each oscillator indicating the status of the oscillator:

- **ENABLED** - Indicates that the oscillator is enabled
- **READY** - Start-up time including time-out is exceeded

These status bits are located in the CMU\_STATUS register.

Additionally, the HFXO has a second time-out counter which can be used to achieve deterministic start-up time based on timing from the LFXO, ULFRCO, or LFRCO. This second counter runs off LFECLK and can be programmed via the LFTIMEOUT bitfield in the CMU\_HFXOCTRL register. It can be used when waking up from EM2 when either ULFRCO, LFRCO or LFXO is already running and stable. In this case the HFXO ready assertion can be delayed with the number of LFECLK cycles as programmed in LFTIMEOUT. The HFXO ready signal is asserted when both the TIMEOUT counter (configured via the CMU\_HFXOCTRL register) and the LFTIMEOUT counter (configured via CMU\_HFXOCTRL register) have timed out as shown in [Figure 12.2 CMU Deterministic HFXO startup using LFTIMEOUT on page 248](#). The TIMEOUT should cover the actual crystal startup time. Typically the time base used for the TIMEOUT counter is not as accurate as the time base accuracy that can be achieved for the LFTIMEOUT counter, specifically if that one is based on the LFXO timing. If LFTIMEOUT is triggered before TIMEOUT is triggered, then the LFTIMEOUTERR bitfield in CMU\_IF will be set to 1. Note that use of LFTIMEOUT requires that the peripheral causing the wake-up is on the LFECLK domain. The intended use scenario is for example to wake up from EM2 by the RTCC triggering RAC wake-up via the PRS, which in turn can wake up the entire system. The RAC wake-up causes an automatic start of the HFXO in case the AUTOSTARTRDYSEL\_RAC bit in CMU\_HFXOCTRL is set to 1. Assertion of the HFXO ready signal, and therefore the radio start timing, can then be made deterministic by using LFTIMEOUT.

**Figure 12.2. CMU Deterministic HFXO startup using LFTIMEOUT**

The startup behavior of the HFXO also depends on how and how long the HFXO is disabled. This can be controlled by configuring the XT12GND, and XT02GND bitfields in the CMU\_HFXOCTRL register.

### 12.3.2.3 Switching Clock Source

The HFRCO oscillator is a low energy oscillator with extremely short start-up time. Therefore, this oscillator is always chosen by hardware as the clock source for HFCLK when the device starts up (e.g. after reset and after waking up from EM2 DeepSleep and EM3 Stop). After reset, the HFRCO frequency is 19 MHz.

Software can switch between the different clock sources at run-time. For example, when the HFRCO is the clock source, software can switch to HFXO by writing the field HF in the CMU\_HFCLKSEL command register. See [Figure 12.3 CMU Switching from HFRCO to HFXO before HFXO is ready on page 249](#) for a description of the sequence of events for this specific operation.

#### Note:

Before switching the HFCLKSRC to HFXO via the HF bitfield in CMU\_HFCLKSEL it is important to first enable the HFXO. Switching to a disabled oscillator will effectively stop HFSRCCLK and only a reset can recover the system.

When selecting an oscillator which has been enabled, but which is not ready yet, the HFSRCCLK will stop for the duration of the oscillator start-up time since the oscillator driving it is not ready. This effectively stalls the Core Modules and the High-Frequency Peripherals. It is possible to avoid this by first enabling the target oscillator (e.g. HFXO) and then waiting for that oscillator to become ready before switching the clock source. This way, the system continues to run on the HFRCO until the target oscillator (e.g. HFXO) has timed out and provides a reliable clock. This sequence of events is shown in [Figure 12.4 CMU Switching from HFRCO to HFXO after HFXO is ready on page 250](#).

A separate flag is set when the oscillator is ready. This flag can also be configured to generate an interrupt.

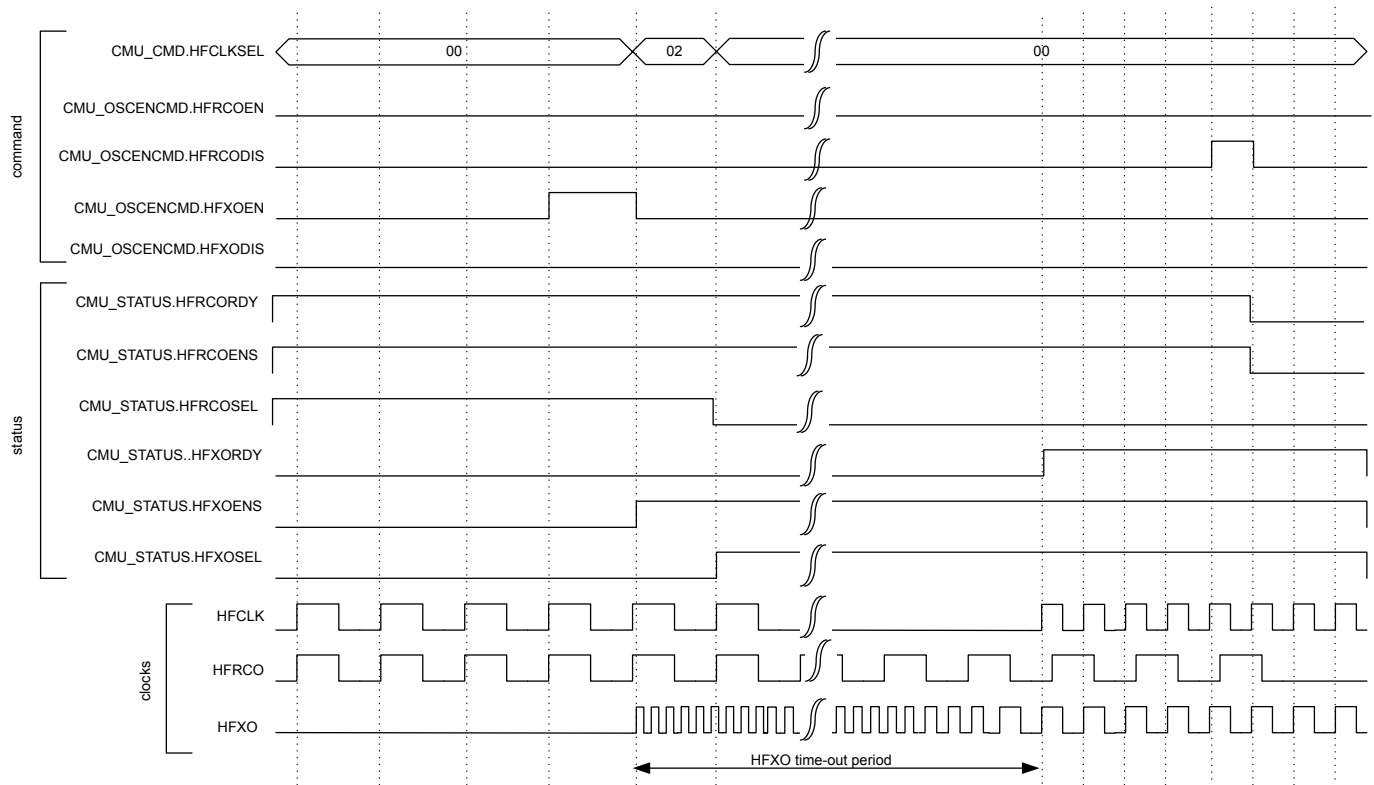

Figure 12.3. CMU Switching from HFRCO to HFXO before HFXO is ready

**Figure 12.4. CMU Switching from HFRCO to HFXO after HFXO is ready**

Switching clock source for LFACLK, LFBCLK, and LFECLK is done by setting the LFA, LFB and LFE bitfields in `CMU_LFACLKSEL`, `CMU_LFBCLKSEL`, and `CMU_LFECLKSEL` respectively. To ensure no stalls in the Low Energy Peripherals, the clock source should be ready before switching to it.

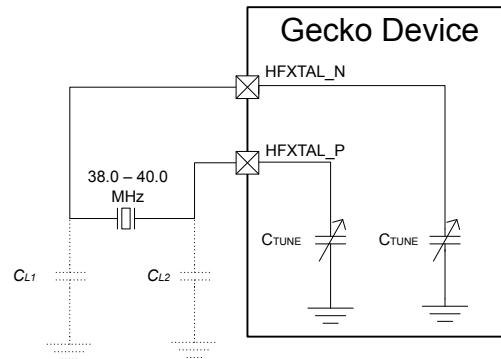

**Note:**

To save energy, remember to turn off all oscillators not in use.

### 12.3.2.4 HFXO Configuration

The High Frequency Crystal Oscillator needs to be configured to ensure safe startup for the given crystal. Refer to the Device Data-sheet and application notes for guidelines in selecting correct components and crystals as well as for configuration trade-offs.

The HFXO crystal is connected to the HFXTAL\_N/HFXTAL\_P pins as shown in [Figure 12.5 HFXO Pin Connection on page 251](#)

**Figure 12.5. HFXO Pin Connection**

By default the HFXO is started in crystal mode, but it is possible to connect an active external sine wave or square wave clock source to the HFXTAL\_N pin of the HFXO. By configuring the MODE field in CMU\_HFXOCTRL to EXTCLK, the HFXO can be bypassed and the source clock can be provided through the HFXTAL\_N pin.

Upon enabling the HFXO, a hardware state machine sequentially applies the configurable startup state and steady state control settings from the CMU\_HFXOSTARTUPCTRL and CMU\_HFXOSTEADYSTATECTRL registers. Configuration is required for both the startup state and the steady state of the HFXO. After reaching the steady operation state of the HFXO, further optimization can optionally be performed to optimize the HFXO for noise and current consumption. Optimization for noise can be performed by an automatic Peak Detection Algorithm (PDA). Optimization for current can be performed by an automatic Shunt Current Optimization algorithm (SCO). HFXO operation is possible without PDA and SCO at the cost of higher noise and current consumption than required.

Upon fully disabling the HFXO, the HFXTAL\_N and HFXTAL\_P pins can optionally be automatically pulled to ground as configured via the XT12GND and XTO2GND bits respectively from the CMU\_HFXOCTRL register. Do not set XT12GND to 1 when the HFXO is in EXTCLK mode and an external wave is connected.

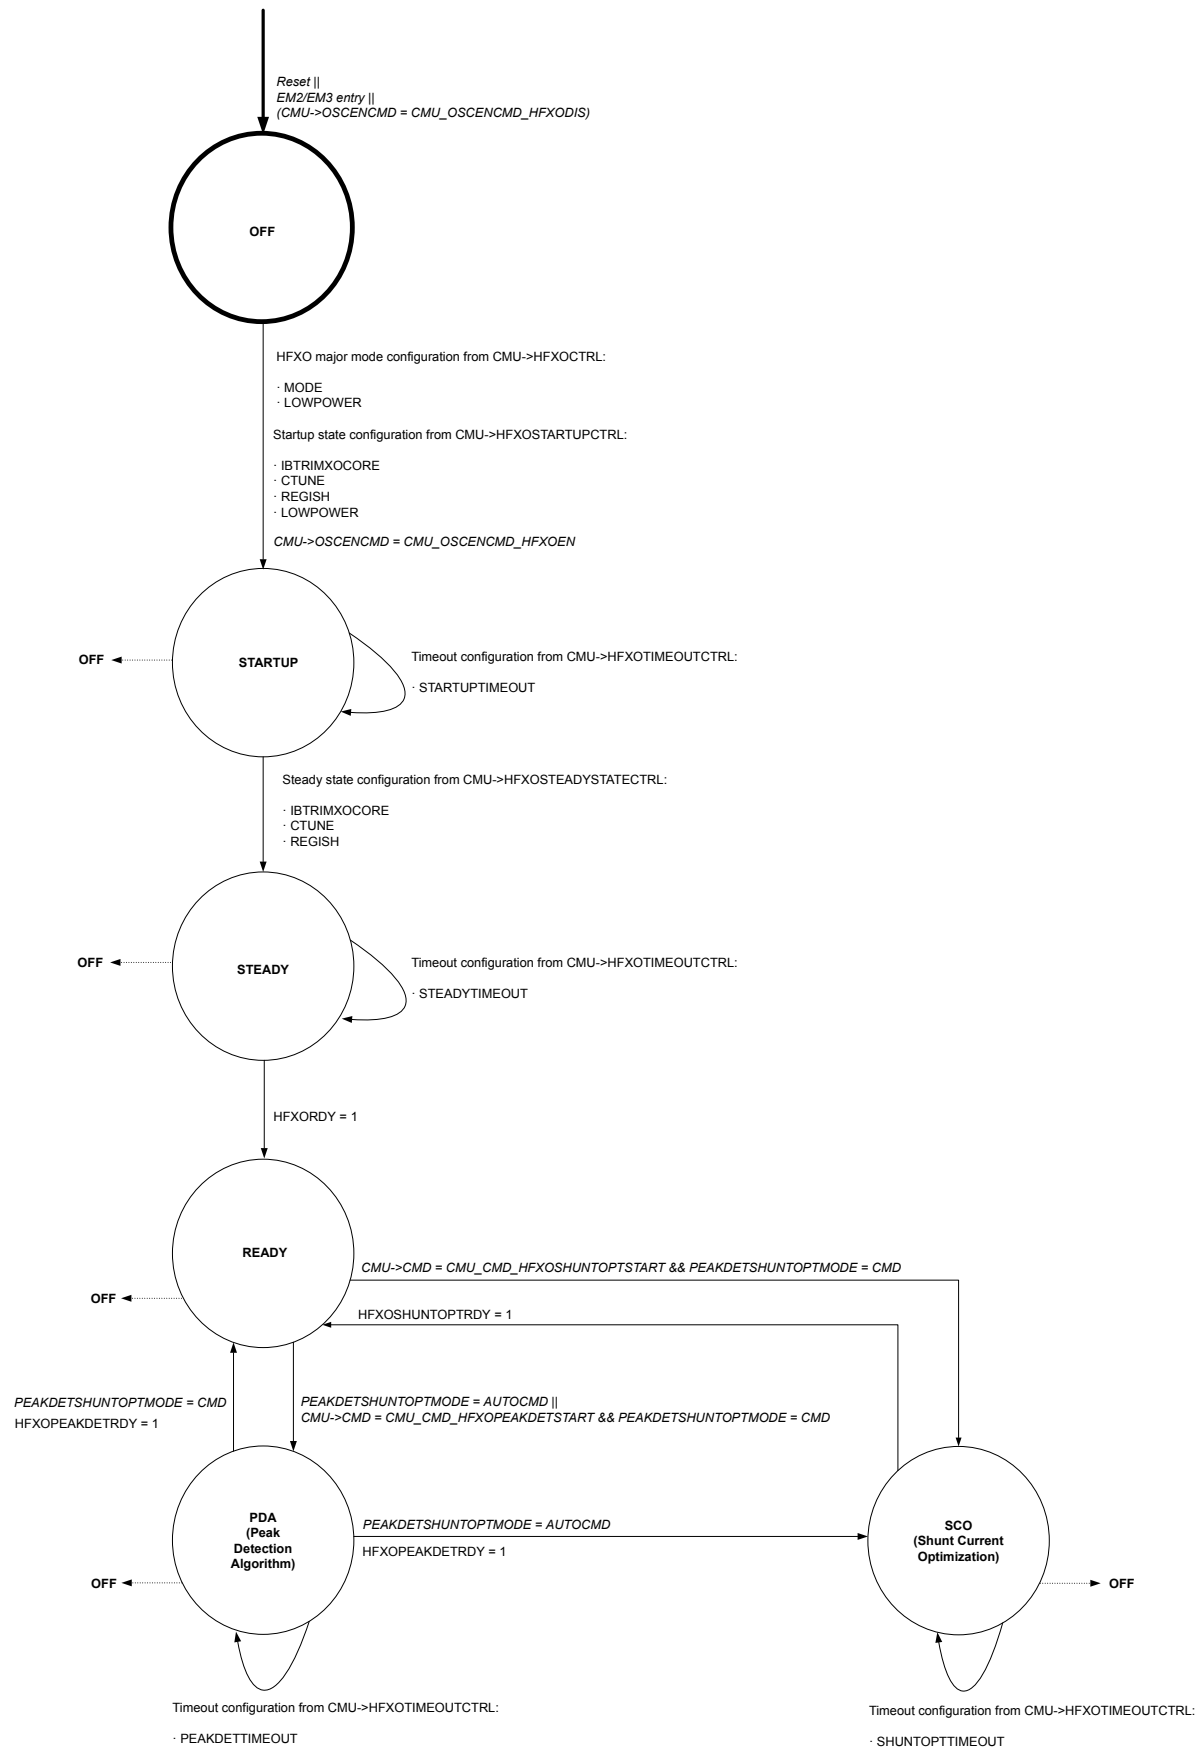

Figure 12.6. CMU HFXO control state machine

Refer to the Device Datasheet to find the configuration values for a given crystal. The startup state configuration needs to be written into the IBTRIMXOCORE and CTUNE bitfields of the CMU\_HFXOSTARTUPCTRL register. The duration of the startup phase is configured in the STARTUPTIMEOUT bitfield of the CMU\_HFXOTIMEOUTCTRL register. Similarly, the Device Datasheet provides the steady state configuration depending on the crystal's CL, RESR and oscillation frequency. This configuration is programmed into the IBTRIMXOCORE, REGISH and CTUNE bitfields of the CMU\_HFXOSTEADYSTATECTRL register. The duration of the steady phase is configured in the STEADYTIMEOUT bitfield of the CMU\_HFXOTIMEOUTCTRL register.

All HFXO configuration needs to be performed prior to enabling the HFXO via HFXOEN in CMU\_OSCENCMD unless noted otherwise. The HFXOENS flag in CMU\_STATUS indicates if the HFXO has been successfully enabled. Once the HFXO startup time (STARTUPTIMEOUT plus STEADYTIMEOUT) has exceeded, the HFXORDY flag in CMU\_STATUS. If PDA and SCO are enabled, the HFXOPEAKDETRDY and HFXOSHUNTOPTRDY flags in the CMU\_STATUS register indicate when these algorithms are ready and it is advised to also wait for these flags before using the HFXO.

The HFXO crystal bias current may be optimized and set to a value which decreases output phase noise without sacrificing PSR. This is done by programming the recommended IBTRIMXOCORE value into the CMU\_HFXOSTEADYSTATECTRL register. The built-in Peak Detector Algorithm (PDA) performs further optimization to accommodate for process variations. Once PDA is ready as indicated by the HFXOPEAKDETRDY flag, the found optimal bias current setting is available in the IBTRIMXOCORE bitfield of the CMU\_HFXO-TRIMSTATUS register. This IBTRIMXOCORE setting should be saved and can be applied directly during a future HFXO startup as a low noise setting by programming it into the corresponding bitfield in CMU\_HFXOSTEADYSTATECTRL while the HFXO is off.

If low noise is not required, the same PDA algorithm can be configured to optimize the HFXO for low current consumption by enabling LOWPOWER in the CMU\_HFXOCTRL register before starting up the HFXO. The found IBTRIMXOCORE setting can be saved as a future low current setting.

Default PDA is started automatically once the HFXO has become ready. Repeated PDA can be triggered by writing HFXOPEAKDETSTART to 1 in the CMU\_CMD register. PDA can also be triggered only by the command register by configuring PEAKDETSHUNTOPTMODE to CMD in the CMU\_HFXOCTRL register before starting the HFXO. For PDA to work correctly, the REGISHUPPER bitfield of CMU\_HFXOSTEADYSTATECTRL should be programmed to the value of the steady state REGISH + 3. The PEAKDETTIMEOUT bitfield in the CMU\_HFXOTIMEOUTCTRL register is used to time the PDA steps and needs to be configured according to the Device Datasheet for the given crystal. The PEAKDETEN bitfield of the CMU\_HFXOSTEADYSTATECTRL register is only used during manual (i.e. fully software controlled) peak detection and is ignored during automatic or command based triggering of the PDA. Note that the manual PDA mode is not recommended for general usage and therefore it is not further described. PDA should not be used when using an external wave as clock source.

Current consumption can be (further) reduced by running Shunt Current Optimization (SCO) after PDA. Once SCO is ready as indicated by the HFXOSHUNTOPTRDY flag, the found optimal regulator output current setting is available in the REGISH bitfield of the CMU\_HFXOTRIMSTATUS register. This REGISH setting should be saved and can be applied directly during a future HFXO startup as a low current setting by programming it into the corresponding bitfield in CMU\_HFXOSTEADYSTATECTRL while the HFXO is off. Normally SCO is run only for initial HFXO start up. The amplitude of the oscillator is not strongly dependent on temperature, but further optimization may be done each time that the temperature changes significantly. In that case, run SCO again by writing HFXOSHUNTOPTSTART to 1 in the CMU\_CMD register. SCO depends on the LOWPOWER setting in the CMU\_HFXOCTRL and needs to be re-run if that value has been changed. SCO should not be run when the HFXO is in use by the Radio Transceiver.

Default SCO is started automatically once the HFXO has become ready and PDA has finished. Repeated SCO can be triggered by writing HFXOSHUNTOPTSTART to 1 in the CMU\_CMD register. SCO can also be triggered only by the command register by configuring PEAKDETSHUNTOPTMODE to CMD in the CMU\_HFXOCTRL register before starting the HFXO. For SCO to work correctly, the REGISHUPPER bitfield of CMU\_HFXOSTEADYSTATECTRL should be programmed to the value of the steady state REGISH + 3. The SHUNTOPTTIMEOUT bitfield in the CMU\_HFXOTIMEOUTCTRL register is used to time the SCO steps and needs to be configured according to the Device Datasheet for the given crystal. The REGSELILOW bitfield of the CMU\_HFXOSTEADYSTATECTRL register is only used during manual (i.e. fully software controlled) shunt current optimization and is ignored during automatic or command based triggering of the SCO. Note that the manual SCO mode is not recommended for general usage and therefore it is not further described.

### 12.3.2.5 LFXO Configuration

The Low Frequency Crystal Oscillator (LFXO) is default configured to ensure safe startup for all crystals. In order to optimize startup time and power consumption for a given crystal, it is possible to adjust the startup gain in the oscillator by programming the GAIN field in CMU\_LFXOCTRL. Refer to the Device Datasheet and application notes for guidelines in selecting correct components and crystals as well as for configuration trade-offs.

The LFXO can be retained on in EM4 Hibernate/Shutoff. In that case its required configuration is latched/retained throughout EM4 even though the CMU\_LFXOCTRL register itself will be reset. Upon EM4 exit, the CMU\_LFXOCTRL register therefore needs to be reconfigured to its original settings and the LFXO needs to be restarted via CMU\_OSCENCMD, before optionally unlatching the retained LFXO configuration by writing 1 to EM4UNLATCH in the EMU\_CMD register. The LFXO startup time is configured via the TIMEOUT bitfield of the CMU\_LFXOCTRL register. If the LFXO has been retained throughout EM4 Hibernate/Shutoff, it can be quickly restarted for use as LFACLK, LFBCLK or LFECLK by using its minimum TIMEOUT setting. While retained, the LFXO can be used down to EM4 Hibernate as source for LFECLK and down to EM4 Shutoff as source for RFSENSECLK and CRYOCLK.

The LFXO crystal is connected to the LFXTAL\_N/LFXTAL\_P pins as shown in [Figure 12.7 LFXO Pin Connection on page 254](#)

**Figure 12.7. LFXO Pin Connection**

By configuring the MODE field in CMU\_LFXOCTRL, the LFXO can be bypassed, and an external clock source can be connected to the LFXTAL\_N pin of the LFXO oscillator. If MODE is set to BUFEXTCLK, an external active sine source can be used as clock source. If MODE is set to DIGEXTCLK, an external active CMOS source can be used as clock source.

The LFXO includes on-chip tunable capacitance, which can replace external load capacitors. The TUNING bitfield of the CMU\_LFXOCTRL register is used to tune the internal load capacitance connected between LFXTAL\_P and ground and LFXTAL\_N and ground symmetrically. The capacitance range and step size information is available in the device datasheets. Use the formula below to calculate the TUNING bitfield:

$$\text{TUNING} = ((\text{desiredTotalLoadCap} * 2 - \text{Min}(C_{\text{LFXO\_T}})) / C_{\text{LFXO\_TS}})$$

**Figure 12.8. CMU LFXO Tuning Capacitance Equation**

These tunable capacitors can also be used to compensate for temperature drift of the XTAL in software. Crystals normally have a temperature dependency which is given by a parabolic function. The crystal has highest frequency at its turnover temperature, normally 25C. The frequency is reduced following a parabola for higher and lower temperatures. The LFXO offers a mechanism to internally add capacitance on the LFXTAL\_N and LFXTAL\_P pins (in parallel to an optional external load capacitance). The variation in frequency as a function of temperature can therefore be compensated by adjusting the load capacitance. When the temperature compensation scheme is used, the maximum internal capacitance should be used to obtain good frequency matching at the turnover temperature. For higher and lower temperatures one then has the maximum tuning range available. The external load capacitance must then of course be reduced accordingly. Note that the ADC ([24. ADC - Analog to Digital Converter](#)) includes an embedded temperature sensor and that the EMU ([11. EMU - Energy Management Unit](#)) offers a temperature management interface, both of which can be used in combination with this LFXO temperature compensation scheme.

The XTAL oscillation amplitude can be controlled via the HIGHAMPL bitfield in CMU\_LFXOCTRL. Setting HIGHAMPL to 1 will result in higher amplitude, which in turn provides safer operation, somewhat improved duty cycle, and lower sensitivity to noise at the cost of increased current consumption.

The AGC bit of the CMU\_LFXOCTRL register is used to turn on or off the Automatic Gain Control module that adjusts the amplitude of the XTAL. When disabled, the LFXO will run at the startup current and the XTAL will oscillate rail to rail, again providing safer operation, improved duty cycle, and lower sensitivity to noise at the cost of increased current consumption.

### 12.3.2.6 HFRCO and AUXHFRCO Configuration

It is possible to calibrate the HFRCO and AUXHFRCO to achieve higher accuracy (see the device datasheets for details on accuracy). The frequency is adjusted by changing the TUNING and FINETUNING bitfields in CMU\_HFRCOCTRL and CMU\_AUXHFRCOCTRL. Changing to a higher value will result in a lower frequency. Please refer to the datasheet for stepsize details.

The HFRCO and AUXHFRCO can be set to one of several different frequency bands from 1 MHz to 38 MHz by setting the FREQRANGE field in CMU\_HFRCOCTRL and CMU\_AUXHFRCOCTRL. The HFRCO and AUXHFRCO frequency bands are calibrated during production test, and the production tested calibration values can be read from the Device Information (DI) page. The DI page contains a separate tuning value for each frequency band. During reset, HFRCO and AUXHFRCO tuning values are set to the production calibrated values for the 19 MHz band, which is the default frequency band. When changing to a different HFRCO or AUXHFRCO band, make sure to also update the TUNING value and other bitfields in the CMU\_HFRCOCTRL and CMU\_AUXHFRCOCTRL registers. Typically the entire register is written with a value obtained from the Device Information (DI) page. Please refer to for information on which frequency band settings are stored in the DI page.

The frequency can be tuned more accurately, at the cost of increased current consumption, via the FINETUNING bitfield if finetuning has been enabled via the FINETUNINGEN bit. The HFRCO and AUXHFRCO both contain a local prescaler, which can be used in combination with any FREQRANGE setting. These prescalers allow the output clocks to be divided by 1, 2, or 4 as configured in the CLKDIV bitfield.

### 12.3.2.7 LFRCO Configuration

It is possible to calibrate the LFRCO to achieve higher accuracy (see the device datasheets for details on accuracy). The frequency is adjusted by changing the TUNING bitfield in CMU\_LFRCOCTRL. Changing to a higher value will result in a lower frequency. Please refer to the datasheet for stepsize details.

The LFRCO can be retained on in EM4 Hibernate/Shutoff. In that case its required configuration is latched/retained throughout EM4 even though the CMU\_LFRCOCTRL register itself will be reset. Upon EM4 exit the CMU\_LFRCOCTRL register therefore needs to be reconfigured to its original settings and the LFRCO needs to be restarted via CMU\_OSCENCMD, before optionally unlatching the retained LFRCO configuration by writing 1 to EM4UNLATCH in the EMU\_CMD register. The LFRCO startup time is configured via the TIMEOUT bitfield of the CMU\_LFRCOCTRL register. Default its 16 cycle startup should be used. However, in case the LFRCO has been retained throughout EM4 Hibernate/Shutoff, it can be quickly restarted for use as LFACLK or LFBCLK by using its minimum TIMEOUT setting. While retained, the LFRCO can be used down to EM4 Hibernate as source for LFECLK and down to EM4 Shutoff as source for RFSENSECLK and CRYOCLK.

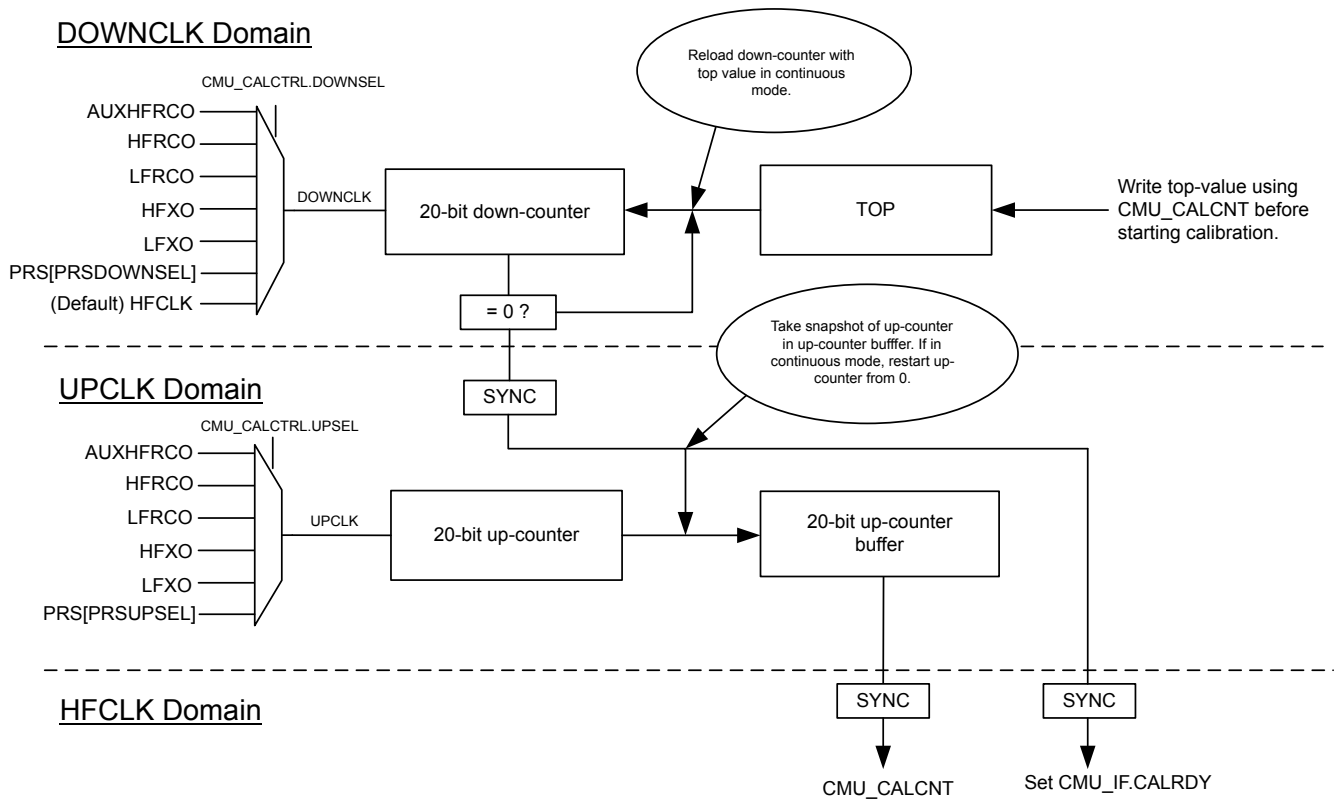

The LFRCO is also calibrated in production and its TUNING values are set to the correct value during reset.

The LFRCO can be put in duty cycle mode by setting the ENVREF bit in CMU\_LFRCOCTRL to 1 before starting the LFRCO. This will reduce current consumption, but will result in slightly worse accuracy especially at high temperatures. Setting the ENCHOP and/or ENDEM bitfields to 1 in the CMU\_LFRCOCTRL register will improve the average LFRCO frequency accuracy at the cost of a worse cycle-to-cycle accuracy.

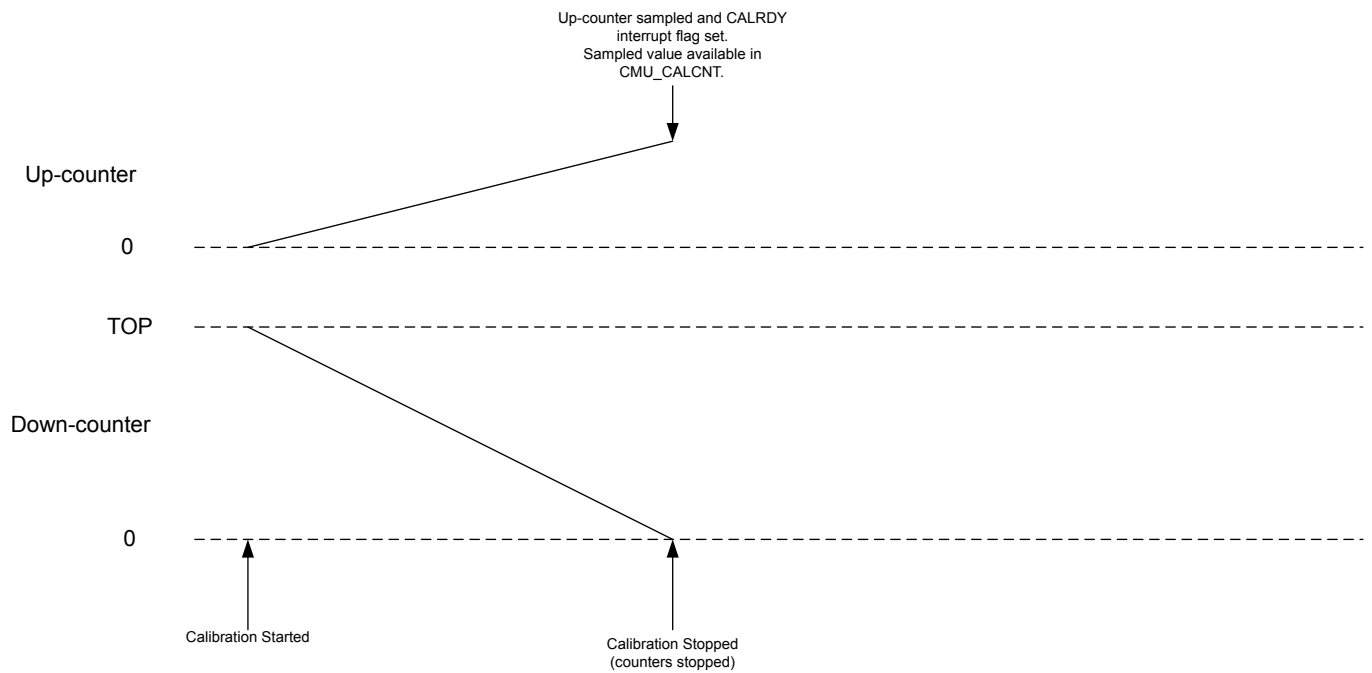

### 12.3.2.8 RC Oscillator Calibration

The CMU has built-in HW support to efficiently calibrate the RC oscillators (LFRCO, HFRCO, AUXHFRCO) at run-time, see [Figure 12.9 HW-support for RC Oscillator Calibration on page 256](#) for an illustration of this circuit. The concept is to select a reference and compare the RC frequency with the reference frequency. When the calibration circuit is started, one down-counter running on a selectable clock (DOWNSEL in CMU\_CALCTRL) and one up-counter running on a selectable clock (UPSEL in CMU\_CALCTRL) are started simultaneously. The top value for the down-counter must be written to CMU\_CALCNT before calibration is started. The down-counter counts for CMU\_CALCNT+1 cycles. When the down-counter has reached 0, the up-counter is sampled and the CALRDY interrupt flag is set. If CONT in CMU\_CALCTRL is cleared, the counters are stopped after finishing the ongoing calibration. If continuous mode is selected by setting CONT in CMU\_CALCTRL the down-counter reloads the top value and continues counting and the up-counter restarts from 0. Software can then read out the sampled up-counter value from CMU\_CALCNT. The up-counter has counted (the sampled value)+1 cycles. The ratio between the reference and the oscillator subject to the calibration can easily be found using top+1 and sample+1. Overflows of the up-counter will not occur. If the up-counter reaches its top value before the down-counter reaches 0, the up-counter stays at its top value. Calibration can be stopped by writing CALSTOP in CMU\_CMD. With this HW support, it is simple to write efficient calibration algorithms in software.

**Figure 12.9. HW-support for RC Oscillator Calibration**

The counter operation for single and continuous mode are shown in [Figure 12.10 Single Calibration \(CONT=0\) on page 257](#) and [Figure 12.11 Continuous Calibration \(CONT=1\) on page 257](#) respectively.

**Figure 12.10. Single Calibration (CONT=0)**

**Figure 12.11. Continuous Calibration (CONT=1)**

### 12.3.2.9 Automatic HFXO Start

The enabling of the HFXO and its selection as HFCLKSRC source can be performed automatically by hardware. Automatic HFXO enable and select can for example be used upon wake-up of the Radio Controller (RAC). Automatic control of the HFXO is controlled via the AUTOSTARTRDYSEL, AUTOSTARTSELEMEM1 and AUTOSTARTEM0EM1 bits in the CMU\_HFXOCTRL register. It further depends on the energy mode of the EFR32 and on the status of the RAC.

The HFXO autostart functionality is typically used when the RAC is used. The RAC module always requires the HFXO for its operation. The hardware requirement from RAC for an HFXO based HFSRCCLK is indicated in the HFXOREQ bitfield of the CMU\_STATUS register. This requirement in itself does not lead to an automatic enable or select of the HFXO.

An automatic HFXO enable is performed only if any of the following conditions are met:

- EFR32 is in EM0/EM1 and AUTOSTARTEM0EM1 or AUTOSTARTSELEMEM1 are set to 1.
- RAC is awake and AUTOSTARTRDYSEL is set to 1.

An automatic HFXO select is performed only if any of the following conditions is met:

- EFR32 is in EM0/EM1 and AUTOSTARTSELEMEM1 is set to 1.
- RAC is awake, HFXO is ready, and AUTOSTARTRDYSEL is set to 1.

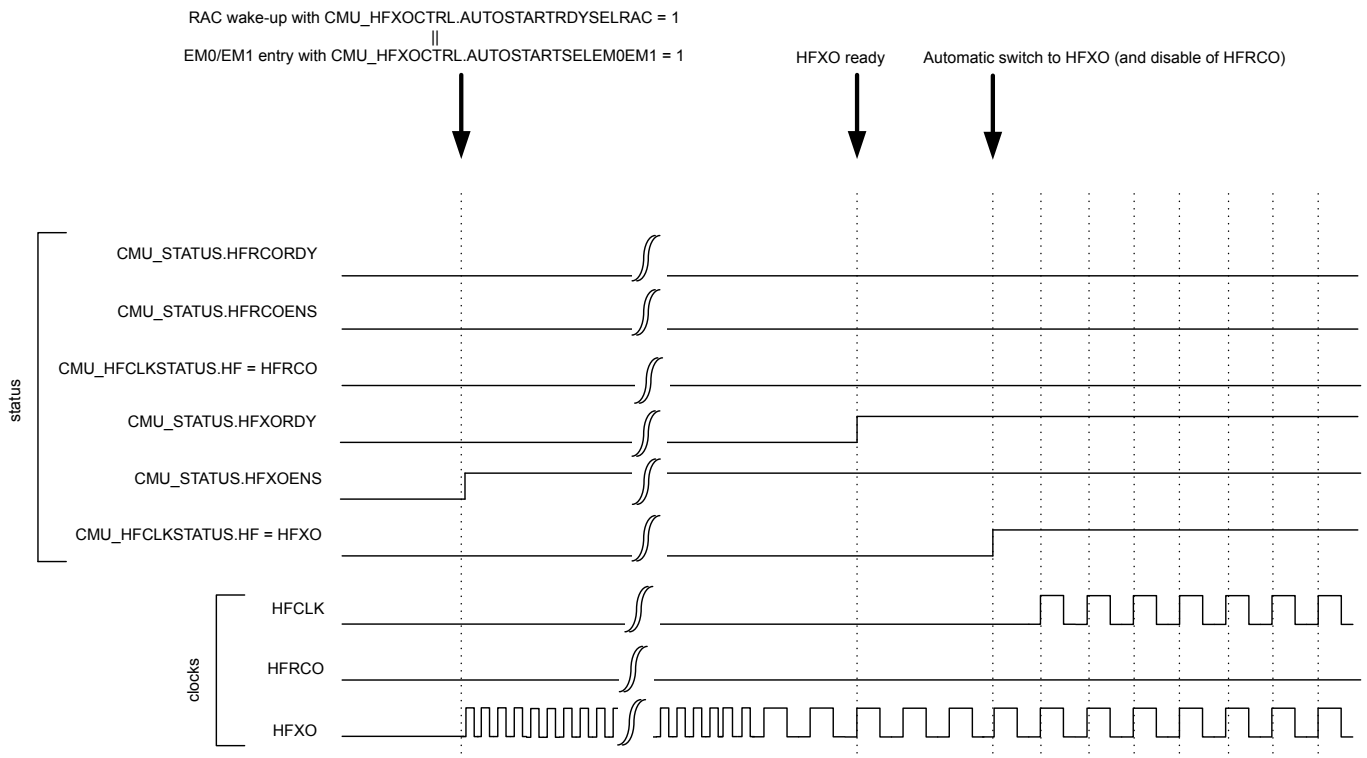

Whenever any of the conditions for automatic HFXO enable is met, software is not allowed to disable the HFXO. An attempt to do so (e.g. by writing 1 to the HFXODIS bit) is ignored and causes the HFXODISERR bit in the CMU\_IF register to be set to 1. Similarly, whenever any of the conditions for automatic HFXO selection is met, software is not allowed to deselect the HFXO as clock source for HFSRCCLK. An attempt to do so (e.g. by selecting another clock source via CMU\_HFCLKSEL) is ignored and causes the HFXODISERR bit in the CMU\_IF register to be set to 1. Note that CMUERR is not implied by HFXODISERR. CMUERR will not get set to 1 for the above scenarios in which HFXODISERR gets set.

Software can only disable or deselect the HFXO after removing all of the HFXO automatic enable or select reasons. Note that if the autostart functionality is not used, software can always disable or deselect the HFXO even if hardware requires the HFXO as indicated via HFXOREQ bitfield in CMU\_STATUS. The HFXODISERR flag will not get set in that case. The HFXO is only disabled by hardware upon EM2, EM3 or EM4 entry.

In case that AUTOSTARTSELEMEM1 is set to 1 in EM0/EM1 (irrespective of the other autostart bits), the HFXO select will occur immediately, even if HFXO is not ready yet. Upon wake-up into EM0/EM1 this can therefore lead to a relatively long startup time as the system will not start operating from the HFRCO as it would otherwise do. In case of an automatic select triggered by the RAC (while AUTOSTARTSELEMEM1 is set to 0), such a select will only occur upon the HFXO becoming ready and software can select and use another clock source in the mean time.

A typical use scenario of the AUTOSTARTRDYSEL bit is as follows. Set the AUTOSTARTRDYSEL bit in the CMU\_HFXOCTRL register to 1 and set up the RTCC to periodically generate a compare match. Setup a PRS channel which uses this RTCC compare match as its source and allow the PRS channel to cause a wake-up into EM1. Setup the RAC to use the PRS channel as its source for TXEN or RXEN. Now, when the EFR32 is in EM2 and the RTCC generates a compare match, a wake-up into EM1 will occur and the HFXO will automatically start and become selected after which the RAC can perform its work and trigger a transition back into EM2 when done. The system started, used, and stopped the HFXO without ever being in EM0.

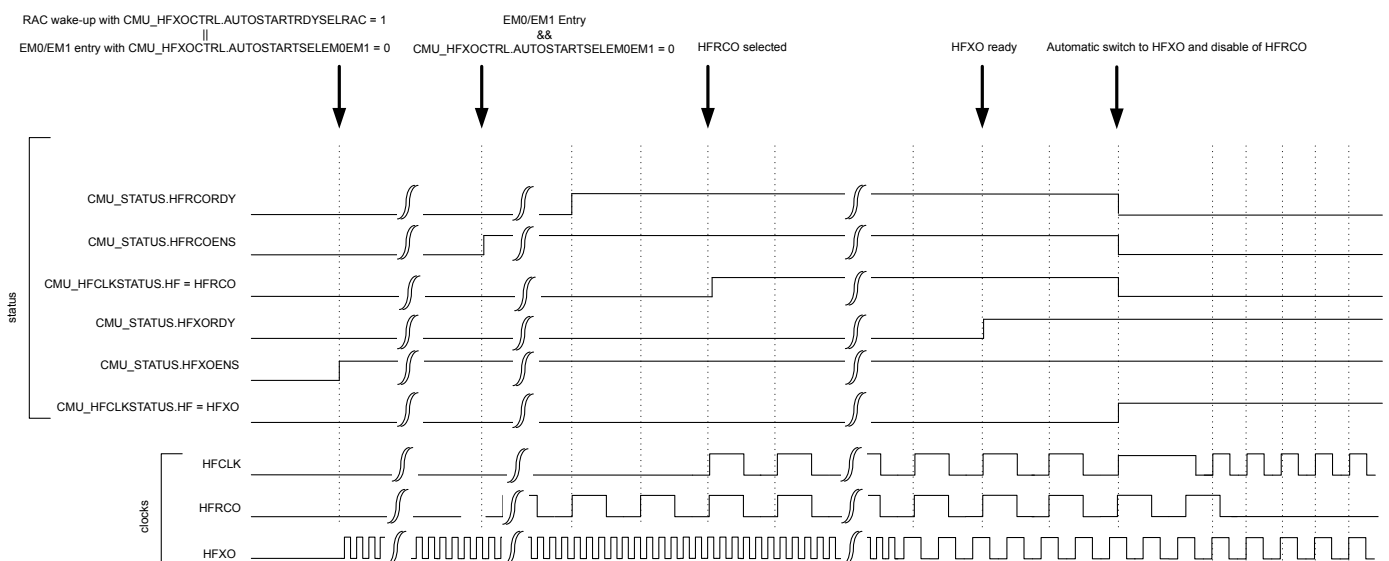

Note that the user should take care that the settings in the MSC\_READCTRL and CMU\_CTRL registers, as described in [12.3.3 Configuration For Operating Frequencies](#), are compatible with 40 MHz HFXO operation before enabling the HFXO automatic startup feature. A basic automatic HFXO start scenario is shown in [Figure 12.12 CMU Automatic startup and selection of HFXO on page 259](#).

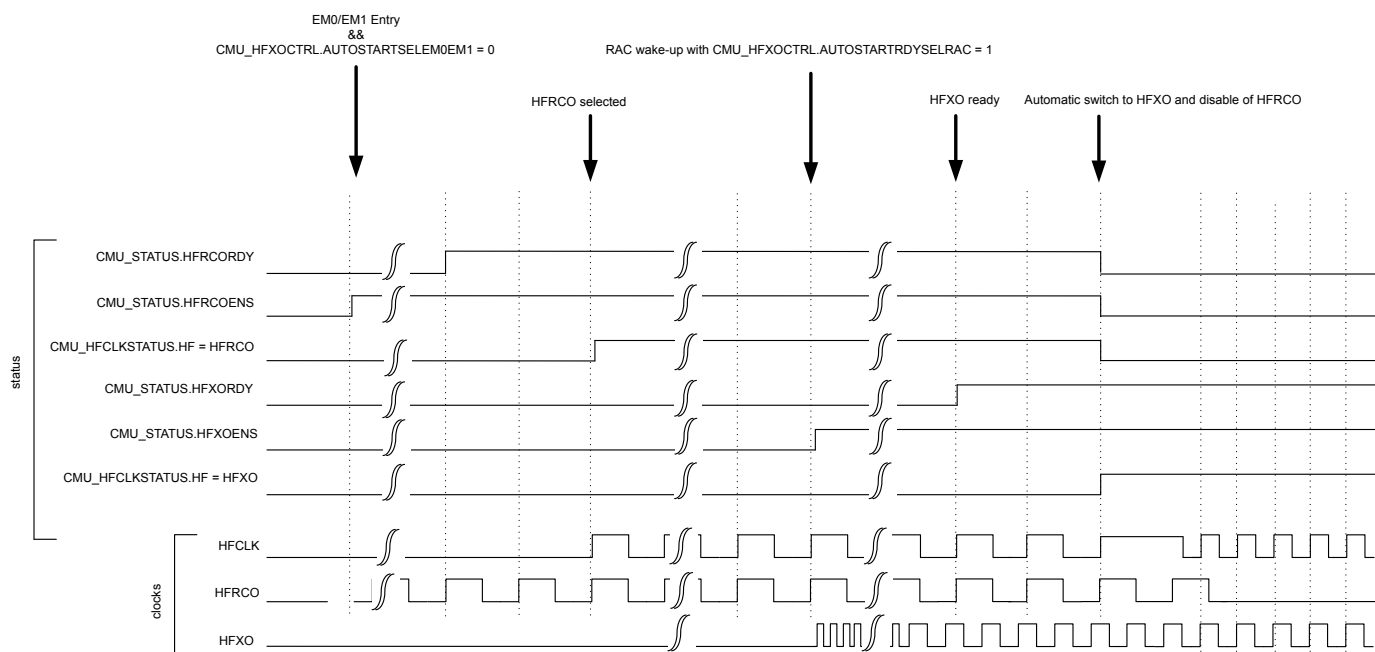

**Figure 12.12. CMU Automatic startup and selection of HFXO**

If an automatic selection of HFXO is performed, which switches the clock source used for HFCLKSRC, then the HFXOAUTOSW bit in CMU\_IF is set to 1. After automatic enable and selection of the HFXO, the HFRCO is automatically disabled in case it is running. The disabling of a running HFRCO is signalled via the HFRCODIS bit in CMU\_IF. This only applies to the HFRCO. If for example the LFXO was used as HFSRCCLK at the time of automatic selection of the HFXO, the LFXO remains unaffected.

The interaction between automatic HFXO startup and selection with startup and selection of HFRCO is shown in [Figure 12.13 CMU HFRCO startup/selection while awaiting automatic HFXO startup/selection on page 259](#) and [Figure 12.14 CMU Automatic HFXO start-up/selection while HFRCO started/selected on page 260](#).

**Figure 12.13. CMU HFRCO startup/selection while awaiting automatic HFXO startup/selection**

**Figure 12.14. CMU Automatic HFXO startup/selection while HFRCO started/selected**

### 12.3.3 Configuration For Operating Frequencies

The HFXO is capable of driving crystals up to 40 MHz, which allows the EFR32 to run at up to this frequency. However, the Memory System Controller (MSC) and the Low Energy Peripheral Interface need to be configured correctly to allow operation at higher frequencies as explained below.

The MODE bitfield in MSC\_READCTRL makes sure the flash is able to operate at the given HFCLK frequency by inserting wait states for flash accesses. The required settings for controlling flash wait states are shown in [Table 12.2 Configuration For Operating Frequencies: Flash Wait States on page 261](#). The WSHFLE bitfield in CMU\_CTRL is used to ensure that the Low Energy Peripheral Interface is able to operate at the given HFBUSCLK<sub>LE</sub> frequency by inserting wait states when using this interface. The required settings are shown in [Table 12.3 Configuration For Operating Frequencies: Low Energy Peripheral Interface on page 261](#). The HFCLKLEPRESC bitfield in CMU\_HFPRESC is used to control the HFCLKLE frequency. This is required in case LE peripherals use HFCLKLE as clock source for LFACLK or LFECLK. The required settings to ensure a valid operating frequency for LFACLK/LFECLK are shown in [Table 12.4 Configuration For Operating Frequencies: Using HFCLKLE as LFACLK/LFECLK on page 261](#).

Before going to a high frequency, make sure the registers in the table have the correct values. When going down in frequency, make sure to keep the registers at the values required by the higher frequency until after the switch has been done.

**Table 12.2. Configuration For Operating Frequencies: Flash Wait States**

Condition	MODE in MSC_READCTRL
HFCLK ≤ 25 MHz	WS0 / WS1
HFCLK > 25 MHz	WS1

**Table 12.3. Configuration For Operating Frequencies: Low Energy Peripheral Interface**

Condition	WSHFLE in CMU_CTRL
HFBUSCLK <sub>LE</sub> ≤ 32 MHz	0 / 1
HFBUSCLK <sub>LE</sub> > 32 MHz	1

**Table 12.4. Configuration For Operating Frequencies: Using HFCLKLE as LFACLK/LFECLK**

Condition	HFCLKLEPRESC in CMU_HFPRESC
HFBUSCLK <sub>LE</sub> ≤ 32 MHz	DIV2 / DIV4
HFBUSCLK <sub>LE</sub> > 32 MHz	DIV4

### 12.3.4 Energy Modes

The availability of oscillators and system clocks depends on the chosen energy mode. Default the high frequency oscillators (HFRCO, AUXHFRCO, and HFXO) and high frequency clocks (HFSRCLK, HFCLK, HFCORECLK, HFBUSCLK, HFPERCLK, HFRADIOCLK, HFCLKLE) are available down to EM1 Sleep. From EM2 DeepSleep onwards these oscillators and clocks are normally off, although special cases exist as summarized in [Table 12.5 Oscillator and clock availability in Energy Modes on page 262](#) and [Table 11.2 EMU Energy Mode Overview on page 188](#). The CMU overview figure in [Figure 12.1 CMU Overview on page 241](#) also indicates which oscillators and clocks can be used in what energy modes.

The low frequency oscillators (LFRCO and LFXO) are available in all energy modes except in EM3 Stop when they are off by definition. Default these oscillators are also off in EM4 Hibernate and EM4 Shutoff, but they can be retained on in these states as well if needed. The ultra low frequency oscillator (ULFRCO) is default on in all energy modes, except for EM4 Shutoff, but it can be retained on in that state as well if needed. The low frequency clocks (LFACLK, LFBCLK, LFECLK, WDOGCLK, RFSENSECLK, and CRYOCLK) are in various power domains and therefore their availability not only depends on the chosen clock source, but also on the chosen energy mode as indicated in [Table 12.5 Oscillator and clock availability in Energy Modes on page 262](#).

**Table 12.5. Oscillator and clock availability in Energy Modes**

	EM0 Active/EM1 Sleep	EM2 DeepSleep	EM3 Stop	EM4 Hibernate	EM4 Shutoff
HFRCO	On <sup>1</sup>	Off	Off	Off	Off
HFXO	On <sup>1</sup>	Off	Off	Off	Off
AUXHFRCO	On <sup>1</sup>	On <sup>2</sup>	On <sup>2</sup>	Off	Off
LFRCO, LFXO	On <sup>1</sup>	On <sup>1</sup>	Off	Retained on <sup>3</sup>	Retained on <sup>3</sup>
ULFRCO	On	On	On	On	Retained on <sup>3</sup>
HFSRCLK, HFCLK, HFCORECLK, HFBUSCLK, HFPERCLK, HFRADIOCLK, HFCLKLE	On <sup>1</sup>	Off	Off	Off	Off
AUXCLK	On <sup>1</sup>	On <sup>2</sup>	On <sup>2</sup>	Off	Off
LFACLK, LFBCLK	On <sup>1</sup>	On <sup>1</sup>	On <sup>4</sup>	Off	Off
LFECLK	On <sup>1</sup>	On <sup>1</sup>	On <sup>4</sup>	Retained on <sup>3</sup>	Off
WDOGCLK	On <sup>1</sup>	On <sup>1</sup>	On <sup>4</sup>	Off	Off
CRYOCLK	On <sup>1</sup>	On <sup>1</sup>	On <sup>4</sup>	Retained on <sup>3</sup>	Retained on <sup>3</sup>
RFSENSECLK	On <sup>1</sup>	On <sup>1</sup>	On <sup>4</sup>	Retained on <sup>3</sup>	Retained on <sup>3</sup>

- 1 Under software control.
- 2 Default off, but kept active if used by the ADC.
- 3 Default off, but can be retained on.
- 4 On only if ULFRCO is used as clock source.

### 12.3.5 Clock Output on a Pin

It is possible to configure the CMU to output clocks on the CMU\_CLK0 and CMU\_CLK1 pins. This clock selection is done using the CLKOUTSEL0 and CLKOUTSEL1 bitfields respectively in CMU\_CTRL. The required output pins must be enabled in the CMU\_ROUTEPEEN register and the pin locations can be configured in the CMU\_ROUTELOC0 register. The following clocks can be output on a pin:

- HFSRCCLK and HFEXPCLK. The HFSRCCLK is the high frequency clock before any prescaling has been applied. The HFEXPCLK is a prescaled version of HFCLK as controlled by the HFEXPPRESC bitfield in the CMU\_HFPRESC register.
- The unqualified clock output from any of the oscillators (ULFRCO, LFRCO, LFXO, HFXO). Note that these unqualified clocks can exhibit glitches or skewed duty-cycle during startup and therefore these clock outputs are normally not used before observing the related ready flag being set to 1 in CMU\_STATUS.
- The qualified clock from any of the oscillators (ULFRCO, LFRCO, LFXO, HFXO, HFRCO, AUXHFRCO). A qualified clock will not have any glitches or skewed duty-cycle during startup. For LFRCO, LFXO and HFXO correct configuration of the TIMEOUT bitfield(s) in CMU\_LFRCOCTRL, CMU\_LFXOCTRL and CMU\_HFXOTIMEOUTCTRL respectively is required to guarantee a properly qualified clock.

HFCLK will not have a 50-50 duty cycle when any other division factor than 1 is used in CMU\_HFPRESC (i.e. if PRESC is not equal to 0). In such a case, the exported HFEXPCLK will therefore also not be 50-50 when its division factor is not set to an even number in CMU\_HFEXPPRESC.

### 12.3.6 Clock Input from a Pin

It is possible to configure the CMU to input a clock from the CMU\_CLKI0. This clock can be selected to drive HFSRCCLK and DPLL reference using CMU\_HFCLKSEL and CMU\_DPLLCTRL respectively. The required input pins must be enabled in the CMU\_ROUTEPEEN register and the pin locations can be configured in the CMU\_ROUTELOC1 register.

### 12.3.7 Clock Output on PRS

The CMU can be used as a PRS producer. It can output clocks onto PRS which can be selected by a consumer as CMUCLKOUT0 and CMUCLKOUT1. The clocks which can be produced via CMUCLKOUT0 and CMUCLKOUT1 are selected via the CLKOUTSEL0 and CLKOUTSEL1 fields respectively in CMU\_CTRL.

Note that the CLKOUTSEL0 and CLKOUTSEL1 fields are also used for selecting which clock is output onto a pin as described in [12.3.5 Clock Output on a Pin](#). In contrast with clock output on a pin however, output of a clock onto PRS does not depend on any configuration of the CMU\_ROUTEPEEN and CMU\_ROUTELOC0 registers.

### 12.3.8 Error Handling

Certain restrictions apply to how and when the CMU registers can be configured as is described for the respective registers. Not adhering to these restrictions can lead to unpredictable and non-defined behaviour. Some of these software restrictions are checked in hardware and not adhering to them will cause the CMUERR interrupt flag in CMU\_IF to be set to 1. The restrictions impacting CMUERR are as follows:

- CMU\_HFRCOCTRL should not be written while HFRCOBSY in the CMU\_SYNCBUSY register is set to 1.
- CMU\_AUXHFRCOCTRL should not be written while AUXHFRCOBSY in the CMU\_SYNCBUSY register is set to 1.
- CMU\_HFXOSTARTUPCTRL, CMU\_HFXOSTEADYSTATECTRL and CMU\_HFXOTIMEOUTCTRL should not be written while HFXOBSY in the CMU\_SYNCBUSY register is set to 1. Note that writes to CMU\_HFXOCTRL do not impact CMUERR. Although most of its bitfields need to be configured before enabling the HFXO, it is allowed to change the AUTOSTART bits (i.e. AUTOSTARTRDYSEL, AUTOSTARTSELEMEM0EM1 and AUTOSTARTEMEM0EM1) at any time.
- HFXO should not be enabled before it has been properly disabled (so only enable HFXO when HFXOENS=0 or HFXOBSY=0). Likewise, HFXO should not be disabled before it has been properly enabled (so only disable HFXO when HFXOENS=1 or HFXOBSY=0).
- CMU\_LFRCOCTRL should not be written while LFRCOBSY in the CMU\_SYNCBUSY register is set to 1. The GMCCURTUNE bitfield should not be written with a differing value while the LFRCOVREFBSY flag is set to 1.
- CMU\_LFXOCTRL should not be written while LFXOBSY in the CMU\_SYNCBUSY register is set to 1.

### 12.3.9 Interrupts

The interrupts generated by the CMU module are combined into one interrupt vector. If CMU interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in CMU\_IF and their corresponding bits in CMU\_IEN are set.

### 12.3.10 Wake-up

The CMU can be (partially) active all the way down to EM4 Shutoff. It can wake up the CPU from EM2 upon LFRCO or LFXO becoming ready as LFRCORDY and LFXORDY can be used as wake-up interrupt.

### 12.3.11 Protection

It is possible to lock the control- and command registers to prevent unintended software writes to critical clock settings. This is controlled by the CMU\_LOCK register.

## 12.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	CMU_CTRL	RW	CMU Control Register
0x010	CMU_HFRCOCTRL	RWH	HFRCO Control Register
0x018	CMU_AUXHFRCOCTRL	RW	AUXHFRCO Control Register
0x020	CMU_LFRCOCTRL	RW	LFRCO Control Register
0x024	CMU_HFXOCTRL	RW	HFXO Control Register
0x028	CMU_HFXOCTRL1	RW	HFXO Control 1
0x02C	CMU_HFXOSTARTUPCTRL	RW	HFXO Startup Control
0x030	CMU_HFXOSTEADYSTATECTRL	RW	HFXO Steady State control

13		AUXHFRCOQ		AUXHFRCO (qualified)
14		HFXOQ		HFXO (qualified)
15		HFSRCCLK		HFSRCCLK

### 12.5.2 CMU\_HFRCTRL - HFRCO Control Register

Write this register to set the frequency band in which the HFRCO is to operate. Always update all fields in this registers at once by writing the value for the desired band, which has been obtained from the Device Information page entry for that band. The TUNING, FINETUNING, FINETUNINGEN and CLKDIV bitfields can be used to tune a specific band (FREQRANGE) of the oscillator to a non-preconfigured frequency. When changing this setting there will be no glitches on the HFRCO output, hence it is safe to change this setting even while the system is running on the HFRCO. Only write CMU\_HFRCTRL when it is ready for an update as indicated by HFRCOBSY=0 in CMU\_SYNCBUSY.

Offset	Bit Position																																					
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset	0xB				0	0x0				1	0x2				0x08								0x1F								0x3C							
Access	RWH				RWH	RWH				RWH	RWH				RWH								RWH								RWH							
Name	VREFTC				FINETUNINGEN	CLKDIV				LDOHP	CMPBIAS				FREQRANGE								FINETUNING								TUNING							

Bit	Name	Reset	Access	Description
31:28	VREFTC	0xB	RWH	<b>HFRCO Temperature Coefficient Trim on Comparator Reference</b> Writing this field adjusts the temperature coefficient trim on comparator reference.
27	FINETUNINGEN	0	RWH	<b>Enable reference for fine tuning</b> Settings this bit enables HFRCO fine tuning.
26:25	CLKDIV	0x0	RWH	<b>Locally divide HFRCO Clock Output</b> Writing this field configures the HFRCO clock output divider.
	Value	Mode		Description
	0	DIV1		Divide by 1.
	1	DIV2		Divide by 2.
	2	DIV4		Divide by 4.
24	LDOHP	1	RWH	<b>HFRCO LDO High Power Mode</b> Settings this bit puts the HFRCO LDO in high power mode.
23:21	CMPBIAS	0x2	RWH	<b>HFRCO Comparator Bias Current</b> Writing this field adjusts the HFRCO comparator bias current.
20:16	FREQRANGE	0x08	RWH	<b>HFRCO Frequency Range</b> Writing this field adjusts the HFRCO frequency range.
15:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13:8	FINETUNING	0x1F	RWH	<b>HFRCO Fine Tuning Value</b> Writing this field adjusts the HFRCO fine tuning value. Higher value means lower frequency. Fine tuning is only enabled when FINETUNINGEN is set.
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:0	TUNING	0x3C	RWH	<b>HFRCO Tuning Value</b> Writing this field adjusts the HFRCO tuning value. Higher value means lower frequency.

### 12.5.3 CMU\_AUXHFRCTRL - AUXHFRCO Control Register

Write this register with the production calibrated values from the Device Info pages. The TUNING, FINETUNING, FINETUNINGEN and CLKDIV bitfields can be used to tune a specific band (FREQRANGE) of the oscillator to a non-preconfigured frequency. Only write CMU\_AUXHFRCTRL when it is ready for an update as indicated by AUXHFRCOBSY=0 in CMU\_SYNCBUSY.

Offset	Bit Position																																
0x018	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13:8	FINETUNING	0x1F	RW	<b>AUXHFRCO Fine Tuning Value</b>  Writing this field adjusts the AUXHFRCO fine tuning value. Higher value means lower frequency. Fine tuning is only enabled when FINETUNINGEN is set.												
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>														
6:0	TUNING	0x3C	RW	<b>AUXHFRCO Tuning Value</b>  Writing this field adjusts the AUXHFRCO tuning value. Higher value means lower frequency.												

## 12.5.4 CMU\_LFRCOCTRL - LFRCO Control Register

Offset	Bit Position																																		
0x020	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reset	0x8							0x1							1	1	0											0x100							
Access	RW							RW							RW	RW	RW											RW							
Name	GMCCURTUNE							TIMEOUT							ENDEM	ENCHOP	ENVREF						TUNING												

Bit	Name	Reset	Access	Description
31:28	GMCCURTUNE	0x8	RW	<b>Tuning of gmc current</b>  Set to tune GMC current. This field is updated with the production calibrated value during reset, and the reset value might therefore vary between devices.
27:26	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
25:24	TIMEOUT	0x1	RW	<b>LFRCO Timeout</b>  Configures the start-up delay for LFRCO. Do not change while LFRCO is enabled. When starting up the LFRCO after it has been completely turned off, use TIMEOUT=16cycles. If the LFRCO has been retained on in EM4, then the TIMEOUT=2cycles configuration is also allowed when re-enabling the LFRCO after EM4 exit (as it is still running).
	Value	Mode	Description	
	0	2CYCLES	Timeout period of 2 cycles	
	1	16CYCLES	Timeout period of 16 cycles	
	2	32CYCLES	Timeout period of 32 cycles	
23:19	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
18	ENDEM	1	RW	<b>Enable dynamic element matching</b>  Set to enable dynamic element matching. This improves average frequency accuracy at the cost of increased jitter.
17	ENCHOP	1	RW	<b>Enable comparator chopping</b>  Set to enable comparator chopping. This improves average frequency accuracy at the cost of increased jitter.
16	ENVREF	0	RW	<b>Enable duty cycling of vref</b>  Set to enable duty cycling of vref. Clear during calibration of LFRCO. Only change when LFRCO is off.
15:9	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
8:0	TUNING	0x100	RW	<b>LFRCO Tuning Value</b>  Writing this field adjusts the LFRCO frequency (the higher the value, the lower the frequency). This field is updated with the production calibrated value during reset, and the reset value might therefore vary between devices.

## 12.5.5 CMU\_HFXOCTRL - HFXO Control Register

Offset	Bit Position																																		
0x024	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3	16CYCLES	Timeout period of 16 cycles																													
4	32CYCLES	Timeout period of 32 cycles																													
5	64CYCLES	Timeout period of 64 cycles																													
6	1KCYCLES	Timeout period of 1024 cycles																													
7	4KCYCLES	Timeout period of 4096 cycles																													
23:11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>																													
10	XTO2GND	0	RW	<b>Clamp HFXTAL_P pin to ground when HFXO oscillator is off.</b>  Set to enable grounding of HFXTAL_P pin when HFXO oscillator is off																											
9	XTI2GND	0	RW	<b>Clamp HFXTAL_N pin to ground when HFXO oscillator is off.</b>  Set to enable grounding of HFXTAL_N pin when HFXO oscillator is off. Do not enable if MODE=EXTCLK and an external source is supplied.																											
8	LOWPOWER	0	RW	<b>Low power mode control. PSR performance is reduced to enable low current consumption.</b>  Set LOWPOWER=0 for RF performance. Set LOWPOWER=1 for non RF performance (not compatible with Radio operation).																											
7:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>																													
5:4	PEAKDETSHUN-TOPTMODE	0x0	RW	<b>HFXO Automatic Peak Detection and shunt current optimization mode</b>																											

Bit	Name	Reset	Access	Description
Set to AUTOCMD to allow automatic HFXO peak detection and shunt current optimization (MANUAL mode provides direct control of IBTRIMXOCORE, REGISH, PEAKDETEN, REGSELILOW).				
	Value	Mode		Description
	0	AUTOCMD		Automatic control of HFXO peak detection and shunt optimization sequences. CMU_CMD HFXOPEAKDETSTART and HFXOSHUNTOPTSTART can also be used.
	1	CMD		CMU_CMD HFXOPEAKDETSTART and HFXOSHUNTOPTSTART can be used to trigger peak detection and shunt optimization sequences.
	2	MANUAL		CMU_HFXOSTEADYSTATECTRL IBTRIMXOCORE, REGISH, REGSELILOW, and PEAKDETEN are under full software control and are allowed to be changed once HFXO is ready.
3:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	MODE	0	RW	<b>HFXO Mode</b>
Set this to configure the external source for the HFXO. The oscillator setting takes effect when 1 is written to HFXOEN in CMU_OSCENCMD.				
	Value	Mode		Description
	0	XTAL		38 MHz - 40 MHz crystal oscillator
	1	EXTCLK		External clock can be supplied (square or wave) on HFXTAL_N pin.

Access						RW							RW			RW		RW	RW	0			RW				RW				RW						
Name						TIMEOUT							BUFCUR				CUR		AGC	HIGHAMPL				GAIN				MODE				TUNING					

Bit	Name	Reset	Access	Description
31:27	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
26:24	TIMEOUT	0x7	RW	<b>LFXO Timeout</b>  Configures the start-up delay for LFXO. Do not change while LFXO is enabled. When starting up the LFXO after it has been completely turned off, use the TIMEOUT setting required by the XTAL. If the LFXO has been retained on in EM4, then the TIMEOUT=2cycles configuration is also allowed when re-enabling the LFXO after EM4 exit (as it is still running).
Value		Mode	Description	
0		2CYCLES	Timeout period of 2 cycles	
1		256CYCLES	Timeout period of 256 cycles	
2		1KCYCLES	Timeout period of 1024 cycles	
3		2KCYCLES	Timeout period of 2048 cycles	
4		4KCYCLES	Timeout period of 4096 cycles	
5		8KCYCLES	Timeout period of 8192 cycles	
6		16KCYCLES	Timeout period of 16384 cycles	
7		32KCYCLES	Timeout period of 32768 cycles	
23:21	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
20	BUFCUR	0	RW	<b>LFXO Buffer Bias Current</b>  The default value is intended to cover all use cases and reprogramming is not recommended. Do not change while LFXO is enabled.
19:18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17:16	CUR	0x0	RW	<b>LFXO Current Trim</b>  The default value is intended to cover all use cases and reprogramming is not recommended. Do not change while LFXO is enabled.
15	AGC	1	RW	<b>LFXO AGC Enable</b>  Set this bit to enable automatic gain control which limits XTAL oscillation amplitude. Do not change while LFXO is enabled.
14	HIGHAMPL	0	RW	<b>LFXO High XTAL Oscillation Amplitude Enable</b>  Set this bit to enable high XTAL oscillation amplitude. Do not change while LFXO is enabled.
13	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
12:11	GAIN	0x2	RW	<b>LFXO Startup Gain</b>  The optimal value for maximum startup margin depends on the chosen XTAL. Please refer to the Device Datasheet or Simplicity Studio for more information.
10	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
9:8	MODE	0x0	RW	<b>LFXO Mode</b>  Set this to configure the external source for the LFXO. Do not change while LFXO is enabled. The oscillator setting takes effect when 1 is written to LFXOEN in CMU_OSCENCMD. The oscillator setting is reset to default when 1 is written to LFXODIS in CMU_OSCENCMD.
Value		Mode	Description	
0		XTAL	32768 Hz crystal oscillator	

Bit	Name	Reset	Access	Description
	1	BUFEXTCLK		An AC coupled buffer is coupled in series with LFXTAL_N pin, suitable for external sinus wave (32768 Hz).
	2	DIGEXTCLK		Digital external clock on LFXTAL_N pin. Oscillator is effectively by-passed.
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:0	TUNING	0x00	RW	<b>LFXO Internal Capacitor Array Tuning Value</b>  Writing this field adjusts the internal load capacitance connected between LFXTAL_P and ground and LFXTAL_N and ground symmetrically (the higher the value, the higher the capacitance, the lower the frequency). Only increment or decrement by 1 LSB at a time.

Bit	Name	Reset	Access	Description
31:3	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
2:0	SELECTED	0x1	R	<b>HFCLK Selected</b> Clock selected as HFCLK clock source.
	Value	Mode	Description	
	1	HFRCO	HFRCO is selected as HFCLK clock source	
	2	HFXO	HFXO is selected as HFCLK clock source	
	3	LFRCO	LFRCO is selected as HFCLK clock source	
	4	LFXO	LFXO is selected as HFCLK clock source	

## 12.5.22 CMU\_HFXOTRIMSTATUS - HFXO Trim Status

Offset	Bit Position																															
0x09C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																						0xA			0x00							
Access																						R			R							
Name																						REGISH			IBTRIMXOCORE							

Bit	Name	Reset	Access	Description
31:11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
10:7	REGISH	0xA	R	Value of REGISH found by automatic HFXO shunt current optimization algorithm. Can be used as initial value for REGISH value in the CMU_HFXOSTEADYSTATECTRL register if HFXO is to be started again.
6:0	IBTRIMXOCORE	0x00	R	Value of IBTRIMXOCORE found by automatic HFXO peak detection algorithm. Can be used as initial value for IBTRIMXOCORE in the CMU_HFXOSTEADYSTATECTRL register if HFXO is to be started again.

### 12.5.23 CMU\_IF - Interrupt Flag Register

Offset	Bit Position																			
0x0A0	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12
Reset	0															0	0	0	0	0
Access	R															R	R	R	R	R
Name	CMUERR															LTIMEOUTERR	HFRCODIS	HFXOSHUNTOPTRDY	HFXOPEAKDETRDY	HFXOPEAKDETRERR
																HFXOAUTOSW	HFXODISERR			

Bit	Name	Reset	Access	Description
31	CMUERR	0	R	<b>CMU Error Interrupt Flag</b> Set upon illegal CMU write attempt (e.g. writing CMU_LFRCOCTRL while LFRCOBSY is set).
30:15	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
14	LFTIMEOUTERR	0	R	<b>Low Frequency Timeout Error Interrupt Flag</b> Set when LFTIMEOUT of CMU_HFXOCTRL triggers before the combined STARTUPTIMEOUT plus STEADYTIMEOUT of the CMU_HFXOTIMEOUTCTRL register triggers.
13	HFRCODIS	0	R	<b>HFRCO Disable Interrupt Flag</b> Set when a running HFRCO is disabled because of automatic HFXO start and selection.
12	HFXOSHUNTOPTRDY	0	R	<b>HFXO Automatic Shunt Current Optimization Ready Interrupt Flag</b> Set when automatic HFXO shunt current optimization is ready.
11	HFXOPEAKDETRDY	0	R	<b>HFXO Automatic Peak Detection Ready Interrupt Flag</b> Set when automatic HFXO peak detection is ready.
10	HFXOPEAKDETRERR	0	R	<b>HFXO Automatic Peak Detection Error Interrupt Flag</b> Set when automatic HFXO peak detection failed.
9	HFXOAUTOSW	0	R	<b>HFXO Automatic Switch Interrupt Flag</b> Set when automatic selection of HFXO causes a switch of the source clock used for HFCLKSRC.
8	HFXODISERR	0	R	<b>HFXO Disable Error Interrupt Flag</b> Set when software tries to disable/deselect the HFXO in case the automatic enable/select reason is met. The HFXO was not disabled/deselected.
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6	CALOF	0	R	<b>Calibration Overflow Interrupt Flag</b> Set when calibration overflow has occurred (i.e. if a new calibration completes before CMU_CALCNT has been read).
5	CALRDY	0	R	<b>Calibration Ready Interrupt Flag</b> Set when calibration is completed.
4	AUXHFRCORDY	0	R	<b>AUXHFRCO Ready Interrupt Flag</b> Set when AUXHFRCO is ready (start-up time exceeded).
3	LFXORDY	0	R	<b>LFXO Ready Interrupt Flag</b> Set when LFXO is ready (start-up time exceeded). LFXORDY can be used as wake-up interrupt.
2	LFRCORDY	0	R	<b>LFRCO Ready Interrupt Flag</b> Set when LFRCO is ready (start-up time exceeded). LFRCORDY can be used as wake-up interrupt.
1	HFXORDY	0	R	<b>HFXO Ready Interrupt Flag</b> Set when HFXO is ready (start-up time exceeded).
0	HFRCORDY	1	R	<b>HFRCO Ready Interrupt Flag</b> Set when HFRCO is ready (start-up time exceeded).

Write any other value than the unlock code to lock CMU_CTRL, CMU_HFRCCOCTRL, CMU_AUXHFRCCOCTRL, CMU_LFRCCOCTRL, CMU_ULFRCCOCTRL, CMU_HFXOCTRL, CMU_HFXOCTRL1, CMU_LFXOCTRL, CMU_OSCENCMD, CMU_CMD, CMU_DBGCLKSEL, CMU_HFCLKSEL, CMU_LFCLKSEL, CMU_HFBUSCLKEN0, CMU_HFCOR-ECLKEN0, CMU_HFPERCLKEN0, CMU_HFRADIOCLKEN0, CMU_HFRADIOALTCLKEN0, CMU_HFRADIOPRESC, CMU_HFRADIOALTPRESC, CMU_HFPRESC, CMU_HFCOREPRESC, CMU_HFPERPRESC, CMU_HFEXPPRESC, CMU_LFRCLKEN0, CMU_LFRPRESC0, CMU_LFACLKEN0, CMU_LFBCLKEN0, CMU_LFECLKEN0, CMU_LFAPRESC0, CMU_LFBPRESC0, CMU_LFEPRESC0, CMU_ADCCTRL and CMU_PCNTCTRL from editing. Write the unlock code to unlock. When reading the register, bit 0 is set when the lock is enabled.				

Mode	Value	Description
Read Operation		
UNLOCKED	0	CMU registers are unlocked
LOCKED	1	CMU registers are locked
Write Operation		
LOCK	0	Lock CMU registers
UNLOCK	0x580E	Unlock CMU registers

## 13. RTCC - Real Time Counter and Calendar

### Quick Facts

#### What?

The Real Time Counter and Calendar (RTCC) is a 32-bit counter ensuring timekeeping in low energy modes. The RTCC also includes a calendar mode for easy time and date keeping. In addition, the RTCC includes 128 bytes of general purpose retention data, allowing persistent data storage in all energy modes except EM4S.

#### Why?

Timekeeping over long time periods while using as little power as possible is required in many low power applications.

#### How?

A low frequency oscillator is used as clock signal and the RTCC has three different Capture/Compare channels which can trigger wake-up, generate PRS signalling, or capture system events. 32-bit resolution and selectable prescaling allows the system to stay in low energy modes for long periods of time and still maintain reliable timekeeping.

### 13.1 Introduction

The Real Time Counter and Calendar (RTCC) contains a 32-bit counter/calendar in combination with a 15-bit pre-counter to allow flexible prescaling of the main counter. The RTCC is available in all energy modes except EM4S.

Three individually configurable Capture/Compare channels are available in the RTCC. These can be used to trigger interrupts, generate PRS signals, capture system events, and to wake the device up from a low energy mode. The RTCC also includes 128 bytes of general purpose storage, and a Binary Coded Decimal (BCD) calendar mode, enabling easy time and date keeping.

## 13.2 Features

- 32-bit Real Time Counter.
- 15-bit pre-counter, for flexible frequency scaling or for use as an independent counter.
- EM4H operation and wakeup.
- 128 byte general purpose retention data.
- Oscillator failure detection.
- Can continue through system reset; only reset by power loss, pin, or software reset.
- Calendar mode.
  - BCD encoding.
  - Three programmable alarms.
  - Leap year correction.
- Three Capture/Compare registers.
  - Capture of PRS events from other parts of the system.
  - Compare match or input capture can trigger interrupts.
  - Compare register 1, RTCC\_CC1\_CCV can be used as a top value for the main counter.
  - Compare register 0, RTCC\_CC0\_CCV can be used as a top value for the pre-counter.
  - Compare match events are available to other peripherals through the Peripheral Reflex System (PRS).

## 13.3 Functional Description

The RTCC is a 32-bit up-counter with three Capture/Compare channels. In addition, the RTCC includes a 15-bit pre-counter which can be used as an independent counter, or to prescale the main counter. An overview of the RTCC module is shown in [Figure 13.1 RTCC Overview on page 327](#).

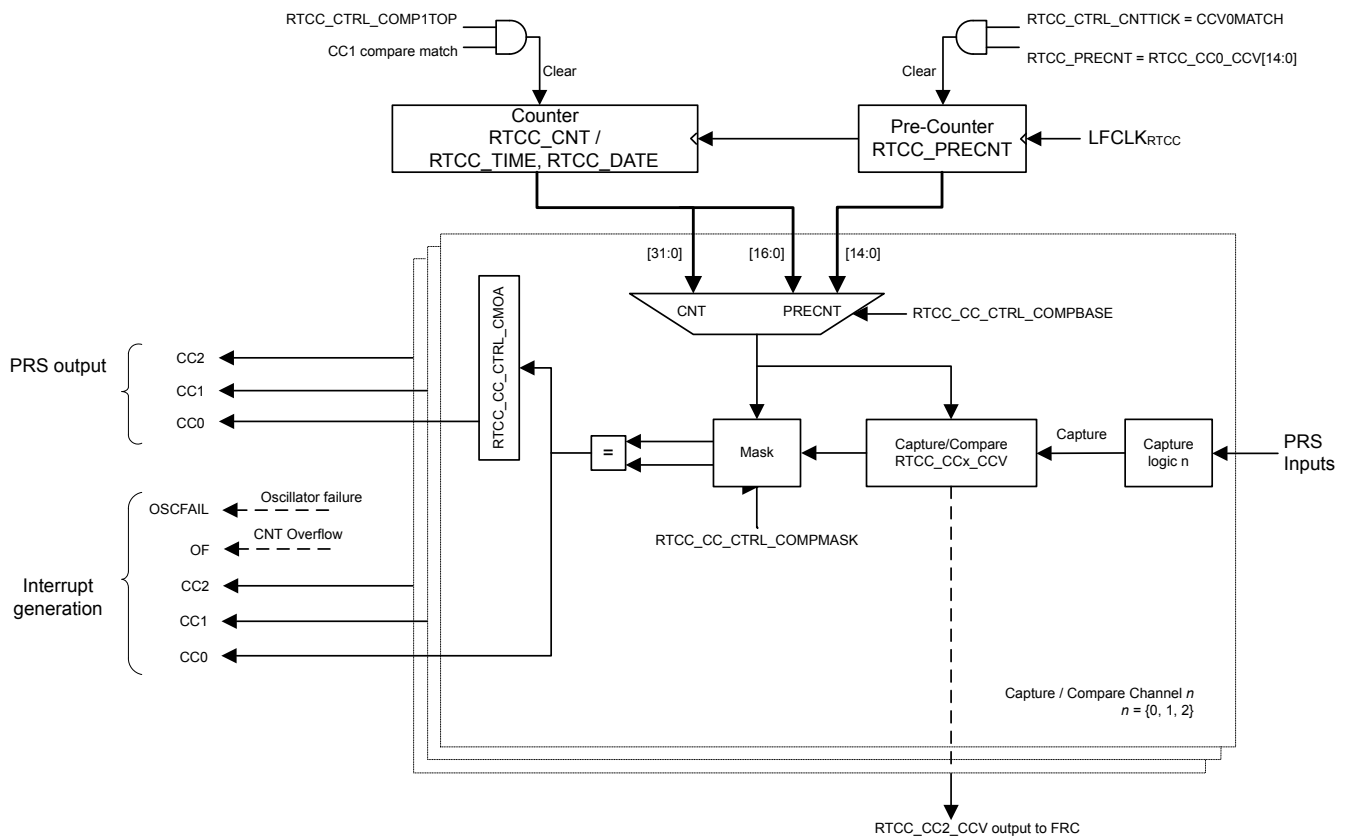

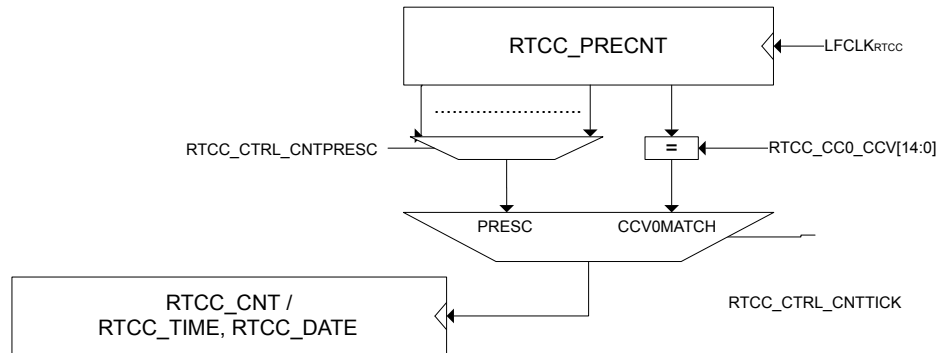

Figure 13.1. RTCC Overview

### 13.3.1 Counter

The RTCC consists of two counters; the 32-bit main counter, RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode), and a 15-bit pre-counter, RTCC\_PRECNT. The pre-counter can be used as an independent counter, or to generate a specific frequency for the main counter. In both configurations, the pre-counter can be used to generate compare match events or be captured in the Capture/Compare channels as a result of an external PRS event. Refer to [13.3.2 Capture/Compare Channels](#) for details on how to configure the Capture/Compare channels for use with the pre-counter.

**Figure 13.2. RTCC counters**

The RTCC is enabled by setting the **ENABLE** bit in **RTCC\_CTRL**. When the RTCC is enabled, the pre-counter (**RTCC\_PRECNT**) increments upon each positive clock edge of **LFCLK<sub>RTCC</sub>**. If **CNTTICK** in **RTCC\_CTRL** is set to **PRESC**, the pre-counter will continue to count up, wrapping around to zero when it overflows. If **CNTTICK** in **RTCC\_CTRL** is set to **CCV0MATCH**, the pre-counter will wrap around when it hits the value configured in **RTCC\_CC0\_CCv**.

The main counter of the RTCC, **RTCC\_CNT**, has two modes; normal mode and calendar mode. In normal mode, the main counter is available in **RTCC\_CNT** and increments upon each tick given from the pre-counter. Refer to [13.3.1.1 Normal Mode](#) for a description on how to configure the frequency of these ticks. In calendar mode, the counter value is available in **RTCC\_TIME** and **RTCC\_DATE**, keeping track of seconds, minutes, hours, day of month, day of week, months, and years, all encoded in BCD format. Refer to [13.3.1.2 Calendar Mode](#) for details on this mode. The mode of the main counter is configured in **CNTMODE** in **RTCC\_CTRL**. The differences between the two modes are summarized below.

- **Normal mode**
  - Incremental counter, **RTCC\_CNT**.
  - **RTCC\_CCx\_CCv** used for Capture/Compare value.
- **Calendar mode**
  - BCD counters, **RTCC\_DATE**, **RTCC\_TIME**.
  - **RTCC\_CCx\_TIME** and **RTCC\_CCx\_DATE** used for Capture/Compare value.

**Note:** The mode of the RTCC must be configured for **CALENDAR** mode in **RTCC\_CTRL\_CNTMODE** before writing to the mode dependent registers, **RTCC\_TIME**, **RTCC\_DATE**, **RTCC\_CCx\_TIME**, and **RTCC\_CCx\_DATE**. Writes to these registers when in **NORMAL** mode will be ignored.

### 13.3.1.1 Normal Mode

The main counter can receive a tick based on different tapplings from the pre-counter, allowing the ticks to be power of 2 divisions of the  $LFCLK_{RTCC}$ . For more accurate configuration of the tick frequency,  $RTCC\_CC0\_CCV[14:0]$  can be used as a top value for  $RTCC\_PRECNT$ . When reaching the top value, the main counter receives a tick, and the pre-counter wraps around. [Table 13.1 RTCC Resolution vs Overflow,  \$F\_{LFCLK} = 32768\$  Hz on page 329](#) summarizes the resolutions available when using a 32768 Hz oscillator as source for  $LFCLK_{RTCC}$ .

**Table 13.1. RTCC Resolution vs Overflow,  $F_{LFCLK} = 32768$  Hz**

RTCC_CTRL_CNTTICK	RTCC_CTRL_CNTPRESC	Main counter period, $T_{CNT}$	Overflow
CCV0MATCH	Don't care	$(RTCC\_CC0\_CCV + 1)/F_{LFCLK}$ s	$2^{32} \cdot T_{CNT}$ seconds
PRESC	DIV1	30.5 $\mu$ s	36.4 hours
	DIV2	61 $\mu$ s	72.8 hours
	DIV4	122 $\mu$ s	145.6 hours
	DIV8	244 $\mu$ s	12 days
	DIV16	488 $\mu$ s	24 days
	DIV32	977 $\mu$ s	48 days
	DIV64	1.95 ms	97 days
	DIV128	3.91 ms	194 days
	DIV256	7.81 ms	388 days
	DIV512	15.6 ms	776 days
	DIV1024	31.25 ms	4.2 years
	DIV2048	62.5 ms	8.5 years
	DIV4096	0.125 s	17 years
	DIV8192	0.25 s	34 years
	DIV16384	0.5 s	68 years
	DIV32768	1 s	136 years

By default, the counter will keep counting until it reaches the top value, 0xFFFFFFFF, before it wraps around and continues counting from zero. By setting CCV1TOP in  $RTCC\_CTRL$ , a Capture/Compare channel 1 compare match will result in the main counter wrapping to 0. The timer will then wrap around on a channel 1 compare match ( $RTCC\_CNT = RTCC\_CC1\_CCV$ ). If using the CCV1TOP setting, make sure to set this bit prior to or at the same time the RTCC is enabled. Setting CCV1TOP after enabling the RTCC ( $RTCC\_CTRL\_MODE \neq DISABLED$ ) may cause unintended operation (e.g. if  $RTCC\_CNT > RTCC\_CC1\_CCV$ ,  $RTCC\_CNT$  will wrap when reaching 0xFFFFFFFF rather than  $RTCC\_CC1\_CCV$ ).

### 13.3.1.2 Calendar Mode

The RTCC includes a calendar mode which implements time and date decoding in hardware. Calendar mode is enabled by configuring CNTMODE in RTCC\_CTRL to CALENDAR. When in calendar mode, the counter value is available in RTCC\_TIME and RTCC\_DATE. RTCC\_TIME shows seconds, minutes, and hours while RTCC\_DATE shows day of month, month, year, and day of week. RTCC\_TIME and RTCC\_DATE are encoded in BCD format. In calendar mode, the pre-counter should be configured to give ticks with a period of one second, i.e. RTCC\_CTRL\_CNTTICK should be set to PRESC, and the CNTPRESC bitfield of the RTCC\_CTRL register should be set to DIV32768 if a 32768 Hz clock source is used.

In calendar mode, the time and date registers of the capture compare channels, RTCC\_CCx\_TIME and RTCC\_CCx\_DATE, are used to set compare values. Compare values can be set on seconds, minutes, hours, days, and months. Whether day of week, or day of month is used for a Capture/Compare channel is configured in RTCC\_CCx\_CTRL\_DAYCC in the respective Capture/Compare channel.

The RTCC will automatically compensate for 28-, 29- (leap year), 30-, and 31-day months. The day of week counter, RTCC\_DATE\_DAYOW, is a three bit counter incrementing when RTCC\_TIME\_HOURLT overflows, wrapping around every seventh day. Automatic leap year correction, extending the month of February from 28 to 29 days every fourth year is by default enabled, but can be disabled by setting the LYEARCHCORRDIS bit in RTCC\_CTRL. The pseudocode for leap year correction is as follows:

```
if RTCC_DATE YEART modulo 2 = 0:
    if RTCC_DATE YEARU modulo 4 = 0:
        leap_year = true
    else:
        leap_year = false
else:
    if (RTCC_DATE YEARU + 2) modulo 4 = 0:
        leap_year = true
    else:
        leap_year = false
```

The seconds, minute, hour segments are represented in 24-hour BCD format. The month segments are enumerated as shown in [Table 13.2 RTCC calendar enumeration on page 330](#).

**Table 13.2. RTCC calendar enumeration**

Month	RTCC_DATE_MONTHT	RTCC_DATE_MONTHU
January	0b0	0b0001
February	0b0	0b0010
March	0b0	0b0011
April	0b0	0b0100
May	0b0	0b0101
June	0b0	0b0110
July	0b0	0b0111
August	0b0	0b1000
September	0b0	0b1001
October	0b1	0b0000
November	0b1	0b0001
December	0b1	0b0010

### 13.3.1.3 RTCC Initialization

The counters of the RTCC, RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode) and RTCC\_PRECNT, can at any time be written by software, as long as the registers are not locked using RTCC\_LOCKKEY. All RTCC registers use the immediate synchronization scheme, described in [4.3.1 Writing](#).

**Note:** Writing to the RTCC\_PRECNT register may alter the frequency of the ticks for the RTCC\_CNT register.

### 13.3.2 Capture/Compare Channels

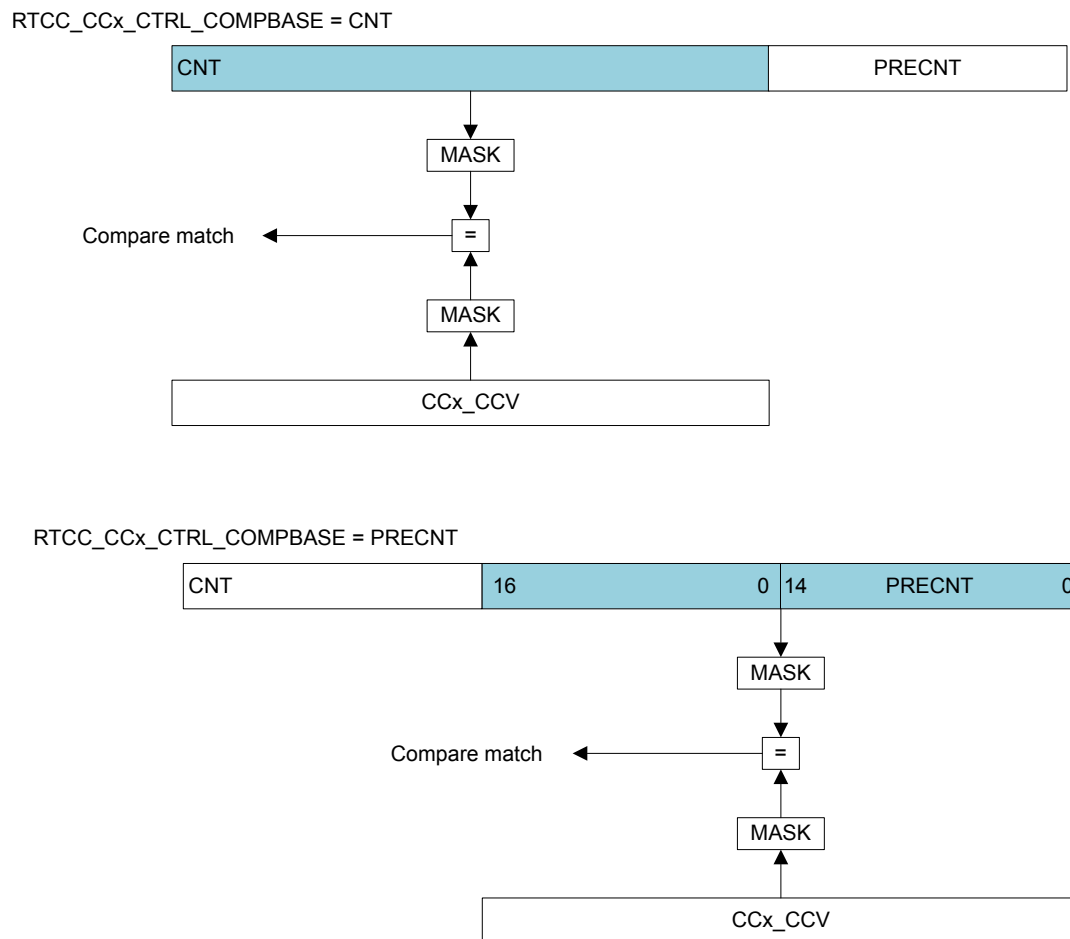

Three capture/compare channels are available in the RTCC. Each channel can be configured as input capture or output compare, by setting the corresponding MODE in the RTCC\_CCx\_CTRL register.

**Figure 13.3. RTCC Compare match and PRS output illustration**

In input capture mode the RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode) register is captured into the RTCC\_CCx\_CCv (RTCC\_CCx\_TIME and RTCC\_CCx\_DATE in calendar mode) register when an edge is detected on the selected PRS input channel. The active capture edge is configured in the ICEDGE control bits.

In output compare mode the compare values are set by writing to the RTCC compare channel registers RTCC\_CCx\_CCv (RTCC\_CCx\_TIME and RTCC\_CCx\_DATE in calendar mode). These values will be compared to the main counter, RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode), or a mixture of the main counter and the pre-counter, as illustrated in [Figure 13.4 RTCC Compare base illustration on page 332](#). Compare base for the capture compare channels is set by configuring COMP-BASE in RTCC\_CCx\_CTRL.

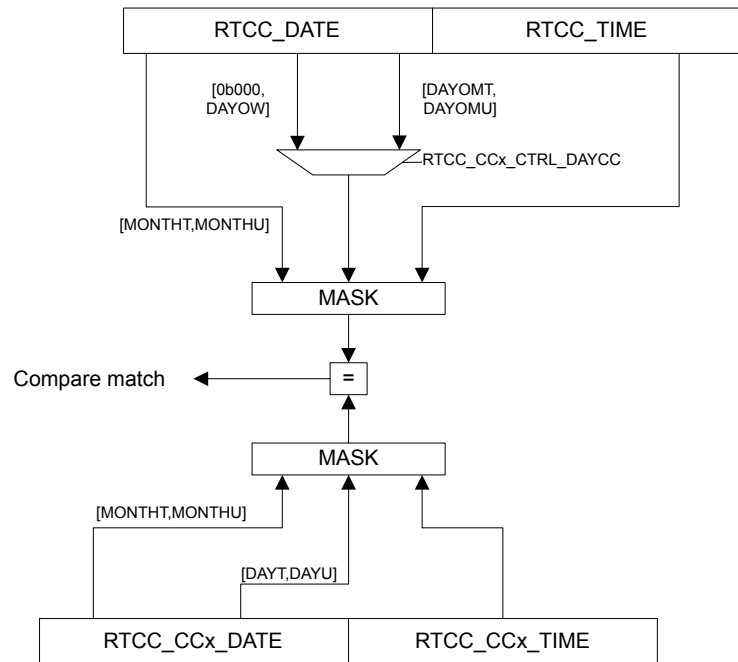

**Figure 13.4. RTCC Compare base illustration**

Table 13.3 RTCC Capture/Compare subjects on page 332 summarizes which registers being subject to comparison for different configurations of RTCC\_CTRL\_CNTMODE and RTCC\_CCx\_CTRL\_COMPBASE.

**Table 13.3. RTCC Capture/Compare subjects**

RTCC_CTRL_CNTMODE	NORMAL	CALENDAR
RTCC_CCx_CTRL_COMPBASE = CNT	RTCC_CNT vs. RTCC_CCx_CCV	RTCC_TIME vs. RTCC_CCx_TIME and RTCC_DATE vs. RTCC_CCx_DATE
RTCC_CCx_CTRL_COMPBASE = PRECNT	{RTCC_CNT[16:0],RTCC_PRECNT[14:0]} vs. RTCC_CCx_CCV	RTCC_PRECNT vs. RTCC_CCx_CCV[14:0]

Figure 13.5 RTCC Compare in calendar mode, COMPBASE = CNT on page 333 illustrates how the compare events are evaluated when in calendar mode with RTCC\_CCx\_CTRL\_COMPBASE = CNT. The SECU, SECT, MINU, MINT, HOURU, HOURT, MONTHU, and MONTHT bitfields in RTCC\_CCx\_TIME and RTCC\_CCx\_DATE are compared to the corresponding bitfields in RTCC\_DATE and RTCC\_TIME. The DAYU and DAYT bitfields in RTCC\_CCx\_DATE will be compared to {RTCC\_DATE\_DAYOMT, RTCC\_DATE\_DAYOMU} if DAYCC in RTCC\_CCx\_CTRL is set to MONTH. If DAYCC in RTCC\_CCx\_CTRL is set to WEEK, the DAYU and DAYT bitfields in RTCC\_CCx\_DATE will be compared to {0b000, RTCC\_DATE\_DAYOW}.

**Figure 13.5. RTCC Compare in calendar mode, COMPBASE = CNT**

To generate periodically recurring events, is possible to mask out parts of the compare match values. By configuring COMPMASK in RTCC\_CCx\_CTRL, parts of the compare values will be masked out, limiting which part of the compare register being subject to comparison with the counter. [Figure 13.6 RTCC Compare mask illustration, COMPMASK=11 on page 333](#) illustrates the effect of COMPMASK when in normal mode and calendar mode.

**Figure 13.6. RTCC Compare mask illustration, COMPMASK=11**

Upon a compare match, the respective Capture/Compare interrupt flag CCx is set. Additionally, the event selected by the CMOA setting is generated on the corresponding PRS output. This is illustrated in [Figure 13.3 RTCC Compare match and PRS output illustration on page 331](#).

### 13.3.3 Interrupts and PRS Output

The RTCC has one interrupt for each of its 3 Capture/Compare channels, CC0, CC1, and CC2. Each Capture/Compare channel has a PRS output with configurable actions upon compare match.

The interrupt flag CNTTICK is set each time the main counter receives a tick (each second in calendar mode). In calendar mode, there are also interrupt flags being set each minute, hour, day, week, and month.

Upon oscillator failure detection, the OSCFAIL flag will be set.

### 13.3.3.1 Main Counter Tick PRS Output

To output the ticks for the main counter on PRS, it is possible to use a Capture/Compare channel and mask all the bits, i.e. `RTCC_CCx_CTRL_COMPBASE=CNT` and `RTCC_CCx_CTRL_COMPMASK=31`. PRS output of main counter ticks does not work if the main counter is not prescaled.

**Note:**

To be able to mask all bits in the main counter, `RTCC_CTRL_CNTMODE` has to be set to `CALENDAR`. In `NORMAL` mode, the least significant bit can not be masked out.

### 13.3.4 Energy Mode Availability

The RTCC is available in all Energy Modes except EM4S. To enable RTCC operation in EM4H, the `EMU_EM4CTRL` register in the EMU has to be configured. Any enabled RTCC interrupt will wake the system up from EM4H; if EM4WU if `RTCC_EM4WUEN` is set. Refer to [11. EMU - Energy Management Unit](#) for details on how to configure the EMU.

### 13.3.5 Register Lock

To prevent accidental writes to the RTCC registers, the `RTCC_LOCKKEY` register can be written to any other value than the unlock value. To unlock the register, write the unlock value to `RTCC_LOCKKEY`. Registers affected by this lock are:

- `RTCC_CTRL`
- `RTCC_PRECNT`
- `RTCC_CNT`
- `RTCC_TIME`
- `RTCC_DATE`
- `RTCC_IEN`
- `RTCC_POWERDOWN`
- `RTCC_CCx_CTRL`
- `RTCC_CCx_CCV`
- `RTCC_CCx_TIME`
- `RTCC_CCx_DATE`

### 13.3.6 Oscillator Failure Detection

To be able to detect OSC failure, the RTCC includes a security mechanism ensuring that at least three OSC cycles are detected within one period of the `ULFRCO`. If no OSC cycles are detected, the `OSCFail` interrupt flag is set. OSC failure detection is enabled by setting the `OSCFDETEN` bit in `RTCC_CTRL`.

### 13.3.7 Retention Registers

The RTCC includes 32 x 32 bit registers which can be retained in all energy modes except EM4S. The registers are accessible through the `RETx_REG` registers. Retention is by default enabled in EM0 Active through EM4 Hibernate/Shutoff. The registers can be shut off to save power by setting the `RAM` bit in `RTCC_POWERDOWN`.

**Note:**

The retention registers are mapped to a RAM instance and have undefined state out of reset.

### 13.3.8 Frame Controller Interface

For easy timestamping of frames, `RTCC_CC2_CCV` is directly available for the Frame Controller, `FRC`.

### 13.3.9 Debug Session

By default, the RTCC is halted when code execution is halted from the debugger. By setting the `DEBUGRUN` bit in the `RTCC_CTRL` register, the RTCC will continue to run even when the debugger has halted the system.

### 13.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	RTCC_CTRL	RW	Control Register
0x004	RTCC_PRECNT	RWH	Pre-Counter Value Register
0x008	RTCC_CNT	RWH	Counter Value Register
0x00C	RTCC_COMBCNT	R	Combined Pre-Counter and Counter Value Register
0x010	RTCC_TIME	RWH	Time of day register
0x014	RTCC_DATE	RWH	Date register
0x018	RTCC_IF	R	RTCC Interrupt Flags
0x01C	RTCC_IFS	W1	Interrupt Flag Set Register
0x020	RTCC_IFC	(R)W1	Interrupt Flag Clear Register
0x024	RTCC_IEN	RW	Interrupt Enable Register
0x028	RTCC_STATUS	R	Status register
0x02C	RTCC_CMD	W1	Command Register
0x030	RTCC_SYNCBUSY	R	Synchronization Busy Register
0x034	RTCC_POWERDOWN	RW	Retention RAM power-down register
0x038	RTCC_LOCK	RWH	Configuration Lock Register
0x03C	RTCC_EM4WUEN	RW	Wake Up Enable
0x040	RTCC_CC0_CTRL	RW	CC Channel Control Register
0x044	RTCC_CC0_CCV	RWH	Capture/Compare Value Register
0x048	RTCC_CC0_TIME	RWH	Capture/Compare Time Register
0x04C	RTCC_CC0_DATE	RWH	Capture/Compare Date Register
0x050	RTCC_CC1_CTRL	RW	CC Channel Control Register
0x054	RTCC_CC1_CCV	RWH	Capture/Compare Value Register
0x058	RTCC_CC1_TIME	RWH	Capture/Compare Time Register
0x05C	RTCC_CC1_DATE	RWH	Capture/Compare Date Register
0x060	RTCC_CC2_CTRL	RW	CC Channel Control Register
0x064	RTCC_CC2_CCV	RWH	Capture/Compare Value Register
0x068	RTCC_CC2_TIME	RWH	Capture/Compare Time Register
0x06C	RTCC_CC2_DATE	RWH	Capture/Compare Date Register
0x104	RTCC_RET0_REG	RW	Retention register
...	RTCC_RET <sub>x</sub> _REG	RW	Retention register
0x180	RTCC_RET31_REG	RW	Retention register

### 13.5 Register Description

### 13.5.1 RTCC\_CTRL - Control Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

For more information about Registers, please see <a href="#">4.6.7 Access to Low Energy Coprocessor (Asynchronous Registers)</a> .																																					
Offset	Bit Position																																				
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13		DIV8192	CLK <sub>CNT</sub> = LFECLK <sub>RTCC</sub> /8192	

Bit	Name	Reset	Access	Description
	14	DIV16384		$CLK_{CNT} = LFECLK_{RTCC}/16384$
	15	DIV32768		$CLK_{CNT} = LFECLK_{RTCC}/32768$
7:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5	CCV1TOP	0	RW	<b>CCV1 top value enable</b> When set, the counter wraps around on a CC1 event.
4	PRECCV0TOP	0	RW	<b>Pre-counter CCV0 top value enable.</b> When set, the pre-counter wraps around when PRECNT equals RTCC_CC0_CCV[14:0].
3	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
2	DEBUGRUN	0	RW	<b>Debug Mode Run Enable</b> Set this bit to keep the RTCC running during a debug halt.
	Value	Description		
	0	RTCC is frozen in debug mode		
	1	RTCC is running in debug mode		
1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	ENABLE	0	RW	<b>RTCC Enable</b> Enable the RTCC.

### 13.5.2 RTCC\_PRECNT - Pre-Counter Value Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

Offset	Bit Position																															
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x0000															
Access																	RWH															
Name																	PRECNT															

Bit	Name	Reset	Access	Description
31:15	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
14:0	PRECNT	0x0000	RWH	<b>Pre-Counter Value</b> Gives access to the Pre-counter value of the RTCC.

### 13.5.3 RTCC\_CNT - Counter Value Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

Offset	Bit Position																															
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00000000															
Access																	RWH															
Name																	CNT															

Bit	Name	Reset	Access	Description
31:0	CNT	0x00000000	RWH	<b>Counter Value</b>
				Gives access to the main counter value of the RTCC. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = CALENDAR.

### 13.5.4 RTCC\_COMBCNT - Combined Pre-Counter and Counter Value Register

Offset	Bit Position																															
0x00C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x00000																0x00000															
Access	R																R															
Name	CNTLSB																PRECNT															

Bit	Name	Reset	Access	Description
31:15	CNTLSB	0x00000	R	<b>Counter Value</b>
				Gives access to the 17 LSBs of the main counter, CNT. Register will be read as zero when RTCC_CTRL_CNTMODE = CALENDAR.
14:0	PRECNT	0x0000	R	<b>Pre-Counter Value</b>
				Gives access to the pre-counter, PRECNT. Register will be read as zero when RTCC_CTRL_CNTMODE = CALENDAR.

### 13.5.5 RTCC\_TIME - Time of day register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

Offset	Bit Position																																					
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset											0x0	0x0						0x0					0x0						0x0									
Access											RWH	RWH						RWH					RWH						RWH									
Name											HOURT	HOURU						MINT					MINU						SECT					SECU				

Bit	Name	Reset	Access	Description
31:22	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
21:20	HOURT	0x0	RWH	<b>Hours, tens.</b>  Shows the tens part of the hour counter. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = NORMAL.
19:16	HOURU	0x0	RWH	<b>Hours, units.</b>  Shows the unit part of the hour counter. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = NORMAL.
15	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
14:12	MINT	0x0	RWH	<b>Minutes, tens.</b>  Shows the tens part of the minute counter. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = NORMAL.
11:8	MINU	0x0	RWH	<b>Minutes, units.</b>  Shows the unit part of the minute counter. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = NORMAL.
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:4	SECT	0x0	RWH	<b>Seconds, tens.</b>  Shows the tens part of the second counter. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = NORMAL.
3:0	SECU	0x0	RWH	<b>Seconds, units.</b>  Shows the unit part of the second counter. Register can not be written and will be read as zero when RTCC_CTRL_CNTMODE = NORMAL.

### 13.5.6 RTCC\_DATE - Date register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

Offset	Bit Position																																
0x014	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 14. WDOG - Watchdog Timer

### Quick Facts

#### What?

The WDOG (Watchdog Timer) resets the system in case of a fault condition, and can be enabled in all energy modes as long as the low frequency clock source is available.

#### Why?

If a software failure or external event renders the MCU unresponsive, a Watchdog timeout will reset the system to a known, safe state.

#### How?

An enabled Watchdog Timer implements a configurable timeout period. If the CPU fails to re-start the Watchdog Timer before it times out, a full system reset will be triggered. The Watchdog consumes insignificant power, and allows the device to remain safely in low energy modes for up to 256 seconds at a time.

### 14.1 Introduction

The purpose of the watchdog timer is to generate a reset in case of a system failure to increase application reliability. The failure can be caused by a variety of events, such as an ESD pulse or a software failure.

### 14.2 Features

- Clock input from selectable oscillators
  - Internal 32 kHz RC oscillator
  - Internal 1 kHz RC oscillator
  - External 32.768 kHz XTAL oscillator
- Configurable timeout period from 9 to 256k watchdog clock cycles
- Individual selection to keep running or freeze when entering EM2 DeepSleep or EM3 Stop
- Selection to keep running or freeze when entering debug mode
- Selection to block the CPU from entering Energy Mode 4
- Selection to block the CMU from disabling the selected watchdog clock
- Configurable warning interrupt at 25%, 50%, or 75% of the timeout period
- Configurable window interrupt at 12.5%, 25%, 37.5%, 50%, 62.5%, 75%, 87.5% of the timeout period
- Timeout interrupt
- PRS as a watchdog clear
- Interrupt for the event where a PRS rising edge is absent before a software reset

### 14.3 Functional Description

The watchdog is enabled by setting the EN bit in WDOGN\_CTRL. When enabled, the watchdog counts up to the period value configured through the PERSEL field in WDOGN\_CTRL. If the watchdog timer is not cleared to 0 (by writing a 1 to the CLEAR bit in WDOGN\_CMD) before the period is reached, the chip is reset. If a timely clear command is issued, the timer starts counting up from 0 again. The watchdog can optionally be locked by writing the LOCK bit in WDOGN\_CTRL. Once locked, it cannot be disabled or reconfigured by software.

When the EN bit in WDOGN\_CTRL is cleared to 0, the watchdog counter is reset.

### 14.3.1 Clock Source

Three clock sources are available for use with the watchdog, through the CLKSEL field in WDOGN\_CTRL. The corresponding clocks must be enabled in the CMU. The SWOSCBLOCK bit in WDOGN\_CTRL can be written to prevent accidental disabling of the selected clocks. Also, setting this bit will automatically start the selected oscillator source when the watchdog is enabled. The PERSEL field in WDOGN\_CTRL is used to divide the selected watchdog clock, and the timeout for the watchdog timer can be calculated with the formula:

$$T_{\text{TIMEOUT}} = (2^{3+\text{PERSEL}} + 1) / f$$

where  $f$  is the frequency of the selected clock.

When the watchdog is enabled, it is recommended to clear the watchdog before changing PERSEL.

To use this module, the LE interface clock must be enabled in CMU\_HFCORECLKEN0, in addition to the module clock.

### 14.3.2 Debug Functionality

The watchdog timer can either keep running or be frozen when the device is halted by a debugger. This configuration is done through the DEBUGRUN bit in WDOGN\_CTRL. When code execution is resumed, the watchdog will continue counting where it left off.

### 14.3.3 Energy Mode Handling

The watchdog timer can be configured to either keep on running or freeze when entering EM2 DeepSleep or EM3 Stop. The configuration is done individually for each energy mode in the EM2RUN and EM3RUN bits in WDOGN\_CTRL. When the watchdog has been frozen and is re-entering an energy mode where it is running, the watchdog timer will continue counting where it left off. For the watchdog there is no difference between EM0 Active and EM1 Sleep. The watchdog does not run in EM4 Hibernate/Shutoff. If EM4BLOCK in WDOGN\_CTRL is set, the CPU will be prevented from entering EM4 Hibernate/Shutoff by software request.

#### Note:

If the WDOG is clocked by the LFXO or LFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM3 Stop. When running from the ULFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM4 Hibernate/Shutoff.

### 14.3.4 Register access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#) for a description on how to perform register accesses to Low Energy Peripherals. Note that clearing the EN bit in WDOGN\_CTRL will reset the WDOG module, which will halt any ongoing register synchronization.

#### Note:

Never write to the WDOG registers when it is disabled, except to enable the watchdog by setting the EN bitfield in WDOGN\_CTRL.

### 14.3.5 Warning Interrupt

The watchdog implements a warning interrupt which can be configured to occur at approximately 25%, 50%, or 75% of the timeout period through the WARNSEL field of the WDOGN\_CTRL register. This interrupt can be used to wake up the CPU for clearing the watchdog. The warning point for the watchdog timer can be calculated with the formula:

$$T_{\text{WARNING}} = (2^{3+\text{PERSEL}}) * (\text{WARNSEL} / 4 + 1) / f,$$

where  $f$  is the frequency of the selected clock.

When the watchdog is enabled, it is recommended to clear the watchdog before changing WARNSEL.

### 14.3.6 Window Interrupt

This interrupt occurs when the watchdog is cleared below a certain threshold. This threshold is given by the formula:

$$T_{\text{WARNING}} = (2^{3+\text{PERSEL}}) * (\text{WINSEL}/8) + 1)/f,$$

where  $f$  is the frequency of the selected clock.

This value will be approximately 12.5%, 25%, 37.5%, 50%, 62.5%, 75%, or 87.5% of the timeout value based on the WINSEL field of the WDOGN\_CTRL. [Figure 14.2 WDOG Warning, Window, and Timeout on page 357](#) illustrates the warning, the window, and the time-out interrupts. Also, it shows where the prs rising edge needs to happen. The prs edge detection feature is discussed later.

**Figure 14.2. WDOG Warning, Window, and Timeout**

When the watchdog is enabled, it is recommended to clear the watchdog before changing WINSEL.

### 14.3.7 PRS as Watchdog Clear

The first PRS channel (selected by register `WDOGn_PCH0_PRSCTRL`) can be used to clear the watchdog counter. To enable this feature, `CLRSRC` must be set to 1. [Figure 14.2 PRS Clearing WDOG on page 358](#) shows how the PRS channel takes over the wdog clear function. Clearing the WDOG with the PRS is mutually exclusive of clearing the WDT by software.

Figure 14.2. PRS Clearing WDOG

### 14.3.8 PRS Rising Edge Monitoring

PRS channels can be used to monitor multiple processes. If enabled, every time the watch dog timer is cleared the PRS channels are checked and any channel which has not seen an event can trigger an interrupt.

Figure 14.3. PRS Edge Monitoring in WDOG

## 14.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	WDOG_CTRL	RW	Control Register
0x004	WDOG_CMD	W1	Command Register
0x008	WDOG_SYNCBUSY	R	Synchronization Busy Register
0x00C	WDOGn_PCH0_PRSCTRL	RW	PRS Control Register
0x010	WDOGn_PCH1_PRSCTRL	RW	PRS Control Register
0x01C	WDOG_IF	R	Watchdog Interrupt Flags

0	TOUT	0	RW	<b>TOUT Interrupt Enable</b> Enable/disable the TOUT interrupt

## 15. PRS - Peripheral Reflex System

### Quick Facts

#### What?

The PRS (Peripheral Reflex System) allows configurable, fast, and autonomous communication between peripherals.

#### Why?

Events and signals from one peripheral can be used as input signals or triggers by other peripherals. Besides reducing software overhead and thus current consumption, this reduces latency and ensures predictable timing.

#### How?

Without CPU intervention the peripherals can send Reflex signals (both pulses and level) to each other in single- or chained steps. The peripherals can be set up to perform actions based on the incoming Reflex signals. This results in improved system performance and reduced energy consumption.

### 15.1 Introduction

The Peripheral Reflex System (PRS) is a network allowing direct communication between different peripheral modules without involving the CPU. Peripheral modules which send out Reflex signals are called producers. The PRS routes these reflex signals through reflex channels to consumer peripherals which perform actions depending on the Reflex signals received. The format for the Reflex signals is not given, but edge triggers and other functionality can be applied by the PRS.

### 15.2 Features

- 12 Configurable Reflex Channels
  - Each channel can be connected to any producing peripheral, including the PRS channels
  - Consumers can choose which channel to listen to
  - Selectable edge detector (Rising, falling and both edges)
  - Configurable AND and OR between channels
  - Optional channel invert
  - PRS can generate event to CPU
  - Two independent DMA requests based on PRS channels
- Software controlled channel output
  - Configurable level
  - Triggered pulses

## 15.3 Functional Description

An overview of the PRS module is shown in [Figure 15.1 PRS Overview on page 371](#). The PRS contains 12 Reflex channels. All channels can select any Reflex signal offered by the producers. The consumers can choose which PRS channel to listen to and perform actions based on the Reflex signals routed through that channel. The Reflex signals can be both edge signals and level signals.

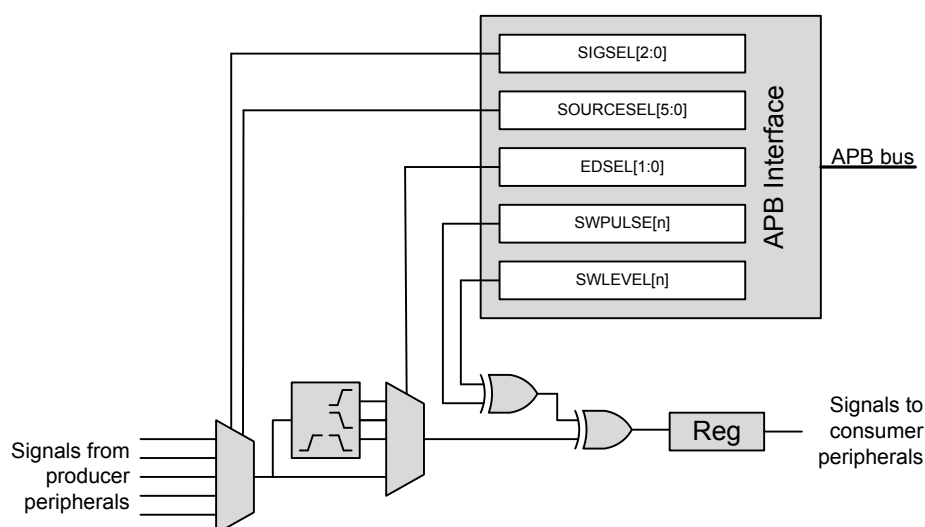

Figure 15.1. PRS Overview

### 15.3.1 Channel Functions

Different functions can be applied to a reflex signal within the PRS. Each channel includes an edge detector to enable generation of pulse signals from level signals. The PRS channels can also be manually triggered by writing to PRS\_SWPULSE or PRS\_SWLEVEL. SWLEVEL[n] is a programmable level for each channel and holds the value it is programmed to. Setting SWPULSE[n] will cause the PRS channel to output a high pulse that is one HFBUSCLK cycle wide. The SWLEVEL[n] and SWPULSE[n] signals are then XOR'ed with the selected input from the producers to form the output signal sent to the consumers listening to the channel. For example, when SWLEVEL[n] is set, if a producer produces a signal of 1, this will cause a channel output of 0.

#### 15.3.1.1 Asynchronous Mode

Reflex channels can operate in two modes, synchronous or asynchronous. In synchronous mode reflex signals are clocked on the HFCLK, and can be used by any reflex consumer. However, this will not work in EM2/EM3, since the HFCLK will be turned off.

Asynchronous reflex channels are not clocked on HFCLK, and can be used even in EM2/EM3. However, the asynchronous mode can only be used by a subset of the reflex consumers.

The asynchronous reflex signals generated by the producers are indicated in the SIGSEL field in PRS\_CHx\_CTRL. The consumers capable of utilizing asynchronous reflex signals include the LEUART and the PCNT. The USART can also consume some particular asynchronous signals. Please refer to the respective modules for details on how to configure them to use the PRS.

**Note:** If a Reflex channel with ASYNC set is used in a consumer not supporting asynchronous reflexes, the behaviour is undefined

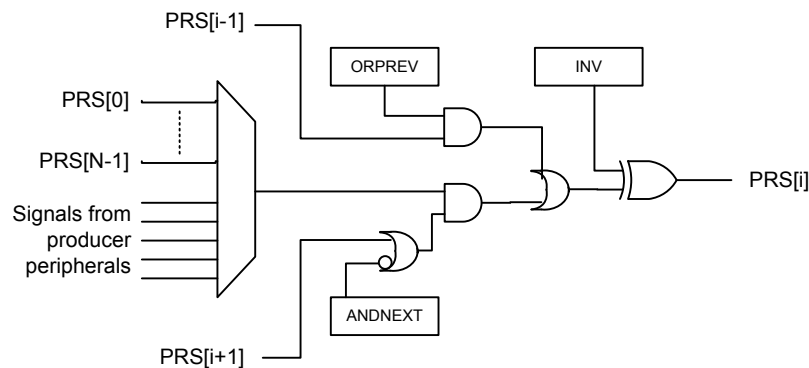

### 15.3.1.2 Edge Detection and Clock Domains

Using EDSEL in PRS\_CHx\_CTRL, edge detection can be applied to a PRS signal. When edge detection is enabled, changes in the PRS input will result in a pulse on the PRS channel. This requires that the ASYNC bit in PRS\_CHx\_CTRL is cleared. Signals on the PRS input must be at least one HFBUSCLK period wide in order to be detected properly. This applies to all cases when ASYNC is not used in the PRS.

For communication between peripherals on different prescaled clocks (e.g. between peripherals on HFBUSCLK and HFPERCLK), there are two options. For level signals, no action is needed, but software must make sure that the level signals are held long enough for the destination domain to detect them. For pulse signals, edge detection should be enabled (by configuring EDSEL in PRS\_CHx\_CTRL to positive edge, negative edge, or both) and STRETCH in PRS\_CHx\_CTRL should be set. When edge detection and stretch are enabled on a PRS source, the output on the PRS channel is held long enough for the destination domain to detect the pulse. This also works if there are multiple destination domains running at different frequencies.

### 15.3.1.3 Configurable PRS Logic

Each PRS channel has three logic functions that can be used by themselves or in combination. The selected PRS source can be AND'ed with the next PRS channel output, OR'ed with the previous PRS channel output and inverted. This is shown in [Figure 15.1 PRS Overview on page 371](#). The order of the functions is important. If OR and AND are enabled at the same time, AND is applied first, and then OR.

**Figure 15.2. Configurable PRS Logic**

In addition to the logic functions that can combine a PRS channel with one of its neighbors, a PRS channel can also select any other PRS channel as input. This can allow relatively complex logic functions to be created.

### 15.3.2 Producers

Through SOURCESEL in PRS\_CHx\_CTRL, each PRS channel selects signal producers. Each producer outputs one or more signals which can be selected by setting the SIGSEL field in PRS\_CHx\_CTRL. Setting the SOURCESEL bits to 0 (Off) leads to a constant 0 output from the input mux. An overview of the available producers can be found in the SOURCESEL and SIGSEL fields in PRS\_CHx\_CTRL.

### 15.3.3 Consumers

Consumer peripherals (Listed in [Table 15.1 Reflex Consumers on page 373](#)) can be set to listen to a PRS channel and perform an action based on the signal received on that channel. While most consumers expect a pulse input, some can handle level inputs as well.

**Table 15.1. Reflex Consumers**

Module	Reflex Input	Input Format
TIMER	Compare/Capture Channel	Pulse / Level
	Alternate Input for DTI	Level
	Alternate Input for DTI Fault 0	Level
	Alternate Input for DTI Fault 1	Level
USART	RX/TX Trigger	Pulse
	Alternate Input for IrDA	Level
	Alternate Input for RX	Level
	Alternate Input for CLK	Level
ADC	Single Sample Trigger	Pulse
	Scan Sequence Trigger	Pulse
IDAC	Alternate Input for OUTMODE	Level
CMU	Alternate Input for Calibration Up-Counter	Level
	Alternate Input for Calibration Down-Counter	Level
LEUART	Alternate Input for RX	Level
PCNT	Compare/Clear Trigger	Pulse/Level
	Alternate Input for S0IN	Level
	Alternate Input for S1IN	Level
WDOG	Peripheral Watchdog	Pulse
LETIMER	Start LETIMER	Pulse
	Stop LETIMER	Pulse
	Clear LETIMER	Pulse
RTCC	Compare/Capture Channel	Pulse/Level
PRS	Set Event	Pulse
	DMA Request 0	Pulse
	DMA Request 1	Pulse

### 15.3.4 Event on PRS

The PRS can be used to send events to the MCU. This is very useful in combination with the Wait For Event (WFE) instruction. A single PRS channel can be selected for this using SEVONPRSEL in PRS\_CTRL, and the feature is enabled by setting SEVONPRS in the same register.

Using SEVONPRS, one can e.g. set up a timer to trigger an event to the MCU periodically, every time letting the MCU pass through a WFE instruction in its program. This can help in performance-critical sections where timing is known, and the goal is to wait for an event, then execute some code, then wait for an event, then execute some code and so on.

### 15.3.5 DMA Request on PRS

Up to two independent DMA requests can be generated by the PRS. The PRS signals triggering the DMA requests are selected with the DMAREQxSEL fields in DMA\_CTRL. The DMA requests are cleared on write to the DMAREQxSEL fields and when the DMA services the requests. The requests are set whenever the selected PRS signals are high.

The selected PRS signals must have ASYNC cleared when they are used as inputs to the DMA. Edge detection in the PRS can be enabled to only trigger transfers on edges.

### 15.3.6 Example

The example below (illustrated in [Figure 15.3 TIMER0 overflow starting ADC0 single conversions through PRS channel 5. on page 374](#)) shows how to set up ADC0 to start single conversions every time TIMER0 overflows (one HFPERCLK cycle high pulse), using PRS channel 5:

- Set SOURCESEL in PRS\_CH5\_CTRL to TIMER0 as input to PRS channel 5.
- Set SIGSEL in PRS\_CH5\_CTRL to select the overflow signal (from TIMER0).
- Configure ADC0 with the desired conversion set-up.
- Set SINGLEPRSEN in ADC0\_SINGLECTRL to 1 to enable single conversions to be started by a high PRS input signal.
- Set SINGLEPRSSEL in ADC0\_SINGLECTRL to 0x5 to select PRS channel 5 as input to start the single conversion.
- Start TIMER0 with the desired TOP value, an overflow PRS signal is output automatically on overflow.

Note that the ADC results needs to be fetched either by the CPU or DMA.

**Figure 15.3. TIMER0 overflow starting ADC0 single conversions through PRS channel 5.**

## 15.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	PRS_SWPULSE	W1	Software Pulse Register

## 15.5 Register Description

### 15.5.1 PRS\_SWPULSE - Software Pulse Register

Offset	Bit Position																																																
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																	
Reset																					0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
Access																					W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1
Name																					CH11PULSE	CH10PULSE	CH9PULSE	CH8PULSE	CH7PULSE	CH6PULSE	CH5PULSE	CH4PULSE	CH3PULSE	CH2PULSE	CH1PULSE	CH0PULSE																	

Bit	Name	Reset	Access	Description
31:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11	CH11PULSE	0	W1	<b>Channel 11 Pulse Generation</b> See bit 0.
10	CH10PULSE	0	W1	<b>Channel 10 Pulse Generation</b> See bit 0.
9	CH9PULSE	0	W1	<b>Channel 9 Pulse Generation</b> See bit 0.
8	CH8PULSE	0	W1	<b>Channel 8 Pulse Generation</b> See bit 0.
7	CH7PULSE	0	W1	<b>Channel 7 Pulse Generation</b> See bit 0.
6	CH6PULSE	0	W1	<b>Channel 6 Pulse Generation</b> See bit 0.
5	CH5PULSE	0	W1	<b>Channel 5 Pulse Generation</b> See bit 0.
4	CH4PULSE	0	W1	<b>Channel 4 Pulse Generation</b> See bit 0.
3	CH3PULSE	0	W1	<b>Channel 3 Pulse Generation</b> See bit 0.
2	CH2PULSE	0	W1	<b>Channel 2 Pulse Generation</b> See bit 0.
1	CH1PULSE	0	W1	<b>Channel 1 Pulse Generation</b> See bit 0.
0	CH0PULSE	0	W1	<b>Channel 0 Pulse Generation</b>  Write to 1 to generate one HFPERCLK cycle high pulse. This pulse is XOR'ed with the corresponding bit in the SWLEVEL register and the selected PRS input signal to generate the channel output.

## 15.5.2 PRS\_SWLEVEL - Software Level Register

Offset	Bit Position																																															
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12																												
Reset																					RW	0	RW	0	RW	0	RW	0	RW	0	RW	0	RW	0	RW	0												
Access																																																
Name																					CH11LEVEL		CH10LEVEL		CH9LEVEL		CH8LEVEL		CH7LEVEL		CH6LEVEL		CH5LEVEL		CH4LEVEL		CH3LEVEL		CH2LEVEL		CH1LEVEL		CH0LEVEL					

Bit	Name	Reset	Access	Description
31:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11	CH11LEVEL See bit 0.	0	RW	Channel 11 Software Level
10	CH10LEVEL See bit 0.	0	RW	Channel 10 Software Level
9	CH9LEVEL See bit 0.	0	RW	Channel 9 Software Level
8	CH8LEVEL See bit 0.	0	RW	Channel 8 Software Level
7	CH7LEVEL See bit 0.	0	RW	Channel 7 Software Level
6	CH6LEVEL See bit 0.	0	RW	Channel 6 Software Level
5	CH5LEVEL See bit 0.	0	RW	Channel 5 Software Level
4	CH4LEVEL See bit 0.	0	RW	Channel 4 Software Level
3	CH3LEVEL See bit 0.	0	RW	Channel 3 Software Level
2	CH2LEVEL See bit 0.	0	RW	Channel 2 Software Level
1	CH1LEVEL See bit 0.	0	RW	Channel 1 Software Level
0	CH0LEVEL The value in this register is XOR'ed with the corresponding bit in the SWPULSE register and the selected PRS input signal to generate the channel output.	0	RW	Channel 0 Software Level

## 15.5.3 PRS\_ROUTE PEN - I/O Routing Pin Enable Register

Offset	Bit Position																																																
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																	
Reset																					0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
Access																					RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW
Name																					CH11PEN	CH10PEN	CH9PEN	CH8PEN	CH7PEN	CH6PEN	CH5PEN	CH4PEN	CH3PEN	CH2PEN	CH1PEN	CH0PEN																	

Bit	Name	Reset	Access	Description
31:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11	CH11PEN	0	RW	<b>CH11 Pin Enable</b> When set, GPIO output from PRS channel 11 is enabled
10	CH10PEN	0	RW	<b>CH10 Pin Enable</b> When set, GPIO output from PRS channel 10 is enabled
9	CH9PEN	0	RW	<b>CH9 Pin Enable</b> When set, GPIO output from PRS channel 9 is enabled
8	CH8PEN	0	RW	<b>CH8 Pin Enable</b> When set, GPIO output from PRS channel 8 is enabled
7	CH7PEN	0	RW	<b>CH7 Pin Enable</b> When set, GPIO output from PRS channel 7 is enabled
6	CH6PEN	0	RW	<b>CH6 Pin Enable</b> When set, GPIO output from PRS channel 6 is enabled
5	CH5PEN	0	RW	<b>CH5 Pin Enable</b> When set, GPIO output from PRS channel 5 is enabled
4	CH4PEN	0	RW	<b>CH4 Pin Enable</b> When set, GPIO output from PRS channel 4 is enabled
3	CH3PEN	0	RW	<b>CH3 Pin Enable</b> When set, GPIO output from PRS channel 3 is enabled
2	CH2PEN	0	RW	<b>CH2 Pin Enable</b> When set, GPIO output from PRS channel 2 is enabled
1	CH1PEN	0	RW	<b>CH1 Pin Enable</b> When set, GPIO output from PRS channel 1 is enabled
0	CH0PEN	0	RW	<b>CH0 Pin Enable</b> When set, GPIO output from PRS channel 0 is enabled

15.5.4 PRS\_ROUTELOC0 - I/O Routing Location Register

Offset	Bit Position																															
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 16. PCNT - Pulse Counter

### Quick Facts

#### What?

The Pulse Counter (PCNT) decodes incoming pulses. The module has a quadrature mode which may be used to decode the speed and direction of a mechanical shaft. PCNT can operate in EM0 Active down to EM3 Stop.

#### Why?

The PCNT generates an interrupt after a specific number of pulses (or rotations), eliminating the need for timing- or I/O interrupts and CPU processing to measure pulse widths, etc.

#### How?

PCNT uses the LFACLK or may be externally clocked from a pin. The module incorporates an 16-bit up/down-counter to keep track of incoming pulses or rotations.

### 16.1 Introduction

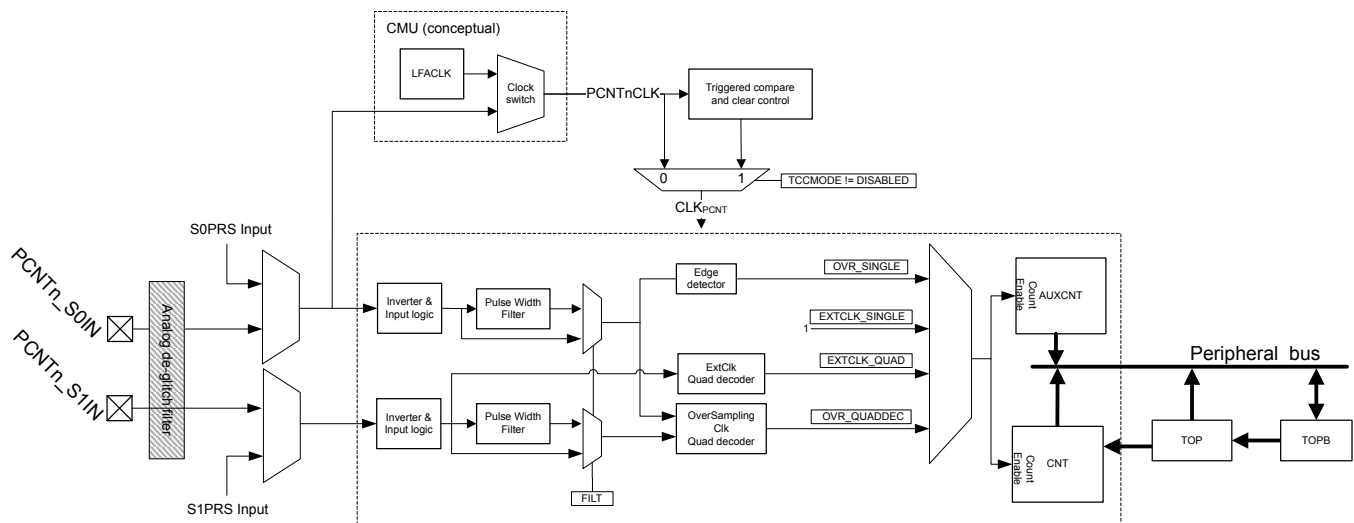

The Pulse Counter (PCNT) can be used for counting incoming pulses on a single input or to decode quadrature encoded inputs in EM0 Active down to EM3 Stop. It can run from the internal LFACLK while counting pulses on the PCNTn\_S0IN pin. Or, alternately, the PCNTn\_S0IN pin may be used as an external clock source that runs both the PCNT counter and register access.

### 16.2 Features

- 16-bit counter with reload register
- Auxiliary counter for counting a single direction
- Single input oversampling up/down counter mode
- Externally clocked single input pulse up/down counter mode
- Quadrature decoder modes
  - Externally clocked quadrature decoder 1X mode
  - Oversampling quadrature decoder 1X, 2X and 4X modes
- Interrupt on counter underflow and overflow
- Interrupt when a direction change is detected (quadrature decoder mode only)
- Optional pulse width filter
- Optional input inversion/edge detect select
- Optional inputs from PRS
- Asynchronously triggered compare and clear

## 16.3 Functional Description

An overview of the PCNT module is shown in [Figure 16.1 PCNT Overview on page 398](#).

**Figure 16.1. PCNT Overview**

### 16.3.1 Pulse Counter Modes

The pulse counter can operate in single input oversampling mode (OVSSINGLE), externally clocked single input counter mode (EXTCLKSINGLE), externally clocked quadrature decoder mode (EXTCLKQUAD) and oversampling quadrature decoder modes (OVSSQUAD1X, OVSSQUAD2X and OVSSQUAD4X). The following sections describe operation of each of these modes and how they are enabled. Input timing constraints are described in [16.3.6 Clock Sources](#) and [16.3.7 Input Filter](#).

#### 16.3.1.1 Single Input Oversampling Mode

This mode is enabled by writing OVSSINGLE to the MODE field in the PCNTn\_CTRL register and disabled by writing DISABLE to the same field. The LFACLK clock source to the pulse counter is configured by clearing PCNT0CLKSEL in the CMU\_PCNTCTRL in the Clock Management Unit (CMU), [12. CMU - Clock Management Unit](#).

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn\_CTRL register. Additionally, the PCNTn\_S0IN input may be inverted, so that falling edges are counted, by setting the EDGE bit in the PCNTn\_CTRL register.

If S1CDIR in the PCNTn\_CTRL register is cleared, PCNTn\_S0IN is the only observed input in this mode. The PCNTn\_S0IN input is sampled by the LFACLK and the number of detected positive or negative edges on PCNTn\_S0IN appears in PCNTn\_CNT. The counter may be configured to count down by setting the CNTDIR bit in PCNTn\_CTRL. Default is to count up.

The counting direction can also be controlled externally in this mode by setting S1CDIR. This will make the input value on PCNTn\_S1IN decide the direction counted on a PCNTn\_S0IN edge. If PCNTn\_S1IN is high, the count is done according to CNTDIR in PCNTn\_CTRL. If low, the count direction is opposite.

#### 16.3.1.2 Externally Clocked Single Input Counter Mode

This mode is enabled by writing EXTCLKSINGLE to the MODE field in the PCNTn\_CTRL register and disabled by writing DISABLE to the same field. The external pin clock source is configured by setting PCNT0CLKSEL in the CMU\_PCNTCTRL register ([12. CMU - Clock Management Unit](#)).

Positive edges on PCNTn\_S0IN are used to clock the counter. Similar to the oversampled mode, PCNTn\_S1IN is used to determine the count direction if S1CDIR is set. If not, CNTDIR in PCNTn\_CTRL solely defines count direction.

The digital pulse width filter is not available in this mode. The analog de-glitch filter in the GPIO pads is capable of removing some unwanted noise. However, this mode may be susceptible to spikes and unintended pulses from devices such as mechanical switches, and is therefore most suited to take input from electronic sensors etc. that generate single wire pulses.

### 16.3.1.3 Quadrature decoder modes

Two different types of quadrature decoding is supported in the pulse counter: the externally clocked (Asynchronous) quadrature decoding and the oversampling (Synchronous) quadrature decoding. The externally clocked mode supports 1X quadrature decoding whereas the oversampling mode supports 1X, 2X and 4X quadrature decoding. These modes are described in detail in [16.3.1.4 Externally Clocked Quadrature Decoder Mode](#) and [16.3.1.5 Oversampling Quadrature Decoder Mode](#).

### 16.3.1.4 Externally Clocked Quadrature Decoder Mode

This mode is enabled by writing EXTCLKQUAD to the MODE field in PCNTn\_CTRL and disabled by writing DISABLE to the same field. The external pin clock source is configured by setting PCNT0CLKSEL in the CMU\_PCNTCTRL register (12. CMU - Clock Management Unit).

In this mode, both edges on PCNTn\_S0IN pin are used to sample PCNTn\_S1IN pin, in order to decode the quadrature code. A quadrature coded signal contains information about the relative speed and direction of a rotating shaft as illustrated by Figure 16.2 PCNT Quadrature Coding on page 400, hence the direction of the counter register PCNTn\_CNT is controlled automatically.

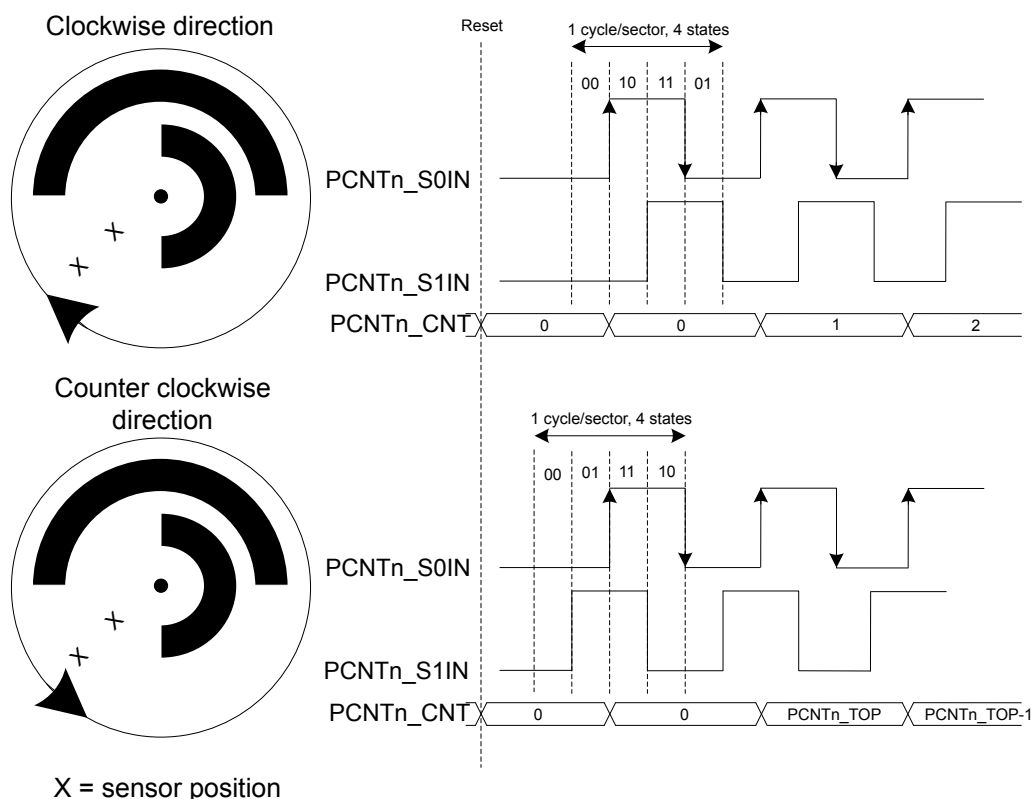

Figure 16.2. PCNT Quadrature Coding

If PCNTn\_S0IN leads PCNTn\_S1IN in phase, the direction is clockwise, and if it lags in phase the direction is counter-clockwise. Default behavior is illustrated by Figure 16.2 PCNT Quadrature Coding on page 400.

The counter direction may be read from the DIR bit in the PCNTn\_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn\_IF register is generated when a direction change is detected. When a change is detected, the DIR bit in the PCNTn\_STATUS register must be read to determine the current new direction.

**Note:**

The sector disc illustrated in the figure may be finer grained in some systems. Typically, they may generate 2-4 PCNTn\_S0IN wave periods per 360° rotation.

The direction of the quadrature code and control of the counter is generated by the simple binary function outlined by Table 16.1 PCNT QUAD Mode Counter Control Function on page 401. Note that this function also filters some invalid inputs that may occur when the shaft changes direction or temporarily toggles direction.

**Table 16.1. PCNT QUAD Mode Counter Control Function**

Inputs		Control/Status	
S1IN posedge	S1IN negedge	Count Enable	CNTDIR status bit
0	0	0	0
0	1	1	0
1	0	1	1
1	1	0	0

**Note:**

PCNTn\_S1IN is sampled on both edges of PCNTn\_S0IN.

### 16.3.1.5 Oversampling Quadrature Decoder Mode

There are three Oversampling Quadrature Decoder Modes supported: 1X, 2X and 4X. These modes are enabled by writing OVSQUAD1X, OVSQUAD2X and OVSQUAD4X, respectively, to the MODE field in PCNTn\_CTRL and disabled by writing DISABLE to the same field. The LFACLK clock source to the pulse counter must be configured by clearing PCNT0CLKSEL in the CMU\_PCNTCTRL in the Clock Management Unit (CMU), [12. CMU - Clock Management Unit](#).

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn\_CTRL register. The filter applies to both inputs PCNTn\_S0IN and PCNTn\_S1IN. The filter length is configured by FILTLEN in PCNTn\_OVSCFG register.

Based on the modes selected, the decoder updates the counter on different events. In the OVSQUAD1X mode, the counter is updated on the rising edge of the PCNTn\_S0IN input when counting up, and on the negedge of the PCNTn\_S0IN input when counting down. In the OVSQUAD2X mode, the counter is updated on both edges of PCNTn\_S0IN input. In the OVSQUAD4X mode the counter is updated on both edges of both inputs PCNTn\_S0IN and PCNTn\_S1IN. [Table 16.2 PCNT OVSQUAD 1X, 2X and 4X Mode Counter Control Function on page 402](#) outlines the increment or decrement of the counter based on the Quadrature Mode selected.

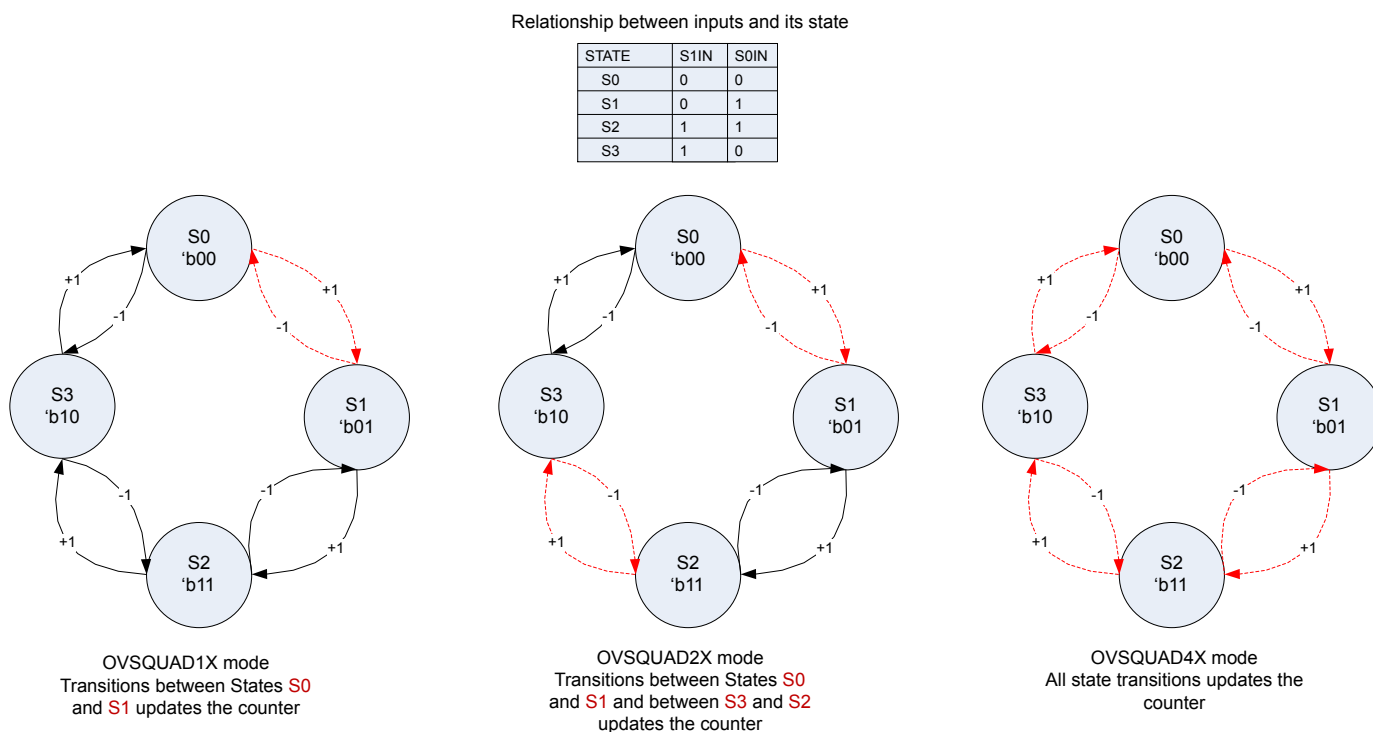

**Note:**

The decoding behavior of OVSQUAD1X mode is slightly different compared to EXTCLKQUAD mode(also 1X mode). In the EXTCLKQUAD mode, the counter is updated only on the posedge of S0IN input. However, in the OVSQUAD1X mode, the counter is updated on the posedge of S0IN when counting up and on the negedge of S0IN when counting down.

**Table 16.2. PCNT OVSQUAD 1X, 2X and 4X Mode Counter Control Function**

Direction	Previous State		Next State		OVSQUAD MODE		
	S1IN	S0IN	S1IN	S0IN	1X	2X	4X
Clockwise	0	0	0	1	+1	+1	+1
	0	1	1	1			+1
	1	1	1	0		+1	+1
	1	0	0	0			+1
Counter Clock-wise	1	0	1	1		-1	-1
	1	1	0	1			-1
	0	1	0	0	-1	-1	-1
	0	0	1	0			-1

[Figure 16.3 PCNT State transitions for different Oversampling Quadrature Decoder Modes on page 403](#) illustrates the different states of the quadrature input and the state transitions that updates the counter for the different modes. Each cycle of the input states results in 1 update, 2 updates and 4 updates of the counter for OVSQUAD1X, OVSQUAD2X and OVSQUAD4X modes respectively.

**Figure 16.3. PCNT State transitions for different Oversampling Quadrature Decoder Modes**

The counter direction can be read from the DIR bit in PCNTn\_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn\_IF is generated when the direction change is detected. When a change is detected, the DIR bit in the PCNTn\_STATUS register must be read to determine the new direction.

In the oversampling quadrature decoder modes, the maximum input toggle frequency supported is 8KHz. For frequencies of 8KHz and higher, incorrect decoding occurs. The different decoding modes and the counter updates are further illustrated by [Figure 16.4 PCNT Oversampling Quadrature Decoder 1X mode on page 403](#), [Figure 16.5 PCNT Oversampling Quadrature Decoder 2X mode on page 404](#) and [Figure 16.6 PCNT Oversampling Quadrature Decoder 4X mode on page 404](#).

**Figure 16.4. PCNT Oversampling Quadrature Decoder 1X mode**

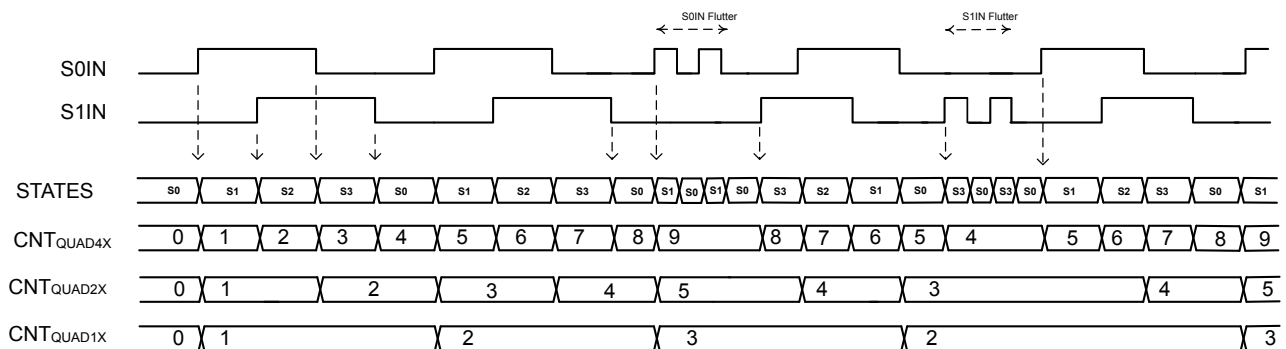

**Figure 16.5. PCNT Oversampling Quadrature Decoder 2X mode**

**Figure 16.6. PCNT Oversampling Quadrature Decoder 4X mode**

The above modes, by default are prone to flutter effects in the inputs PCNTn\_S0IN and PCNTn\_S1IN. When this occurs, the counter changes directions rapidly causing DIRCNG interrupts and unnecessarily waking the core. To prevent this, set FLUTERRM in PCNTn\_OVSCFG register. When enabled, flutter is removed, thus preventing unnecessary wakeup of the core. The flutter removal logic works by preventing update of the counter value if the wheel keeps changing direction as a result of flutter. The counter is only updated if the current and previous state transition of the rotation are in the same direction. These state transitions are quadrature decoder mode specific. The highlighted state transitions in [Figure 16.3 PCNT State transitions for different Oversampling Quadrature Decoder Modes on page 403](#) are the ones considered for the different quadrature decoder modes. [Figure 16.7 PCNT Oversampling Quadrature Decoder with Flutter Removal on page 404](#) shows how the counter is updated for the different quadrature decoder modes with flutter removal FLUTERRM enabled in PCNTn\_OVSCFG.

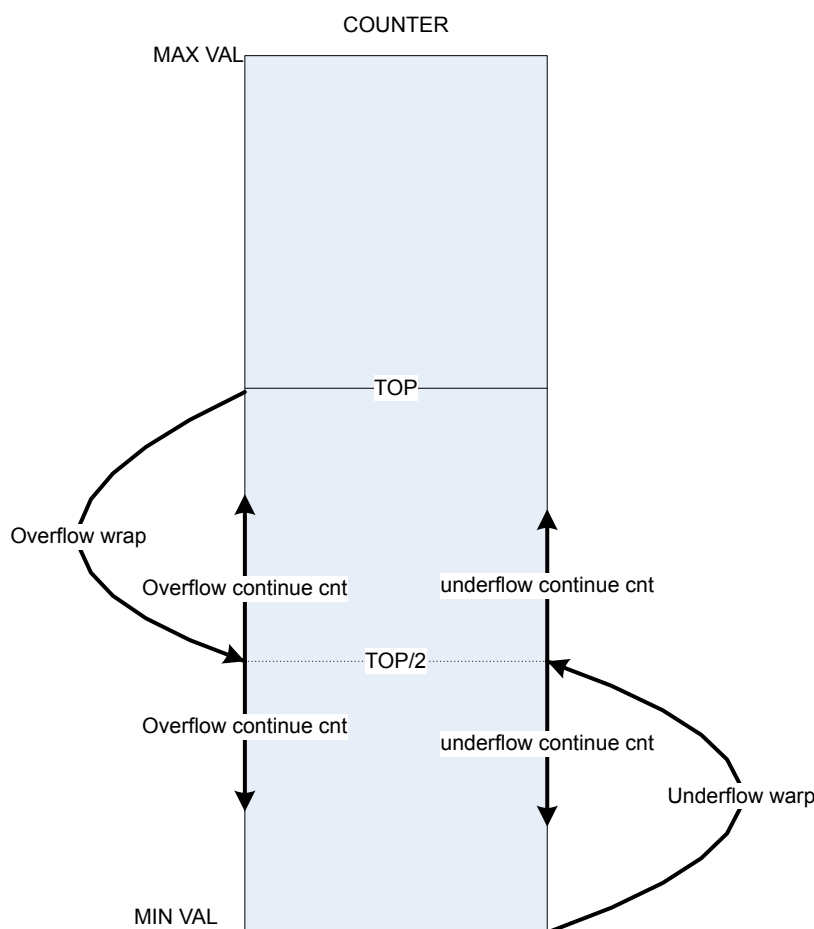

**Figure 16.7. PCNT Oversampling Quadrature Decoder with Flutter Removal**

### 16.3.2 Hysteresis

By default the pulse counter wraps to 0 when passing the configured top value, and wraps to the top value when counting down from 0. On these events, a system will likely want to wake up to store and track the overflow count. This is fine if the pulse counter is tracking a monotonic value or a value that does not change directions frequently. In the latter scenario, if the counter changes directions around the overflow/underflow point, the system will have to wake up frequently to keep track of the rotations, resulting in higher current consumption.

To solve this, the pulse counter has a way of introducing hysteresis to the counter. When HYST in PCNTn\_CTRL is set, the pulse counter will always wrap to TOP/2 on underflows and overflows. This takes the counter away from the area where it might overflow or underflow, removing the problem. [Figure 16.8 PCNT Hysteresis behavior of Counter on page 405](#) illustrates the hysteresis behavior.

**Figure 16.8. PCNT Hysteresis behavior of Counter**

Given a starting value of 0 for the counter, the absolute count value when hysteresis is enabled can be calculated with the equations [Figure 16.9 Absolute position with hysteresis and even TOP value on page 405](#) or [Figure 16.10 Absolute position with hysteresis and odd TOP value on page 405](#), depending on whether the TOP value is even or odd.

$$CNT_{abs} = CNT - UF_{CNT} \times (TOP/2+1) + OF_{CNT} \times (TOP/2+1)$$

**Figure 16.9. Absolute position with hysteresis and even TOP value**

$$CNT_{abs} = CNT - UF_{CNT} \times (TOP/2+1) + OF_{CNT} \times (TOP/2+2)$$

**Figure 16.10. Absolute position with hysteresis and odd TOP value**

### 16.3.3 Auxiliary counter

To be able to keep explicit track of counting in one direction in addition to the regular counter which counts both up and down, the auxiliary counter can be used. The pulse counter can, for instance, be configured to keep track of the absolute rotation of the wheel, while at the same time the auxiliary counter can keep track of how much the wheel has reversed.

The auxiliary counter is enabled by configuring AUXCNTEV in PCNTn\_CTRL. It will always count up, but it can be configured whether it should count up on up-events, down-events or both, keeping track of rotation either way or general movement. The value of the auxiliary counter can be read from the PCNTn\_AUXCNT register.

Overflows on the auxiliary counter happen when the auxiliary counter passes the top value of the pulse counter, configured in PCNTn\_TOP. In that event, the AUXOF interrupt flag is set, and the auxiliary counter wraps to 0.

As the auxiliary counter, the main counter can be configured to count only on certain events. This is done through CNTEV in PCNTn\_CTRL, and it is possible like for the auxiliary counter, to make the main counter count on only up and down events. The difference between the counters is that where the auxiliary counter will only count up, the main counter will count up or down depending on the direction of the count event.

### 16.3.4 Triggered compare and clear

The pulse counter features triggered compare and clear. When enabled, a configurable trigger will induce a comparison between the main counter, PCNTn\_CNT, and the top value, PCNTn\_TOP. After the comparison, the counter is cleared. The trigger for a compare and clear event is configured in the TCCMODE bit-field in PCNTn\_CTRL. There are two options, LFA and PRS. If LFA is selected, the pulse counter will be compared with the top value, and cleared every  $2^N$  LFA clock cycle (where N is the value of TCCPRESC in PCNTn\_CTRL). If a PRS trigger is selected, the active PRS channel is configured in TCCPRSEL in PCNTn\_CTRL. The PRS input can be inverted by setting TCCPRSPOL, triggering the compare and clear on the negative edge of the PRS input. The PRS input can also be used as a gate for the pulse counter clock. This is enabled by setting PRSGATEEN in PCNTn\_CTRL.

#### Note:

When PRSGATEEN is set, the clock to the entire pulse counter will be gated by the PRS input, meaning that register writes will not take effect while the gated clock is inactive.

Comparison with PCNTn\_TOP can be performed in three ways: range, greater than or equal, and less than or equal. TCCCOMP in PCNTn\_CTRL configures comparison mode. Upon a compare match, the TCC interrupt is set, and the PRS output from the pulse counter is set. The PRS output will remain set until the next compare and clear event. Triggered compare and clear is intended for use when the pulse counter is configured to count up. In this mode, PCNTn\_CNT will not wrap to 0 when hitting PCNTn\_TOP, it will keep counting. In addition, the counter will not overflow, it will rather stop counting, just setting the overflow interrupt flag.

Figure 16.11 PCNT Triggered compare and clear on page 407 shows an overview of the control circuitry for triggered compare and clear. The control circuitry includes two positive edge detectors (PED) and glitch filters, used to generate clocks for the pulse counter. The two clock outputs are mutually exclusive: If both edge detectors receive a pulse at the same time, the output pulse from one of them will be postponed until the other edge detectors output pulse has completed.

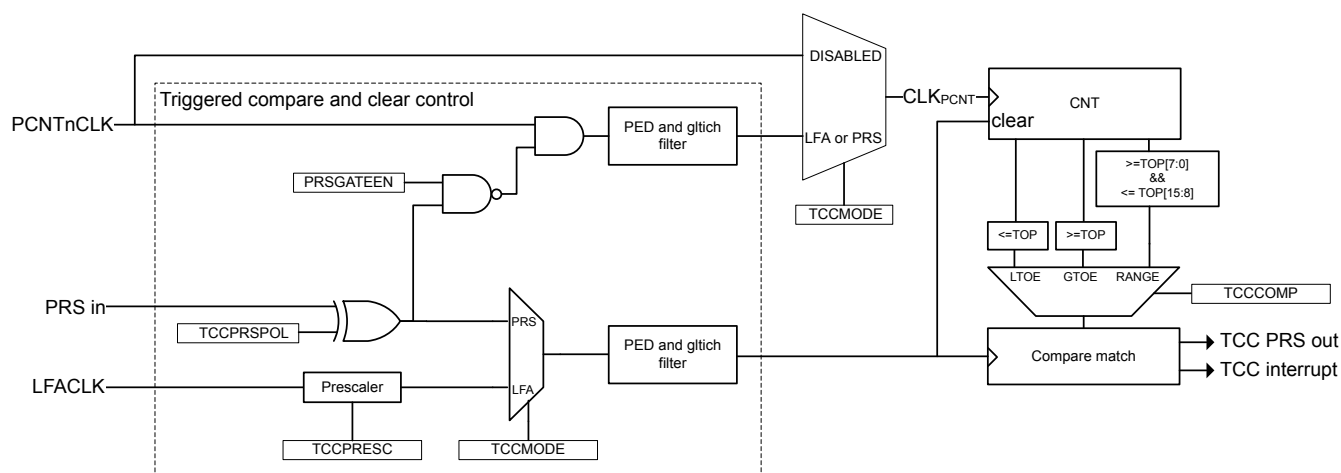

Figure 16.11. PCNT Triggered compare and clear

#### Note:

TCCMODE, TCCPRESC, PRSGATEEN, TCCPRSPOL, and TCCPRSEL in PCNTn\_CTRL should only be altered when RSTEN in PCNTn\_CTRL is set.

### 16.3.5 Register Access

The counter-clock domain may be clocked externally. To update the counter-clock domain registers from software in this mode, 2-3 clock pulses on the external clock are needed to synchronize accesses to the externally clocked domain. Clock source switching is controlled from the registers in the CMU ([12. CMU - Clock Management Unit](#)).

When the RSTEN bit in the PCNTn\_CTRL register is set, the PCNT clock domain is asynchronously held in reset. The reset is synchronously released two PCNT clock edges after the RSTEN bit in the PCNTn\_CTRL register is cleared by software. This asynchronous reset restores the reset values in PCNTn\_TOP, PCNTn\_CNT and other control registers in the PCNT clock domain.

CNTRSTEN works in a similar manner as RSTEN, but only resetting the counter, CNT. Note that the counter is also reset by RSTEN.

AUXCNTRSTEN works in a similar manner as RSTEN, but only resetting the auxiliary counter, PCNTn\_AUXCNT. Note that the auxiliary counter is also reset by RSTEN.

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#) for a description on how to perform register accesses to Low Energy Peripherals.

**Note:**

PCNTn\_TOP and PCNTn\_CNT are read-only registers. When writing to PCNTn\_TOPB, make sure that the counter value, PCNTn\_CNT, can not exceed the value written to PCNTn\_TOPB within two clock cycles.

### 16.3.6 Clock Sources

The pulse counter may be clocked from two possible clock sources: LFACLK or an external clock. The clock selection is configured by the PCNT0CLKSEL bit in the CMU\_PCNTCTRL in the Clock Management Unit (CMU), [12. CMU - Clock Management Unit](#). The default clock source is the LFACLK.

This PCNT module may also use PCNTn\_S0IN as an external clock to clock the counter (EXTCLKSINGLE mode) and to sample PCNTn\_S1IN (EXTCLKQUAD mode). Setup, hold and max frequency constraints for PCNTn\_S0IN and PCNTn\_S1IN for these modes are specified in the device datasheet.

To use this module, the LE interface clock must be enabled in CMU\_HFBUSCLKEN0, in addition to the module clock in CMU\_PCNTCTRL.

**Note:**

PCNT Clock Domain Reset, RSTEN, should be set when changing clock source for PCNT. If changing to an external clock source, the clock pin has to be enabled as input prior to de-asserting RSTEN. Changing clock source without asserting RSTEN results in undefined behaviour.

### 16.3.7 Input Filter

An optional pulse width filter is available in OVSSINGLE and OVSQUAD modes, when LFACLK is selected as a clock source for the Pulse Counter in CMU [12. CMU - Clock Management Unit](#). The filter is enabled by writing 1 to the FILT bit in the PCNTn\_CTRL register. When enabled, the high and low periods of PCNTn\_S0IN and PCNTn\_S1IN must be stable for a programmable number of consecutive clock cycles before the edge is passed to the edge detector. The filter length should be programmed in FILTLEN field of the PCNTn\_OVSCFG register.

The filter length is given by [Figure 16.12 PCNT Input Filter length Equation on page 408](#):

$$\text{Filter length} = (\text{FILTLEN} + 5) \text{ LFACLK cycles}$$

**Figure 16.12. PCNT Input Filter length Equation**

The maximum filter length configured is 260 LFACLK cycles.

In EXTCLKSINGLE and EXTCLKQUAD mode, there is no digital pulse width filter available.

### 16.3.8 Edge Polarity

The edge polarity can be set by configuring the EDGE bit in the PCNTn\_CTRL register. When this bit is cleared, the pulse counter counts positive edges of PCNTn\_S0IN input. When this bit is set, the pulse counter counts negative edges in OVSSINGLE mode. Also, when the EDGE bit is set in the OVSSINGLE and EXTCLKSINGLE modes, the PCNTn\_S1IN input is inverted. In OVSQUAD 1X-4X modes the EDGE bit inverts both inputs.

**Note:**

The EDGE bit in PCNTn\_CTRL has no effect in EXTCLKQUAD mode.

### 16.3.9 PRS and PCNTn\_S0IN,PCNTn\_S1IN Inputs

It is possible to receive input from PRS on both PCNTn\_S0IN (or PCNTn\_S1IN) by setting S0PRSEN (or S1PRSEN) in PCNTn\_INPUT. The PRS channel used can be selected using S0PRSSEL (or S1PRSSEL) in PCNTn\_INPUT.

In the Oversampling quadrature decoder modes, the input frequency should be less than 8KHz to ensure correct functionality.

PCNT module generates three PRS outputs the TCC PRS output, the CNT OF/UF PRS output and the CNT DIR PRS output. The TCC PRS is generated on compare match of TCC event. The CNT OF/UF combined PRS is generated when the counter overflow or underflows. The CNT DIR PRS is a level PRS and indicates the current direction of count of counter CNT

**Note:**

S0PRSEN,S1PRSEN,S0PRSSEL,S1PRSSEL should only be altered when RSTEN in PCNTn\_CTRL is set.

### 16.3.10 Interrupts

The interrupt generated by PCNT uses the PCNTn\_INT interrupt vector. Software must read the PCNTn\_IF register to determine which module interrupt that generated the vector invocation.

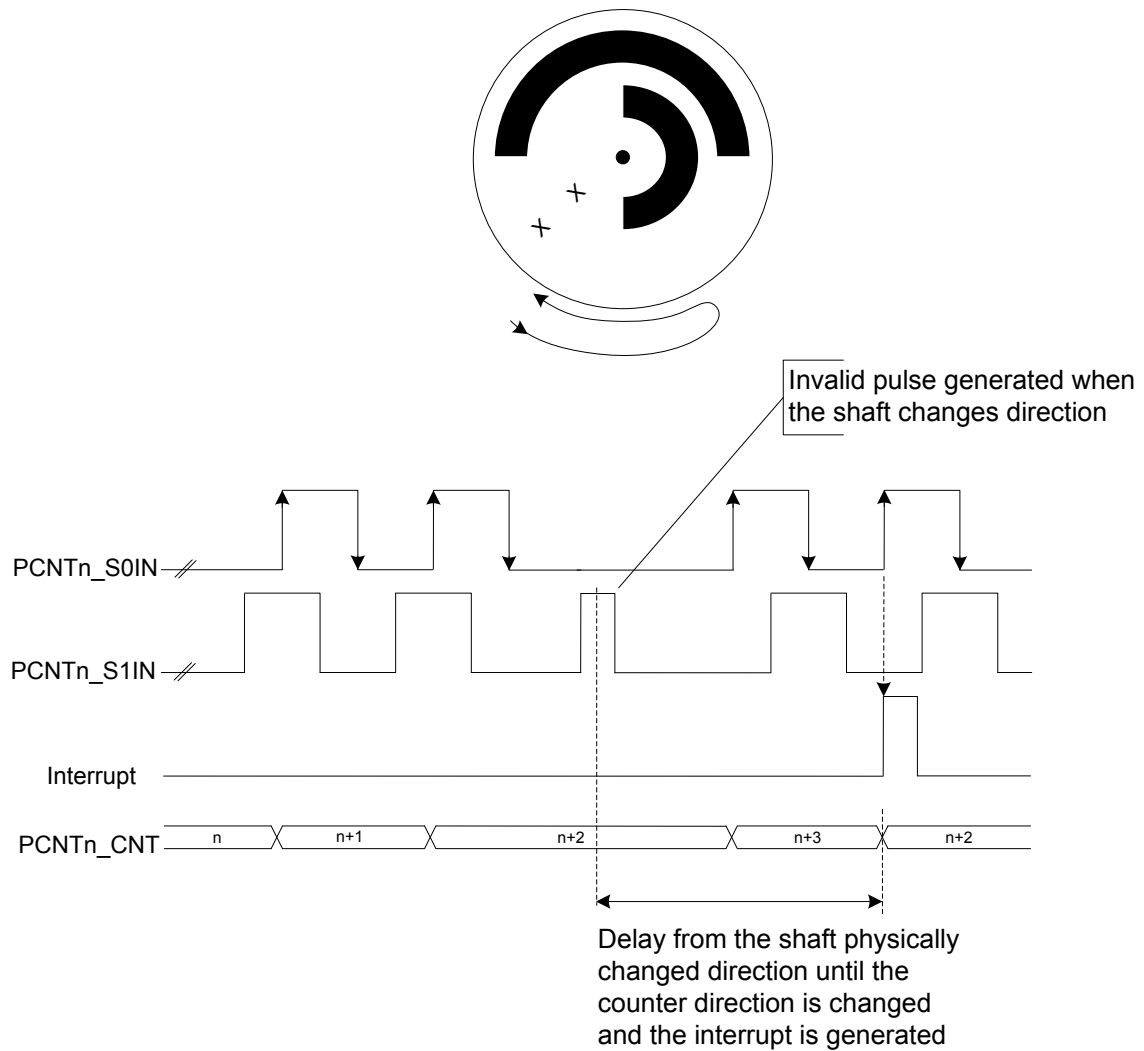

#### 16.3.10.1 Underflow and Overflow Interrupts

The underflow interrupt flag (UF) is set when the counter counts down from 0. I.e. when the value of the counter is 0 and a new pulse is received. The PCNTn\_CNT register is loaded with the PCNTn\_TOP value after this event.

The overflow interrupt flag (OF) is set when the counter counts up from the PCNTn\_TOP (reload) value. I.e. if PCNTn\_CNT = PCNTn\_TOP and a new pulse is received. The PCNTn\_CNT register is loaded with the value 0 after this event.

### 16.3.10.2 Direction Change Interrupt

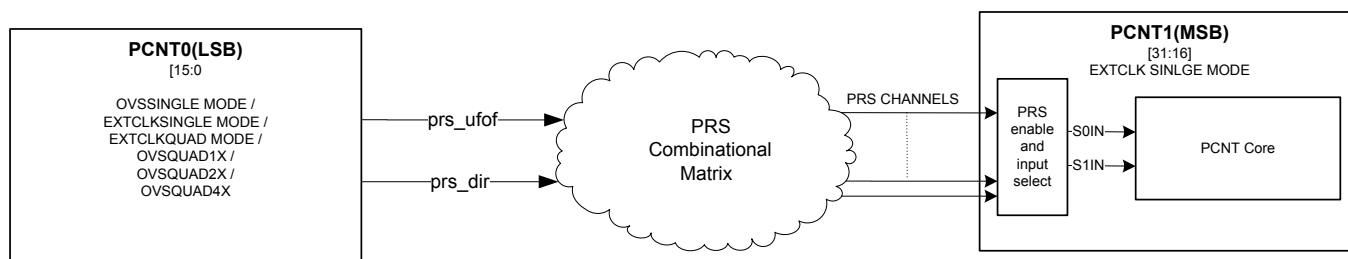

The PCNTn\_PCNT module sets the DIRCNG interrupt flag (PCNTn\_IF register) for EXTCLKQUAD and OVSQUAD1X-4X modes when the direction of the quadrature code changes. The behavior of this interrupt in the EXTCLKQUAD mode is illustrated by [Figure 16.13 PCNT Direction Change Interrupt \(DIRCNG\) Generation on page 410](#).

**Figure 16.13. PCNT Direction Change Interrupt (DIRCNG) Generation**

### 16.3.11 Cascading Pulse Counters

When two or more Pulse Counters are available, it is possible to cascade them. For example two 16-bit Pulse Counters can be cascaded to form a 32-bit pulse counter. This can be done with the help of the CNT UF/OF PRS and CNT DIR PRS outputs. The figure [Figure 16.14 PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT on page 411](#) illustrates this structure.

**Figure 16.14. PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT**

For cascading of Pulse Counters to work, the PCNT1 according to the figure [Figure 16.14 PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT on page 411](#) should be programmed in EXTCLKSINGLE mode and its S0IN and S1IN inputs should be configured to prs\_ufof and prs\_dir of PCNT0 respectively. In addition to this, a strict programming sequence needs to be followed to ensure both PCNTs are in sync with each other.

- Configure PCNT0 registers. eg. PCNT0\_INPUT, PCNT0\_CTRL, PCNT0\_OVSCFG etc.
- Wait for PCNT0\_SYCNBUSY to be cleared to ensure the registers are synchronized to the asynchronous clock domain.
- Hold PCNT0 in sw reset by setting PCNT0\_CTRL\_RSTEN.
- Configure PCNT1\_CTRL to EXTCLKSINGLE mode with S1CDIR and CNTDIR bit set. Configure INPUT to accept "prs\_ufof" and "prs\_dir" of PCNT0 on S0IN and S1IN respectively.
- Wait for PCNTn\_SYCNBUSY to be cleared to ensure the registers are synchronized to the asynchronous clock domain. Use three PRS\_SWPULSE on the S0IN prs channel to ensure this synchronization.
- Hold PCNT1 in sw reset by setting PCNT1\_CTRL\_RSTEN.
- Clear PCNT1\_CTRL\_RSTEN and synchronize it by asserting two PRS\_SWPULSE on the S0IN input.
- Finally clear PCNT0\_CTRL\_RSTEN and start counting.

**Note:**

When RSTEN in PCNTn\_CTRL is set, the TOP value in the Pulse Counter gets cleared. Therefore, in order to update the TOP value while RSTEN is set, assert TOPBHFEN bit in PCNTn\_CTRL. This will update the TOP value with the TOPB value even without having to synchronize the TOPB value. This only works if TOPBHFEN and TOPB are configured while RSTEN in PCNTn\_CTRL is set.

## 16.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	PCNTn_CTRL	RW	Control Register
0x004	PCNTn_CMD	W1	Command Register
0x008	PCNTn_STATUS	R	Status Register
0x00C	PCNTn_CNT	R	Counter Value Register
0x010	PCNTn_TOP	R	Top Value Register
0x014	PCNTn_TOPB	RW	Top Value Buffer Register
0x018	PCNTn_IF	R	Interrupt Flag Register
0x01C	PCNTn_IFS	W1	Interrupt Flag Set Register
0x020	PCNTn_IFC	(R)W1	Interrupt Flag Clear Register
0x024	PCNTn_IEN	RW	Interrupt Enable Register
0x02C	PCNTn_ROUTELOC0	RW	I/O Routing Location Register
0x040	PCNTn_FREEZE	RW	Freeze Register
0x044	PCNTn_SYNCBUSY	R	Synchronization Busy Register
0x064	PCNTn_AUXCNT	R	Auxiliary Counter Value Register
0x068	PCNTn_INPUT	RW	PCNT Input Register
0x06C	PCNTn_OVSCFG	RW	Oversampling Config Register

## 16.5 Register Description

### 16.5.1 PCNTn\_CTRL - Control Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

20:19	TCCPRESC	0x0	RW	<b>Set the LFA prescaler for triggered compare and clear</b> Selects the prescaler value for LFA compare and clear events																																							

Bit	Name	Reset	Access	Description
	Value	Mode		Description
	0	DIV1		Compare and clear event each LFA cycle.
	1	DIV2		Compare and clear performed on every other LFA cycle.
	2	DIV4		Compare and clear performed on every 4th LFA cycle.
	3	DIV8		Compare and clear performed on every 8th LFA cycle.
18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17:16	TCCMODE	0x0	RW	<b>Sets the mode for triggered compare and clear</b> Selects whether compare and clear should be triggered on each LFA clock, or from PRS
	Value	Mode		Description
	0	DISABLED		Triggered compare and clear not enabled.
	1	LFA		Compare and clear performed on each (optionally prescaled) LFA clock cycle.
	2	PRS		Compare and clear performed on positive PRS edges.
15	EDGE	0	RW	<b>Edge Select</b> Determines the polarity of the incoming edges. This bit should be written when PCNT is in DISABLE mode, otherwise the behavior is unpredictable. This bit used only in OVSSINGLE, EXTCLKSINGLE and OVSQUAD1X-4X modes.
	Value	Mode		Description
	0	POS		Positive edges on the PCNTn_S0IN inputs are counted in OVSSINGLE mode. Does not invert PCNTn_S1IN input in OVSSINGLE and EXTCLKSINGLE modes
	1	NEG		Negative edges on the PCNTn_S0IN inputs are counted in OVSSINGLE mode. Inverts the PCNTn_S1IN input in OVSSINGLE and EXTCLKSINGLE modes
14	CNTDIR	0	RW	<b>Non-Quadrature Mode Counter Direction Control</b> The direction of the counter must be set in the OVSSINGLE and EXTCLKSINGLE modes. This bit is ignored in EXTCLKQUAD mode as the direction is automatically detected.
	Value	Mode		Description
	0	UP		Up counter mode.
	1	DOWN		Down counter mode.
13:12	AUXCNTEV	0x0	RW	<b>Controls when the auxiliary counter counts</b> Selects whether the auxiliary counter responds to up-count events, down-count events or both
	Value	Mode		Description
	0	NONE		Never counts.
	1	UP		Counts up on up-count events.
	2	DOWN		Counts up on down-count events.
	3	BOTH		Counts up on both up-count and down-count events.
11:10	CNTEV	0x0	RW	<b>Controls when the counter counts</b>

Bit	Name	Reset	Access	Description
Selects whether the regular counter responds to up-count events, down-count events or both				
	Value	Mode		Description
	0	BOTH		Counts up on up-count and down on down-count events.
	1	UP		Only counts up on up-count events.
	2	DOWN		Only counts down on down-count events.
	3	NONE		Never counts.
9	S1CDIR	0	RW	<b>Count direction determined by S1</b>  S1 gives the direction of counting when in the OVSSINGLE or EXTCLKSINGLE modes. When S1 is high, the count direction is given by CNTDIR, and when S1 is low, the count direction is the opposite
8	HYST	0	RW	<b>Enable Hysteresis</b>  When hysteresis is enabled, the PCNT will always overflow and underflow to TOP/2.
7	DEBUGHALT	0	RW	<b>Debug Mode Halt Enable</b>  Set to halt the PCNT in debug mode only in OVSSINGLE and OVSQUAD modes. When in EXTCLKSINGLE or EXTCLKQUAD modes, DEBUGHALT does not halt the Pulse Counter.
	Value			Description
	0			PCNT is running in debug mode.
	1			PCNT is frozen in debug mode.
6	AUXCNRSTEN	0	RW	<b>Enable AUXCNT Reset</b>  The auxiliary counter, AUXCNT, is asynchronously held in reset when this bit is set. The reset is synchronously released two PCNT clock edges after this bit is cleared. If an external clock is used, the reset should be performed by setting and clearing the bit without pending for SYNCBUSY bit.
5	CNTRSTEN	0	RW	<b>Enable CNT Reset</b>  The counter, CNT, is asynchronously held in reset when this bit is set. The reset is synchronously released two PCNT clock edges after this bit is cleared. If an external clock is used, the reset should be performed by setting and clearing the bit without pending for SYNCBUSY bit. This action clears the counter to its reset value
4	RSTEN	0	RW	<b>Enable PCNT Clock Domain Reset</b>  The PCNT clock domain is asynchronously held in reset when this bit is set. The reset is synchronously released two PCNT clock edges after this bit is cleared. If an external clock is used, the reset should be performed by setting and clearing the bit without pending for SYNCBUSY bit.
3	FILT	0	RW	<b>Enable Digital Pulse Width Filter</b>  The filter passes all high and low periods that are at least (FILTLEN+5) clock cycles wide. This filter is only available in OVSSINGLE, OVSQUAD1X-4X modes.
2:0	MODE	0x0	RW	<b>Mode Select</b>  Selects the mode of operation. The corresponding clock source must be selected from the CMU.
	Value	Mode		Description
	0	DISABLE		The module is disabled.
	1	OVSSINGLE		Single input LFACTK oversampling mode (available in EM0-EM3).
	2	EXTCLKSINGLE		Externally clocked single input counter mode (available in EM0-EM3).
	3	EXTCLKQUAD		Externally clocked quadrature decoder mode (available in EM0-EM3).

Bit	Name	Reset	Access	Description
4		OVSQUAD1X		LFACLK oversampling quadrature decoder 1X mode (available in EM0-EM3).
5		OVSQUAD2X		LFACLK oversampling quadrature decoder 2X mode (available in EM0-EM3).
6		OVSQUAD4X		LFACLK oversampling quadrature decoder 4X mode (available in EM0-EM3).

### 16.5.2 PCNTn\_CMD - Command Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

## 17. I<sup>2</sup>C - Inter-Integrated Circuit Interface

### Quick Facts

#### What?

The I<sup>2</sup>C interface allows communication on I<sup>2</sup>C-buses with the lowest energy consumption possible.

#### Why?

I<sup>2</sup>C is a popular serial bus that enables communication with a number of external devices using only two I/O pins.

#### How?

With the help of DMA, the I<sup>2</sup>C interface allows I<sup>2</sup>C communication with minimal CPU intervention. Address recognition is available in all energy modes (except EM4), allowing the MCU to wait for data on the I<sup>2</sup>C-bus with sub- $\mu$ A current consumption.

### 17.1 Introduction

The I<sup>2</sup>C module provides an interface between the MCU and a serial I<sup>2</sup>C-bus. It is capable of acting as both a master and a slave and supports multi-master buses. Standard-mode, fast-mode and fast-mode plus speeds are supported, allowing transmission rates all the way from 10 kbit/s up to 1 Mbit/s. Slave arbitration and timeouts are also provided to allow implementation of an SMBus compliant system. The interface provided to software by the I<sup>2</sup>C module allows precise control of the transmission process and highly automated transfers. Automatic recognition of slave addresses is provided in all energy modes (except EM4).

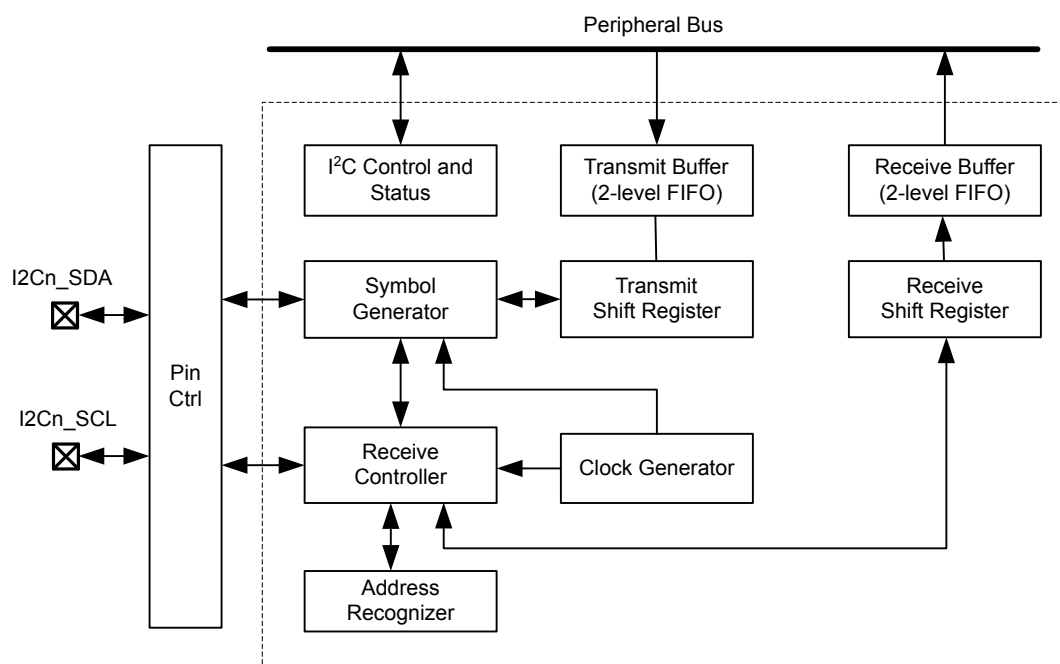

### 17.2 Features

- True multi-master capability
- Support for different bus speeds
  - Standard-mode (Sm) bit rate up to 100 kbit/s
  - Fast-mode (Fm) bit rate up to 400 kbit/s
  - Fast-mode Plus (Fm+) bit rate up to 1 Mbit/s
- Arbitration for both master and slave (allows SMBus ARP)
- Clock synchronization and clock stretching
- Hardware address recognition
  - 7-bit masked address
  - General call address
  - Active in all energy modes (except EM4)
- 10-bit address support
- Error handling
  - Clock low timeout
  - Clock high timeout
  - Arbitration lost
  - Bus error detection
- Separate receive/ transmit 2-level buffers, with additional separate shift registers
- Full DMA support

### 17.3 Functional Description

An overview of the I2C module is shown in [Figure 17.1 I2C Overview on page 432](#).

**Figure 17.1. I2C Overview**

17.3.1 I2C-Bus Overview

The I<sup>2</sup>C-bus uses two wires for communication; a serial data line (SDA) and a serial clock line (SCL) as shown in [Figure 17.2 I2C-Bus Example on page 433](#). As a true multi-master bus it includes collision detection and arbitration to resolve situations where multiple masters transmit data at the same time without data loss.

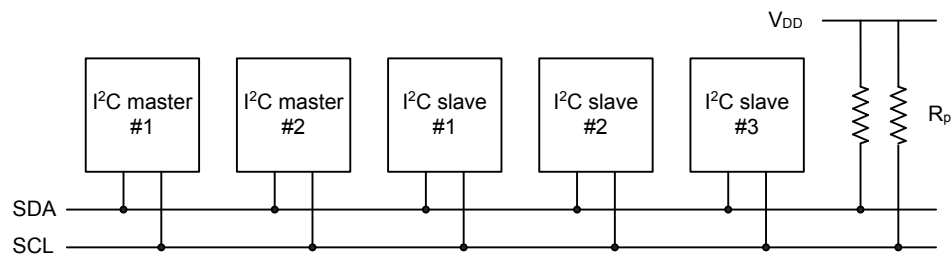

Figure 17.2. I2C-Bus Example

Each device on the bus is addressable by a unique address, and an I<sup>2</sup>C master can address all the devices on the bus, including other masters.

Both the bus lines are open-drain. The maximum value of the pull-up resistor can be calculated as a function of the maximal rise-time **tr** for the given bus speed, and the estimated bus capacitance **Cb** as shown in [Figure 17.3 I2C Pull-up Resistor Equation on page 433](#).

$$R_{p(max)} = (tr/0.8473) \times C_b.$$

Figure 17.3. I2C Pull-up Resistor Equation

The maximal rise times for 100 kHz, 400 kHz and 1 MHz I<sup>2</sup>C are 1 μs, 300 ns and 120 ns respectively.

**Note:**

The GPIO drive strength can be used to control slew rate.

**Note:**

If **V<sub>dd</sub>** drops below the voltage on SCL and SDA lines, the MCU could become back powered and pull the SCL and SDA lines low.

### 17.3.1.1 START and STOP Conditions

START and STOP conditions are used to initiate and stop transactions on the I<sup>2</sup>C-bus. All transactions on the bus begin with a START condition (S) and end with a STOP condition (P). As shown in [Figure 17.4 I2C START and STOP Conditions on page 434](#), a START condition is generated by pulling the SDA line low while SCL is high, and a STOP condition is generated by pulling the SDA line high while SCL is high.

**Figure 17.4. I2C START and STOP Conditions**

The START and STOP conditions are easily identifiable bus events as they are the only conditions on the bus where a transition is allowed on SDA while SCL is high. During the actual data transmission, SDA is only allowed to change while SCL is low, and must be stable while SCL is high. One bit is transferred per clock pulse on the I<sup>2</sup>C-bus as shown in [Figure 17.5 I2C Bit Transfer on I<sup>2</sup>C-Bus on page 434](#).

**Figure 17.5. I2C Bit Transfer on I<sup>2</sup>C-Bus**

### 17.3.1.2 Bus Transfer

When a master wants to initiate a transfer on the bus, it waits until the bus is idle and transmits a START condition on the bus. The master then transmits the address of the slave it wishes to interact with and a single R/W bit telling whether it wishes to read from the slave (R/W bit set to 1) or write to the slave (R/W bit set to 0).

After the 7-bit address and the R/W bit, the master releases the bus, allowing the slave to acknowledge the request. During the next bit-period, the slave pulls SDA low (ACK) if it acknowledges the request, or keeps it high if it does not acknowledge it (NACK).

Following the address acknowledge, either the slave or master transmits data, depending on the value of the R/W bit. After every 8 bits (one byte) transmitted on the SDA line, the transmitter releases the line to allow the receiver to transmit an ACK or a NACK. Both the data and the address are transmitted with the most significant bit first.

The number of bytes in a bus transfer is unrestricted. The master ends the transmission after a (N)ACK by sending a STOP condition on the bus. After a STOP condition, any master wishing to initiate a transfer on the bus can try to gain control of it. If the current master wishes to make another transfer immediately after the current, it can start a new transfer directly by transmitting a repeated START condition (Sr) instead of a STOP followed by a START.

Examples of I<sup>2</sup>C transfers are shown in [Figure 17.6 I2C Single Byte Write to Slave on page 435](#), [Figure 17.7 I2C Double Byte Read from Slave on page 435](#), and [Figure 17.8 I2C Single Byte Write, then Repeated Start and Single Byte Read on page 435](#). The identifiers used are:

- ADDR - Address
- DATA - Data
- S - Start bit
- Sr - Repeated start bit
- P - Stop bit
- W/R - Read(1)/Write(0)
- A - ACK
- N - NACK

**Figure 17.6. I2C Single Byte Write to Slave**

**Figure 17.7. I2C Double Byte Read from Slave**

**Figure 17.8. I2C Single Byte Write, then Repeated Start and Single Byte Read**

### 17.3.1.3 Addresses

I<sup>2</sup>C supports both 7-bit and 10-bit addresses. When using 7-bit addresses, the first byte transmitted after the START-condition contains the address of the slave that the master wants to contact. In the 7-bit address space, several addresses are reserved. These addresses are summarized in [Table 17.1 I<sup>2</sup>C Reserved I<sup>2</sup>C Addresses on page 436](#), and include a General Call address which can be used to broadcast a message to all slaves on the I<sup>2</sup>C-bus.

**Table 17.1. I<sup>2</sup>C Reserved I<sup>2</sup>C Addresses**

I <sup>2</sup> C Address	R/W	Description
0000-000	0	General Call address
0000-000	1	START byte
0000-001	X	Reserved for the C-Bus format
0000-010	X	Reserved for a different bus format
0000-011	X	Reserved for future purposes
0000-1XX	X	Reserved for future purposes
1111-1XX	X	Reserved for future purposes
1111-0XX	X	10 Bit slave addressing mode

### 17.3.1.4 10-bit Addressing

To address a slave using a 10-bit address, two bytes are required to specify the address instead of one. The seven first bits of the first byte must then be 1111 0XX, where XX are the two most significant bits of the 10-bit address. As with 7-bit addresses, the eighth bit of the first byte determines whether the master wishes to read from or write to the slave. The second byte contains the eight least significant bits of the slave address.

When a slave receives a 10-bit address, it must acknowledge both the address bytes if they match the address of the slave.

When performing a master transmitter operation, the master transmits the two address bytes and then the remaining data, as shown in [Figure 17.9 I<sup>2</sup>C Master Transmitter/Slave Receiver with 10-bit Address on page 436](#).

**Figure 17.9. I<sup>2</sup>C Master Transmitter/Slave Receiver with 10-bit Address**

When performing a master receiver operation however, the master first transmits the two address bytes in a master transmitter operation, then sends a repeated START followed by the first address byte and then receives data from the addressed slave. The slave addressed by the 10-bit address in the first two address bytes must remember that it was addressed, and respond with data if the address transmitted after the repeated start matches its own address. An example of this (with one byte transmitted) is shown in [Figure 17.10 I<sup>2</sup>C Master Receiver/Slave Transmitter with 10-bit Address on page 436](#).

**Figure 17.10. I<sup>2</sup>C Master Receiver/Slave Transmitter with 10-bit Address**

### 17.3.1.5 Arbitration, Clock Synchronization, Clock Stretching

Arbitration and clock synchronization are features aimed at allowing multi-master buses. Arbitration occurs when two devices try to drive the bus at the same time. If one device drives it low, while the other drives it high, the one attempting to drive it high will not be able to do so due to the open-drain bus configuration. Both devices sample the bus, and the one that was unable to drive the bus in the desired direction detects the collision and backs off, letting the other device continue communication on the bus undisturbed.

Clock synchronization is a means of synchronizing the clock outputs from several masters driving the bus at once, and is a requirement for effective arbitration.

Slaves on the bus are allowed to force the clock output on the bus low in order to pause the communication on the bus and give themselves time to process data or perform any real-time tasks they might have. This is called clock stretching.

Arbitration is supported by the I<sup>2</sup>C module for both masters and slaves. Clock synchronization and clock stretching is also supported.

### 17.3.2 Enable and Reset

The I<sup>2</sup>C is enabled by setting the EN bit in the I2Cn\_CTRL register. Whenever this bit is cleared, the internal state of the I<sup>2</sup>C is reset, terminating any ongoing transfers.

#### Note:

When enabling the I<sup>2</sup>C, the ABORT command or the Bus Idle Timeout feature must be applied prior to use even if the BUSY flag is not set.

### 17.3.3 Safely Disabling and Changing Slave Configuration

The I<sup>2</sup>C slave is partially asynchronous, and some precautions are necessary to always ensure a safe slave disable or slave configuration change. These measures should be taken, if (while the slave is enabled) the user cannot guarantee that an address match will not occur at the exact time of slave disable or slave configuration change.

Worst case consequences for an address match while disabling slave or changing configuration is that the slave may end up in an undefined state. To reset the slave back to a known state, the EN bit in I2Cn\_CTRL must be reset. This should be done regardless of whether the slave is going to be re-enabled or not.

### 17.3.4 Clock Generation

The SCL signal generated by the I<sup>2</sup>C master determines the maximum transmission rate on the bus. The clock is generated as a division of the peripheral clock, and is given by the following equation:

$$f_{SCL} = f_{HFPERCLK} / (((N_{low} + N_{high}) \times (DIV + 1)) + 8),$$

**Figure 17.11. I2C Maximum Transmission Rate**

$N_{low}$  and  $N_{high}$  in combination with the synchronization cycles (discussed below) specify the number of prescaled clock cycles in the low and high periods of the clock signal respectively. The worst case low and high periods of the signal are:

$$T_{high} \geq ((N_{high}) \times (DIV + 1) + 4) / f_{HFPERCLK},$$

$$T_{low} \geq (N_{low} \times (DIV + 1) + 4) / f_{HFPERCLK}.$$

**Figure 17.12. I2C High and Low Cycles Equations**

In worst case,  $T_{high}$  and  $T_{low}$  can be 1  $f_{HFPERCLK}$  cycle longer than the number found by above equations due to synchronization uncertainty (i.e., if the synchronization takes 3  $f_{HFPERCLK}$  cycles instead of 2). Similarly, in the worst case the number 8 in the denominator in  $f_{SCL}$  equation can be 9 (if the synchronization cycles were 3 instead of 2 in  $T_{high}$  or  $T_{low}$ ) or 10 (if synchronization cycles were 3 in both  $T_{high}$  and  $T_{low}$ ). The values of  $N_{low}$  and  $N_{high}$  and thus the ratio between the high and low parts of the clock signal is controlled by CLHR in the I2Cn\_CTRL register.

#### Note:

DIV must be set to 1 during slave mode operation.

### 17.3.5 Arbitration

Arbitration is enabled by default, but can be disabled by setting the ARBDIS bit in I2Cn\_CTRL. When arbitration is enabled, the value on SDA is sensed every time the I<sup>2</sup>C module attempts to change its value. If the sensed value is different than the value the I<sup>2</sup>C module tried to output, it is interpreted as a simultaneous transmission by another device, and that the I<sup>2</sup>C module has lost arbitration.

Whenever arbitration is lost, the ARBLOST interrupt flag in I2Cn\_IF is set, any lines held are released, and the I<sup>2</sup>C device goes idle. If an I<sup>2</sup>C master loses arbitration during the transmission of an address, another master may be trying to address it. The master therefore receives the rest of the address, and if the address matches the slave address of the master, the master goes into either slave transmitter or slave receiver mode.

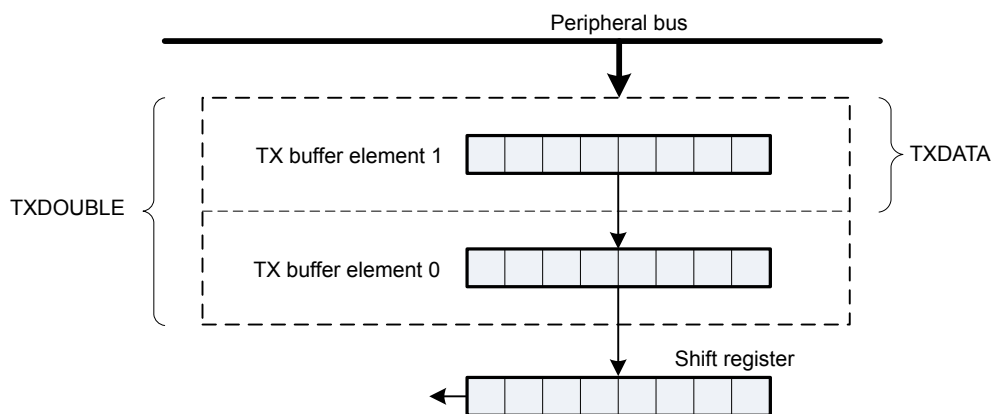

#### Note:

Arbitration can be lost both when operating as a master and when operating as a slave.

### 17.3.6 Buffers

#### 17.3.6.1 Transmit Buffer and Shift Register

The I<sup>2</sup>C transmitter has a 2-level FIFO transmit buffer and a transmit shift register as shown in [Figure 17.1 I2C Overview on page 432](#). A byte is loaded into the transmit buffer by writing to I2Cn\_TXDATA or 2 bytes can be loaded simultaneously in the transmit buffer by writing to I2Cn\_TXDOUBLE. [Figure 17.13 I2C Transmit Buffer Operation on page 438](#) shows the basics of the transmit buffer. When the transmit shift register is empty and ready for new data, the byte from the transmit buffer is then loaded into the shift register. The byte is then kept in the shift register until it is transmitted. When a byte has been transmitted, a new byte is loaded into the shift register (if available in the transmit buffer). If the transmit buffer is empty, then the shift register also remains empty. The TXC flag in I2Cn\_STATUS and the TXC interrupt flags in I2Cn\_IF are then set, signaling that the transmit shift register is out of data. TXC is cleared when new data becomes available, but the TXC interrupt flag must be cleared by software.

**Figure 17.13. I2C Transmit Buffer Operation**

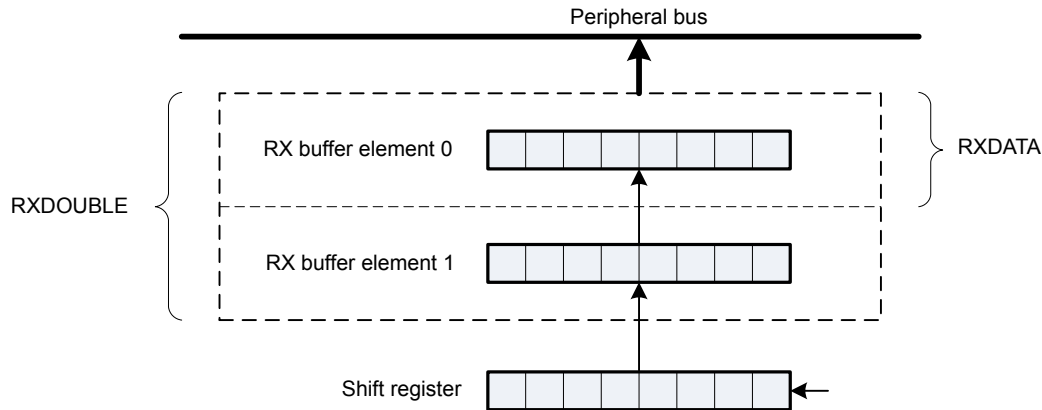

The TXBL flags in the I2Cn\_STATUS and I2Cn\_IF are used to indicate the level of the transmit buffer. TXBIL in I2Cn\_CTRL controls the level at which these flag bits are set. If TXBIL is cleared, the flags are set whenever the transmit buffer becomes empty (used when transmitting using I2Cn\_TXDOUBLE). If TXBIL is set, the flags are set whenever the transmit buffer goes from full to half-empty or empty (used when transmitting with I2Cn\_TXDATA). Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when the condition becomes false.

If an attempt is made to write more bytes to the transmit buffer than the space available, the TXOF interrupt flag in I2Cn\_IF is set, indicating the overflow. The data already in the buffer remains preserved, and no new data is written.

The transmit buffer and the transmit shift register can be cleared by setting command bit CLEAR\_TX in I2Cn\_CMD. This will prevent the I<sup>2</sup>C module from transmitting the data in the buffer and the shift register, and will make them available for new data. Any byte currently being transmitted will not be aborted. Transmission of this byte will be completed.

### 17.3.6.2 Receive Buffer and Shift Register

The I<sup>2</sup>C receiver uses a 2-level FIFO receive buffer and a receive shift register as shown in [Figure 17.14 I2C Receive Buffer Operation on page 439](#). When a byte has been fully received by the receive shift register, it is loaded into the receive buffer if there is room for it, making the shift register empty to receive another byte. Otherwise, the byte waits in the shift register until space becomes available in the buffer.

**Figure 17.14. I2C Receive Buffer Operation**

When a byte becomes available in the receive buffer, the RXDATAV in I2Cn\_STATUS and RXDATAV interrupt flag in I2Cn\_IF are set. When the buffer becomes full, RXFULL in the I2Cn\_STATUS and I2Cn\_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more byte.

The data can be fetched from the buffer in two ways. I2Cn\_RXDATA gives access to the received byte (if two bytes are received then the one received first is fetched first). I2Cn\_RXDOUBLE makes it possible to read the two received bytes simultaneously. If an attempt is made to read more bytes from the buffer than available, the RXUF interrupt flag in I2Cn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

When using I2Cn\_RXDOUBLE to pick data, AUTOACK in I2Cn\_CTRL should be set to 1. This ensures that an ACK is automatically sent out after the first byte is received so that the reception of the next byte can begin. In order to stop receiving data bytes, a NACK must be sent out through the I2Cn\_CMD register.

I2Cn\_RXDATAP and I2Cn\_RXDOUBLEP can be used to read data from the receive buffer without removing it from the buffer. The RXUF interrupt flag in I2Cn\_IF will never be set as a result of reading from I2Cn\_RXDATAP and I2Cn\_RXDOUBLEP, but the data read through I2Cn\_RXDATAP when the receive buffer is empty is still undefined.

Once a transaction is complete (STOP sent or received), the receive buffer needs to be flushed (all received data must be read) before starting a new transaction.

### 17.3.7 Master Operation

A bus transaction is initiated by transmitting a START condition (S) on the bus. This is done by setting the START bit in I2Cn\_CMD. The command schedules a START condition, and makes the I<sup>2</sup>C module generate a start condition whenever the bus becomes free.

The I<sup>2</sup>C-bus is considered busy whenever another device on the bus transmits a START condition. Until a STOP condition is detected, the bus is owned by the master issuing the START condition. The bus is considered free when a STOP condition is transmitted on the bus. After a STOP is detected, all masters that have data to transmit send a START condition and begin transmitting data. Arbitration ensures that collisions are avoided.

When the START condition has been transmitted, the master must transmit a slave address (ADDR) with an R/W bit on the bus. If this address is available in the transmit buffer, the master transmits it immediately, but if the buffer is empty, the master holds the I<sup>2</sup>C-bus while waiting for software to write the address to the transmit buffer.

After the address has been transmitted, a sequence of bytes can be read from or written to the slave, depending on the value of the R/W bit (bit 0 in the address byte). If the bit was cleared, the master has entered a master transmitter role, where it now transmits data to the slave. If the bit was set, it has entered a master receiver role, where it now should receive data from the slave. In either case, an unlimited number of bytes can be transferred in one direction during the transmission.

At the end of the transmission, the master either transmits a repeated START condition (Sr) if it wishes to continue with another transfer, or transmits a STOP condition (P) if it wishes to release the bus. When operating in the master mode, HFPERCLK frequency must be higher than 2 MHz for Standard-mode, 9 MHz for Fast-mode, and 20 MHz for Fast-mode Plus.

### 17.3.7.1 Master State Machine

The master state machine is shown in [Figure 17.15 I2C Master State Machine on page 441](#). A master operation starts in the far left of the state machine, and follows the solid lines through the state machine, ending the operation or continuing with a new operation when arriving at the right side of the state machine.

Branches in the path through the state machine are the results of bus events and choices made by software, either directly or indirectly. The dotted lines show where I<sup>2</sup>C-specific interrupt flags are set along the path and the full-drawn circles show places where interaction may be required by software to let the transmission proceed.

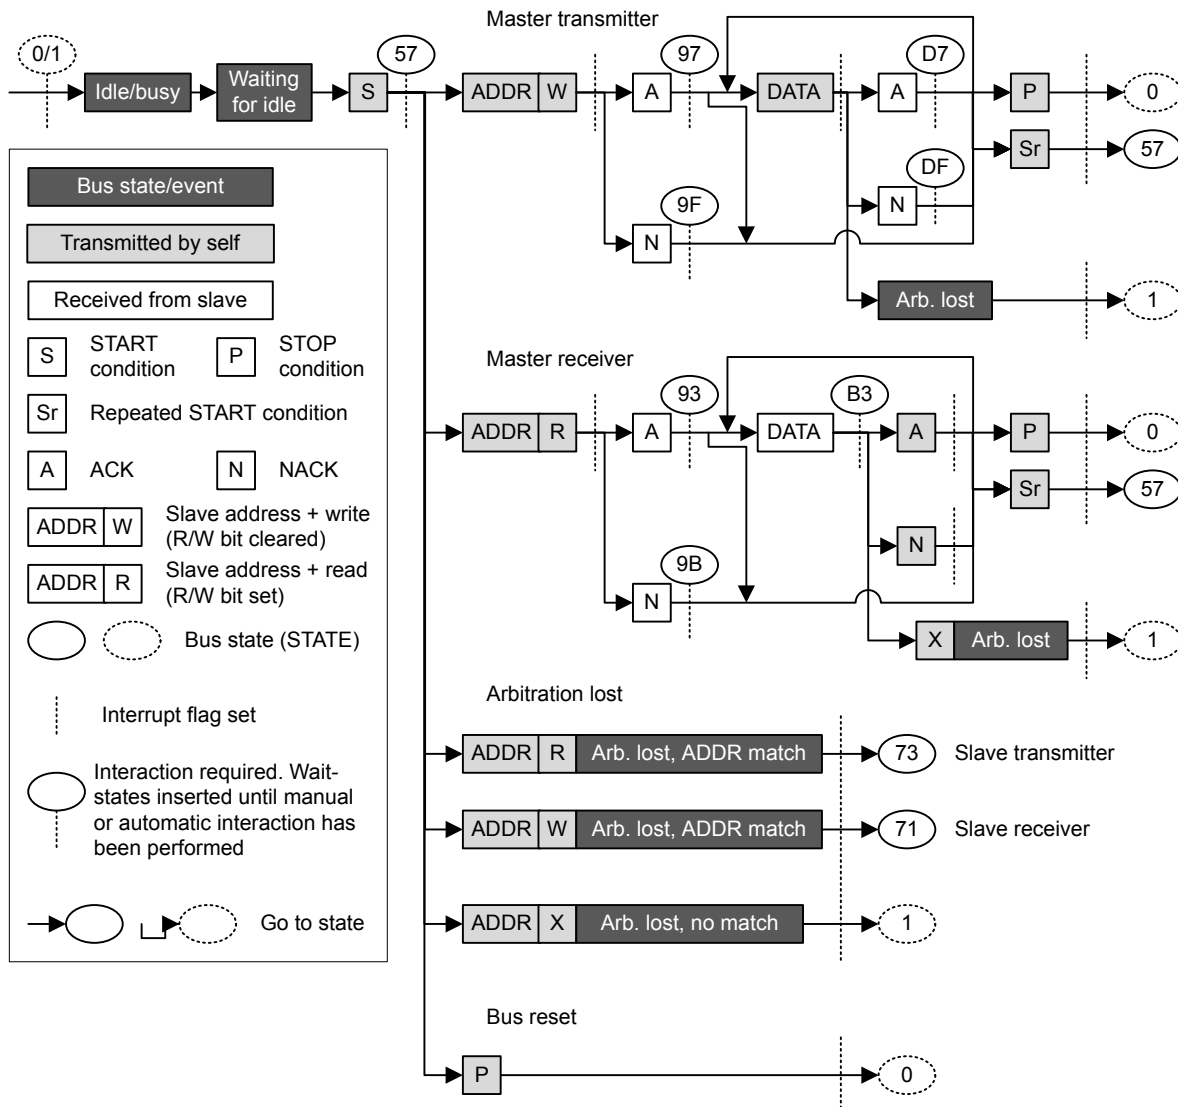

Figure 17.15. I2C Master State Machine

### 17.3.7.2 Interactions

Whenever the I<sup>2</sup>C module is waiting for interaction from software, it holds the bus clock SCL low, freezing all bus activities, and the BUSHOLD interrupt flag in I2Cn\_IF is set. The action(s) required by software depends on the current state the of the I<sup>2</sup>C module. This state can be read from the I2Cn\_STATE register.

As an example, [Table 17.3 I2C Master Transmitter on page 444](#) shows the different states the I<sup>2</sup>C goes through when operating as a Master Transmitter, i.e., a master that transmits data to a slave. As seen in the table, when a start condition has been transmitted, a requirement is that there is an address and an R/W bit in the transmit buffer. If the transmit buffer is empty, then the BUSHOLD interrupt flag is set, and the bus is held until data becomes available in the buffer. While waiting for the address, I2Cn\_STATE has a value 0x57, which can be used to identify exactly what the I<sup>2</sup>C module is waiting for.

**Note:**

The bus would never stop at state 0x57 if the address was available in the transmit buffer.

The different interactions used by the I<sup>2</sup>C module are listed in [Table 17.2 I2C Interactions in Prioritized Order on page 442](#) in a prioritized order. If the I<sup>2</sup>C module is in such a state that multiple courses of action are possible, then the action chosen is the one that has the highest priority. For example, after sending out a START, if an address is present in the buffer and a STOP is also pending, then the I<sup>2</sup>C will send out the STOP since it has the higher priority.

**Table 17.2. I2C Interactions in Prioritized Order**

Interaction	Priority	Software action	Automatically continues if
STOP*	1	Set the STOP command bit in I2Cn_CMD	PSTOP is set (STOP pending) in I2Cn_STATUS
ABORT	2	Set the ABORT command bit in I2Cn_CMD	Never, the transmission is aborted
CONT*	3	Set the CONT command bit in I2Cn_CMD	PCONT is set in I2Cn_STATUS (CONT pending)
NACK*	4	Set the NACK command bit in I2Cn_CMD	PNACK is set in I2Cn_STATUS (NACK pending)
ACK*	5	Set the ACK command bit in I2Cn_CMD	AUTOACK is set in I2Cn_CTRL or PACK is set in I2Cn_STATUS (ACK pending)
ADDR+W -> TXDATA	6	Write an address to the transmit buffer with the R/W bit set	Address is available in transmit buffer with R/W bit set
ADDR+R -> TXDATA	7	Write an address to the transmit buffer with the R/W bit cleared	Address is available in transmit buffer with R/W bit cleared
START*	8	Set the START command bit in I2Cn_CMD	PSTART is set in I2Cn_STATUS (START pending)
TXDATA/ TXDOUBLE	9	Write data to the transmit buffer	Data is available in transmit buffer
RXDATA/ RXDOUBLE	10	Read data from receive buffer	Space is available in receive buffer
None	11	No interaction is required	

The commands marked with a \* in [Table 17.2 I2C Interactions in Prioritized Order on page 442](#) can be issued before an interaction is required. When such a command is issued before it can be used/consumed by the I<sup>2</sup>C module, the command is set in a pending state, which can be read from the STATUS register. A pending START command can for instance be identified by PSTART having a high value.

Whenever the I<sup>2</sup>C module requires an interaction, it checks the pending commands. If one or a combination of these can fulfill an interaction, they are consumed by the module and the transmission continues without setting the BUSHOLD interrupt flag in I2Cn\_IF to get an interaction from software. The pending status of a command goes low when it is consumed.

When several interactions are possible from a set of pending commands, the interaction with the highest priority, i.e., the interaction closest to the top of [Table 17.2 I2C Interactions in Prioritized Order on page 442](#) is applied to the bus.

Pending commands can be cleared by setting the CLEARPC command bit in I2Cn\_CMD.

#### 17.3.7.3 Automatic ACK Interaction

When receiving addresses and data, an ACK command in I2Cn\_CMD is normally required after each received byte. When AUTOACK is set in I2Cn\_CTRL, an ACK is always pending, and the ACK-pending bit PACK in I2Cn\_STATUS is thus always set, even after an ACK has been consumed. This is used when data is picked using I2Cn\_RXDOUBLE and can also be used with I2Cn\_RXDATA in order to reduce the amount of software interaction required during a transfer.

#### 17.3.7.4 Reset State

After a reset, the state of the I<sup>2</sup>C-bus is unknown. To avoid interrupting transfers on the I<sup>2</sup>C-bus after a reset of the I<sup>2</sup>C module or the entire MCU, the I<sup>2</sup>C-bus is assumed to be busy when coming out of a reset, and the BUSY flag in I2Cn\_STATUS is thus set. To be able to carry through master operations on the I<sup>2</sup>C-bus, the bus must be idle.

The bus goes idle when a STOP condition is detected on the bus, but on buses with little activity, the time before the I<sup>2</sup>C module detects that the bus is idle can be significant. There are two ways of assuring that the I<sup>2</sup>C module gets out of the busy state.

- Use the ABORT command in I2Cn\_CMD. When the ABORT command is issued, the I<sup>2</sup>C module is instructed that the bus is idle. The I<sup>2</sup>C module can then initiate master operations.
- Use the Bus Idle Timeout. When SCL has been high for a long period of time, it is very likely that the bus is idle. Set BITO in I2Cn\_CTRL to an appropriate timeout period and set GIBITO in I2Cn\_CTRL. If activity has not been detected on the bus within the timeout period, the bus is then automatically assumed idle, and master operations can be initiated.

**Note:**

If operating in slave mode, the above approach is not necessary.

### 17.3.7.5 Master Transmitter

To transmit data to a slave, the master must operate as a master transmitter. [Table 17.3 I2C Master Transmitter on page 444](#) shows the states the I<sup>2</sup>C module goes through while acting as a master transmitter. Every state where an interaction is required has the possible interactions listed, along with the result of the interactions. The table also shows which interrupt flags are set in the different states. The interrupt flags enclosed in parenthesis may be set. If the BUSHOLD interrupt in I2Cn\_IF is set, the module is waiting for an interaction, and the bus is frozen. The value of I2Cn\_STATE will be equal to the values given in the table when the BUSHOLD interrupt flag is set, and can be used to determine which interaction is required to make the transmission continue.

The interrupt flag START in I2Cn\_IF is set when the I<sup>2</sup>C module transmits the START.

A master operation is started by issuing a START command by setting START in I2Cn\_CMD. ADDR+W, i.e., the address of the slave + the R/W bit is then required by the I<sup>2</sup>C module. If this is not available in the transmit buffer, then the bus is held and the BUSHOLD interrupt flag is set. The value of I2Cn\_STATE will then be 0x57. As seen in the table, the I<sup>2</sup>C module also stops in this state if the address is not available after a repeated start condition.

To continue, write a byte to I2Cn\_TXDATA with the address of the slave in the 7 most significant bits and the least significant bit cleared (ADDR+W). This address will then be transmitted, and the slave will reply with an ACK or a NACK. If no slave replies to the address, the response will also be NACK. If the address was acknowledged, the master now has four choices. It can send data by placing it in I2Cn\_TXDATA/ I2Cn\_TXDOUBLE (the master should check the TXBL interrupt flag before writing to the transmit buffer), this data is then transmitted. The master can also stop the transmission by sending a STOP, it can send a repeated start by sending START, or it can send a STOP and then a START as soon as possible. If the master wishes to make another transfer immediately after the current, the preferred way is to start a new transfer directly by transmitting a repeated START instead of a STOP followed by a START. This is so because if a STOP is sent out, then any master wishing to initiate a transfer on the bus can try to gain control of it.

If a NACK was received, the master has to issue a CONT command in addition to providing data in order to continue transmission. This is not standard I<sup>2</sup>C, but is provided for flexibility. The rest of the options are similar to when an ACK was received.

If a new byte was transmitted, an ACK or NACK is received after the transmission of the byte, and the master has the same options as for when the address was sent.

The master may lose arbitration at any time during transmission. In this case, the ARBLOST interrupt flag in I2Cn\_IF is set. If the arbitration was lost during the transfer of an address, and SLAVE in I2Cn\_CTRL is set, the master then checks which address was transmitted. If it was the address of the master, then the master goes to slave mode.

After a master has transmitted a START and won any arbitration, it owns the bus until it transmits a STOP. After a STOP, the bus is released, and arbitration decides which bus master gains the bus next. The MSTOP interrupt flag in I2Cn\_IF is set when a STOP condition is transmitted by the master.

**Table 17.3. I2C Master Transmitter**

I2Cn_STATE	Description	I2Cn_IF	Required interaction	Response
0x57	Start transmitted	START interrupt flag (BUSHOLD interrupt flag)	ADDR+W -> TXDATA	ADDR+W will be sent
			STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
0x57	Repeated start transmitted	START interrupt flag (BUSHOLD interrupt flag)	ADDR+W -> TXDATA	ADDR+W will be sent
			STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
-	ADDR+W transmitted	TXBL interrupt flag (TXC interrupt flag)	None	

I2Cn_STATE	Description	I2Cn_IF	Required interaction	Response
0x97	ADDR+W transmitted, ACK received	ACK interrupt flag (BUSHOLD interrupt flag)	TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0x9F	ADDR+W transmitted, NACK received	NACK (BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
-	Data transmitted	TXBL interrupt flag (TXC interrupt flag)	None	
0xD7	Data transmitted, ACK received	ACK interrupt flag (BUSHOLD interrupt flag)	TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0xDF	Data transmitted, NACK received	NACK (BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
-	Stop transmitted	MSTOP interrupt flag	None	
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	
			START	START will be sent when bus becomes idle

### 17.3.7.6 Master Receiver

To receive data from a slave, the master must operate as a master receiver, see [Table 17.4 I2C Master Receiver on page 446](#). This is done by transmitting ADDR+R as the address byte instead of ADDR+W, which is transmitted to become a master transmitter. The address byte loaded into the data register thus has to contain the 7-bit slave address in the 7 most significant bits of the byte, and have the least significant bit set.

When the address has been transmitted, the master receives an ACK or a NACK. If an ACK is received, the ACK interrupt flag in I2Cn\_IF is set, and if space is available in the receive shift register, reception of a byte from the slave begins. If the receive buffer and shift register is full however, the bus is held until data is read from the receive buffer or another interaction is made. Note that the STOP and START interactions have a higher priority than the data-available interaction, so if a STOP or START command is pending, the highest priority interaction will be performed, and data will not be received from the slave.

If a NACK was received, the CONT command in I2Cn\_CMD has to be issued in order to continue receiving data, even if there is space available in the receive buffer and/or shift register.

After a data byte has been received the master must ACK or NACK the received byte. If an ACK is pending or AUTOACK in I2Cn\_CTRL is set, an ACK is sent automatically and reception continues if space is available in the receive buffer.

If a NACK is sent, the CONT command must be used in order to continue transmission. If an ACK or NACK is issued along with a START or STOP or both, then the ACK/NACK is transmitted and the reception is ended. If START in I2Cn\_CMD is set alone, a repeated start condition is transmitted after the ACK/NACK. If STOP in I2Cn\_CMD is set, a stop condition is sent regardless of whether START is set. If START is set in this case, it is set as pending.

As when operating as a master transmitter, arbitration can be lost as a master receiver. When this happens the ARBLOST interrupt flag in I2Cn\_IF is set, and the master has a possibility of being selected as a slave given the correct conditions.

**Table 17.4. I2C Master Receiver**

I2Cn_STATE	Description	I2Cn_IF	Required interaction	Response
0x57	START transmitted	START interrupt flag (BUSHOLD interrupt flag)	ADDR+R -> TXDATA	ADDR+R will be sent
			STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
0x57	Repeated START transmitted	START interrupt flag(BUSHOLD interrupt flag)	ADDR+R -> TXDATA	ADDR+R will be sent
			STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
-	ADDR+R transmitted	TXBL interrupt flag (TXC interrupt flag)	None	
0x93	ADDR+R transmitted, ACK received	ACK interrupt flag(BUSHOLD)	RXDATA	Start receiving
			STOP	STOP will be sent and the bus released
			START	Repeated START will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0x9B	ADDR+R transmitted, NACK received	NACK(BUSHOLD)	CONT + RXDATA	Continue, start receiving
			STOP	STOP will be sent and the bus released
			START	Repeated START will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle

I2Cn_STATE	Description	I2Cn_IF	Required in-teraction	Response
0xB3	Data received	RXDATA interrupt flag(BUSHOLD inter-rupt flag)	ACK + RXDA-TA	ACK will be transmitted, reception continues
			NACK + CONT + RXDATA	NACK will be transmitted, reception continues
			ACK/NACK + STOP	ACK/NACK will be sent and the bus will be re-leased.
			ACK/NACK + START	ACK/NACK will be sent, and then a repeated start condition.
			ACK/NACK + STOP + START	ACK/NACK will be sent and the bus will be re-leased. Then a START will be sent when the bus becomes idle
-	Stop received	MSTOP interrupt flag	None	
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	
			START	START will be sent when bus becomes idle

### 17.3.8 Bus States

The I2Cn\_STATE register can be used to determine which state the I<sup>2</sup>C module and the I<sup>2</sup>C bus are in at a given time. The register consists of the STATE bit-field, which shows which state the I<sup>2</sup>C module is at in any ongoing transmission, and a set of single-bits, which reveal the transmission mode, whether the bus is busy or idle, and whether the bus is held by this I<sup>2</sup>C module waiting for a software response.

The possible values of the STATE field are summarized in [Table 17.5 I2C STATE Values on page 448](#). When this field is cleared, the I<sup>2</sup>C module is not a part of any ongoing transmission. The remaining status bits in the I2Cn\_STATE register are listed in [Table 17.6 I2C Transmission Status on page 448](#).

**Table 17.5. I2C STATE Values**

Mode	Value	Description
IDLE	0	No transmission is being performed by this module.
WAIT	1	Waiting for idle. Will send a start condition as soon as the bus is idle.
START	2	Start being transmitted
ADDR	3	Address being transmitted or has been received
ADDRACK	4	Address ACK/NACK being transmitted or received
DATA	5	Data being transmitted or received
DATAACK	6	Data ACK/NACK being transmitted or received

**Table 17.6. I2C Transmission Status**

Bit	Description
BUSY	Set whenever there is activity on the bus. Whether or not this module is responsible for the activity cannot be determined by this byte.
MASTER	Set when operating as a master. Cleared at all other times.
TRANSMITTER	Set when operating as a transmitter; either a master transmitter or a slave transmitter. Cleared at all other times
BUSHOLD	Set when the bus is held by this I <sup>2</sup> C module because an action is required by software.
NACK	Only valid when bus is held and STATE is ADDRACK or DATAACK. In that case it is set if a NACK was received. In all other cases, the bit is cleared.

**Note:**

I2Cn\_STATE reflects the internal state of the I<sup>2</sup>C module, and therefore only held constant as long as the bus is held, i.e., as long as BUSHOLD in I2Cn\_STATUS is set.

### 17.3.9 Slave Operation

The I<sup>2</sup>C module operates in master mode by default. To enable slave operation, i.e., to allow the device to be addressed as an I<sup>2</sup>C slave, the SLAVE bit in I2Cn\_CTRL must be set. In this case the I<sup>2</sup>C module operates in a mixed mode, both capable of starting transmissions as a master, and being addressed as a slave. When operating in the slave mode, HFPERCLK frequency must be higher than 2 MHz for Standard-mode, 5 MHz for Fast-mode, and 14 MHz for Fast-mode Plus.

### 17.3.9.1 Slave State Machine

The slave state machine is shown in [Figure 17.16 I2C Slave State Machine on page 449](#). The dotted lines show where I<sup>2</sup>C-specific interrupt flags are set. The full-drawn circles show places where interaction may be required by software to let the transmission proceed.

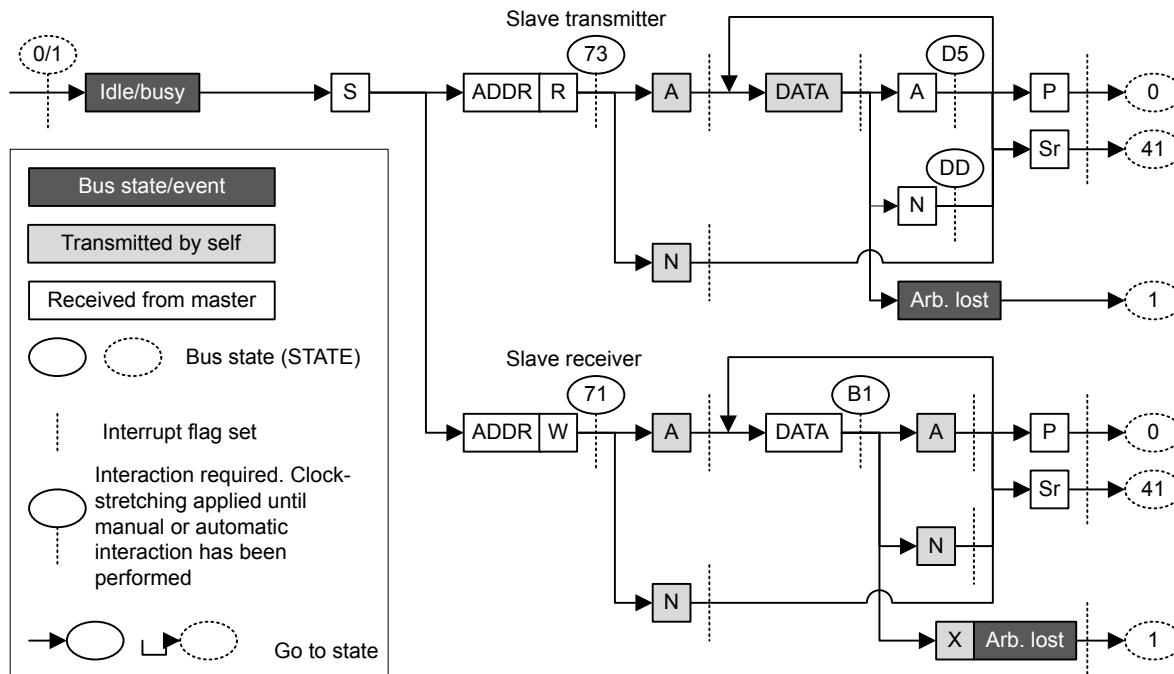

Figure 17.16. I2C Slave State Machine

### 17.3.9.2 Address Recognition

The I<sup>2</sup>C module provides automatic address recognition for 7-bit addresses. 10-bit address recognition is not fully automatic, but can be assisted by the 7-bit address comparator as shown in [17.3.11 Using 10-bit Addresses](#). Address recognition is supported in all energy modes (except EM4).

The slave address, i.e., the address which the I<sup>2</sup>C module should be addressed with, is defined in the I2Cn\_SADDR register. In addition to the address, a mask must be specified, telling the address comparator which bits of an incoming address to compare with the address defined in I2Cn\_SADDR. The mask is defined in I2Cn\_SADDRMASK, and for every zero in the mask, the corresponding bit in the slave address is treated as a don't-care, i.e., the 0-masked bits are ignored.

An incoming address that fails address recognition is automatically replied to with a NACK. Since only the bits defined by the mask are checked, a mask with a value 0x00 will result in all addresses being accepted. A mask with a value 0x7F will only match the exact address defined in I2Cn\_SADDR, while a mask 0x70 will match all addresses where the three most significant bits in I2Cn\_SADDR and the incoming address are equal.

If GCAMEN in I2Cn\_CTRL is not set, the start-byte, i.e., the general call address with the R/W bit set is ignored unless it is included in the defined slave address and the address mask.

When an address is accepted by the address comparator, the decision of whether to ACK or NACK the address is passed to software.

### 17.3.9.3 Slave Transmitter

When SLAVE in I2Cn\_CTRL is set, the RSTART interrupt flag in I2Cn\_IF will be set when repeated START conditions are detected. After a START or repeated START condition, the bus master will transmit an address along with an R/W bit. If there is no room in the receive shift register for the address, the bus will be held by the slave until room is available in the shift register. Transmission then continues and the address is loaded into the shift register. If this address does not pass address recognition, it is automatically NACK'ed by the slave, and the slave goes to an idle state. The address byte is in this case discarded, making the shift register ready for a new address. It is not loaded into the receive buffer.

If the address was accepted and the R/W bit was set (R), indicating that the master wishes to read from the slave, the slave now goes into the slave transmitter mode. Software interaction is now required to decide whether the slave wants to acknowledge the request or not. The accepted address byte is loaded into the receive buffer like a regular data byte. If no valid interaction is pending, the bus is held until the slave responds with a command. The slave can reject the request with a single NACK command.

The slave will in that case go to an idle state, and wait for the next start condition. To continue the transmission, the slave must make sure data is loaded into the transmit buffer and send an ACK. The loaded data will then be transmitted to the master, and an ACK or NACK will be received from the master.

Data transmission can also continue after a NACK if a CONT command is issued along with the NACK. This is not standard I<sup>2</sup>C however.

If the master responds with an ACK, it may expect another byte of data, and data should be made available in the transmit buffer. If data is not available, the bus is held until data is available.

If the response is a NACK however, this is an indication of that the master has received enough bytes and wishes to end the transmission. The slave now automatically goes idle, unless CONT in I2Cn\_CMD is set and data is available for transmission. The latter is not standard I<sup>2</sup>C.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag in I2Cn\_IF is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag is not set.

#### Note:

The SSTOP interrupt flag in I2Cn\_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn\_CTRL is set and a STOP condition is detected

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn\_IF is set, the bus is released and the slave goes idle.

See [Table 17.7 I2C Slave Transmitter on page 450](#) for more information.

**Table 17.7. I2C Slave Transmitter**

I2Cn_STATE	Description	I2Cn_IF	Required interaction	Response
0x41	Repeated START received	RSTART interrupt flag (BUSHOLD interrupt flag)	RXDATA	Receive and compare address
0x75	ADDR + R received	ADDR interrupt flag	ACK + TXDATA	ACK will be sent, then DATA
		RXDATA interrupt flag	NACK	NACK will be sent, slave goes idle
		(BUSHOLD interrupt flag)	NACK + CONT + TXDATA	NACK will be sent, then DATA.
-	Data transmitted	TXBL interrupt flag (TXC interrupt flag)	None	
0xD5	Data transmitted, ACK received	ACK interrupt flag (BUSHOLD interrupt flag)	TXDATA	DATA will be transmitted

I2Cn_STATE	Description	I2Cn_IF	Required interaction	Response
0xDD	Data transmitted, NACK received	NACK interrupt flag	None	The slave goes idle
		(BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be transmitted
-	Stop received	SSTOP interrupt flag	None	The slave goes idle
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	The slave goes idle
			START	START will be sent when the bus becomes idle

### 17.3.9.4 Slave Receiver

A slave receiver operation is started in the same way as a slave transmitter operation, with the exception that the address transmitted by the master has the R/W bit cleared (W), indicating that the master wishes to write to the slave. The slave then goes into slave receiver mode.

To receive data from the master, the slave should respond to the address with an ACK and make sure space is available in the receive buffer. Transmission will then continue, and the slave will receive a byte from the master.

If a NACK is sent without a CONT, the transmission is ended for the slave, and it goes idle. If the slave issues both the NACK and CONT commands and has space available in the receive buffer, it will be open for continuing reception from the master.

When a byte has been received from the master, the slave must ACK or NACK the byte. The responses here are the same as for the reception of the address byte.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag in I2Cn\_IF is not set.

**Note:**

The SSTOP interrupt flag in I2Cn\_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn\_CTRL is set and a STOP condition is detected

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn\_IF is set, the bus is released and the slave goes idle.

See [Table 17.8 I2C - Slave Receiver on page 452](#) for more information.

**Table 17.8. I2C - Slave Receiver**

I2Cn_STATE	Description	I2Cn_IF	Required interaction	Response
-	Repeated START received	RSTART interrupt flag (BUSHOLD interrupt flag)	RXDATA	Receive and compare address
0x71	ADDR + W received	ADDR interrupt flag RXDATA interrupt flag (BUSHOLD interrupt flag)	ACK + RXDATA	ACK will be sent and data will be received
			NACK	NACK will be sent, slave goes idle
			NACK + CONT + RXDATA	NACK will be sent and DATA will be received.
0xB1	Data received	RXDATA interrupt flag (BUSHOLD interrupt flag)	ACK + RXDATA	ACK will be sent and data will be received
			NACK	NACK will be sent and slave will go idle
			NACK + CONT + RXDATA	NACK will be sent and data will be received
-	Stop received	SSTOP interrupt flag	None	The slave goes idle
			START	START will be sent when bus becomes idle
-	Arbitration lost	ARBLOST interrupt flag	None	The slave goes idle
			START	START will be sent when the bus becomes idle

### 17.3.10 Transfer Automation

The I<sup>2</sup>C can be set up to complete transfers with a minimal amount of interaction.

### 17.3.10.1 DMA

DMA can be used to automatically load data into the transmit buffer and load data out from the receive buffer. When using DMA, software is thus relieved of moving data to and from memory after each transferred byte.

### 17.3.10.2 Automatic ACK

When AUTOACK in I2Cn\_CTRL is set, an ACK is sent automatically whenever an ACK interaction is possible and no higher priority interactions are pending.

### 17.3.10.3 Automatic STOP

A STOP can be generated automatically on two conditions. These apply only to the master transmitter.

If AUTOSN in I2Cn\_CTRL is set, the I<sup>2</sup>C module ends a transmission by transmitting a STOP condition when operating as a master transmitter and a NACK is received.

If AUTOSE in I2Cn\_CTRL is set, the I<sup>2</sup>C module always ends a transmission when there is no more data in the transmit buffer. If data has been transmitted on the bus, the transmission is ended after the (N)ACK has been received by the slave. If a START is sent when no data is available in the transmit buffer and AUTOSE is set, then the STOP condition is sent immediately following the START. Software must thus make sure data is available in the transmit buffer before the START condition has been fully transmitted if data is to be transferred.

### 17.3.11 Using 10-bit Addresses

When using 10-bit addresses in slave mode, set the I2Cn\_SADDR register to 1111 0XX where XX are the two most significant bits of the 10-bit address, and set I2Cn\_SADDRMASK to 0xFF. Address matches will now be given on all 10-bit addresses where the two most significant bits are correct.

When receiving an address match, the slave must acknowledge the address and receive the first data byte. This byte contains the second part of the 10-bit address. If it matches the address of the slave, the slave should ACK the byte to continue the transmission, and if it does not match, the slave should NACK it.

When the master is operating as a master transmitter, the data bytes will follow after the second address byte. When the master is operating as a master receiver however, a repeated START condition is sent after the second address byte. The address sent after this repeated START is equal to the first of the address bytes transmitted previously, but now with the R/W byte set, and only the slave that found a match on the entire 10-bit address in the previous message should ACK this address. The repeated start should take the master into a master receiver mode, and after the single address byte sent this time around, the slave begins transmission to the master.

### 17.3.12 Error Handling

#### Note:

The setting of GCAMEN and SLAVE fields in the I2Cn\_CTRL register and the registers I2Cn\_SADDR and I2Cn\_ROUTELOC0 are considered static. This means that these need to be set before an I<sup>2</sup>C transaction starts and need to stay stable during the entire transaction.

#### 17.3.12.1 ABORT Command

Some bus errors may require software intervention to be resolved. The I<sup>2</sup>C module provides an ABORT command, which can be set in I2Cn\_CMD, to help resolve bus errors.

When the bus for some reason is locked up and the I<sup>2</sup>C module is in the middle of a transmission it cannot get out of, or for some other reason the I<sup>2</sup>C wants to abort a transmission, the ABORT command can be used.

Setting the ABORT command will make the I<sup>2</sup>C module discard any data currently being transmitted or received, release the SDA and SCL lines and go to an idle mode. ABORT effectively makes the I<sup>2</sup>C module forget about any ongoing transfers.

#### 17.3.12.2 Bus Reset

A bus reset can be performed by setting the START and STOP commands in I2Cn\_CMD while the transmit buffer is empty. A START condition will then be transmitted, immediately followed by a STOP condition. A bus reset can also be performed by transmitting a START command with the transmit buffer empty and AUTOSE set.

### 17.3.12.3 I2C-Bus Errors

An I<sup>2</sup>C-bus error occurs when a START or STOP condition is misplaced, which happens when the value on SDA changes while SCL is high during bit-transmission on the I<sup>2</sup>C-bus. If the I<sup>2</sup>C module is part of the current transmission when a bus error occurs, any data currently being transmitted or received is discarded, SDA and SCL are released, the BUSERR interrupt flag in I2Cn\_IF is set to indicate the error, and the module automatically takes a course of action as defined in [Table 17.9 I2C Bus Error Response on page 454](#).

**Table 17.9. I2C Bus Error Response**

	Misplaced START	Misplaced STOP
In a master/slave operation	Treated as START. Receive address.	Go idle. Perform any pending actions.

### 17.3.12.4 Bus Lockup

A lockup occurs when a master or slave on the I<sup>2</sup>C-bus has locked the SDA or SCL at a low value, preventing other devices from putting high values on the bus, and thus making communication on the bus impossible.

Many slave-only devices operating on an I<sup>2</sup>C-bus are not capable of driving SCL low, but in the rare case that SCL is stuck LOW, the advice is to apply a hardware reset signal to the slaves on the bus. If this does not work, cycle the power to the devices in order to make them release SCL.

When SDA is stuck low and SCL is free, a master should send 9 clock pulses on SCL while tristating the SDA. This procedure is performed in the GPIO module after clearing the I2C\_ROUTE register and disabling the I2C module. The device that held the bus low should release it sometime within those 9 clocks. If not, use the same approach as for when SCL is stuck, resetting and possibly cycling power to the slaves.

Lockup of SDA can be detected by keeping count of the number of continuous arbitration losses during address transmission. If arbitration is also lost during the transmission of a general call address, i.e., during the transmission of the STOP condition, which should never happen during normal operation, this is a good indication of SDA lockup.

Detection of SCL lockups can be done using the timeout functionality defined in [17.3.12.6 Clock Low Timeout](#)

### 17.3.12.5 Bus Idle Timeout

When SCL has been high for a significant amount of time, this is a good indication of that the bus is idle. On an SMBus system, the bus is only allowed to be in this state for a maximum of 50  $\mu$ s before the bus is considered idle.

The bus idle timeout BITO in I2Cn\_CTRL can be used to detect situations where the bus goes idle in the middle of a transmission. The timeout can be configured in BITO, and when the bus has been idle for the given amount of time, the BITO interrupt flag in I2Cn\_IF is set. The bus can also be set idle automatically on a bus idle timeout. This is enabled by setting GIBITO in I2Cn\_CTRL.

When the bus idle timer times out, it wraps around and continues counting as long as its condition is true. If the bus is not set idle using GIBITO or the ABORT command in I2Cn\_CMD, this will result in periodic timeouts.

**Note:**

This timeout will be generated even if SDA is held low.

The bus idle timeout is active as long as the bus is busy, i.e., BUSY in I2Cn\_STATUS is set. The timeout can be used to get the I<sup>2</sup>C module out of the busy-state it enters when reset, see [17.3.7.4 Reset State](#).

### 17.3.12.6 Clock Low Timeout

The clock timeout, which can be configured in CLTO in I2Cn\_CTRL, starts counting whenever SCL goes low, and times out if SCL does not go high within the configured timeout. A clock low timeout results in CLTOIF in I2Cn\_IF being set, allowing software to take action.

When the timer times out, it wraps around and continues counting as long as SCL is low. An SCL lockup will thus result in periodic clock low timeouts as long as SCL is low.

### 17.3.12.7 Clock Low Error

The I<sup>2</sup>C module can continue transmission in parallel with another device for the entire transaction, as long as the two communications are identical. A case may arise when (before an arbitration has been decided upon) the I<sup>2</sup>C module decides to send out a repeated START or a STOP condition while the other device is still sending data. In the I<sup>2</sup>C protocol specifications, such a combination results in an undefined condition. The I<sup>2</sup>C deals with this by generating a clock low error. This means that if the I<sup>2</sup>C is transmitting a repeated START or a STOP condition and another device (another master or a misbehaving slave) pulls SCL low before the I<sup>2</sup>C sends out the START/STOP condition on SDA, a clock low error is generated. The CLERR interrupt flag is then set in the I2Cn\_IF register, any held lines are released and the I<sup>2</sup>C device goes to idle.

### 17.3.13 DMA Support

The I<sup>2</sup>C module has full DMA support. A request for the DMA controller to write to the I<sup>2</sup>C transmit buffer can come from TXBL (transmit buffer has room for more data). The DMA controller can write to the transmit buffer using the I2Cn\_TXDATA or the I2Cn\_TXDOUBLE register. In order to write to the I2Cn\_TXDOUBLE register (i.e., transferring 2 bytes simultaneously to the transmit buffer using the DMA), DMA\_USEBURSTS needs to be set to 1 for the selected DMA channel. This ensures that the transfer is made to the transmit buffer only when both buffer elements are empty. For performing a DMA write to the I2Cn\_TXDATA register, DMA\_USEBURSTC needs to be set to 1 for the selected DMA channel. This ensures that a DMA transfer is made even when the transmit buffer is half-empty.

A request for the DMA controller to read from the I<sup>2</sup>C receive buffer can come from RXDATAV (data available in the receive buffer). To receive from I2Cn\_RXDOUBLE (i.e., receive only when both buffer elements are full), DMA\_USEBURSTS needs to be set to 1 for the selected DMA channel. In order to receive from I2Cn\_RXDATA through the DMA, DMA\_USEBURSTC needs to be set to 1. This ensures that the data gets picked up even when the receive buffer is half-full.

### 17.3.14 Interrupts

The interrupts generated by the I<sup>2</sup>C module are combined into one interrupt vector, I2C\_INT. If I<sup>2</sup>C interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in I2Cn\_IF and their corresponding bits in I2Cn\_IEN are set.

### 17.3.15 Wake-up

The I<sup>2</sup>C receive section can be active all the way down to energy mode EM3 Stop, and can wake up the CPU on address interrupt. All address match modes are supported.

## 17.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	I2Cn_CTRL	RW	Control Register
0x004	I2Cn_CMD	W1	Command Register
0x008	I2Cn_STATE	R	State Register
0x00C	I2Cn_STATUS	R	Status Register
0x010	I2Cn_CLKDIV	RW	Clock Division Register
0x014	I2Cn_SADDR	RW	Slave Address Register
0x018	I2Cn_SADDRMASK	RW	Slave Address Mask Register
0x01C	I2Cn_RXDATA	R(a)	Receive Buffer Data Register
0x020	I2Cn_RXDOUBLE	R(a)	Receive Buffer Double Data Register
0x024	I2Cn_RXDATAP	R	Receive Buffer Data Peek Register
0x028	I2Cn_RXDOUBLEP	R	Receive Buffer Double Data Peek Register
0x02C	I2Cn_TXDATA	W	Transmit Buffer Data Register
0x030	I2Cn_TXDOUBLE	W	Transmit Buffer Double Data Register
0x034	I2Cn_IF	R	Interrupt Flag Register
0x038	I2Cn_IFS	W1	Interrupt Flag Set Register
0x03C	I2Cn_IFC	(R)W1	Interrupt Flag Clear Register
0x040	I2Cn_IEN	RW	Interrupt Enable Register
0x044	I2Cn_ROUTEPEN	RW	I/O Routing Pin Enable Register
0x048	I2Cn_ROUTELOC0	RW	I/O Routing Location Register

1	A bus idle timeout tells the I <sup>2</sup> C module that the bus is idle, allowing new transfers to be initiated.																								
14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>																							
13:12	BITO	0x0	RW	<b>Bus Idle Timeout</b>  Use to generate a timeout when SCL has been high for a given amount time between a START and STOP condition. When in a bus transaction, i.e. the BUSY flag is set, a timer is started whenever SCL goes high. When the timer reaches the value defined by BITO, it sets the BITO interrupt flag. The BITO interrupt flag will then be set periodically as long as SCL remains high. The bus idle timeout is active as long as BUSY is set. It is thus stopped automatically on a timeout if GIBITO is set. It is also stopped a STOP condition is detected and when the ABORT command is issued. The timeout is activated whenever the bus goes BUSY, i.e. a START condition is detected. The timeout value can be calculated by  $\text{timeout} = \text{PCC}/(\text{f}_{\text{SCL}} \times (\text{N}_{\text{low}} + \text{N}_{\text{high}}))$ <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>0</td><td>OFF</td><td>Timeout disabled</td></tr><tr><td>1</td><td>40PCC</td><td>Timeout after 40 prescaled clock cycles. 9:8	CLHR	0x0	RW	<b>Clock Low High Ratio</b> Determines the ratio between the low and high parts of the clock signal generated on SCL as master.
	Value	Mode	Description	
	0	STANDARD	The ratio between low period and high period counters ( $N_{low}:N_{high}$ ) is 4:4	
	1	ASYMMETRIC	The ratio between low period and high period counters ( $N_{low}:N_{high}$ ) is 6:3	
	2	FAST	The ratio between low period and high period counters ( $N_{low}:N_{high}$ ) is 11:6	
7	TXBIL	0	RW	<b>TX Buffer Interrupt Level</b> Determines the interrupt and status level of the transmit buffer.
	Value	Mode	Description	
	0	EMPTY	TXBL status and the TXBL interrupt flag are set when the transmit buffer becomes empty. TXBL is cleared when the buffer becomes non-empty.	
	1	HALFFULL	TXBL status and the TXBL interrupt flag are set when the transmit buffer goes from full to half-full or empty. TXBL is cleared when the buffer becomes full.	
6	GCAMEN	0	RW	<b>General Call Address Match Enable</b> Set to enable address match on general call in addition to the programmed slave address.
	Value	Description		
	0	General call address will be NACK'ed if it is not included by the slave address and address mask.		
	1	When a general call address is received, a software response is required.		
5	ARBDIS	0	RW	<b>Arbitration Disable</b> A master or slave will not release the bus upon losing arbitration.
	Value	Description		
	0	When a device loses arbitration, the ARB interrupt flag is set and the bus is released.		
	1	When a device loses arbitration, the ARB interrupt flag is set, but communication proceeds.		
4	AUTOSN	0	RW	<b>Automatic STOP on NACK</b> Write to 1 to make a master transmitter send a STOP when a NACK is received from a slave.
	Value	Description		
	0	Stop is not automatically sent if a NACK is received from a slave.		

Bit	Name	Reset	Access	Description
	1			The master automatically sends a STOP if a NACK is received from a slave.
3	AUTOSE	0	RW	<b>Automatic STOP when Empty</b> Write to 1 to make a master transmitter send a STOP when no more data is available for transmission.
	Value			Description
	0			A stop must be sent manually when no more data is to be transmitted.
	1			The master automatically sends a STOP when no more data is available for transmission.
2	AUTOACK	0	RW	<b>Automatic Acknowledge</b> Set to enable automatic acknowledges.
	Value			Description
	0			Software must give one ACK command for each ACK transmitted on the I <sup>2</sup> C bus.
	1			Addresses that are not automatically NACK'ed, and all data is automatically acknowledged.
1	SLAVE	0	RW	<b>Addressable as Slave</b> Set this bit to allow the device to be selected as an I <sup>2</sup> C slave.
	Value			Description
	0			All addresses will be responded to with a NACK
	1			Addresses matching the programmed slave address or the general call address (if enabled) require a response from software. Other addresses are automatically responded to with a NACK.
0	EN	0	RW	<b>I<sup>2</sup>C Enable</b> Use this bit to enable or disable the I <sup>2</sup> C module.
	Value			Description
	0			The I <sup>2</sup> C module is disabled. And its internal state is cleared
	1			The I <sup>2</sup> C module is enabled.

## 17.5.2 I2Cn\_CMD - Command Register

Offset	Bit Position																							
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8

### 17.5.7 I2Cn\_SADDRMASK - Slave Address Mask Register

Offset	Bit Position																																
0x018	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																									0x00								
Access																									RW								
Name																									MASK								

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:1	MASK	0x00	RW	<b>Slave Address Mask</b>  Specifies the significant bits of the slave address. Setting the mask to 0x00 will match all addresses, while setting it to 0x7F will only match the exact address specified by ADDR.
0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

### 17.5.8 I2Cn\_RXDATA - Receive Buffer Data Register (Actionable Reads)

Offset	Bit Position																															
0x01C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									R							
Name																									RXDATA							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	RXDATA	0x00	R	<b>RX Data</b>  Use this register to read from the receive buffer. Buffer is emptied on read access.

## 17.5.9 I2Cn\_RXDOUBLE - Receive Buffer Double Data Register (Actionable Reads)

Offset	Bit Position																															
0x020	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00								0x00							
Access																	R								R							
Name																	RXDATA1								RXDATA0							

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:8	RXDATA1	0x00	R	<b>RX Data 1</b> Second byte read from buffer. Buffer is emptied on read access.
7:0	RXDATA0	0x00	R	<b>RX Data 0</b> First byte read from buffer. Buffer is emptied on read access.

## 17.5.10 I2Cn\_RXDATAP - Receive Buffer Data Peek Register

Offset	Bit Position																															
0x024	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									R							
Name																									RXDATAP							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	RXDATAP	0x00	R	<b>RX Data Peek</b> Use this register to read from the receive buffer. Buffer is not emptied on read access.

## 17.5.11 I2Cn\_RXDOUBLEP - Receive Buffer Double Data Peek Register

Offset	Bit Position																															
0x028	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00								0x00							
Access																	R								R							
Name																	RXDATAP1								RXDATAP0							

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:8	RXDATAP1	0x00	R	<b>RX Data 1 Peek</b> Second byte read from buffer. Buffer is not emptied on read access.
7:0	RXDATAP0	0x00	R	<b>RX Data 0 Peek</b> First byte read from buffer. Buffer is not emptied on read access.

## 17.5.12 I2Cn\_TXDATA - Transmit Buffer Data Register

Offset	Bit Position																															
0x02C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									W							
Name																									TXDATA							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	TXDATA	0x00	W	<b>TX Data</b> Use this register to write a byte to the transmit buffer.

17.5.13 I2Cn\_TXDOUBLE - Transmit Buffer Double Data Register

Offset	Bit Position																															
0x030	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x00								0x00							
Access																	W								W							
Name																	TXDATA1								TXDATA0							

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:8	TXDATA1	0x00	W	<b>TX Data</b> Second byte to write to buffer.
7:0	TXDATA0	0x00	W	<b>TX Data</b> First byte to write to buffer.

17.5.14 I2Cn\_IF - Interrupt Flag Register

Offset	Bit Position																						
0x034	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12			
Reset														R	0	R	0	R	0	R	0	R	0
Access														R	0	R	0	R	0	R	0	R	0
Name														CLERR		RXFULL		SSTOP		CLTO		BITO	
																RXUF		TXOF		BUSHOLD		BUSERR	
																		ARBLOST		MSTOP		NACK	
																		ACK		RXDATAV		TXBL	
																		TXC		ADDR		RSTART	
																				START			

Bit	Name	Reset	Access	Description
31:19	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
18	CLERR	0	R	<b>Clock Low Error Interrupt Flag</b> Set when the clock is pulled low before a START or a STOP condition could be transmitted.
17	RXFULL	0	R	<b>Receive Buffer Full Interrupt Flag</b> Set when the receive buffer becomes full.
16	SSTOP	0	R	<b>Slave STOP condition Interrupt Flag</b> Set when a STOP condition has been received. Will be set regardless of the slave being involved in the transaction or not.
15	CLTO	0	R	<b>Clock Low Timeout Interrupt Flag</b> Set on each clock low timeout. The timeout value can be set in CLTO bit field in the I2Cn_CTRL register.
14	BITO	0	R	<b>Bus Idle Timeout Interrupt Flag</b> Set on each bus idle timeout. The timeout value can be set in the BITO bit field in the I2Cn_CTRL register.
13	RXUF	0	R	<b>Receive Buffer Underflow Interrupt Flag</b> Set when data is read from the receive buffer through the I2Cn_RXDATA register while the receive buffer is empty. It is also set when data is read through the I2Cn_RXDOUBLE while the buffer is not full.
12	TXOF	0	R	<b>Transmit Buffer Overflow Interrupt Flag</b> Set when data is written to the transmit buffer while the transmit buffer is full.
11	BUSHOLD	0	R	<b>Bus Held Interrupt Flag</b> Set when the bus becomes held by the I <sup>2</sup> C module.
10	BUSERR	0	R	<b>Bus Error Interrupt Flag</b> Set when a bus error is detected. The bus error is resolved automatically, but the current transfer is aborted.
9	ARBLOST	0	R	<b>Arbitration Lost Interrupt Flag</b> Set when arbitration is lost.
8	MSTOP	0	R	<b>Master STOP Condition Interrupt Flag</b> Set when a STOP condition has been successfully transmitted. If arbitration is lost during the transmission of the STOP condition, then the MSTOP interrupt flag is not set.
7	NACK	0	R	<b>Not Acknowledge Received Interrupt Flag</b> Set when a NACK has been received.
6	ACK	0	R	<b>Acknowledge Received Interrupt Flag</b> Set when an ACK has been received.
5	RXDATAV	0	R	<b>Receive Data Valid Interrupt Flag</b> Set when data is available in the receive buffer. Cleared automatically when the receive buffer is read.
4	TXBL	1	R	<b>Transmit Buffer Level Interrupt Flag</b> Set when the transmit buffer becomes empty. Cleared automatically when new data is written to the transmit buffer.
3	TXC	0	R	<b>Transfer Completed Interrupt Flag</b> Set when the transmit shift register becomes empty and there is no more data in the transmit buffer.
2	ADDR	0	R	<b>Address Interrupt Flag</b> Set when incoming address is accepted, i.e. own address or general call address is received.
1	RSTART	0	R	<b>Repeated START condition Interrupt Flag</b>

Bit	Name	Reset	Access	Description
				Set when a repeated start condition is detected.
0	START	0	R	<b>START condition Interrupt Flag</b>
				Set when a start condition is successfully transmitted.

## 17.5.15 I2Cn\_IFS - Interrupt Flag Set Register

Offset	Bit Position																																						
0x038	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 18. USART - Universal Synchronous Asynchronous Receiver/Transmitter

### Quick Facts

#### What?

The USART handles high-speed UART, SPI-bus, SmartCards, and IrDA communication.

#### Why?

Serial communication is frequently used in embedded systems and the USART allows efficient communication with a wide range of external devices.

#### How?

The USART has a wide selection of operating modes, frame formats and baud rates. The multi-processor mode allows the USART to remain idle when not addressed. Triple buffering and DMA support makes high data-rates possible with minimal CPU intervention and it is possible to transmit and receive large frames while the MCU remains in EM1 Sleep.

### 18.1 Introduction

The Universal Synchronous Asynchronous serial Receiver and Transmitter (USART) is a very flexible serial I/O module. It supports full duplex asynchronous UART communication as well as RS-485, SPI, MicroWire and 3-wire. It can also interface with ISO7816 SmartCards, and IrDA devices.

## 18.2 Features

- Asynchronous and synchronous (SPI) communication
- Full duplex and half duplex
- Separate TX/RX enable
- Separate receive / transmit multiple entry buffers, with additional separate shift registers
- Programmable baud rate, generated as an fractional division from the peripheral clock ( $\text{HFPERCLK}_{\text{USARTn}}$ )
- Max bit-rate
  - SPI master mode, peripheral clock rate/2
  - SPI slave mode, peripheral clock rate/8
  - UART mode, peripheral clock rate/16, 8, 6, or 4
- Asynchronous mode supports
  - Majority vote baud-reception
  - False start-bit detection
  - Break generation/detection
  - Multi-processor mode
- Synchronous mode supports
  - All 4 SPI clock polarity/phase configurations
  - Master and slave mode
- Data can be transmitted LSB first or MSB first
- Configurable number of data bits, 4-16 (plus the parity bit, if enabled)
  - HW parity bit generation and check
- Configurable number of stop bits in asynchronous mode: 0.5, 1, 1.5, 2
- HW collision detection
- Multi-processor mode
- IrDA modulator on USART0
- SmartCard (ISO7816) mode
- I2S mode
- Separate interrupt vectors for receive and transmit interrupts
- Loopback mode
  - Half duplex communication
  - Communication debugging
- PRS RX input
- 8 bit Timer
- Hardware Flow Control
- Automatic Baud Rate Detection

18.3 Functional Description

An overview of the USART module is shown in [Figure 18.1 USART Overview](#) on page 485.

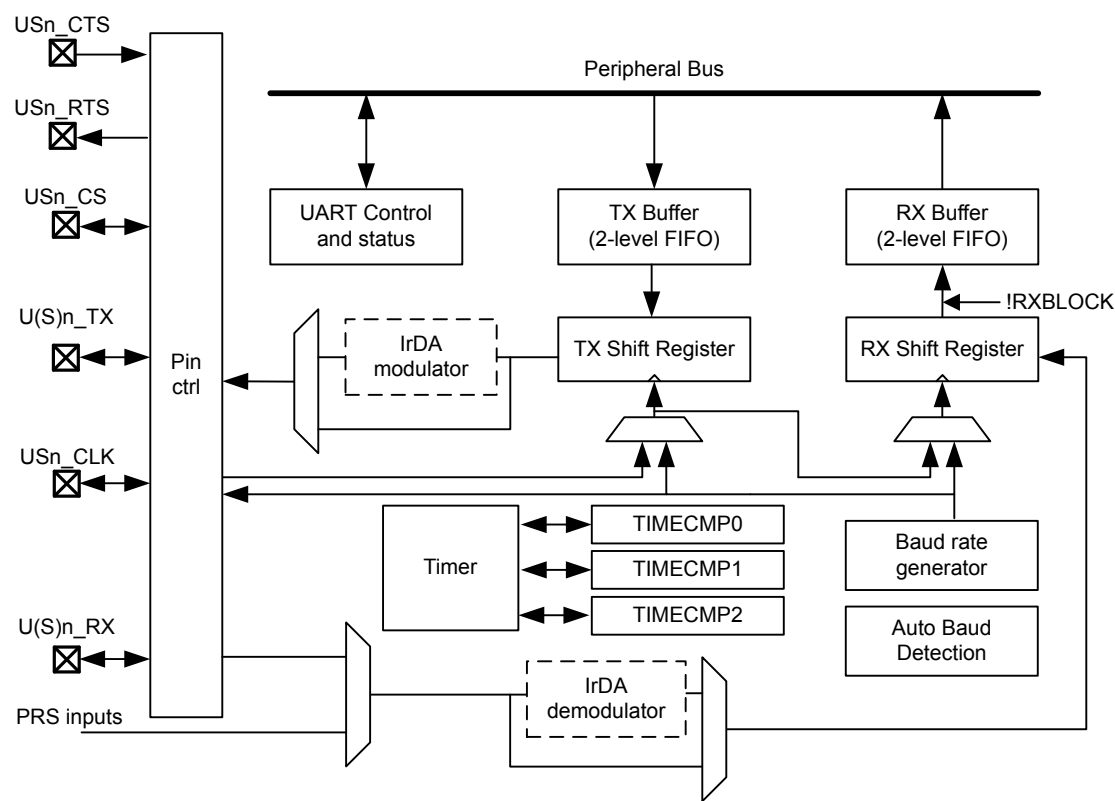

Figure 18.1. USART Overview

### 18.3.1 Modes of Operation

The USART operates in either asynchronous or synchronous mode.

In synchronous mode, a separate clock signal is transmitted with the data. This clock signal is generated by the bus master, and both the master and slave sample and transmit data according to this clock. Both master and slave modes are supported by the USART. The synchronous communication mode is compatible with the Serial Peripheral Interface Bus (SPI) standard.

In asynchronous mode, no separate clock signal is transmitted with the data on the bus. The USART receiver thus has to determine where to sample the data on the bus from the actual data. To make this possible, additional synchronization bits are added to the data when operating in asynchronous mode, resulting in a slight overhead.

Asynchronous or synchronous mode can be selected by configuring SYNC in USARTn\_CTRL. The options are listed with supported protocols in [Table 18.1 USART Asynchronous vs. Synchronous Mode on page 486](#). Full duplex and half duplex communication is supported in both asynchronous and synchronous mode.

**Table 18.1. USART Asynchronous vs. Synchronous Mode**

SYNC	Communication Mode	Supported Protocols
0	Asynchronous	RS-232, RS-485 (w/external driver), IrDA, ISO 7816
1	Synchronous	SPI, MicroWire, 3-wire

[Table 18.2 USART Pin Usage on page 486](#) explains the functionality of the different USART pins when the USART operates in different modes. Pin functionality enclosed in square brackets is optional, and depends on additional configuration parameters. LOOPBK and MASTER are discussed in [18.3.2.14 Local Loopback](#) and [18.3.3.3 Master Mode](#) respectively.

**Table 18.2. USART Pin Usage**

SYNC	LOOPBK	MASTER	Pin functionality			
			U(S)n_TX (MOSI)	U(S)n_RX (MISO)	USn_CLK	USn_CS
0	0	x	Data out	Data in	-	[Driver enable]
0	1	x	Data out/in	-	-	[Driver enable]
1	0	0	Data in	Data out	Clock in	Slave select
1	0	1	Data out	Data in	Clock out	[Auto slave select]
1	1	0	Data out/in	-	Clock in	Slave select
1	1	1	Data out/in	-	Clock out	[Auto slave select]

### 18.3.2 Asynchronous Operation

### 18.3.2.1 Frame Format

The frame format used in asynchronous mode consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 4 to 16 data bits and an optional parity bit. Finally, a number of stop-bits, where the line is driven high, end the frame. An example frame is shown in [Figure 18.2 USART Asynchronous Frame Format on page 487](#).

**Figure 18.2. USART Asynchronous Frame Format**

The number of data bits in a frame is set by DATABITS in USARTn\_FRAME, see [Table 18.3 USART Data Bits on page 487](#), and the number of stop-bits is set by STOPBITS in USARTn\_FRAME, see [Table 18.4 USART Stop Bits on page 487](#). Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY, also in USARTn\_FRAME. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

**Table 18.3. USART Data Bits**

DATA BITS [3:0]	Number of Data bits
0001	4
0010	5
0011	6
0100	7
0101	8 (Default)
0110	9
0111	10
1000	11
1001	12
1010	13
1011	14
1100	15
1101	16

**Table 18.4. USART Stop Bits**

STOP BITS [1:0]	Number of Stop bits
00	0.5
01	1 (Default)
10	1.5
11	2

The order in which the data bits are transmitted and received is defined by MSBF in USARTn\_CTRL. When MSBF is cleared, data in a frame is sent and received with the least significant bit first. When it is set, the most significant bit comes first.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn\_CTRL, and the format expected by the receiver can be inverted by setting RXINV in USARTn\_CTRL. These bits affect the entire frame, not only the data bits. An inverted frame has a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits.

### 18.3.2.2 Parity bit Calculation and Handling

When parity bits are enabled, hardware automatically calculates and inserts any parity bits into outgoing frames, and verifies the received parity bits in incoming frames. This is true for both asynchronous and synchronous modes, even though it is mostly used in asynchronous communication. The possible parity modes are defined in [Table 18.5 USART Parity Bits on page 488](#). When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd.

**Table 18.5. USART Parity Bits**

STOP BITS [1:0]	Description
00	No parity bit (Default)
01	Reserved
10	Even parity
11	Odd parity

### 18.3.2.3 Clock Generation

The USART clock defines the transmission and reception data rate. When operating in asynchronous mode, the baud rate (bit-rate) is given by [Figure 18.3 USART Baud Rate on page 489](#).

$$br = f_{H\text{FPERCLK}} / (\text{oversample} \times (1 + \text{USARTn\_CLKDIV}/256))$$

**Figure 18.3. USART Baud Rate**

where  $f_{H\text{FPERCLK}}$  is the peripheral clock ( $H\text{FPERCLK}_{\text{USARTn}}$ ) frequency and oversample is the oversampling rate as defined by OVS in  $\text{USARTn\_CTRL}$ , see [Table 18.6 USART Oversampling on page 489](#).

**Table 18.6. USART Oversampling**

OVS [1:0]	oversample
00	16
01	8
10	6
11	4

The USART has a fractional clock divider to allow the USART clock to be controlled more accurately than what is possible with a standard integral divider.

The clock divider used in the USART is a 20-bit value, with a 15-bit integral part and an 5-bit fractional part. The fractional part is configured in the lower 5 bits of DIV in  $\text{USART\_CLKDIV}$ . The lowest achievable baud rate at 32 MHz is about 61 bauds/sec.

Fractional clock division is implemented by distributing the selected fraction over thirty two baud periods. The fractional part of the divider tells how many of these periods should be extended by one peripheral clock cycle.

Given a desired baud rate  $br_{\text{desired}}$ , the clock divider  $\text{USARTn\_CLKDIV}$  can be calculated by using [Figure 18.4 USART Desired Baud Rate on page 489](#):

$$\text{USARTn\_CLKDIV} = 256 \times (f_{H\text{FPERCLK}} / (\text{oversample} \times br_{\text{desired}}) - 1)$$

**Figure 18.4. USART Desired Baud Rate**

[Table 18.7 USART Baud Rates @ 4MHz Peripheral Clock with 20 bit CLKDIV on page 489](#) shows a set of desired baud rates and how accurately the USART is able to generate these baud rates when running at a 4 MHz peripheral clock, using 16x or 8x oversampling.

**Table 18.7. USART Baud Rates @ 4MHz Peripheral Clock with 20 bit CLKDIV**

Desired baud rate [baud/s]	USARTn_OVS =00			USARTn_OVS =01		
	USARTn_CLKDIV/256 (to 32nd position)	Actual baud rate [baud/s]	Error %	USARTn_CLKDIV/256 (to 32nd position)	Actual baud rate [baud/s]	Error %
600	415,6563	600,015	0,003	832,3438	599,9925	-0,001
1200	207,3438	1199,94	-0,005	415,6563	1200,03	0,003
2400	103,1563	2400,24	0,010	207,3438	2399,88	-0,005
4800	51,09375	4799,04	-0,020	103,1563	4800,48	0,010
9600	25,03125	9603,842	0,040	51,09375	9598,08	-0,020

38400	5,5	38461,54	0,160	12,03125	38369,3	-0,080

Desired baud rate [baud/s]	USARTn_OVS =00			USARTn_OVS =01		
	USARTn_CLKDIV/256 (to 32nd position)	Actual baud rate [baud/s]	Error %	USARTn_CLKDIV/256 (to 32nd position)	Actual baud rate [baud/s]	Error %
57600	3,34375	57553,96	-0,080	7,6875	57553,96	-0,080
76800	2,25	76923,08	0,160	5,5	76923,08	0,160
115200	1,15625	115942	0,644	3,34375	115107,9	-0,080
230400	0,09375	228571,4	-0,794	1,15625	231884,1	0,644

#### 18.3.2.4 Auto Baud Detection

Setting AUTOBAUDEN in USARTn\_CLKDIV uses the first frame received to automatically set the baud rate provided that it contains 0x55 (IrDA uses 0x00). AUTOBAUDEN can be used in a simple LIN configuration to auto detect the SYNC byte. The receiver will measure the number of local clock cycles between the beginning of the START bit and the beginning of the 8th data bit. The DIV field in USARTn\_CLKDIV will be overwritten with the new value. The OVS in USARTn\_CTRL and the +1 count of the Baud Rate equation are already factored into the result that gets written into the DIV field. To restart autobaud detection, clear AUTOBAUDEN and set it high again. Since the auto baud detection is done over 8 baud times, only the upper 3 bits of the fractional part of the clock divider are populated.

#### 18.3.2.5 Data Transmission

Asynchronous data transmission is initiated by writing data to the transmit buffer using one of the methods described in [18.3.2.6 Transmit Buffer Operation](#). When the transmission shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available.

Transmission is enabled through the command register USARTn\_CMD by setting TXEN, and disabled by setting TXDIS in the same command register. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in USARTn\_STATUS.

When the USART transmitter is enabled and there is no data in the transmit shift register or transmit buffer, the TXC flag in USARTn\_STATUS and the TXC interrupt flag in USARTn\_IF are set, signaling that the transmission is complete. The TXC status flag is cleared when a new frame becomes available for transmission, but the TXC interrupt flag must be cleared by software.

### 18.3.2.6 Transmit Buffer Operation

The transmit-buffer is a multiple entry FIFO buffer. A frame can be loaded into the buffer by writing to USARTn\_TXDATA, USARTn\_TXDATAx, USARTn\_TXDOUBLE or USARTn\_TXDOUBLEX. Using USARTn\_TXDATA allows 8 bits to be written to the buffer, while using USARTn\_TXDOUBLE will write 2 frames of 8 bits to the buffer. If 9-bit frames are used, the 9th bit of the frames will in these cases be set to the value of BIT8DV in USARTn\_CTRL.

To set the 9th bit directly and/or use transmission control, USARTn\_TXDATAx and USARTn\_TXDOUBLEX must be used. USARTn\_TXDATAx allows 9 data bits to be written, as well as a set of control bits regarding the transmission of the written frame. Every frame in the buffer is stored with 9 data bits and additional transmission control bits. USARTn\_TXDOUBLEX allows two frames, complete with control bits to be written at once. When data is written to the transmit buffer using USARTn\_TXDATAx and USARTn\_TXDOUBLEX, the 9th bit(s) written to these registers override the value in BIT8DV in USARTn\_CTRL, and alone define the 9th bits that are transmitted if 9-bit frames are used. [Figure 18.5 USART Transmit Buffer Operation on page 491](#) shows the basics of the transmit buffer when DATABITS in USARTn\_FRAME is configured to less than 10 bits.

**Figure 18.5. USART Transmit Buffer Operation**

When writing more frames to the transmit buffer than there is free space for, the TXOF interrupt flag in USARTn\_IF will be set, indicating the overflow. The data already in the transmit buffer is preserved in this case, and no data is written.

In addition to the interrupt flag TXC in USARTn\_IF and status flag TXC in USARTn\_STATUS which are set when the transmission is complete, TXBL in USARTn\_STATUS and the TXBL interrupt flag in USARTn\_IF are used to indicate the level of the transmit buffer. TXBIL in USARTn\_CTRL controls the level at which these bits are set. If TXBIL is cleared, they are set whenever the transmit buffer becomes empty, and if TXBIL is set, they are set whenever the transmit buffer goes from full to half-full or empty. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when their condition becomes false.

There is a TXIDLE status bit in USARTn\_STATUS to provide an indication of when the transmitter is idle. The combined count of TX buffer element 0, TX buffer element 1, and TX shift register is called TXBUFCNT in USARTn\_STATUS. For large frames, the count is only of TX buffer entry 0 and the TX shifter register.

The transmit buffer, including the transmit shift register can be cleared by setting CLEARTX in USARTn\_CMD. This will prevent the USART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed.

### 18.3.2.7 Frame Transmission Control

The transmission control bits, which can be written using USARTn\_TXDATAx and USARTn\_TXDOUBLEX, affect the transmission of the written frame. The following options are available:

- **Generate break:** By setting TXBREAK, the output will be held low during the stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than a USART frame are thus not supported by the USART. GPIO can be used for this.
- **Disable transmitter after transmission:** If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- **Enable receiver after transmission:** If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.
- **Unblock receiver after transmission:** If UBRXAT is set, the receiver is unblocked and RXBLOCK is cleared after the frame has been fully transmitted.
- **Tristate transmitter after transmission:** If TXTRIAT is set, TXTRI is set after the frame has been fully transmitted, tristating the transmitter output. Tristating of the output can also be performed automatically by setting AUTOTRI. If AUTOTRI is set TXTRI is always read as 0.

#### Note:

When in SmartCard mode with repeat enabled, none of the actions, except generate break, will be performed until the frame is transmitted without failure. Generation of a break in SmartCard mode with repeat enabled will cause the USART to detect a NACK on every frame.

### 18.3.2.8 Data Reception

Data reception is enabled by setting RXEN in USARTn\_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start baud of a new frame. When a start baud is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start baud. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available. If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the shift register is overwritten, and the RXOF interrupt flag in USARTn\_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in USARTn\_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in USARTn\_STATUS.

### 18.3.2.9 Receive Buffer Operation

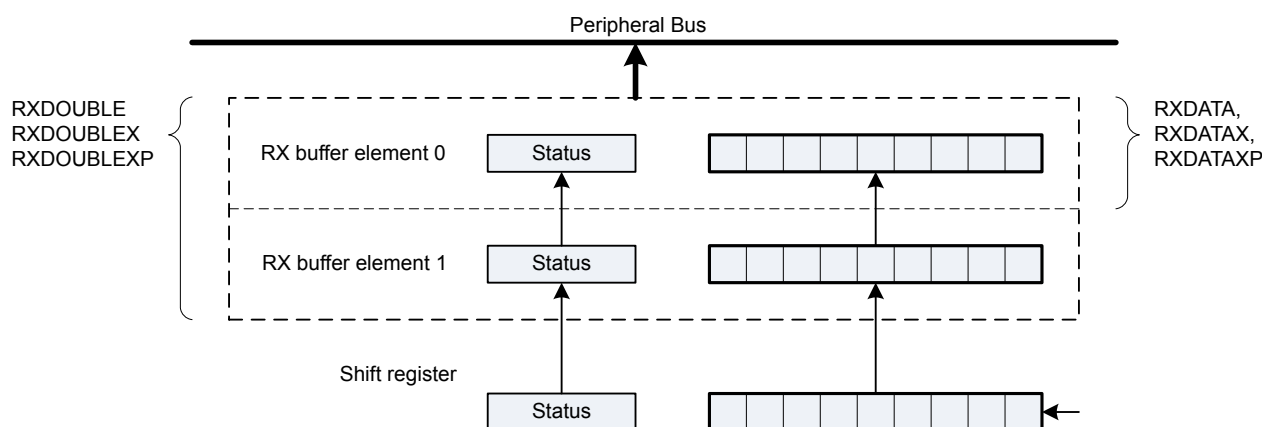

When data becomes available in the receive buffer, the RXDATAV flag in USARTn\_STATUS, and the RXDATAV interrupt flag in USARTn\_IF are set, and when the buffer becomes full, RXFULL in USARTn\_STATUS and the RXFULL interrupt flag in USARTn\_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more frame.

Data can be read from the receive buffer in a number of ways. USARTn\_RXDATA gives access to the 8 least significant bits of the received frame, and USARTn\_RXDOUBLE makes it possible to read the 8 least significant bits of two frames at once, pulling two frames from the buffer. To get access to the 9th, most significant bit, USARTn\_RXDATA9 must be used. This register also contains status information regarding the frame. USARTn\_RXDOUBLE9 can be used to get two frames complete with the 9th bits and status bits.

When a frame is read from the receive buffer using USARTn\_RXDATA or USARTn\_RXDATA9, the frame is pulled out of the buffer, making room for a new frame. USARTn\_RXDOUBLE and USARTn\_RXDOUBLE9 pull two frames out of the buffer. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in USARTn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can be read from the receive buffer without removing the data by using USARTn\_RXDATA9 and USARTn\_RXDOUBLE9. USARTn\_RXDATA9 gives access the first frame in the buffer with status bits, while USARTn\_RXDOUBLE9 gives access to both frames with status bits. The data read from these registers when the receive buffer is empty is undefined. If the receive buffer contains one valid frame, the first frame in USARTn\_RXDOUBLE9 will be valid. No underflow interrupt is generated by a read using these registers, i.e. RXUF in USARTn\_IF is never set as a result of reading from USARTn\_RXDATA9 or USARTn\_RXDOUBLE9.

The basic operation of the receive buffer when DATABITS in USARTn\_FRAME is configured to less than 10 bits is shown in [Figure 18.6 USART Receive Buffer Operation on page 493](#).

**Figure 18.6. USART Receive Buffer Operation**

The receive buffer, including the receive shift register can be cleared by setting CLEARRX in USARTn\_CMD. Any frame currently being received will not be discarded.

### 18.3.2.10 Blocking Incoming Data

When using hardware frame recognition, as detailed in [18.3.2.20 Multi-Processor Mode](#) and [18.3.2.21 Collision Detection](#), it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in USARTn\_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV flag in USARTn\_STATUS or the RXDATAV interrupt flag in USARTn\_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in USARTn\_CMD and disabled by setting RXBLOCKDIS also in USARTn\_CMD. There is one exception where data is loaded into the receive buffer even when RXBLOCK is set. This is when an address frame is received when operating in multi-processor mode. See [18.3.2.20 Multi-Processor Mode](#) for more information.

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in USARTn\_IF being set while RXBLOCK in USARTn\_STATUS is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

**Note:**

If a frame is received while RXBLOCK in USARTn\_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time.

The overflow interrupt flag RXOF in USARTn\_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK in USARTn\_STATUS is set.

### 18.3.2.11 Clock Recovery and Filtering

The receiver samples the incoming signal at a rate 16, 8, 6 or 4 times higher than the given baud rate, depending on the oversampling mode given by OVS in USARTn\_CTRL. Lower oversampling rates make higher baud rates possible, but give less room for errors.

When a high-to-low transition is registered on the input while the receiver is idle, this is recognized as a start-bit, and the baud rate generator is synchronized with the incoming frame.

For oversampling modes 16, 8 and 6, every bit in the incoming frame is sampled three times to gain a level of noise immunity. These samples are aimed at the middle of the bit-periods, as visualized in [Figure 18.7 USART Sampling of Start and Data Bits on page 495](#). With OVS=0 in USARTn\_CTRL, the start and data bits are thus sampled at locations 8, 9 and 10 in the figure, locations 4, 5 and 6 for OVS=1 and locations 3, 4, and 5 for OVS=2. The value of a sampled bit is determined by majority vote. If two or more of the three bit-samples are high, the resulting bit value is high. If the majority is low, the resulting bit value is low.

Majority vote is used for all oversampling modes except 4x oversampling. In this mode, a single sample is taken at position 3 as shown in [Figure 18.7 USART Sampling of Start and Data Bits on page 495](#).

Majority vote can be disabled by setting MVDIS in USARTn\_CTRL.

If the value of the start bit is found to be high, the reception of the frame is aborted, filtering out false start bits possibly generated by noise on the input.

**Figure 18.7. USART Sampling of Start and Data Bits**

If the baud rate of the transmitter and receiver differ, the location each bit is sampled will be shifted towards the previous or next bit in the frame. This is acceptable for small errors in the baud rate, but for larger errors, it will result in transmission errors.

When the number of stop bits is 1 or more, stop bits are sampled like the start and data bits as seen in [Figure 18.8 USART Sampling of Stop Bits when Number of Stop Bits are 1 or More on page 496](#). When a stop bit has been detected by sampling at positions 8, 9 and 10 for normal mode, or 4, 5 and 6 for smart mode, the USART is ready for a new start bit. As seen in [Figure 18.8 USART Sampling of Stop Bits when Number of Stop Bits are 1 or More on page 496](#), a stop-bit of length 1 normally ends at c, but the next frame will be received correctly as long as the start-bit comes after position a for OVS=0 and OVS=3, and b for OVS=1 and OVS=2.

**Figure 18.8. USART Sampling of Stop Bits when Number of Stop Bits are 1 or More**

When working with stop bit lengths of half a baud period, the above sampling scheme no longer suffices. In this case, the stop-bit is not sampled, and no framing error is generated in the receiver if the stop-bit is not generated. The line must still be driven high before the next start bit however for the USART to successfully identify the start bit.

#### 18.3.2.12 Parity Error

When parity bits are enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in an incoming frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR in USARTn\_IF. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the USARTn\_RXDATA, USARTn\_RXDATAEXP, USARTn\_RXDOUBLEX or USARTn\_RXDOUBLEXP registers.

If ERRSTX in USARTn\_CTRL is set, the transmitter is disabled on received parity and framing errors. If ERRSRX in USARTn\_CTRL is set, the receiver is disabled on parity and framing errors.

#### 18.3.2.13 Framing Error and Break Detection

A framing error is the result of an asynchronous frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected in an incoming frame, the framing error bit FERR in the frame is set. The interrupt flag FERR in USARTn\_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the USARTn\_RXDATA, USARTn\_RXDATAEXP, USARTn\_RXDOUBLEX or USARTn\_RXDOUBLEXP registers.

If ERRSTX in USARTn\_CTRL is set, the transmitter is disabled on parity and framing errors. If ERRSRX in USARTn\_CTRL is set, the receiver is disabled on parity and framing errors.

### 18.3.2.14 Local Loopback

The USART receiver samples U(S)n\_RX by default, and the transmitter drives U(S)n\_TX by default. This is not the only option however. When LOOPBK in USARTn\_CTRL is set, the receiver is connected to the U(S)n\_TX pin as shown in [Figure 18.9 USART Local Loopback on page 497](#). This is useful for debugging, as the USART can receive the data it transmits, but it is also used to allow the USART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the U(S)n\_TX pin must be enabled as an output in the GPIO.

Figure 18.9. USART Local Loopback

### 18.3.2.15 Asynchronous Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

### 18.3.2.16 Single Data-link

In this setup, the USART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in USARTn\_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the USART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. This is done by setting the command bit TXTRIEN in USARTn\_CMD, which tristates the transmitter. Before transmitting data, the command bit TXTRIDIS, also in USARTn\_CMD, must be set to enable transmitter output again. Whether or not the output is tristated at a given time can be read from TXTRI in USARTn\_STATUS. If TXTRI is set when transmitting data, the data is shifted out of the shift register, but is not put out on U(S)n\_TX.

When operating a half duplex data bus, it is common to have a bus master, which first transmits a request to one of the bus slaves, then receives a reply. In this case, the frame transmission control bits, which can be set by writing to USARTn\_TXDATAx, can be used to make the USART automatically disable transmission, tristate the transmitter and enable reception when the request has been transmitted, making it ready to receive a response from the slave.

The timer, [18.3.10 Timer](#), can also be used to add delay between the RX and TX frames so that the interrupt service routine has time to process data that was just received before transmitting more data. Also hardware flow control is another method to insert time for processing the frame. RTS and CTS can be used to halt either the link partner's transmitter or the local transmitter. See the section on hardware flow control, [18.3.4 Hardware Flow Control](#), for more details.

Tristating the transmitter can also be performed automatically by the USART by using AUTOTRI in USARTn\_CTRL. When AUTOTRI is set, the USART automatically tristates U(S)n\_TX whenever the transmitter is idle, and enables transmitter output when the transmitter goes active. If AUTOTRI is set TXTRI is always read as 0.

#### Note:

Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

### 18.3.2.17 Single Data-link with External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of tristating the transmitter when receiving data, the external driver must be disabled.

This can be done manually by assigning a GPIO to turn the driver on or off, or it can be handled automatically by the USART. If AUTOCS in USARTn\_CTRL is set, the USn\_CS output is automatically activated a configurable number of baud periods before the transmitter starts transmitting data, and deactivated a configurable number of baud periods after the last bit has been transmitted and there is no more data in the transmit buffer to transmit. The number of baud periods are controlled by CSSETUP and CSHOLD in USARTn\_TIMING. This feature can be used to turn the external driver on when transmitting data, and turn it off when the data has been transmitted.

The timer, [18.3.10 Timer](#), can also be used to configure CSSETUP and CSHOLD values between 1 to 256 baud-times by using TCMVAL0, TCMVAL1, or TCMVAL2 for the TX sequencer.

USn\_CS is immediately deasserted when the transmitter becomes disabled.

[Figure 18.10 USART Half Duplex Communication with External Driver on page 498](#) shows an example configuration where USn\_CS is used to automatically enable and disable an external driver.

**Figure 18.10. USART Half Duplex Communication with External Driver**

The USn\_CS output is active low by default, but its polarity can be changed with CSINV in USARTn\_CTRL. AUTOCS works regardless of which mode the USART is in, so this functionality can also be used for automatic chip/slave select when in synchronous mode (e.g. SPI).

### 18.3.2.18 Two Data-links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

TXARXnEN in USARTn\_TRIGCTRL may be used to automatically start transmission after the end of the RX frame plus any TXSTDELAY and CSSETUP delay in USARTn\_TIMING. For enabling the receiver either use RXENAT in USARTn\_TXDATA or RXATXnEN in USARTn\_TRIGCTRL.

18.3.2.19 Large Frames

As each frame in the transmit and receive buffers holds a maximum of 9 bits, both the elements in the buffers are combined when working with USART-frames of 10 or more data bits.

To transmit such a frame, at least two elements must be available in the transmit buffer. If only one element is available, the USART will wait for the second element before transmitting the combined frame. Both the elements making up the frame are consumed when transmitting such a frame.

When using large frames, the 9th bits in the buffers are unused. For an 11 bit frame, the 8 least significant bits are thus taken from the first element in the buffer, and the 3 remaining bits are taken from the second element as shown in [Figure 18.11 USART Transmission of Large Frames on page 499](#). The first element in the transmit buffer, i.e. element 0 in [Figure 18.11 USART Transmission of Large Frames on page 499](#) is the first element written to the FIFO, or the least significant byte when writing two bytes at a time using USARTn\_TXDOUBLE.

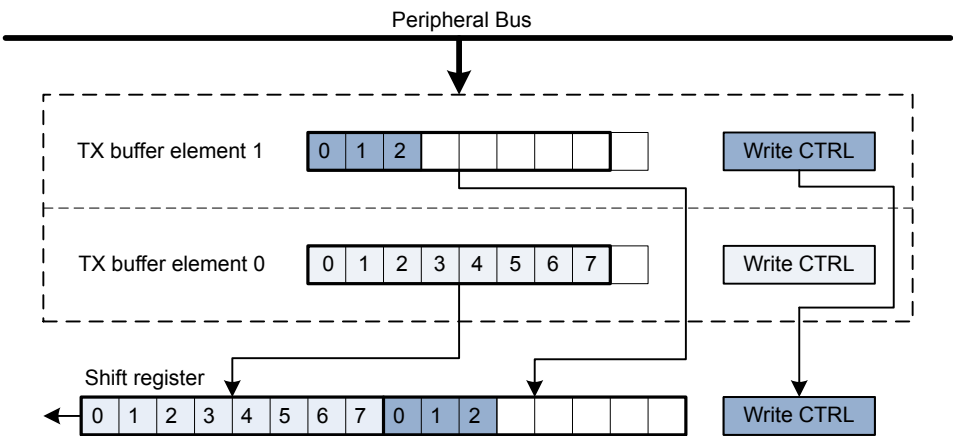

Figure 18.11. USART Transmission of Large Frames

As shown in [Figure 18.11 USART Transmission of Large Frames on page 499](#), frame transmission control bits are taken from the second element in FIFO.

The two buffer elements can be written at the same time using the USARTn\_TXDOUBLE or USARTn\_TXDOUBLEX register. The TXDATAx0 bitfield then refers to buffer element 0, and TXDATAx1 refers to buffer element 1.

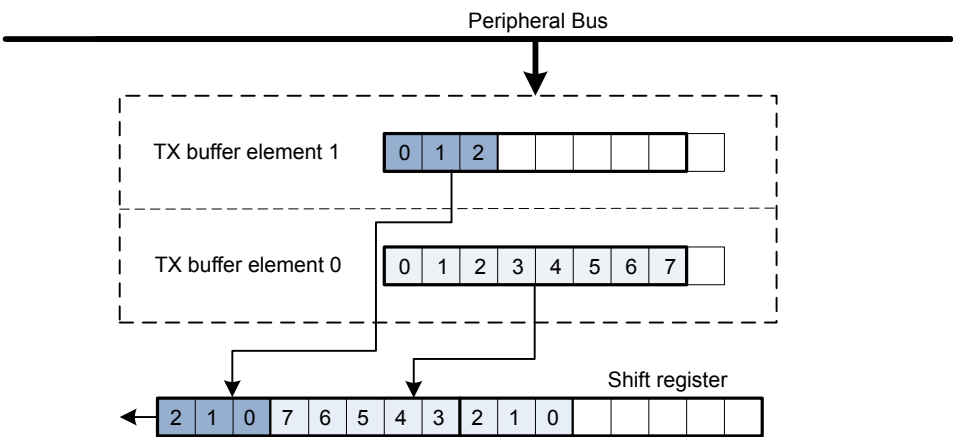

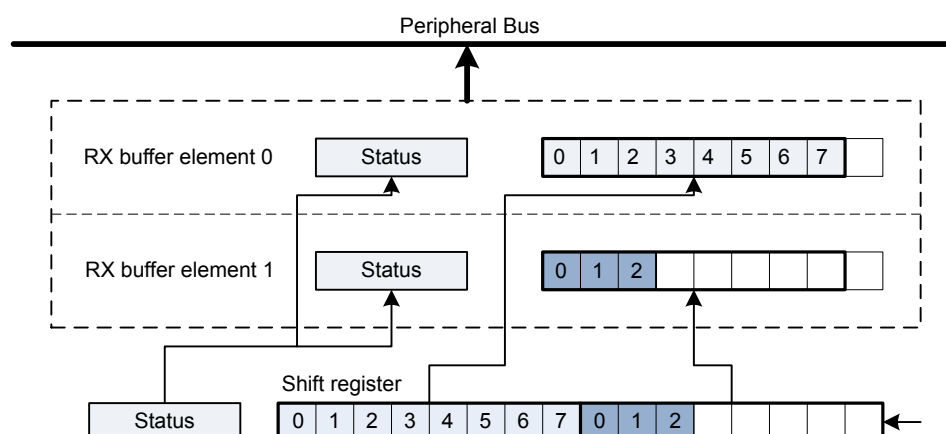

Figure 18.12. USART Transmission of Large Frames, MSBF

[Figure 18.12 USART Transmission of Large Frames, MSBF on page 499](#) illustrates the order of the transmitted bits when an 11 bit frame is transmitted with MSBF set. If MSBF is set and the frame is smaller than 10 bits, only the contents of transmit buffer 0 will be transmitted.

When receiving a large frame, BYTESWAP in USARTn\_CTRL determines the order the way the large frame is split into the two buffer elements. If BYTESWAP is cleared, the least significant 8 bits of the received frame are loaded into the first element of the receive buffer, and the remaining bits are loaded into the second element, as shown in [Figure 18.13 USART Reception of Large Frames on page 500](#). The first byte read from the buffer thus contains the 8 least significant bits. Set BYTESWAP to reverse the order.

The status bits are loaded into both elements of the receive buffer. The frame is not moved from the receive shift register before there are two free spaces in the receive buffer.

**Figure 18.13. USART Reception of Large Frames**

The two buffer elements can be read at the same time using the USARTn\_RXDOUBLE or USARTn\_RXDOUBLEX register. RXDATA0 then refers to buffer element 0 and RXDATA1 refers to buffer element 1.

Large frames can be used in both asynchronous and synchronous modes.

### 18.3.2.20 Multi-Processor Mode

To simplify communication between multiple processors, the USART supports a special multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in USARTn\_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in USARTn\_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in USARTn\_STATUS.

Multi-processor mode is enabled by setting MPM in USARTn\_CTRL, and the value of the 9th bit in address frames can be set in MPAB. Note that the receiver must be enabled for address frames to be detected. The receiver can be blocked however, preventing data from being loaded into the receive buffer while looking for address frames.

Figure 18.14 USART Multi-processor Mode Example on page 501 explains basic usage of the multi-processor mode:

1. All slaves enable multi-processor mode and, enable and block the receiver. They will now not receive data unless it is an address frame. MPAB in USARTn\_CTRL is set to identify frames with the 9th bit high as address frames.
2. The master sends a frame containing the address of a slave and with the 9th bit set
3. All slaves receive the address frame and get an interrupt. They can read the address from the receive buffer. The selected slave unblocks the receiver to start receiving data from the master.
4. The master sends data with the 9th bit cleared
5. Only the slave with RX enabled receives the data. When transmission is complete, the slave blocks the receiver and waits for a new address frame.

**Figure 18.14. USART Multi-processor Mode Example**

When a slave has received an address frame and wants to receive the following data, it must make sure the receiver is unblocked before the next frame has been completely received in order to prevent data loss.

BIT8DV in USARTn\_CTRL can be used to specify the value of the 9th bit without writing to the transmit buffer with USARTn\_TXDATA or USARTn\_TXDOUBLEX, giving higher efficiency in multi-processor mode, as the 9th bit is only set when writing address frames, and 8-bit writes to the USART can be used when writing the data frames.

### 18.3.2.21 Collision Detection

The USART supports a basic form of collision detection. When the receiver is connected to the output of the transmitter, either by using the LOOPBK bit in USARTn\_CTRL or through an external connection, this feature can be used to detect whether data transmitted on the bus by the USART did get corrupted by a simultaneous transmission by another device on the bus.

For collision detection to be enabled, CCEN in USARTn\_CTRL must be set, and the receiver enabled. The data sampled by the receiver is then continuously compared with the data output by the transmitter. If they differ, the CCF interrupt flag in USARTn\_IF is set. The collision check includes all bits of the transmitted frames. The CCF interrupt flag is set once for each bit sampled by the receiver that differs from the bit output by the transmitter. When the transmitter output is disabled, i.e. the transmitter is tristated, collisions are not registered.

### 18.3.2.22 SmartCard Mode

In SmartCard mode, the USART supports the ISO 7816 I/O line T0 mode. With exception of the stop-bits (guard time), the 7816 data frame is equal to the regular asynchronous frame. In this mode, the receiver pulls the line low for one baud, half a baud into the guard time to indicate a parity error. This NAK can for instance be used by the transmitter to re-transmit the frame. SmartCard mode is a half duplex asynchronous mode, so the transmitter must be tristated whenever not transmitting data.

To enable SmartCard mode, set SCMODE in USARTn\_CTRL, set the number of databits in a frame to 8, and configure the number of stopbits to 1.5 by writing to STOPBITS in USARTn\_FRAME.

The SmartCard mode relies on half duplex communication on a single line, so for it to work, both the receiver and transmitter must work on the same line. This can be achieved by setting LOOPBK in USARTn\_CTRL or through an external connection. The TX output should be configured as open-drain in the GPIO module.

When no parity error is identified by the receiver, the data frame is as shown in [Figure 18.15 USART ISO 7816 Data Frame Without Error on page 502](#). The frame consists of 8 data bits, a parity bit, and 2 stop bits. The transmitter does not drive the output line during the guard time.

**Figure 18.15. USART ISO 7816 Data Frame Without Error**

If a parity error is detected by the receiver, it pulls the line I/O line low after half a stop bit, see [Figure 18.16 USART ISO 7816 Data Frame With Error on page 502](#). It holds the line low for one bit-period before it releases the line. In this case, the guard time is extended by one bit period before a new transmission can start, resulting in a total of 3 stop bits.

**Figure 18.16. USART ISO 7816 Data Frame With Error**

On a parity error, the NAK is generated by hardware. The NAK generated by the receiver is sampled as the stop-bit of the frame. Because of this, parity errors when in SmartCard mode are reported with both a parity error and a framing error.

When transmitting a T0 frame, the USART receiver on the transmitting side samples position 16, 17 and 18 in the stop-bit to detect the error signal when in 16x oversampling mode as shown in [Figure 18.17 USART SmartCard Stop Bit Sampling on page 503](#). Sampling at this location places the stop-bit sample in the middle of the bit-period used for the error signal (NAK).

If a NAK is transmitted by the receiver, it will thus appear as a framing error at the transmitter, and the FERR interrupt flag in USARTn\_IF will be set. If SCRETRANS USARTn\_CTRL is set, the transmitter will automatically retransmit a NACK'ed frame. The transmitter will retransmit the frame until it is ACK'ed by the receiver. This only works when the number of databits in a frame is configured to 8.

Set SKIPPERF in USARTn\_CTRL to make the receiver discard frames with parity errors. The PERR interrupt flag in USARTn\_IF is set when a frame is discarded because of a parity error.

**Figure 18.17. USART SmartCard Stop Bit Sampling**

For communication with a SmartCard, a clock signal needs to be generated for the card. This clock output can be generated using one of the timers. See the ISO 7816 specification for more info on this clock signal.

SmartCard T1 mode is also supported. The T1 frame format used is the same as the asynchronous frame format with parity bit enabled and one stop bit. The USART must then be configured to operate in asynchronous half duplex mode.

18.3.3 Synchronous Operation

Most of the features in asynchronous mode are available in synchronous mode. Multi-processor mode can be enabled for 9-bit frames, loopback is available and collision detection can be performed.

18.3.3.1 Frame Format

The frames used in synchronous mode need no start and stop bits since a single clock is available to all parts participating in the communication. Parity bits cannot be used in synchronous mode.

The USART supports frame lengths of 4 to 16 bits per frame. Larger frames can be simulated by transmitting multiple smaller frames, i.e. a 22 bit frame can be sent using two 11-bit frames, and a 21 bit frame can be generated by transmitting three 7-bit frames. The number of bits in a frame is set using DATABITS in USARTn\_FRAME.

The frames in synchronous mode are by default transmitted with the least significant bit first like in asynchronous mode. The bit-order can be reversed by setting MSBF in USARTn\_CTRL.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn\_CTRL, and the format expected by the receiver can be inverted by setting RXINV, also in USARTn\_CTRL.

### 18.3.3.2 Clock Generation

The bit-rate in synchronous mode is given by [Figure 18.18 USART Synchronous Mode Bit Rate on page 504](#). As in the case of asynchronous operation, the clock division factor have a 15-bit integral part and a 5-bit fractional part.

$$br = f_{HPERCLK} / (2 \times (1 + USARTn\_CLKDIV/256))$$

**Figure 18.18. USART Synchronous Mode Bit Rate**

Given a desired baud rate  $br_{desired}$ , the clock divider  $USARTn\_CLKDIV$  can be calculated using [Figure 18.19 USART Synchronous Mode Clock Division Factor on page 504](#)

$$USARTn\_CLKDIV = 256 \times (f_{HPERCLK} / (2 \times br_{desired}) - 1)$$

**Figure 18.19. USART Synchronous Mode Clock Division Factor**

When the USART operates in master mode, the highest possible bit rate is half the peripheral clock rate. When operating in slave mode however, the highest bit rate is an eighth of the peripheral clock:

- Master mode:  $br_{max} = f_{HPERCLK}/2$
- Slave mode:  $br_{max} = f_{HPERCLK}/8$

On every clock edge data on the data lines, MOSI and MISO, is either set up or sampled. When  $CLKPHA$  in  $USARTn\_CTRL$  is cleared, data is sampled on the leading clock edge and set-up is done on the trailing edge. If  $CLKPHA$  is set however, data is set-up on the leading clock edge, and sampled on the trailing edge. In addition to this, the polarity of the clock signal can be changed by setting  $CLKPOL$  in  $USARTn\_CTRL$ , which also defines the idle state of the clock. This results in four different modes which are summarized in [Table 18.8 USART SPI Modes on page 504](#). [Figure 18.20 USART SPI Timing on page 504](#) shows the resulting timing of data set-up and sampling relative to the bus clock.

**Table 18.8. USART SPI Modes**

SPI mode	CLKPOL	CLKPHA	Leading edge	Trailing edge
0	0	0	Rising, sample	Falling, set-up
1	0	1	Rising, set-up	Falling, sample
2	1	0	Falling, sample	Rising, set-up
3	1	1	Falling, set-up	Rising, sample

**Figure 18.20. USART SPI Timing**

If CPHA=1, the TX underflow flag, TXUF, will be set on the first setup clock edge of a frame in slave mode if TX data is not available. If CPHA=0, TXUF is set if data is not available in the transmit buffer three HPERCLK cycles prior to the first sample clock edge. The RXDATAV flag is updated on the last sample clock edge of a transfer, while the RX overflow interrupt flag, RXOF, is set on the first sample clock edge if the receive buffer overflows. When a transfer has been performed, interrupt flags TXBL and TXC are updated on the first setup clock edge of the succeeding frame, or when CS is deasserted.

### 18.3.3.3 Master Mode

When in master mode, the USART is in full control of the data flow on the synchronous bus. When operating in full duplex mode, the slave cannot transmit data to the master without the master transmitting to the slave. The master outputs the bus clock on USn\_CLK.

Communication starts whenever there is data in the transmit buffer and the transmitter is enabled. The USART clock then starts, and the master shifts bits out from the transmit shift register using the internal clock.

When there are no more frames in the transmit buffer and the transmit shift register is empty, the clock stops, and communication ends. When the receiver is enabled, it samples data using the internal clock when the transmitter transmits data. Operation of the RX and TX buffers is as in asynchronous mode.

### 18.3.3.4 Operation of USn\_CS Pin

When operating in master mode, the USn\_CS pin can have one of two functions, or it can be disabled.

If USn\_CS is configured as an output, it can be used to automatically generate a chip select for a slave by setting AUTOCS in USARTn\_CTRL. If AUTOCS is set, USn\_CS is activated before a transmission begins, and deactivated after the last bit has been transmitted and there is no more data in the transmit buffer.

The time between when CS is asserted and the first bit is transmitted can be controlled using the USART Timer and with CSSETUP in USARTn\_TIMING. Any of the three comparators can be used to set this delay. If new data is ready for transmission before CS is deasserted, the data is sent without deasserting CS in between. CSHOLD in USARTn\_TIMING keeps CS asserted after the end of frame for the number of baud-times specified.

By default, USn\_CS is active low, but its polarity can be inverted by setting CSINV in USARTn\_CTRL.

When USn\_CS is configured as an input, it can be used by another master that wants control of the bus to make the USART release it. When USn\_CS is driven low, or high if CSINV is set, the interrupt flag SSM in USARTn\_IF is set, and if CSMA in USARTn\_CTRL is set, the USART goes to slave mode.

### 18.3.3.5 AUTOTX

A synchronous master is required to transmit data to a slave in order to receive data from the slave. In some cases, only a few words are transmitted and a lot of data is then received from the slave. In that case, one solution is to keep feeding the TX with data to transmit, but that consumes system bandwidth. Instead AUTOTX can be used.

When AUTOTX in USARTn\_CTRL is set, the USART transmits data as long as there is available space in the RX shift register for the chosen frame size. This happens even though there is no data in the TX buffer. The TX underflow interrupt flag TXUF in USARTn\_IF is set on the first word that is transmitted which does not contain valid data.

During AUTOTX the USART will always send the previous sent bit, thus reducing the number of transitions on the TX output. So if the last bit sent was a 0, 0's will be sent during AUTOTX and if the last bit sent was a 1, 1's will be sent during AUTOTX.

### 18.3.3.6 Slave Mode

When the USART is in slave mode, data transmission is not controlled by the USART, but by an external master. The USART is therefore not able to initiate a transmission, and has no control over the number of bytes written to the master.

The output and input to the USART are also swapped when in slave mode, making the receiver take its input from USn\_TX (MOSI) and the transmitter drive USn\_RX (MISO).

To transmit data when in slave mode, the slave must load data into the transmit buffer and enable the transmitter. The data will remain in the USART until the master starts a transmission by pulling the USn\_CS input of the slave low and transmitting data. For every frame the master transmits to the slave, a frame is transferred from the slave to the master. After a transmission, MISO remains in the same state as the last bit transmitted. This also applies if the master transmits to the slave and the slave TX buffer is empty.

If the transmitter is enabled in synchronous slave mode and the master starts transmission of a frame, the underflow interrupt flag TXUF in USARTn\_IF will be set if no data is available for transmission to the master.

If the slave needs to control its own chip select signal, this can be achieved by clearing CSPEN in the ROUTE register. The internal chip select signal can then be controlled through CSINV in the CTRL register. The chip select signal will be CSINV inverted, i.e. if CSINV is cleared, the chip select is active and vice versa.

### 18.3.3.7 Synchronous Half Duplex Communication

Half duplex communication in synchronous mode is very similar to half duplex communication in asynchronous mode as detailed in [18.3.2.15 Asynchronous Half Duplex Communication](#). The main difference is that in this mode, the master must generate the bus clock even when it is not transmitting data, i.e. it must provide the slave with a clock to receive data. To generate the bus clock, the master should transmit data with the transmitter tristated, i.e. TXTRI in USARTn\_STATUS set, when receiving data. If 2 bytes are expected from the slave, then transmit 2 bytes with the transmitter tristated, and the slave uses the generated bus clock to transmit data to the master. TXTRI can be set by setting the TXTRIEN command bit in USARTn\_CMD.

#### Note:

When operating as SPI slave in half duplex mode, TX has to be tristated (not disabled) during data reception if the slave is to transmit data in the current transfer.

### 18.3.3.8 I2S

I2S is a synchronous format for transmission of audio data. The frame format is 32-bit, but since data is always transmitted with MSB first, an I2S device operating with 16-bit audio may choose to only process the 16 msb of the frame, and only transmit data in the 16 msb of the frame.

In addition to the bit clock used for regular synchronous transfers, I2S mode uses a separate word clock. When operating in mono mode, with only one channel of data, the word clock pulses once at the start of each new word. In stereo mode, the word clock toggles at the start of new words, and also gives away whether the transmitted word is for the left or right audio channel; A word transmitted while the word clock is low is for the left channel, and a word transmitted while the word clock is high is for the right.

When operating in I2S mode, the CS pin is used as a the word clock. In master mode, this is automatically driven by the USART, and in slave mode, the word clock is expected from an external master.

### 18.3.3.9 Word Format

The general I2S word format is 32 bits wide, but the USART also supports 16-bit and 8-bit words. In addition to this, it can be specified how many bits of the word should actually be used by the USART. These parameters are given by FORMAT in USARTn\_I2SCTRL.

As an example, configuring FORMAT to using a 32-bit word with 16-bit data will make each word on the I2S bus 32-bits wide, but when receiving data through the USART, only the 16 most significant bits of each word can be read out of the USART. Similarly, only the 16 most significant bits have to be written to the USART when transmitting. The rest of the bits will be transmitted as zeroes.

### 18.3.3.10 Major Modes

The USART supports a set of different I2S formats as shown in [Table 18.9 USART I2S Modes on page 507](#), but it is not limited to these modes. MONO, JUSTIFY and DELAY in USARTn\_I2SCTRL can be mixed and matched to create an appropriate format. MONO enables mono mode, i.e. one data stream instead of two which is the default. JUSTIFY aligns data within a word on the I2S bus, either left or right which can be seen in figures [Figure 18.23 USART Left-justified I2S waveform on page 508](#) and [Figure 18.24 USART Right-justified I2S waveform on page 508](#). Finally, DELAY specifies whether a new I2S word should be started directly on the edge of the word-select signal, or one bit-period after the edge.

**Table 18.9. USART I2S Modes**

Mode	MONO	JUSTIFY	DELAY	CLKPOL
Regular I2S	0	0	1	0
Left-Justified	0	0	0	1
Right-Justified	0	1	0	1
Mono	1	0	0	0

The regular I2S waveform is shown in [Figure 18.21 USART Standard I2S waveform on page 507](#) and [Figure 18.22 USART Standard I2S waveform \(reduced accuracy\) on page 507](#). The first figure shows a waveform transmitted with full accuracy. The wordlength can be configured to 32-bit, 16-bit or 8-bit using FORMAT in USARTn\_I2SCTRL. In the second figure, I2S data is transmitted with reduced accuracy, i.e. the data transmitted has less bits than what is possible in the bus format.

Note that the msb of a word transmitted in regular I2S mode is delayed by one cycle with respect to word select

**Figure 18.21. USART Standard I2S waveform**

**Figure 18.22. USART Standard I2S waveform (reduced accuracy)**

A left-justified stream is shown in [Figure 18.23 USART Left-justified I2S waveform on page 508](#). Note that the MSB comes directly after the edge on the word-select signal in contradiction to the regular I2S waveform where it comes one bit-period after.

**Figure 18.23. USART Left-justified I2S waveform**

A right-justified stream is shown in [Figure 18.24 USART Right-justified I2S waveform on page 508](#). The left and right justified streams are equal when the data-size is equal to the word-width.

**Figure 18.24. USART Right-justified I2S waveform**

In mono-mode, the word-select signal pulses at the beginning of each word instead of toggling for each word. Mono I2S waveform is shown in [Figure 18.25 USART Mono I2S waveform on page 508](#).

**Figure 18.25. USART Mono I2S waveform**

### 18.3.3.11 Using I2S Mode

When using the USART in I2S mode, DATABITS in USARTn\_FRAME must be set to 8 or 16 data-bits. 8 databits can be used in all modes, and 16 can be used in the modes where the number of bytes in the I2S word is even. In addition to this, MSBF in USARTn\_CTRL should be set, and CLKPOL and CLKPHA in USARTn\_CTRL should be cleared.

The USART does not have separate TX and RX buffers for left and right data, so when using I2S in stereo mode, the application must keep track of whether the buffers contain left or right data. This can be done by observing TXBLRIGHT, RXDATAVRIGHT and RXFULLRIGHT in USARTn\_STATUS. TXBLRIGHT tells whether TX is expecting data for the left or right channel. It will be set with TXBL if right data is expected. The receiver will set RXDATAVRIGHT if there is at least one right element in the buffer, and RXFULLRIGHT if the buffer is full of right elements.

When using I2S with DMA, separate DMA requests can be used for left and right data by setting DMASPLIT in USARTn\_I2SCTRL.

In both master and slave mode the USART always starts transmitting on the LEFT channel after being enabled. In master mode, the transmission will stop if TX becomes empty. In that case, TXC is set. Continuing the transmission in this case will make the data-stream continue where it left off. To make the USART start on the LEFT channel after going empty, disable and re-enable TX.

### 18.3.4 Hardware Flow Control

Hardware flow control can be used to hold off the link partner's transmission until RX buffer space is available. Use RTSPEN and CTSPEN in USARTn\_ROUTEEN to allocate the hardware flow control to GPIOs. RTS is an out going signal which indicates that RX buffer space is available to receive a frame. The link partner is being requested to send its data when RTS is asserted. CTS is an incoming signal to stop the next TX data from going out. When CTS is negated, the frame currently being transmitted is completed before stopping. CTS indicates that the link partner has RX buffer space available, and the local transmitter is clear to send. Also use CTSEN in USARTn\_CTRLX to enable the CTS input into the TX sequencer. For debug use set DBGHALT in USARTn\_CTRLX which will force the RTS to request one frame from the link partner when the CPU core single steps.

### 18.3.5 Debug Halt

When DBGHALT in USART\_CTRLX is clear, RTS is only dependent on the RX buffer having space available to receive data. Incoming data is always received until both the RX buffer is full and the RX shift register is full regardless of the state of DBGHALT or chip halt. Additional incoming data is discarded. When DBGHALT is set, RTS deasserts on RX buffer full or when chip halt is high. However, a low pulse detected on chip halt will keep RTS asserted when no frame is being received. At the start of frame reception, RTS will deassert if chip halt is high and DBGHALT is set. This behavior allows single stepping to pulse the chip halt low for a cycle, and receive the next frame. The link partner must stop transmitting when RTS is deasserted, or the RX buffer could overflow. All data in the transmit buffer is sent out even when chip halt is asserted; therefore, the DMA will need to be set to stop sending the USART TX data during chip halt.

### 18.3.6 PRS-triggered Transmissions

If a transmission must be started on an event with very little delay, the PRS system can be used to trigger the transmission. The PRS channel to use as a trigger can be selected using TSEL in USARTn\_TRIGCTRL. When a positive edge is detected on this signal, the receiver is enabled if RXTEN in USARTn\_TRIGCTRL is set, and the transmitter is enabled if TXTEN in USARTn\_TRIGCTRL is set. Only one signal input is supported by the USART.

The AUTOTX feature can also be enabled via PRS. If an external SPI device sets a pin high when there is data to be read from the device, this signal can be routed to the USART through the PRS system and be used to make the USART clock data out of the external device. If AUTOTXTEN in USARTn\_TRIGCTRL is set, the USART will transmit data whenever the PRS signal selected by TSEL is high given that there is enough room in the RX buffer for the chosen frame size. Note that if there is no data in the TX buffer when using AUTOTX, the TX underflow interrupt will be set.

AUTOTXTEN can also be combined with TXTEN to make the USART transmit a command to the external device prior to clocking out data. To do this, disable TX using the TXDIS command, load the TX buffer with the command and enable AUTOTXTEN and TXTEN. When the selected PRS input goes high, the USART will now transmit the loaded command, and then continue clocking out while both the PRS input is high and there is room in the RX buffer.

### 18.3.7 PRS RX Input

The USART can be configured to receive data directly from a PRS channel by setting RXPRS in USARTn\_INPUT. The PRS channel used is selected using RXPRSEL in USARTn\_INPUT. This way, for example, a differential RX signal can be input to the ACMP and the output routed via PRS to the USART.

### 18.3.8 PRS CLK Input

The USART can be configured to receive clock directly from a PRS channel by setting CLKPRS in USARTn\_INPUT. The PRS channel used is selected using CLKPRSEL in USARTn\_INPUT. This is useful in synchronous slave mode and can together with RX PRS input be used to input data from PRS.

### 18.3.9 DMA Support

The USART has full DMA support. The DMA controller can write to the transmit buffer using the registers USARTn\_TXDATA, USARTn\_TXDATAx, USARTn\_TXDOUBLE and USARTn\_TXDOUBLEX, and it can read from the receive buffer using the registers USARTn\_RXDATA, USARTn\_RXDATAx, USARTn\_RXDOUBLE and USARTn\_RXDOUBLEX. This enables single byte transfers, 9 bit data + control/status bits, double byte and double byte + control/status transfers both to and from the USART.

A request for the DMA controller to read from the USART receive buffer can come from the following source:

- Data available in the receive buffer
- Data available in the receive buffer and data is for the RIGHT I2S channel. Only used in I2S mode.

A write request can come from one of the following sources:

- Transmit buffer and shift register empty. No data to send.
- Transmit buffer has room for more data
- Transmit buffer has room for RIGHT I2S data. Only used in I2S mode

Even though there are two sources for write requests to the DMA, only one should be used at a time, since the requests from both sources are cleared even though only one of the requests are used.

In some cases, it may be sensible to temporarily stop DMA access to the USART when an error such as a framing error has occurred. This is enabled by setting ERRSDMA in USARTn\_CTRL.

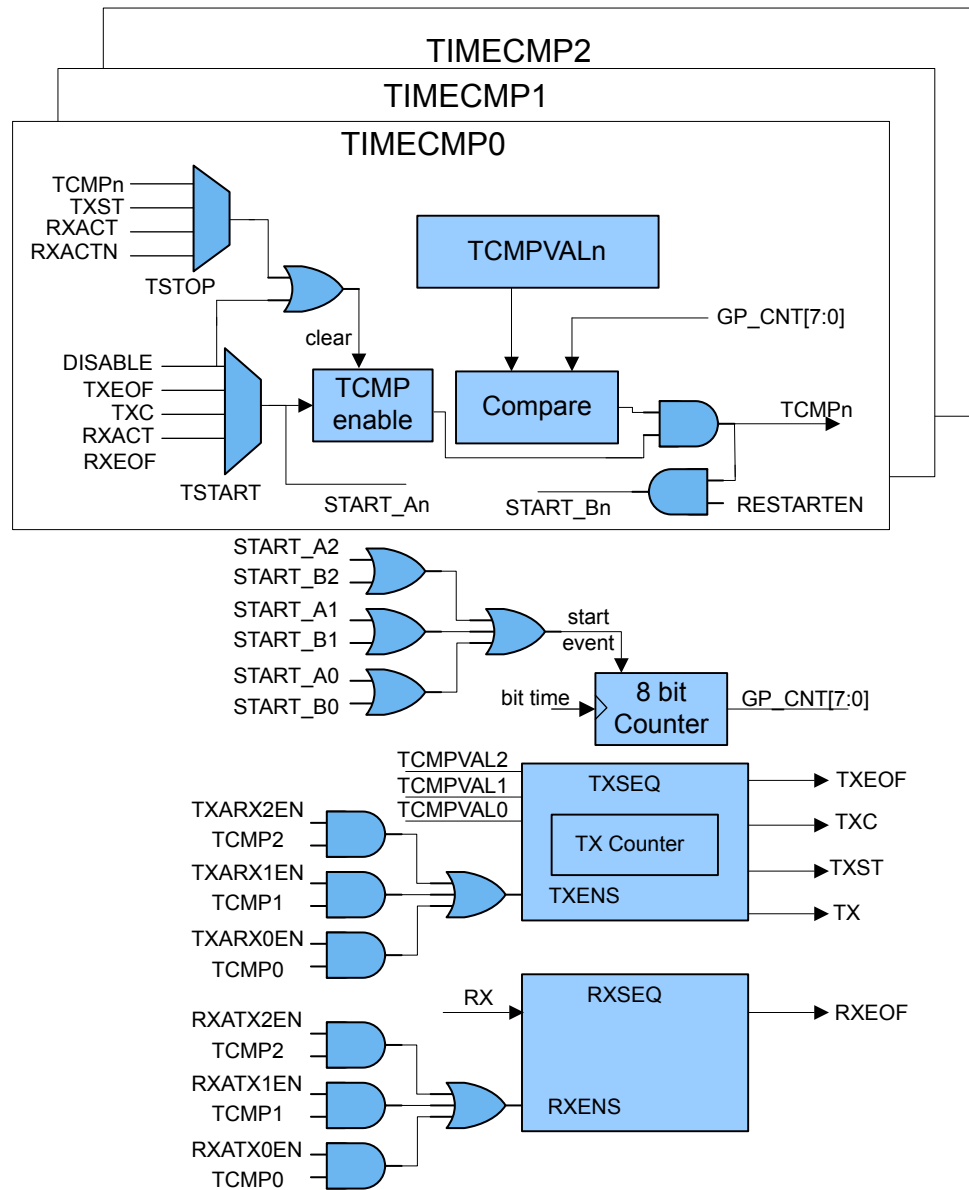

### 18.3.10 Timer

In addition to the TX sequence timer, there is a versatile 8 bit timer that can generate up to three event pulses. These pulses can be used to create timing for a variety of uses such as RX timeout, break detection, response timeout, and RX enable delay. Transmission delay, CS setup, inter-character spacing, and CS hold use the TX sequence counter. The TX sequencer counter can use the three 8 bit compare values or preset values for delays. There is one general counter with three comparators. Each comparator has a start source, a stop source, a restart enable, and a timer compare value. The start source enables the comparator, resets the counter, and starts the counter. If the counter is already running, the start source will reset the counter and restart it.

Any comparator could start the counter using the same start source but have different timing events programmed into TCMPVALn in USARTn\_TIMECMPn. The TCMP0, TCMP1, or TCMP2 events can be preempted by using the comparator stop source to disable the comparator before the counter reaches TCMPVAL0, TCMPVAL1, or TCMPVAL2. If one comparator gets disabled while the other comparator is still enabled, the counter continues counting. By default the counter will count up to 256 and stop unless a RESTARTEN is set in one of the USARTn\_TIMECMPn registers. By using RESTARTEN and an interval programmed into TCMPVAL, an interval timer can be set up. The TSTART field needs to be changed to DISABLE to stop the interval timer. The timer stops running once all of the comparators are disabled. If a comparator's start and stop sources both trigger the same cycle, the TCMPn event triggers, the comparator stays enabled, and the counter begins counting from zero.

The TXDELAY, CSSETUP, ICS, and CSHOLD in USARTn\_TIMING are used to program start of transmission delay, chip select setup delay, inter-character space, and chip select hold delay. Either a preset value of 0, 1, 2, 3, or 7 can be used for any of these delays; or the value in TCMPVALn may be used to set the delay. Using the preset values leaves the TCMPVALn free for other uses. The same TCMPVALn may be used for multiple events that require the same timing. The transmit sequencer's counter can run in parallel with the timer's counter. The counters and controls are shown in [Figure 18.26 USART Timer Block Diagram on page 512](#).

**Figure 18.26. USART Timer Block Diagram**

The following sections will go into more details on programming the various usage cases.

**Table 18.10. USART Application Settings for USARTn\_TIMING and USARTn\_TIMECMPn**

Application	TSTARTn	TSTOPn	TCMPVALn	Other
Response Timeout	TSTART0 = TXEOF	TSTOP0 = RXACT	TCMPVAL0 = 0x08	TCMP0 in USARTn_IEN
Receiver Timeout	TSTART1 = RXEOF	TSTOP1 = RXACT	TCMPVAL1 = 0x08	TCMP1 in USARTn_IEN
Large Receiver Timeout	TSTART1 = RXEOF, TCMP1	TSTOP1 = RXACT	TCMPVAL1 = 0xFF	TCMP1 in USARTn_IEN; TIME-RRESTARTED in USARTn_STATUS; RESTART1EN in USARTn_TIMECMP1

Application	TSTARTn	TSTOPn	TCMPVALn	Other
Break Detect	TSTART1 = RXACT	TSTOP1 = RXACTN	TCMPVAL1 = 0x0C	TCMP1 in USARTn_IEN
TX delayed start of transmission and CS setup	TSTART0 = DISABLE, TSTART1 = DISABLE	TSTOP0 = TCMP0, TSTOP1 = TCMP1	TCMPVAL0 = 0x04, TCMPVAL1 = 0x02	TXDELAY = TCMP0, CSSETUP = TCMP1 in USARTn_TIMING; AUTOCS in USARTn_CTRL
TX inter-character spacing	TSTART2 = DISABLE	TSTOP2 = TCMP2	TCMPVAL2 = 0x03	ICS = TCMP2 in USARTn_TIMING; AUTOCS in USARTn_CTRL
TX Chip Select End Delay	TSTART1 = DISABLE	TSTOP1 = TCMP1	TCMPVAL1 = 0x04	CSHOLD = TCMP1 in USARTn_TIMING; AUTOCS in USARTn_CTRL
Response Delay	TSTART1 = RXEOF	TSTOP1 = TCMP1	TCMPVAL1 = 0x08	TXARX1EN in USARTn_TRIGCTRL
Combined TX and RX Example	TSTART1 = RXEOF, TSTART0 = TXEOF	TSTOP1 = TCMP1, TSTOP0 = TCMP0	TCMPVAL1 = 0x1C, TCMPVAL0 = 0x10	TXARX1EN, RXATX0EN in USARTn_TRIGCTRL; CSSETUP = 0x7, CSHOLD = 0x3 in USARTn_TIMING
Combined Delayed TX and Receiver Timeout Example	TSTART0 = TCMPVAL0, TSTART1 = RXEOF	TSTOP0 = RXACTN, TSTOP1 = RXACT	TCMPVAL0 = 0x20, TCMPVAL1 = 0x0C	TXARX0EN in USARTn_TRIGCTRL; TCMP0 in USARTn_IEN

Table 18.10 USART Application Settings for USARTn\_TIMING and USARTn\_TIMECMPn on page 512 shows some examples of how the USART timer can be programmed for various applications. The following sections will describe more details for each applications shown in the table.

### 18.3.10.1 Response Timeout

Response Timeout is when a UART master sends a frame and expects the slave to respond within a certain number of baud-times. Refer to Table 18.10 USART Application Settings for USARTn\_TIMING and USARTn\_TIMECMPn on page 512 for specific register settings. Comparator 0 will be looking for TX end of frame to use as the timer start source. For this example, a receiver start of frame RXACT has not been detected for 8 baud-times, and the TCMP0 interrupt in USARTn\_IF is set. If an RX start bit is detected before the 8 baud-times, comparator 0 is disabled before the TCMP0 event can trigger.

Figure 18.27. USART Response Timeout

### 18.3.10.2 RX Timeout

A receiver timeout function can be implemented by using the RX end of frame to start comparator 1 and look for the RX start bit RXACT to disable the comparator. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on setting up this example. As long as the next RX start bit occurs before the counter reaches the comparator 1 value TCMPVAL1, the interrupt will not get set. In this example the RX Timeout was set to 8 baud-times. To get an RX timeout larger than 256 baud-times, RESTART1EN in USARTn\_TIMER can be used to restart the counter when it reaches TCMPVAL1. By setting TCMPVAL1 in USARTn\_TIMING to 0xFF, an interrupt will be generated after 256 baud-times. An interrupt service routine can then increment a memory location until the desired timeout is reached. Once the RX start bit is detected, comparator 1 will be disabled. If TIMERRESTARTED in USARTn\_STATUS is clear, the TCMP1 interrupt is the first interrupt after RXEOF.

Figure 18.28. USART RX Timeout

### 18.3.10.3 Break Detect

LIN bus and half-duplex UARTs can take advantage of the timer configured for break detection where RX is held low for a number of baud-times to indicate a break condition. [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) shows the settings for this mode. Each time RX is active (default of low) such as for a start bit, the timer begins counting. If the counter reaches 12 baud-times before RX goes to inactive RXACTN (default of high), an interrupt is asserted.

Figure 18.29. USART Break Detection

#### 18.3.10.4 TX Start Delay

Some applications may require a delay before the start of transmission. This example in [Figure 18.30 USART TXSEQ Timing on page 515](#) shows the TXSEQ timer used to delay the start of transmission by 4 baud times before the start of CS, and by 2 baud times with CS asserted. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on how to configure this mode. The TX sequencer could be enabled on PRS and start the TXSEQ counter running for 4 baud times as programmed in TCMPVAL0. Then CS is asserted for 2 baud times before the transmitter begins sending TX data. TXDELAY in USARTn\_TIMING is the initial delay before any CS assertion, and CSSETUP is the delay during CS assertion. There are several small preset timing values such as 1, 2, 3, or 7 that can be used for some of the TX sequencer timing which leaves TCMPVAL0, TCMPVAL1, and TCMPVAL2 free for other uses.

Figure 18.30. USART TXSEQ Timing

#### 18.3.10.5 Inter-Character Space

In addition to delaying the start of frame transmission, it is sometimes necessary to also delay the time between each transmit character (inter-character space). After the first transmission, the inter-character space will delay the start of all subsequent transmissions until the transmit buffer is empty. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on setting up this example. For this example in [Figure 18.30 USART TXSEQ Timing on page 515](#) ICS is set to TCMP2 in USARTn\_TIMING. To keep CS asserted during the inter-character space, set AUTOCS in USARTn\_CTRL. There are a few small preset timing values provided for TX sequence timing. Using these preset timing values can free up the TCMPVALn for other uses. For this example, the inter-character space is set to 0x03 and a preset value could be used.

#### 18.3.10.6 TX Chip Select End Delay

The assertion of CS can be extended after the final character of the frame by using CSHOLD in USARTn\_TIMING. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on setting up this example. AUTOCS in USARTn\_CTRL needs to be set to extend the CS assertion after the last TX character is transmitted as shown in [Figure 18.30 USART TXSEQ Timing on page 515](#).

#### 18.3.10.7 Response Delay

A response delay can be used to hold off the transmitter until a certain number of baud-times after the RX frame. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on setting up this example. TXARX1EN in USARTn\_TRIGCTRL tells the TX sequencer to trigger after RX EOF plus cmp1val baud times.

Figure 18.31. USART Response Delay

### 18.3.10.8 Combined TX and RX Example

This example describes how to alternate between TX and RX frames. This has a 28 baud-time space after RX and a 16 baud-time space after TX. The TSTART1 in USARTn\_TIMECMP1 is set to RXEOF which uses the the receiver end of frame to start the timer. The TSTOP1 is set to TCMP1 to generate an event after 28 baud times. Set TXARX1EN in USARTn\_TRIGCTRL, and the transmitter is held off until 28 baud times. TCMPVAL in USARTn\_TIMECMP1 is set to 0x1C for 28 baud times. By setting TSTART0 in USARTn\_TIMECMP0 to TXEOF, the timer will be started after the transmission has completed. RXATX0EN in USARTn\_TRIGCTRL is used to delay enabling of the receiver until 16 baud times after the transmitter has completed. Write 0x10 into TCMPVAL of USARTn\_TIMECMP0 for a 16 baud time delay. CS is also asserted 7 baud-times before start of transmission by setting CSSETUP to 0x7 in USARTn\_TIMING. To keep CS asserted for 3 baud-times after transmission completes, CSHOLD is set to 0x3 in USARTn\_TIMING. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on setting up this example.

### 18.3.10.9 Combined TX delay and RX break detect

This example describes how to delay TX transmission after an RX frame and how to have a break condition signal an interrupt. See [Table 18.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 512](#) for details on setting up this example. The TX delay is set up by using transmit after RX, TXARX0EN in USARTn\_TRIGCTRL to start the timer. TSTART0 in USARTn\_TIMECMP0 is set to RXEOF which enables the transitter of the timer delay. For this example TCMPVAL in USARTn\_TIMECMP0 is set to 0x20 to create a 32 baud-time delay between the end of the RX frame and the start of the TX frame. The break detect is configured by setting TSTART1 to RXACT to detect the start bit, and setting TSTOP1 to RXACTN to detect RX going high. In this case the interrupt asserts after RX stays low for 12 baud-times, so TCMPVAL1 is set to 0x0C.

### 18.3.10.10 Other Stop Conditions

There is also a timer stop on TX start using the TXST setting in TSTOP of USARTn\_TIMECMPn. This can be used to see that the DMA has not written to the TXBUFFER for a given time.

### 18.3.11 Interrupts

The interrupts generated by the USART are combined into two interrupt vectors. Interrupts related to reception are assigned to one interrupt vector, and interrupts related to transmission are assigned to the other. Separating the interrupts in this way allows different priorities to be set for transmission and reception interrupts.

The transmission interrupt vector groups the transmission-related interrupts generated by the following interrupt flags:

- TXC
- TXBL
- TXOF
- CCF
- TXIDLE

The reception interrupt on the other hand groups the reception-related interrupts, triggered by the following interrupt flags:

- RXDATAV
- RXFULL
- RXOF
- RXUF
- PERR
- FERR
- MPAF
- SSM
- TCMPn

If USART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in USART\_IF and their corresponding bits in USART\_IEN are set.

### 18.3.12 IrDA Modulator/ Demodulator

The IrDA modulator on USART0 implements the physical layer of the IrDA specification, which is necessary for communication over IrDA. The modulator takes the signal output from the USART module, and modulates it before it leaves USART0. In the same way, the input signal is demodulated before it enters the actual USART module. The modulator is only available on USART0, and implements the original Rev. 1.0 physical layer and one high speed extension which supports speeds from 2.4 kbps to 1.152 Mbps.

The data from and to the USART is represented in a NRZ (Non Return to Zero) format, where the signal value is at the same level through the entire bit period. For IrDA, the required format is RZI (Return to Zero Inverted), a format where a “1” is signalled by holding the line low, and a “0” is signalled by a short high pulse. An example is given in [Figure 18.32 USART Example RZI Signal for a given Asynchronous USART Frame on page 517](#).

**Figure 18.32. USART Example RZI Signal for a given Asynchronous USART Frame**

The IrDA module is enabled by setting IREN. The USART transmitter output and receiver input is then routed through the IrDA modulator.

The width of the pulses generated by the IrDA modulator is set by configuring IRPW in USARTn\_IRCTRL. Four pulse widths are available, each defined relative to the configured bit period as listed in [Table 18.11 USART IrDA Pulse Widths on page 517](#).

**Table 18.11. USART IrDA Pulse Widths**

IRPW	Pulse width OVS=0	Pulse width OVS=1	Pulse width OVS=2	Pulse width OVS=3
00	1/16	1/8	1/6	1/4
01	2/16	2/8	2/6	N/A
10	3/16	3/8	N/A	N/A
11	4/16	N/A	N/A	N/A

By default, no filter is enabled in the IrDA demodulator. A filter can be enabled by setting IRFILT in USARTn\_IRCTRL. When the filter is enabled, an incoming pulse has to last for 4 consecutive clock cycles to be detected by the IrDA demodulator.

Note that by default, the idle value of the USART data signal is high. This means that the IrDA modulator generates negative pulses, and the IrDA demodulator expects negative pulses. To make the IrDA module use RZI signalling, both TXINV and RXINV in USARTn\_CTRL must be set.

The IrDA module can also modulate a signal from the PRS system, and transmit a modulated signal to the PRS system. To use a PRS channel as transmitter source instead of the USART, set IRPRSEN in USARTn\_IRCTRL high. The channel is selected by configuring IRPRSSEL in USARTn\_IRCTRL.

## 18.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	USARTn_CTRL	RW	Control Register
0x004	USARTn_FRAME	RW	USART Frame Format Register
0x008	USARTn_TRIGCTRL	RW	USART Trigger Control register
0x00C	USARTn_CMD	W1	Command Register
0x010	USARTn_STATUS	R	USART Status Register
0x014	USARTn_CLKDIV	RWH	Clock Control Register
0x018	USARTn_RXDATAx	R(a)	RX Buffer Data Extended Register
0x01C	USARTn_RXDATA	R(a)	RX Buffer Data Register
0x020	USARTn_RXDOUBLEX	R(a)	RX Buffer Double Data Extended Register
0x024	USARTn_RXDOUBLE	R(a)	RX FIFO Double Data Register
0x028	USARTn_RXDATAxP	R	RX Buffer Data Extended Peek Register
0x02C	USARTn_RXDOUBLEXP	R	RX Buffer Double Data Extended Peek Register
0x030	USARTn_TXDATAx	W	TX Buffer Data Extended Register
0x034	USARTn_TXDATA	W	TX Buffer Data Register
0x038	USARTn_TXDOUBLEX	W	TX Buffer Double Data Extended Register
0x03C	USARTn_TXDOUBLE	W	TX Buffer Double Data Register
0x040	USARTn_IF	R	Interrupt Flag Register
0x044	USARTn_IFS	W1	Interrupt Flag Set Register
0x048	USARTn_IFC	(R)W1	Interrupt Flag Clear Register
0x04C	USARTn_IEN	RW	Interrupt Enable Register
0x050	USARTn_IRCTRL	RW	IrDA Control Register
0x058	USARTn_INPUT	RW	USART Input Register
0x05C	USARTn_I2SCTRL	RW	I2S Control Register
0x060	USARTn_TIMING	RW	Timing Register
0x064	USARTn_CTRLX	RW	Control Register Extended
0x068	USARTn_TIMECMP0	RW	Used to generate interrupts and various delays
0x06C	USARTn_TIMECMP1	RW	Used to generate interrupts and various delays
0x070	USARTn_TIMECMP2	RW	Used to generate interrupts and various delays
0x074	USARTn_ROUTEPEEN	RW	I/O Routing Pin Enable Register
0x078	USARTn_ROUTELOC0	RW	I/O Routing Location Register
0x07C	USARTn_ROUTELOC1	RW	I/O Routing Location Register

## 18.5 Register Description

### 18.5.1 USARTn\_CTRL - Control Register

Offset	Bit Position																																
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset	0	0	0	0			0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		0x0		0	0	0	0	0	0
Access	RW	RW	RW	RW			RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW		RW		RW	RW	RW	RW	RW	RW
Name	SMSDELAY	MVDIS	AUTOTX	BYTESWAP			SSSEARLY	ERRSTX	ERRSRX	ERRSDMA	BIT8DV	SKIPPERRF	SCRETRANS	SCMODE	AUTOTRI	AUTOCS	CSINV	TXINV	RXINV	TXBIL	CSMA	MSBF	CLKPHA	CLKPOL			OVS	MPAB	MPM	CCEN	LOOPBK	SYNC	

Bit	Name	Reset	Access	Description
31	SMSDELAY	0	RW	<b>Synchronous Master Sample Delay</b> Delay Synchronous Master sample point to the next setup edge to improve timing and allow communication at higher speeds
30	MVDIS	0	RW	<b>Majority Vote Disable</b> Disable majority vote for 16x, 8x and 6x oversampling modes.
29	AUTOTX	0	RW	<b>Always Transmit When RX Not Full</b> Transmits as long as RX is not full. If TX is empty, underflows are generated.
28	BYTESWAP	0	RW	<b>Byteswap In Double Accesses</b> Set to switch the order of the bytes in double accesses.
Value		Description		
0		Normal byte order		
1		Byte order swapped		
27:26	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
25	SSSEARLY	0	RW	<b>Synchronous Slave Setup Early</b> Setup data on sample edge in synchronous slave mode to improve MOSI setup time
24	ERRSTX	0	RW	<b>Disable TX On Error</b> When set, the transmitter is disabled on framing and parity errors (asynchronous mode only) in the receiver.
Value		Description		
0		Received framing and parity errors have no effect on transmitter		
1		Received framing and parity errors disable the transmitter		
23	ERRSRX	0	RW	<b>Disable RX On Error</b> When set, the receiver is disabled on framing and parity errors (asynchronous mode only).
Value		Description		
0		Framing and parity errors have no effect on receiver		
1		Framing and parity errors disable the receiver		
22	ERRSDMA	0	RW	<b>Halt DMA On Error</b> When set, DMA requests will be cleared on framing and parity errors (asynchronous mode only).
Value		Description		
0		Framing and parity errors have no effect on DMA requests from the USART		
1		DMA requests from the USART are blocked while the PERR or FERR interrupt flags are set		
21	BIT8DV	0	RW	<b>Bit 8 Default Value</b> The default value of the 9th bit. If 9-bit frames are used, and an 8-bit write operation is done, leaving the 9th bit unspecified, the 9th bit is set to the value of BIT8DV.
20	SKIPPERRF	0	RW	<b>Skip Parity Error Frames</b>

Bit	Name	Reset	Access	Description						
	When set, the receiver discards frames with parity errors (asynchronous mode only). The PERR interrupt flag is still set.									
19	SCRETRANS	0	RW	<b>SmartCard Retransmit</b>  When in SmartCard mode, a NACK'ed frame will be kept in the shift register and retransmitted if the transmitter is still enabled.						
18	SCMODE	0	RW	<b>SmartCard Mode</b>  Use this bit to enable or disable SmartCard mode.						
17	AUTOTRI	0	RW	<b>Automatic TX Tristate</b>  When enabled, TXTRI is set by hardware whenever the transmitter is idle, and TXTRI is cleared by hardware when transmission starts. <table><tr><td>Value</td><td>Description</td></tr><tr><td>0</td><td>The output on U(S)n_TX when the transmitter is idle is defined by TXINV</td></tr><tr><td>1</td><td>U(S)n_TX is tristated whenever the transmitter is idle</td></tr></table>	Value	Description	0	The output on U(S)n_TX when the transmitter is idle is defined by TXINV	1	U(S)n_TX is tristated whenever the transmitter is idle
Value	Description									
0	The output on U(S)n_TX when the transmitter is idle is defined by TXINV									
1	U(S)n_TX is tristated whenever the transmitter is idle									
16	AUTOCS	0	RW	<b>Automatic Chip Select</b>  When enabled, the output on USn_CS will be activated one baud-period before transmission starts, and deactivated when transmission ends.						
15	CSINV	0	RW	<b>Chip Select Invert</b>  Default value is active low. This affects both the selection of external slaves, as well as the selection of the microcontroller as a slave. <table><tr><td>Value</td><td>Description</td></tr><tr><td>0</td><td>Chip select is active low</td></tr><tr><td>1</td><td>Chip select is active high</td></tr></table>	Value	Description	0	Chip select is active low	1	Chip select is active high
Value	Description									
0	Chip select is active low									
1	Chip select is active high									
14	TXINV	0	RW	<b>Transmitter output Invert</b>  The output from the USART transmitter can optionally be inverted by setting this bit. <table><tr><td>Value</td><td>Description</td></tr><tr><td>0</td><td>Output from the transmitter is passed unchanged to U(S)n_TX</td></tr><tr><td>1</td><td>Output from the transmitter is inverted before it is passed to U(S)n_TX</td></tr></table>	Value	Description	0	Output from the transmitter is passed unchanged to U(S)n_TX	1	Output from the transmitter is inverted before it is passed to U(S)n_TX
Value	Description									
0	Output from the transmitter is passed unchanged to U(S)n_TX									
1	Output from the transmitter is inverted before it is passed to U(S)n_TX									
13	RXINV	0	RW	<b>Receiver Input Invert</b>  Setting this bit will invert the input to the USART receiver. <table><tr><td>Value</td><td>Description</td></tr><tr><td>0</td><td>Input is passed directly to the receiver</td></tr><tr><td>1</td><td>Input is inverted before it is passed to the receiver</td></tr></table>	Value	Description	0	Input is passed directly to the receiver	1	Input is inverted before it is passed to the receiver
Value	Description									
0	Input is passed directly to the receiver									
1	Input is inverted before it is passed to the receiver									
12	TXBIL	0	RW	<b>TX Buffer Interrupt Level</b>  Determines the interrupt and status level of the transmit buffer. <table><tr><td>Value</td><td>Mode</td><td>Description</td></tr><tr><td>0</td><td>EMPTY</td><td>TXBL and the TXBL interrupt flag are set when the transmit buffer becomes empty. TXBL is cleared when the buffer becomes nonempty.</td></tr></table>	Value	Mode	Description	0	EMPTY	TXBL and the TXBL interrupt flag are set when the transmit buffer becomes empty. TXBL is cleared when the buffer becomes nonempty.
Value	Mode	Description								
0	EMPTY	TXBL and the TXBL interrupt flag are set when the transmit buffer becomes empty. TXBL is cleared when the buffer becomes nonempty.								

Bit	Name	Reset	Access	Description
	1	HALFFULL		TXBL and TXBLIF are set when the transmit buffer goes from full to half-full or empty. TXBL is cleared when the buffer becomes full.
11	CSMA	0	RW	<b>Action On Slave-Select In Master Mode</b>  This register determines the action to be performed when slave-select is configured as an input and driven low while in master mode.
	Value	Mode		Description
	0	NOACTION		No action taken
	1	GOTOSLAVEMODE		Go to slave mode
10	MSBF	0	RW	<b>Most Significant Bit First</b>  Decides whether data is sent with the least significant bit first, or the most significant bit first.
	Value			Description
	0			Data is sent with the least significant bit first
	1			Data is sent with the most significant bit first
9	CLKPHA	0	RW	<b>Clock Edge For Setup/Sample</b>  Determines where data is set-up and sampled according to the bus clock when in synchronous mode.
	Value	Mode		Description
	0	SAMPLELEADING		Data is sampled on the leading edge and set-up on the trailing edge of the bus clock in synchronous mode
	1	SAMPLETRAILING		Data is set-up on the leading edge and sampled on the trailing edge of the bus clock in synchronous mode
8	CLKPOL	0	RW	<b>Clock Polarity</b>  Determines the clock polarity of the bus clock used in synchronous mode.
	Value	Mode		Description
	0	IDLELOW		The bus clock used in synchronous mode has a low base value
	1	IDLEHIGH		The bus clock used in synchronous mode has a high base value
7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:5	OVS	0x0	RW	<b>Oversampling</b>  Sets the number of clock periods in a UART bit-period. More clock cycles gives better robustness, while less clock cycles gives better performance.
	Value	Mode		Description
	0	X16		Regular UART mode with 16X oversampling in asynchronous mode
	1	X8		Double speed with 8X oversampling in asynchronous mode
	2	X6		6X oversampling in asynchronous mode
	3	X4		Quadruple speed with 4X oversampling in asynchronous mode
4	MPAB	0	RW	<b>Multi-Processor Address-Bit</b>

Bit	Name	Reset	Access	Description
				Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.
3	MPM	0	RW	<b>Multi-Processor Mode</b> Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame.
	Value			Description
	0			The 9th bit of incoming frames has no special function
	1			An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set
2	CCEN	0	RW	<b>Collision Check Enable</b> Enables collision checking on data when operating in half duplex modus.
	Value			Description
	0			Collision check is disabled
	1			Collision check is enabled. The receiver must be enabled for the check to be performed
1	LOOPBK	0	RW	<b>Loopback Enable</b> Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.
	Value			Description
	0			The receiver is connected to and receives data from U(S)n_RX
	1			The receiver is connected to and receives data from U(S)n_TX
0	SYNC	0	RW	<b>USART Synchronous Mode</b> Determines whether the USART is operating in asynchronous or synchronous mode.
	Value			Description
	0			The USART operates in asynchronous mode
	1			The USART operates in synchronous mode

18.5.2 USARTn\_FRAME - USART Frame Format Register

Offset	Bit Position																																	
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset																				0x1				0x0					0x5					
Access																				RW				RW					RW					
Name																				STOPBITS				PARITY					DATABITS					

Bit	Name	Reset	Access	Description
31:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13:12	STOPBITS	0x1	RW	<b>Stop-Bit Mode</b> Determines the number of stop-bits used.
	Value	Mode	Description	
	0	HALF	The transmitter generates a half stop bit. Stop-bits are not verified by receiver	
	1	ONE	One stop bit is generated and verified	
	2	ONEANDAHALF	The transmitter generates one and a half stop bit. The receiver verifies the first stop bit	
	3	TWO	The transmitter generates two stop bits. The receiver checks the first stop-bit only	
11:10	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
9:8	PARITY	0x0	RW	<b>Parity-Bit Mode</b> Determines whether parity bits are enabled, and whether even or odd parity should be used. Only available in asynchronous mode.
	Value	Mode	Description	
	0	NONE	Parity bits are not used	
	2	EVEN	Even parity are used. Parity bits are automatically generated and checked by hardware.	
	3	ODD	Odd parity is used. Parity bits are automatically generated and checked by hardware.	
7:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3:0	DATABITS	0x5	RW	<b>Data-Bit Mode</b> This register sets the number of data bits in a USART frame.
	Value	Mode	Description	
	1	FOUR	Each frame contains 4 data bits	
	2	FIVE	Each frame contains 5 data bits	
	3	SIX	Each frame contains 6 data bits	
	4	SEVEN	Each frame contains 7 data bits	
	5	EIGHT	Each frame contains 8 data bits	
	6	NINE	Each frame contains 9 data bits	
	7	TEN	Each frame contains 10 data bits	
	8	ELEVEN	Each frame contains 11 data bits	
	9	TWELVE	Each frame contains 12 data bits	
	10	THIRTEEN	Each frame contains 13 data bits	
	11	FOURTEEN	Each frame contains 14 data bits	
	12	FIFTEEN	Each frame contains 15 data bits	

Bit	Name	Reset	Access	Description
	13	SIXTEEN		Each frame contains 16 data bits

### 18.5.3 USARTn\_TRIGCTRL - USART Trigger Control register

Offset	Bit Position																																					
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset													0x0								0	0	0	0	0	0	0	0	0	0								
Access													RW								RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW				
Name													TSEL								RXATX2EN	RXATX1EN	RXATX0EN	TXARX2EN	TXARX1EN	TXARX0EN	AUTOTXTEN	TXTEN		RXTEN								

Bit	Name	Reset	Access	Description
31:20	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
19:16	TSEL	0x0	RW	<b>Trigger PRS Channel Select</b>  Select USART PRS trigger channel. The PRS signal can enable RX and/or TX, depending on the setting of RXTEN and TXTEN.
	Value	Mode		Description
	0	PRSCH0		PRS Channel 0 selected
	1	PRSCH1		PRS Channel 1 selected
	2	PRSCH2		PRS Channel 2 selected
	3	PRSCH3		PRS Channel 3 selected
	4	PRSCH4		PRS Channel 4 selected
	5	PRSCH5		PRS Channel 5 selected
	6	PRSCH6		PRS Channel 6 selected
	7	PRSCH7		PRS Channel 7 selected
	8	PRSCH8		PRS Channel 8 selected
	9	PRSCH9		PRS Channel 9 selected
	10	PRSCH10		PRS Channel 10 selected
	11	PRSCH11		PRS Channel 11 selected
15:13	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
12	RXATX2EN	0	RW	<b>Enable Receive Trigger after TX end of frame plus TCMPVAL2 baud-times</b>  When set, a TX end of frame will trigger the receiver after a TCMPVAL2 baud-time delay
11	RXATX1EN	0	RW	<b>Enable Receive Trigger after TX end of frame plus TCMPVAL1 baud-times</b>  When set, a TX end of frame will trigger the receiver after a TCMPVAL1 baud-time delay
10	RXATX0EN	0	RW	<b>Enable Receive Trigger after TX end of frame plus TCMPVAL0 baud-times</b>  When set, a TX end of frame will trigger the receiver after a TCMPVAL0 baud-time delay
9	TXARX2EN	0	RW	<b>Enable Transmit Trigger after RX End of Frame plus TCMP2VAL</b>  When set, an RX end of frame will trigger the transmitter after TCMP2VAL bit times to force a minimum response delay
8	TXARX1EN	0	RW	<b>Enable Transmit Trigger after RX End of Frame plus TCMP1VAL</b>  When set, an RX end of frame will trigger the transmitter after TCMP1VAL bit times to force a minimum response delay
7	TXARX0EN	0	RW	<b>Enable Transmit Trigger after RX End of Frame plus TCMP0VAL</b>  When set, an RX end of frame will trigger the transmitter after TCMP0VAL bit times to force a minimum response delay
6	AUTOTXTEN	0	RW	<b>AUTOTX Trigger Enable</b>  When set, AUTOTX is enabled as long as the PRS channel selected by TSEL has a high value
5	TXTEN	0	RW	<b>Transmit Trigger Enable</b>  When set, the PRS channel selected by TSEL sets TXEN, enabling the transmitter on positive trigger edges.

Bit	Name	Reset	Access	Description
4	RXTEN	0	RW	<b>Receive Trigger Enable</b>  When set, the PRS channel selected by TSEL sets RXEN, enabling the receiver on positive trigger edges.
3:0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

## 18.5.4 USARTn\_CMD - Command Register

Offset	Bit Position																																																	
0x00C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																		
Reset																					0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
Access																					W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1	W1
Name																					CLEARRX	CLEARTX	TXTRIDIS	TXTRIEN	RXBLOCKDIS	RXBLOCKEN	MASTERDIS	MASTEREN	TXDIS	TXEN	RXDIS	RXEN																		

Bit	Name	Reset	Access	Description
31:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11	CLEARRX	0	W1	<b>Clear RX</b> Set to clear receive buffer and the RX shift register.
10	CLEARTX	0	W1	<b>Clear TX</b> Set to clear transmit buffer and the TX shift register.
9	TXTRIDIS	0	W1	<b>Transmitter Tristate Disable</b> Disables tristating of the transmitter output.
8	TXTRIEN	0	W1	<b>Transmitter Tristate Enable</b> Tristates the transmitter output.
7	RXBLOCKDIS	0	W1	<b>Receiver Block Disable</b> Set to clear RXBLOCK, resulting in all incoming frames being loaded into the receive buffer.
6	RXBLOCKEN	0	W1	<b>Receiver Block Enable</b> Set to set RXBLOCK, resulting in all incoming frames being discarded.
5	MASTERDIS	0	W1	<b>Master Disable</b> Set to disable master mode, clearing the MASTER status bit and putting the USART in slave mode.
4	MASTEREN	0	W1	<b>Master Enable</b> Set to enable master mode, setting the MASTER status bit. Master mode should not be enabled while TXENS is set to 1. To enable both master and TX mode, write MASTEREN before TXEN, or enable them both in the same write operation.
3	TXDIS	0	W1	<b>Transmitter Disable</b> Set to disable transmission.
2	TXEN	0	W1	<b>Transmitter Enable</b> Set to enable data transmission.
1	RXDIS	0	W1	<b>Receiver Disable</b> Set to disable data reception. If a frame is under reception when the receiver is disabled, the incoming frame is discarded.
0	RXEN	0	W1	<b>Receiver Enable</b> Set to activate data reception on U(S)n_RX.

## 18.5.5 USARTn\_STATUS - USART Status Register

Offset	Bit Position																			
0x010	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12
Reset															0x0			0	1	0
Access															R			R	R	R
Name															TXBUFCNT			TIMERRESTARTED	TXIDLE	RXFULLRIGHT
																		R	0	11
																		R	0	10
																		R	0	9
																		R	0	8
																		R	0	7
																		R	1	6
																		R	0	5
																		R	0	4
																		R	0	3
																		R	0	2
																		R	0	1
																		R	0	0

Bit	Name	Reset	Access	Description
31:18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17:16	TXBUFCNT	0x0	R	<b>TX Buffer Count</b>  Count of TX buffer entry 0, entry 1, and TX shift register. For large frames, the count is only of TX buffer entry 0 and the TX shifter register.
15	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
14	TIMERRESTARTED	0	R	<b>The USART Timer restarted itself</b>  When the timer is restarting itself on each TCMP event, a TIMERRESTARTED value of 0x0 indicates the first TCMP event in the sequence of multiple TCMP events. Any non TCMP timer start events will clear TIMERRESTARTED. When there is a TCMP interrupt and TIMERRESTARTED is 0x0, an interrupt service routine can set a TCMP event counter variable in memory to 0x1 to indicate the first TCMP interrupt of the sequence.
13	TXIDLE	1	R	<b>TX Idle</b>  Set when TX idle
12	RXFULLRIGHT	0	R	<b>RX Full of Right Data</b>  When set, the entire RX buffer contains right data. Only used in I2S mode
11	RXDATAVRIGHT	0	R	<b>RX Data Right</b>  When set, reading RXDATA or RXDATAx gives right data. Else left data is read. Only used in I2S mode
10	TXBSRIGHT	0	R	<b>TX Buffer Expects Single Right Data</b>  When set, the TX buffer expects at least a single right data. Else it expects left data. Only used in I2S mode
9	TXBDRIGHT	0	R	<b>TX Buffer Expects Double Right Data</b>  When set, the TX buffer expects double right data. Else it may expect a single right data or left data. Only used in I2S mode
8	RXFULL	0	R	<b>RX FIFO Full</b>  Set when the RXFIFO is full. Cleared when the receive buffer is no longer full. When this bit is set, there is still room for one more frame in the receive shift register.
7	RXDATAV	0	R	<b>RX Data Valid</b>  Set when data is available in the receive buffer. Cleared when the receive buffer is empty.
6	TXBL	1	R	<b>TX Buffer Level</b>  Indicates the level of the transmit buffer. If TXBL is 0x0, TXBL is set whenever the transmit buffer is completely empty. Otherwise TXBL is set whenever the TX Buffer becomes half full.
5	TXC	0	R	<b>TX Complete</b>  Set when a transmission has completed and no more data is available in the transmit buffer and shift register. Cleared when data is written to the transmit buffer.
4	TXTRI	0	R	<b>Transmitter Tristated</b>  Set when the transmitter is tristated, and cleared when transmitter output is enabled. If AUTOTRI in USARTn_CTRL is set this bit is always read as 0.
3	RXBLOCK	0	R	<b>Block Incoming Data</b>  When set, the receiver discards incoming frames. An incoming frame will not be loaded into the receive buffer if this bit is set at the instant the frame has been completely received.
2	MASTER	0	R	<b>SPI Master Mode</b>  Set when the USART operates as a master. Set using the MASTEREN command and clear using the MASTERDIS command.
1	TXENS	0	R	<b>Transmitter Enable Status</b>

Bit	Name	Reset	Access	Description
				Set when the transmitter is enabled.
0	RXENS	0	R	<b>Receiver Enable Status</b>
				Set when the receiver is enabled.

### 18.5.6 USARTn\_CLKDIV - Clock Control Register

Offset	Bit Position																															
0x014	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0										0x00000																					
Access	RW										RWH																					
Name	AUTOBAUDEN										DIV																					

Bit	Name	Reset	Access	Description
31	AUTOBAUDEN	0	RW	<b>AUTOBAUD detection enable</b>
				Detects the baud rate based on receiving a 0x55 frame (0x00 for IrDA). This is used in Asynchronous mode.
30:23	<i>Reserved</i>	<i>To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a></i>		
22:3	DIV	0x00000	RWH	<b>Fractional Clock Divider</b>
				Specifies the fractional clock divider for the USART. Setting AUTOBAUDEN in USARTn_CLKDIV will overwrite the DIV field.
2:0	<i>Reserved</i>	<i>To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a></i>		

### 18.5.7 USARTn\_RXDATAx - RX Buffer Data Extended Register (Actionable Reads)

Offset	Bit Position																																	
0x018	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset																	0	0									0x000							
Access																	R	R									R							
Name																	FERR	PERR									RXDATA							

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15	FERR	0	R	<b>Data Framing Error</b> Set if data in buffer has a framing error. Can be the result of a break condition.
14	PERR	0	R	<b>Data Parity Error</b> Set if data in buffer has a parity error (asynchronous mode only).
13:9	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
8:0	RXDATA	0x000	R	<b>RX Data</b> Use this register to access data read from the USART. Buffer is cleared on read access.

### 18.5.8 USARTn\_RXDATA - RX Buffer Data Register (Actionable Reads)

Offset	Bit Position																															
0x01C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00  R  RXDATA							
Access

Name																	TXDATA1								TXDATA0							

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:8	TXDATA1	0x00	W	<b>TX Data</b> Second frame to write to buffer.
7:0	TXDATA0	0x00	W	<b>TX Data</b> First frame to write to buffer.

### 18.5.17 USARTn\_IF - Interrupt Flag Register

Offset	Bit Position																																									
0x040	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0										
Reset																	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	1	R	0				
Access																	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0	R	0
Name																	TCMP2	TCMP1	TCMP0	TXIDLE	CCF	SSM	MPAF	FERR	PERR	TXUF	TXOF	RXUF	RXOF	RXFULL	RXDATAV	TXBL	TXC									

Bit	Name	Reset	Access	Description
31:17	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
16	TCMP2	0	R	<b>Timer comparator 2 Interrupt Flag</b> Set when the timer reaches the comparator 2 value, TCMP2.
15	TCMP1	0	R	<b>Timer comparator 1 Interrupt Flag</b> Set when the timer reaches the comparator 1 value, TCMP1.
14	TCMP0	0	R	<b>Timer comparator 0 Interrupt Flag</b> Set when the Timer reaches the comparator 0 value, TCMP0.
13	TXIDLE	0	R	<b>TX Idle Interrupt Flag</b> Set when TX goes idle. At this point, transmission has ended
12	CCF	0	R	<b>Collision Check Fail Interrupt Flag</b> Set when a collision check notices an error in the transmitted data.
11	SSM	0	R	<b>Slave-Select In Master Mode Interrupt Flag</b> Set when the device is selected as a slave when in master mode.
10	MPAF	0	R	<b>Multi-Processor Address Frame Interrupt Flag</b> Set when a multi-processor address frame is detected.
9	FERR	0	R	<b>Framing Error Interrupt Flag</b> Set when a frame with a framing error is received while RXBLOCK is cleared.
8	PERR	0	R	<b>Parity Error Interrupt Flag</b> Set when a frame with a parity error (asynchronous mode only) is received while RXBLOCK is cleared.
7	TXUF	0	R	<b>TX Underflow Interrupt Flag</b> Set when operating as a synchronous slave, no data is available in the transmit buffer when the master starts transmission of a new frame.
6	TXOF	0	R	<b>TX Overflow Interrupt Flag</b> Set when a write is done to the transmit buffer while it is full. The data already in the transmit buffer is preserved.
5	RXUF	0	R	<b>RX Underflow Interrupt Flag</b> Set when trying to read from the receive buffer when it is empty.
4	RXOF	0	R	<b>RX Overflow Interrupt Flag</b> Set when data is incoming while the receive shift register is full. The data previously in the shift register is lost.
3	RXFULL	0	R	<b>RX Buffer Full Interrupt Flag</b> Set when the receive buffer becomes full.
2	RXDATAV	0	R	<b>RX Data Valid Interrupt Flag</b> Set when data becomes available in the receive buffer.
1	TXBL	1	R	<b>TX Buffer Level Interrupt Flag</b> Set when buffer becomes empty if buffer level is set to 0x0, or when the number of empty TX buffer elements equals specified buffer level.
0	TXC	0	R	<b>TX Complete Interrupt Flag</b> This interrupt is set after a transmission when both the TX buffer and shift register are empty.

### 18.5.18 USARTn\_IFS - Interrupt Flag Set Register

Offset	Bit Position

2	RXDATAV	0	RW	<b>RXDATAV Interrupt Enable</b> Enable/disable the RXDATAV interrupt
1	TXBL	0	RW	<b>TXBL Interrupt Enable</b> Enable/disable the TXBL interrupt
0	TXC	0	RW	<b>TXC Interrupt Enable</b> Enable/disable the TXC interrupt

## 18.5.21 USARTn\_IRCTRL - IrDA Control Register

Offset	Bit Position																															
0x050	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset													0x0				0								0		0x0		0		0	
Access													RW				RW								RW		RW		RW			
Name													IRPRSEL				IRPRSEN								IRFILT		IRPW		IREN			

Bit	Name	Reset	Access	Description
31:12	<i>Reserved</i>	<i>To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a></i>		
11:8	IRPRSSEL	0x0	RW	<b>IrDA PRS Channel Select</b> A PRS can be used as input to the pulse modulator instead of TX. This value selects the channel to use.
	Value	Mode		Description
	0	PRSCH0		PRS Channel 0 selected
	1	PRSCH1		PRS Channel 1 selected
	2	PRSCH2		PRS Channel 2 selected
	3	PRSCH3		PRS Channel 3 selected
	4	PRSCH4		PRS Channel 4 selected
	5	PRSCH5		PRS Channel 5 selected
	6	PRSCH6		PRS Channel 6 selected
	7	PRSCH7		PRS Channel 7 selected
	8	PRSCH8		PRS Channel 8 selected
	9	PRSCH9		PRS Channel 9 selected
	10	PRSCH10		PRS Channel 10 selected
	11	PRSCH11		PRS Channel 11 selected
7	IRPRSEN	0	RW	<b>IrDA PRS Channel Enable</b> Enable the PRS channel selected by IRPRSSEL as input to IrDA module instead of TX.
6:4	<i>Reserved</i>	<i>To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a></i>		
3	IRFILT	0	RW	<b>IrDA RX Filter</b> Set to enable filter on IrDA demodulator.
	Value			Description
	0			No filter enabled
	1			Filter enabled. IrDA pulse must be high for at least 4 consecutive clock cycles to be detected
2:1	IRPW	0x0	RW	<b>IrDA TX Pulse Width</b> Configure the pulse width generated by the IrDA modulator as a fraction of the configured USART bit period.
	Value	Mode		Description
	0	ONE		IrDA pulse width is 1/16 for OVS=0 and 1/8 for OVS=1
	1	TWO		IrDA pulse width is 2/16 for OVS=0 and 2/8 for OVS=1
	2	THREE		IrDA pulse width is 3/16 for OVS=0 and 3/8 for OVS=1
	3	FOUR		IrDA pulse width is 4/16 for OVS=0 and 4/8 for OVS=1
0	IREN	0	RW	<b>Enable IrDA Module</b> Enable IrDA module and rout USART signals through it.

### 18.5.22 USARTn\_INPUT - USART Input Register

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15	CLKPRS	0	RW	<b>PRS CLK Enable</b> When set, the PRS channel selected as input to CLK.
14:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11:8	CLKPRSSEL	0x0	RW	<b>CLK PRS Channel Select</b> Select PRS channel as input to CLK.
Value		Mode	Description	
0		PRSCH0	PRS Channel 0 selected	
1		PRSCH1	PRS Channel 1 selected	
2		PRSCH2	PRS Channel 2 selected	
3		PRSCH3	PRS Channel 3 selected	
4		PRSCH4	PRS Channel 4 selected	
5		PRSCH5	PRS Channel 5 selected	
6		PRSCH6	PRS Channel 6 selected	
7		PRSCH7	PRS Channel 7 selected	
8		PRSCH8	PRS Channel 8 selected	
9		PRSCH9	PRS Channel 9 selected	
10		PRSCH10	PRS Channel 10 selected	
11		PRSCH11	PRS Channel 11 selected	
7	RXPRS	0	RW	<b>PRS RX Enable</b> When set, the PRS channel selected as input to RX.
6:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3:0	RXPRSSEL	0x0	RW	<b>RX PRS Channel Select</b> Select PRS channel as input to RX.
Value		Mode	Description	
0		PRSCH0	PRS Channel 0 selected	
1		PRSCH1	PRS Channel 1 selected	
2		PRSCH2	PRS Channel 2 selected	
3		PRSCH3	PRS Channel 3 selected	
4		PRSCH4	PRS Channel 4 selected	
5		PRSCH5	PRS Channel 5 selected	
6		PRSCH6	PRS Channel 6 selected	
7		PRSCH7	PRS Channel 7 selected	
8		PRSCH8	PRS Channel 8 selected	
9		PRSCH9	PRS Channel 9 selected	

Bit	Name	Reset	Access	Description
	10	PRSCH10		PRS Channel 10 selected
	11	PRSCH11		PRS Channel 11 selected

18.5.23 USARTn\_I2SCTRL - I2S Control Register

Offset	Bit Position																							
0x05C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8
Reset											0x0												0	0
Access											RW												RW	RW
Name											FORMAT												DELAY	DMASPLIT
																							0	0
																							RW	RW
																							0	0
																							RW	RW
																							EN	

Bit	Name	Reset	Access	Description
31:11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
10:8	FORMAT	0x0	RW	<b>I2S Word Format</b> Configure the data-width used internally for I2S data
	Value	Mode		Description
	0	W32D32		32-bit word, 32-bit data
	1	W32D24M		32-bit word, 32-bit data with 8 lsb masked
	2	W32D24		32-bit word, 24-bit data
	3	W32D16		32-bit word, 16-bit data
	4	W32D8		32-bit word, 8-bit data
	5	W16D16		16-bit word, 16-bit data
	6	W16D8		16-bit word, 8-bit data
	7	W8D8		8-bit word, 8-bit data
7:5	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
4	DELAY	0	RW	<b>Delay on I2S data</b> Set to add a one-cycle delay between a transition on the word-clock and the start of the I2S word. Should be set for standard I2S format
3	DMASPLIT	0	RW	<b>Separate DMA Request For Left/Right Data</b> When set DMA requests for right-channel data are put on the TXBLRIGHT and RXDATAVRIGHT DMA requests.
2	JUSTIFY	0	RW	<b>Justification of I2S Data</b> Determines whether the I2S data is left or right justified
	Value	Mode		Description
	0	LEFT		Data is left-justified
	1	RIGHT		Data is right-justified
1	MONO	0	RW	<b>Stero or Mono</b> Switch between stereo and mono mode. Set for mono
0	EN	0	RW	<b>Enable I2S Mode</b> Set the U(S)ART in I2S mode.

## 18.5.24 USARTn\_TIMING - Timing Register

Offset	Bit Position																															
0x060	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset			0x0				0x0				0x0				0x0																	
Access			RW				RW				RW				RW																	
Name			CSHOLD				ICS				CSSETUP				TXDELAY																	

Bit	Name	Reset	Access	Description
31	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
30:28	CSHOLD	0x0	RW	<b>Chip Select Hold</b>  Chip Select will be asserted after the end of frame transmission. When using TCMPn, normally set TIMECMPn_TSTART to DISABLE to stop general timer and to prevent unwanted interrupts.
	Value	Mode	Description	
	0	ZERO	Disable CS being asserted after the end of transmission	
	1	ONE	CS is asserted for 1 baud-times after the end of transmission	
	2	TWO	CS is asserted for 2 baud-times after the end of transmission	
	3	THREE	CS is asserted for 3 baud-times after the end of transmission	
	4	SEVEN	CS is asserted for 7 baud-times after the end of transmission	
	5	TCMP0	CS is asserted after the end of transmission for TCMPVAL0 baud-times	
	6	TCMP1	CS is asserted after the end of transmission for TCMPVAL1 baud-times	
	7	TCMP2	CS is asserted after the end of transmission for TCMPVAL2 baud-times	
27	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
26:24	ICS	0x0	RW	<b>Inter-character spacing</b>  Inter-character spacing after each TX frame while the TX buffer is not empty. When using USART_TIMECMPn, normally set TSTART to DISABLE to stop general timer and to prevent unwanted interrupts.
	Value	Mode	Description	
	0	ZERO	There is no space between charcters	
	1	ONE	Create a space of 1 baud-times before start of transmission	
	2	TWO	Create a space of 2 baud-times before start of transmission	
	3	THREE	Create a space of 3 baud-times before start of transmission	
	4	SEVEN	Create a space of 7 baud-times before start of transmission	
	5	TCMP0	Create a space of before the start of transmission for TCMPVAL0 baud-times	
	6	TCMP1	Create a space of before the start of transmission for TCMPVAL1 baud-times	
	7	TCMP2	Create a space of before the start of transmission for TCMPVAL2 baud-times	
23	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
22:20	CSSETUP	0x0	RW	<b>Chip Select Setup</b>  Chip Select will be asserted before the start of frame transmission. When using USART_TIMECMPn, normally set TSTART to DISABLE to stop general timer and to prevent unwanted interrupts.
	Value	Mode	Description	
	0	ZERO	CS is not asserted before start of transmission	
	1	ONE	CS is asserted for 1 baud-times before start of transmission	
	2	TWO	CS is asserted for 2 baud-times before start of transmission	

Bit	Name	Reset	Access	Description
	3	THREE		CS is asserted for 3 baud-times before start of transmission
	4	SEVEN		CS is asserted for 7 baud-times before start of transmission
	5	TCMP0		CS is asserted before the start of transmission for TCMPVAL0 baud-times
	6	TCMP1		CS is asserted before the start of transmission for TCMPVAL1 baud-times
	7	TCMP2		CS is asserted before the start of transmission for TCMPVAL2 baud-times
19	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
18:16	TXDELAY	0x0	RW	<b>TX frame start delay</b>  Number of baud-times to delay the start of frame transmission. When using USART_TIMECMPn, normally set TSTART to DISABLE to stop general timer and to prevent unwanted interrupts.
	Value	Mode		Description
	0	DISABLE		Disable - TXDELAY in USARTn_CTRL can be used for legacy
	1	ONE		Start of transmission is delayed for 1 baud-times
	2	TWO		Start of transmission is delayed for 2 baud-times
	3	THREE		Start of transmission is delayed for 3 baud-times
	4	SEVEN		Start of transmission is delayed for 7 baud-times
	5	TCMP0		Start of transmission is delayed for TCMPVAL0 baud-times
	6	TCMP1		Start of transmission is delayed for TCMPVAL1 baud-times
	7	TCMP2		Start of transmission is delayed for TCMPVAL2 baud-times
15:0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

## 18.5.25 USARTn\_CTRLX - Control Register Extended

Offset	Bit Position																											
0x064	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4
Reset																											0	0
Access																											RW	RW
Name																											RTSINV	CTSIN

Bit	Name	Reset	Access	Description
31:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3	RTSINV	0	RW	<b>RTS Pin Inversion</b> When set, the RTS pin polarity is inverted.
	Value	Description		
	0	The USn_RTS pin is low true		
	1	The USn_RTS pin is high true		
2	CTSEN	0	RW	<b>CTS Function enabled</b> When set, frames in the TXBUF <sub>n</sub> will not be sent until link partner asserts CTS. Any data in the TX shift register will continue transmitting, the next TXBUF <sub>n</sub> data will not load into the TX shift register
	Value	Description		
	0	Ignore CTS		
	1	Stop transmitting when CTS is negated		
1	CTSINV	0	RW	<b>CTS Pin Inversion</b> When set, the CTS pin polarity is inverted.
	Value	Description		
	0	The USn_CTS pin is low true		
	1	The USn_CTS pin is high true		
0	DBGHALT	0	RW	<b>Debug halt</b> .
	Value	Description		
	0	Continue to transmit until TX buffer is empty		
	1	Complete the transmission in the shift register and then halt transmission; also negate RTS to stop link partner's transmission during debug HALT. NOTE** The core clock should be equal to or faster than the peripheral clock; otherwise, each single step could transmit multiple frames instead of just transmitting one frame.		

18.5.26 USARTn\_TIMECMP0 - Used to generate interrupts and various delays

## 19. LEUART - Low Energy Universal Asynchronous Receiver/Transmitter

### Quick Facts

#### What?

The LEUART provides full UART communication using a low frequency 32.768 kHz clock, and has special features for communication without CPU intervention.

#### Why?

It allows UART communication to be performed in low energy modes, using only a few  $\mu\text{A}$  during active communication and only 150 nA when waiting for incoming data.

#### How?

A low frequency clock signal allows communication with less energy. Using DMA, the LEUART can transmit and receive data with minimal CPU intervention. Special UART-frames can be configured to help control the data flow, further automating data transmission.

### 19.1 Introduction

The unique Low Energy UART (LEUART) is a UART that allows two-way UART communication on a strict power budget. Only a 32.768 kHz clock is needed to allow UART communication up to 9600 baud.

Even when the EFM is in low energy mode EM2 DeepSleep (with most core functionality turned off), the LEUART can wait for an incoming UART frame while having an extremely low energy consumption. When a UART frame is completely received, the CPU can quickly be woken up. Alternatively, multiple frames can be transferred via the Direct Memory Access (DMA) module into RAM memory before waking up the CPU.

Received data can optionally be blocked until a configurable start frame is detected. A signal frame can be configured to generate an interrupt indicating the end of a data transmission. The start frame and signal frame can be used in combination to handle higher level communication protocols.

Similarly, data can be transmitted in EM2 DeepSleep either on a frame-by-frame basis with data from the CPU or through use of the DMA.

The LEUART includes all necessary hardware support to make asynchronous serial communication possible with minimal software overhead and low energy consumption.

## 19.2 Features

- Low energy asynchronous serial communications
- Full/half duplex communication
- Separate TX / RX enable
- Separate double buffered transmit buffer and receive buffer
- Programmable baud rate, generated as a fractional division of the LFBCLK
  - Supports baud rates from 300 baud to 9600 baud
- Can use a high frequency clock source for even higher baud rates
- Configurable number of data bits: 8 or 9 (plus parity bit, if enabled)
- Configurable parity: off, even or odd
  - HW parity bit generation and check
- Configurable number of stop bits, 1 or 2
- Capable of sleep-mode wake-up on received frame
  - Either wake-up on any received byte or
  - Wake up only on specified start and signal frames
- Supports transmission and reception in EM0 Active, EM1 Sleep and EM2 DeepSleep with
  - Full DMA support
  - Specified start-frame can start reception automatically
- IrDA modulator (pulse generator, pulse extender)
- Multi-processor mode
- Loopback mode
  - Half duplex communication
  - Communication debugging
- PRS RX input

### 19.3 Functional Description

An overview of the LEUART module is shown in [Figure 19.1 LEUART Overview on page 579](#).

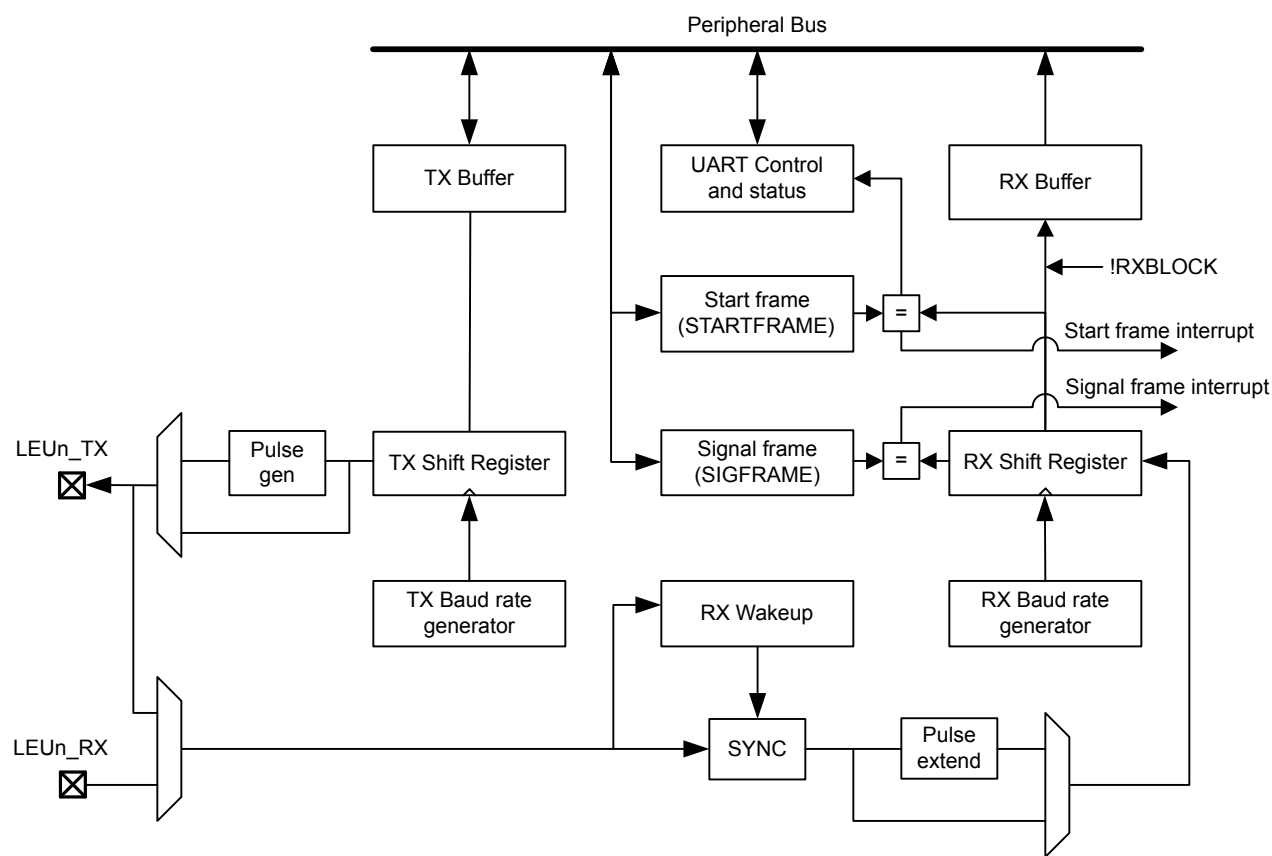

Figure 19.1. LEUART Overview

### 19.3.1 Frame Format

The frame format used by the LEUART consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 8 or 9 data bits and an optional parity bit. The data is transmitted with the least significant bit first. Finally, a number of stop-bits, where the line is driven high, end the frame. The frame format is shown in [Figure 19.2 LEUART Asynchronous Frame Format on page 580](#).

**Figure 19.2. LEUART Asynchronous Frame Format**

The number of data bits in a frame is set by DATABITS in LEUARTn\_CTRL, and the number of stop-bits is set by STOPBITS in LEUARTn\_CTRL. Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY in LEUARTn\_CTRL. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

The frame format used by the LEUART can be inverted by setting INV in LEUARTn\_CTRL. This affects the entire frame, resulting in a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits. INV should only be changed while the receiver is disabled.

#### 19.3.1.1 Parity Bit Calculation and Handling

Hardware automatically inserts parity bits into outgoing frames and checks the parity bits of incoming frames. The possible parity modes are defined in [Table 19.1 LEUART Parity Bit on page 580](#). When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd. When parity bits are disabled, which is the default configuration, the parity bit is omitted.

**Table 19.1. LEUART Parity Bit**

PARITY [1:0]	Description
00	No parity (default)
01	Reserved
10	Even parity
11	Odd parity

See [19.3.5.4 Parity Error](#) for more information on parity bit handling.

### 19.3.2 Clock Source

The LEUART clock source is selected by the LFB bit field the CMU\_LFCLKSEL register. The clock is prescaled by the LEUARTn bit-field in the CMU\_LFBPRESC0 register and enabled by the LEUARTn bit in the CMU\_LFBCLKEN0. See [Figure 12.1 CMU Overview on page 241](#) for a diagram of the clocking structure.

To use this module, the LE interface clock must be enabled in CMU\_HFBUSCLKEN0, in addition to the module clock.

### 19.3.3 Clock Generation

The LEUART clock defines the transmission and reception data rate. The clock generator employs a fractional clock divider to allow baud rates that are not attainable by integral division of the 32.768 kHz clock that drives the LEUART.

The clock divider used in the LEUART is a 14-bit value, with a 9-bit integral part and a 5-bit fractional part. The baud rate of the LEUART is given by :

$$br = fLEUARTn / (1 + LEUARTn\_CLKDIV / 256)$$

**Figure 19.3. LEUART Baud Rate Equation**

where fLEUARTn is the clock frequency supplied to the LEUART. The value of LEUARTn\_CLKDIV thus defines the baud rate of the LEUART. The integral part of the divider is right-aligned in the upper 24 bits of LEUARTn\_CLKDIV and the fractional part is left-aligned in the lower 8 bits. The divider is thus a 256th of LEUARTn\_CLKDIV as seen in the equation.

As an example let us assume fLEUART = 22.5Khz and the value of DIV in LEUARTn\_CLKDIV is 0x0028 (LEUARTn\_CLKDIV = 0x00000140). The baud rate = 22.5Khz/(1 + 0x140 / 256) = 22.5Khz / 2.25 = 10Khz.

For a desired baud rate br<sub>DESIRED</sub>, LEUARTn\_CLKDIV can be calculated by using:

$$LEUARTn\_CLKDIV = 256 \times (fLEUARTn/br_{DESIRED} - 1)$$

**Figure 19.4. LEUART CLKDIV Equation**

It's important to note that this equation results in a 32bit value for the LEUARTn\_CLKDIV register but only bits [16:3] are valid and all others must be 0. For example if we have a 32Khz clock and wish to achieve a baud rate of 10Khz the equation above results in a LEUARTn\_CLKDIV value of 0x233. However, the actual value of the register will be 0x230 since bits [2:0] cannot be set. This limits the best achievable accuracy. In this example the actual baud rate will be 32Khz / (1+ 0x230/255) = 10.039Khz instead of 32Khz / (1+ 0x233/255) = 10.002Khz.

[Table 19.2 LEUART Baud Rates on page 581](#) lists a set of desired baud rates and the closest baud rates reachable by the LEUART with a 32.768 kHz clock source. It also shows the average baud rate error.

**Table 19.2. LEUART Baud Rates**

Desired baud rate	LEUARTn_CLKDIV	LEUARTn_CLKDIV/256	Actual baud rate	Error [%]
300	27704	108,21875	300,0217	0.01
600	13728	53,625	599,8719	-0.02
1200	6736	26,3125	1199,744	-0.02
2400	3240	12,65625	2399,487	-0.02
4800	1488	5,8125	4809,982	0.21
9600	616	2,40625	9619,963	0.21

### 19.3.4 Data Transmission

Data transmission is initiated by writing data to the transmit buffer using one of the methods described in [19.3.4.1 Transmit Buffer Operation](#). When the transmit shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available. Transmission is enabled through the command register LEUARTn\_CMD by setting TXEN, and disabled by setting TXDIS. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in LEUARTn\_STATUS. After a transmission, when there is no more data in the shift register or transmit buffer, the TXC flag in LEUARTn\_STATUS and the TXC interrupt flag in LEUARTn\_IF are set, signaling that the transmitter is idle. The TXC status flag is cleared when a new byte becomes available for transmission, but the TXC interrupt flag must be cleared by software.

### 19.3.4.1 Transmit Buffer Operation

A frame can be loaded into the transmit buffer by writing to LEUARTn\_TXDATA or LEUARTn\_TXDATAx. Using LEUARTn\_TXDATA allows 8 bits to be written to the buffer. If 9 bit frames are used, the 9th bit will in that case be set to the value of BIT8DV in LEUARTn\_CTRL. To set the 9th bit directly and/or use transmission control, LEUARTn\_TXDATAx must be used. When writing data to the transmit buffer using LEUARTn\_TXDATAx, the 9th bit written to LEUARTn\_TXDATAx overrides the value in BIT8DV, and alone defines the 9th bit that is transmitted if 9-bit frames are used.

If a write is attempted to the transmit buffer when it is not empty, the TXOF interrupt flag in LEUARTn\_IF is set, indicating the overflow. The data already in the buffer is in that case preserved, and no data is written.

In addition to the interrupt flag TXC in LEUARTn\_IF and the status flag TXC in LEUARTn\_STATUS which are set when the transmitter becomes idle, TXBL in LEUARTn\_STATUS and the TXBL interrupt flag in LEUARTn\_IF are used to indicate the level of the transmit buffer. Whenever the transmit buffer becomes empty, these flags are set high. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when data is written to the transmit buffer.

There is also TXIDLE status in LEUARTn\_STATUS which can be used to detect when the transmit state machine is in the idle state.

The transmit buffer, including the TX shift register can be cleared by setting command bit CLEAR\_TX in LEUARTn\_CMD. This will prevent the LEUART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed. An overview of the operation of the transmitter is shown in [Figure 19.5 LEUART Transmitter Overview on page 582](#).

Figure 19.5. LEUART Transmitter Overview

### 19.3.4.2 Frame Transmission Control

The transmission control bits, which can be written using LEUARTn\_TXDATAx, affect the transmission of the written frame. The following options are available:

- **Generate break:** By setting TXBREAK, the output will be held low during the first stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high for one bit period before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than an UART frame are thus not supported by the LEUART. GPIO can be used for this. Note that when AUTOTRI in LEUARTn\_CTRL is used, the transmitter is not tristated before the high-bit after the break has been transmitted.
- **Disable transmitter after transmission:** If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- **Enable receiver after transmission:** If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.

The transmission control bits in the LEUART cannot tristate the transmitter. This is performed automatically by hardware if AUTOTRI in LEUARTn\_CTRL is set. See [19.3.7 Half Duplex Communication](#) for more information on half duplex operation.

### 19.3.5 Data Reception

Data reception is enabled by setting RXEN in LEUARTn\_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start bit of a new frame. When a start bit is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start bit. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available.

If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the receive shift register is overwritten, and the RXOF interrupt flag in LEUARTn\_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in LEUARTn\_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in LEUARTn\_STATUS.

The receive buffer can be cleared by setting command bit CLEARRX in LEUARTn\_CMD. This will make it available for new data. Any frame currently being received will not be aborted and will become the first received frame when complete.

#### 19.3.5.1 Receive Buffer Operation

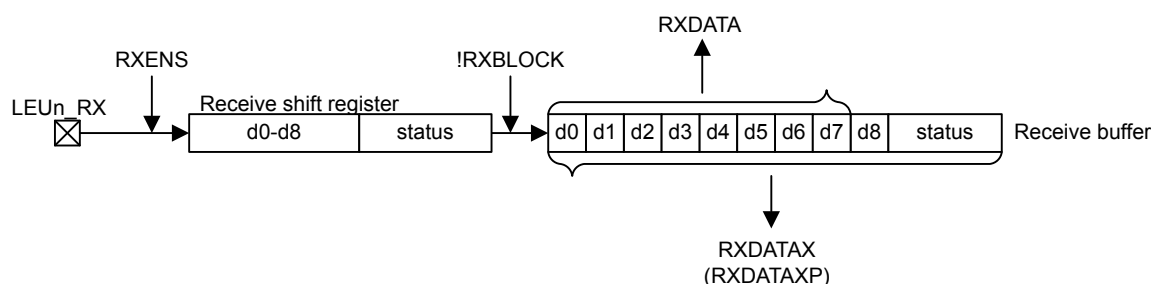

When data becomes available in the receive buffer, the RXDATAV flag in LEUARTn\_STATUS and the RXDATAV interrupt flag in LEUARTn\_IF are set. Both the RXDATAV status flag and the RXDATAV interrupt flag are cleared by hardware when data is no longer available, i.e. when data has been read out of the buffer.

Data can be read from receive buffer using either LEUARTn\_RXDATA or LEUARTn\_RXDATAx. LEUARTn\_RXDATA gives access to the 8 least significant bits of the received frame, while LEUARTn\_RXDATAx must be used to get access to the 9th, most significant bit. The LEUARTn\_RXDATAx register also contains status information regarding the frame.

When a frame is read from the receive buffer using LEUARTn\_RXDATA or LEUARTn\_RXDATAx, the frame is removed from the buffer, making room for a new one. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in LEUARTn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can also be read from the receive buffer without removing the data by using LEUARTn\_RXDATAxP, which gives access to the frame in the buffer including control bits. Data read from this register when the receive buffer is empty is undefined. No underflow interrupt is generated by a read using LEUARTn\_RXDATAxP, i.e. the RXUF interrupt flag is never set as a result of reading from LEUARTn\_RXDATAxP.

An overview of the operation of the receiver is shown in [Figure 19.6 LEUART Receiver Overview on page 583](#).

**Figure 19.6. LEUART Receiver Overview**

### 19.3.5.2 Blocking Incoming Data

When using hardware frame recognition, as detailed in [19.3.5.6 Programmable Start Frame](#), [19.3.5.7 Programmable Signal Frame](#), and [19.3.5.8 Multi-Processor Mode](#), it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in LEUARTn\_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV bit in LEUARTn\_STATUS or the RXDATAV interrupt flag in LEUARTn\_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in LEUARTn\_CMD and disabled by setting RXBLOCKDIS also in LEUARTn\_CMD. There are two exceptions where data is loaded into the receive buffer even when RXBLOCK is set. The first is when an address frame is received when in operating in multi-processor mode as shown in [19.3.5.8 Multi-Processor Mode](#). The other case is when receiving a start-frame when SFUBRX in LEUARTn\_CTRL is set; see [19.3.5.6 Programmable Start Frame](#).

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in LEUARTn\_IF being set while RXBLOCK is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

#### Note:

If a frame is received while RXBLOCK in LEUARTn\_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time.

The overflow interrupt flag RXOF in LEUARTn\_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK is set.

### 19.3.5.3 Data Sampling

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Except for the start-bit, only a single sample is taken of each of the incoming bits.

The length of a bit-period is given by  $1 + \text{LEUARTn\_CLKDIV}/256$ , as a number of 32.768 kHz clock periods. Let the clock cycle where a start-bit is first detected be given the index 0. The optimal sampling point for each bit in the UART frame is then given by the following equation:

$$S_{\text{opt}}(n) = n (1 + \text{LEUARTn\_CLKDIV}/256) + \text{CLKDIV}/512$$

**Figure 19.7. LEUART Optimal Sampling Point**

where n is the bit-index.

Since samples are only done on the positive edges of the 32.768 kHz clock, the actual samples are performed on the closest positive edge, i.e. the edge given by the following equation:

$$S(n) = \text{floor}(n \times (1 + \text{LEUARTn\_CLKDIV}/256) + \text{LEUARTn\_CLKDIV}/512)$$

**Figure 19.8. LEUART Actual Sampling Point**

The sampling location will thus have jitter according to difference between  $S_{\text{opt}}$  and S. The start-bit is found at  $n=0$ , then follows the data bits, any parity bit, and the stop bits.

If the value of the start-bit is found to be high, then the start-bit is discarded, and the receiver waits for a new start-bit.

### 19.3.5.4 Parity Error

When the parity bit is enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in a frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the LEUARTn\_RXDATA register.

### 19.3.5.5 Framing Error and Break Detection

A framing error is the result of a received frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected, the framing error bit FERR in the received frame is set. The interrupt flag FERR in LEUARTn\_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the LEUARTn\_RXDATA or LEUARTn\_RXDATAEXP registers.

### 19.3.5.6 Programmable Start Frame

The LEUART can be configured to start receiving data when a special start frame is detected on the input. This can be useful when operating in low energy modes, allowing other devices to gain the attention of the LEUART by transmitting a given frame.

When SFUBRX in LEUARTn\_CTRL is set, an incoming frame matching the frame defined in LEUARTn\_STARTFRAME will result in RXBLOCK in LEUARTn\_STATUS being cleared. This can be used to enable reception when a specified start frame is detected. If the receiver is enabled and blocked, i.e. RXENS and RXBLOCK in LEUARTn\_STATUS are set, the receiver will receive all incoming frames, but unless an incoming frame is a start frame it will be discarded and not loaded into the receive buffer. When a start frame is detected, the block is cleared, and frames received from that point, including the start frame, are loaded into the receive buffer.

An incoming start frame results in the STARTF interrupt flag in LEUARTn\_IF being set, regardless of the value of SFUBRX in LEUARTn\_CTRL. This allows an interrupt to be made when the start frame is detected.

When 8 data-bit frame formats are used, only the 8 least significant bits of LEUARTn\_STARTFRAME are compared to incoming frames. The full length of LEUARTn\_STARTFRAME is used when operating with frames consisting of 9 data bits.

#### Note:

The receiver must be enabled for start frames to be detected. In addition, a start frame with a parity error or framing error is not detected as a start frame.

### 19.3.5.7 Programmable Signal Frame

As well as the configurable start frame, a special signal frame can be specified. When a frame matching the frame defined in LEUARTn\_SIGFRAME is detected by the receiver, the SIGF interrupt flag in LEUARTn\_IF is set. As for start frame detection, the receiver must be enabled for signal frames to be detected.

One use of the programmable signal frame is to signal the end of a multi-frame message transmitted to the LEUART. An interrupt will then be triggered when the packet has been completely received, allowing software to process it. Used in conjunction with the programmable start frame and DMA, this makes it possible for the LEUART to automatically begin the reception of a packet on a specified start frame, load the entire packet into memory, and give an interrupt when reception of a packet has completed. The device can thus wait for data packets in EM2 DeepSleep, and only be woken up when a packet has been completely received.

A signal frame with a parity error or framing error is not detected as a signal frame.

### 19.3.5.8 Multi-Processor Mode

To simplify communication between multiple processors and maintain compatibility with the USART, the LEUART supports a multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in LEUARTn\_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in LEUARTn\_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in LEUARTn\_STATUS.

Multi-processor mode is enabled by setting MPM in LEUARTn\_CTRL. The mode can be used in buses with multiple slaves, allowing the slaves to be addressed using the special address frames. An addressed slave, which was previously blocking reception using RXBLOCK, would then unblock reception, receive a message from the bus master, and then block reception again, waiting for the next message. See the USART for a more detailed example.

#### Note:

The programmable start frame functionality can be used for automatic address matching, enabling reception on a correctly configured incoming frame.

An address frame with a parity error or a framing error is not detected as an address frame. The Start, Signal, and address frames should not be set to match the same frame since each of these uses separate synchronization to the peripheral clock domain.

### 19.3.6 Loopback

The LEUART receiver samples LEUn\_RX by default, and the transmitter drives LEUn\_TX by default. This is not the only configuration however. When LOOPBK in LEUARTn\_CTRL is set, the receiver is connected to the LEUn\_TX pin as shown in [Figure 19.9 LEUART Local Loopback on page 586](#). This is useful for debugging, as the LEUART can receive the data it transmits, but it is also used to allow the LEUART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the LEUn\_TX pin must be enabled as an output in the GPIO.

Figure 19.9. LEUART Local Loopback

### 19.3.7 Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

### 19.3.7.1 Single Data-link

In this setup, the LEUART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in LEUARTn\_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the LEUART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. If AUTOTRI in LEUARTn\_CTRL is set, the LEUART automatically tristates LEUn\_TX whenever the transmitter is inactive. It is then the responsibility of the software protocol to make sure the transmitter is not transmitting data whenever incoming data is expected.

The transmitter can also be tristated from software by configuring the GPIO pin as an input and disabling the LEUART output on LEUn\_TX.

#### Note:

Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

### 19.3.7.2 Single Data-link with External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of Tristating the transmitter when receiving data, the external driver must be disabled. The USART has hardware support for automatically turning the driver on and off. When using the LEUART in such a setup, the driver must be controlled by a GPIO. [Figure 19.10 LEUART Half Duplex Communication with External Driver on page 587](#) shows an example configuration using an external driver.

**Figure 19.10. LEUART Half Duplex Communication with External Driver**

### 19.3.7.3 Two Data-links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

### 19.3.8 Transmission Delay

By configuring TXDELAY in LEUARTn\_CTRL, the transmitter can be forced to wait a number of bit-periods from when it is ready to transmit data, to when it actually transmits the data. This delay is only applied to the first frame transmitted after the transmitter has been idle. When transmitting frames back-to-back the delay is not introduced between the transmitted frames.

This is useful on half duplex buses, because the receiver always returns received frames to software during the first stop-bit. The bus may still be driven for up to 3 bit periods, depending on the current frame format. Using the transmission delay, a transmission can be started when a frame is received, and it is possible to make sure that the transmitter does not begin driving the output before the frame on the bus is completely transmitted.

To route the UART TX and RX signals to a pin first select the desired pins using the RXLOC and TXLOC fields in the LEUARTn\_ROUTESLOC0 register. Then enable the connection using TXPEN and RXPEN in the LEUARTn\_ROUTEPEN register. See the device data-sheet for mappings between UART locations (LOC0, LOC1, etc.) and device pins (PA0, PA1, etc.).

### 19.3.9 PRS RX Input

In addition to receiving data on an external pin the LEUART can be configured to receive data directly from a PRS channel by setting `RX_PRS` in `LEUARTn_INPUT`. The PRS channel used can be selected using `RX_PRS_SEL` in `LEUARTn_INPUT`. See the PRS chapter for more details on the PRS block.

For example the output of a comparator could be routed to the LEUART through the PRS to allow for receiving a signal with low peak-to-peak voltage or a significant DC offset.

### 19.3.10 DMA Support

The LEUART has full DMA support in energy modes EM0 Active – EM2 DeepSleep. The DMA controller can write to the transmit buffer using the registers `LEUARTn_TXDATA` and `LEUARTn_TXDATA_X`, and it can read from receive buffer using the registers `LEUARTn_RXDATA` and `LEUARTn_RXDATA_X`. This enables single byte transfers and 9 bit data + control/status bits transfers both to and from the LEUART. The DMA will start up the HFRCO and run from this when it is waken by the LEUART in EM2. The HFRCO is disabled once the transaction is done.

A request for the DMA controller to read from the receive buffer can come from one of the following sources:

- Receive buffer full

A write request can come from one of the following sources:

- Transmit buffer and shift register empty. No data to send.
- Transmit buffer empty

In some cases, it may be sensible to temporarily stop DMA access to the LEUART when a parity or framing error has occurred. This is enabled by setting `ERRSDMA` in `LEUARTn_CTRL`. When this bit is set, the DMA controller will not get requests from the receive buffer if a framing error or parity error is detected in the received byte. The `ERRSDMA` bit applies only to the RX DMA.

When operating in EM2 DeepSleep, the DMA controller must be powered up in order to perform the transfer. This is automatically performed for read operations if `RXDMAWU` in `LEUARTn_CTRL` is set and for write operations if `TXDMAWU` in `LEUARTn_CTRL` is set. To make sure the DMA controller still transfers bits to and from the LEUART in low energy modes, these bits must thus be configured accordingly.

#### Note:

When `RXDMAWU` or `TXDMAWU` is set, the system will not be able to go to EM2 DeepSleep/EM3 Stop before all related LEUART DMA requests have been processed. This means that if `RXDMAWU` is set and the LEUART receives a frame, the system will not be able to go to EM2 DeepSleep/EM3 Stop before the frame has been read from the LEUART. In order for the system to go to EM2 during the last byte transmission, `LEUART_CTRL_TXDMAWU` must be cleared in the DMA interrupt service routine. This is because `TXBL` will be high during that last byte transfer.

### 19.3.11 Pulse Generator/ Pulse Extender

The LEUART has an optional pulse generator for the transmitter output, and a pulse extender on the receiver input. These are enabled by setting PULSEEN in LEUARTn\_PULSECTRL, and with INV in LEUARTn\_CTRL set, they will change the output/input format of the LEUART from NRZ to RZI as shown in [Figure 19.11 LEUART - NRZ vs. RZI on page 589](#).

**Figure 19.11. LEUART - NRZ vs. RZI**

If PULSEEN in LEUARTn\_PULSECTRL is set while INV in LEUARTn\_CTRL is cleared, the output waveform will look like RZI shown in [Figure 19.11 LEUART - NRZ vs. RZI on page 589](#), only inverted.

The width of the pulses from the pulse generator can be configured using PULSEW in LEUARTn\_PULSECTRL. The generated pulse width is PULSEW + 1 cycles of the 32.768 kHz clock, which makes pulse width from 31.25µs to 500µs possible.

Since the incoming signal is only sampled on positive clock edges, the width of the incoming pulses must be at least two 32.768 kHz clock periods wide for reliable detection by the LEUART receiver. They must also be shorter than half a UART bit period.

At 2400 baud or lower, the pulse generator is able to generate RZI pulses compatible with the IrDA physical layer specification. The external IrDA device must generate pulses of sufficient length for successful two-way communication.

PULSEFILT in the LEUARTn\_PULSECTRL register can be used to extend the minimum receive pulse width from 2 clock periods to 3 clock periods.

#### 19.3.11.1 Interrupts

The interrupts generated by the LEUART are combined into one interrupt vector. If LEUART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in LEUARTn\_IF and their corresponding bits in LEUART\_IEN are set.

#### 19.3.12 Register access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#) for a description on how to perform register accesses to Low Energy Peripherals.

The registers LEUARTn\_FREEZE and LEUARTn\_SYNCBUSY are used for synchronization of this peripheral.

## 19.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	LEUARTn_CTRL	RW	Control Register
0x004	LEUARTn_CMD	W1	Command Register
0x008	LEUARTn_STATUS	R	Status Register
0x00C	LEUARTn_CLKDIV	RW	Clock Control Register
0x010	LEUARTn_STARTFRAME	RW	Start Frame Register
0x014	LEUARTn_SIGFRAME	RW	Signal Frame Register
0x018	LEUARTn_RXDATAx	R(a)	Receive Buffer Data Extended Register
0x01C	LEUARTn_RXDATA	R(a)	Receive Buffer Data Register
0x020	LEUARTn_RXDATAxP	R	Receive Buffer Data Extended Peek Register
0x024	LEUARTn_TXDATAx	W	Transmit Buffer Data Extended Register
0x028	LEUARTn_TXDATA	W	Transmit Buffer Data Register
0x02C	LEUARTn_IF	R	Interrupt Flag Register
0x030	LEUARTn_IFS	W1	Interrupt Flag Set Register
0x034	LEUARTn_IFC	(R)W1	Interrupt Flag Clear Register
0x038	LEUARTn_IEN	RW	Interrupt Enable Register
0x03C	LEUARTn_PULSECTRL	RW	Pulse Control Register
0x040	LEUARTn_FREEZE	RW	Freeze Register
0x044	LEUARTn_SYNCBUSY	R	Synchronization Busy Register
0x054	LEUARTn_ROUTE PEN	RW	I/O Routing Pin Enable Register
0x058	LEUARTn_ROUTELOC0	RW	I/O Routing Location Register
0x064	LEUARTn_INPUT	RW	LEUART Input Register

## 19.5 Register Description

### 19.5.1 LEUARTn\_CTRL - Control Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

For more information about Registers please see <a href="#">the Access to Low Energy Peripherals (Non-volatile Registers)</a> .

Name																	TXDELAY	TXDMAWU	RXDMAWU	BIT8DV	MPAB	MPM	SFUBRX	LOOPBK	ERRSDMA	INV	STOPBITS	PARITY	DATABITS	AUTOTRI													

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:14	TXDELAY	0x0	RW	<b>TX Delay Transmission</b> Configurable delay before new transfers. Frames sent back-to-back are not delayed.
	Value	Mode		Description
	0	NONE		Frames are transmitted immediately
	1	SINGLE		Transmission of new frames are delayed by a single bit period
	2	DOUBLE		Transmission of new frames are delayed by two bit periods
	3	TRIPLE		Transmission of new frames are delayed by three bit periods
13	TXDMAWU	0	RW	<b>TX DMA Wakeup</b> Set to wake the DMA controller up when in EM2 and space is available in the transmit buffer.
	Value			Description
	0			While in EM2, the DMA controller will not get requests about space being available in the transmit buffer
	1			DMA is available in EM2 for the request about space available in the transmit buffer
12	RXDMAWU	0	RW	<b>RX DMA Wakeup</b> Set to wake the DMA controller up when in EM2 and data is available in the receive buffer.
	Value			Description
	0			While in EM2, the DMA controller will not get requests about data being available in the receive buffer
	1			DMA is available in EM2 for the request about data in the receive buffer
11	BIT8DV	0	RW	<b>Bit 8 Default Value</b> When 9-bit frames are transmitted, the default value of the 9th bit is given by BIT8DV. If TXDATA is used to write a frame, then the value of BIT8DV is assigned to the 9th bit of the outgoing frame. If a frame is written with TXDATAx however, the default value is overridden by the written value.
10	MPAB	0	RW	<b>Multi-Processor Address-Bit</b> Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.
9	MPM	0	RW	<b>Multi-Processor Mode</b> Set to enable multi-processor mode.
	Value			Description
	0			The 9th bit of incoming frames have no special function
	1			An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set
8	SFUBRX	0	RW	<b>Start-Frame Unblock RX</b> Clears RXBLOCK when the start-frame is found in the incoming data. The start-frame is loaded into the receive buffer.

Bit	Name	Reset	Access	Description
	Value			Description
	0			Detected start-frames have no effect on RXBLOCK
	1			When a start-frame is detected, RXBLOCK is cleared and the start-frame is loaded into the receive buffer
7	LOOPBK	0	RW	<b>Loopback Enable</b> Set to connect receiver to LEUn_TX instead of LEUn_RX.
	Value			Description
	0			The receiver is connected to and receives data from LEUn_RX
	1			The receiver is connected to and receives data from LEUn_TX
6	ERRSDMA	0	RW	<b>Clear RX DMA On Error</b> When set, RX DMA requests will be cleared on framing and parity errors.
	Value			Description
	0			Framing and parity errors have no effect on DMA requests from the LEUART
	1			RX DMA requests from the LEUART are disabled if a framing error or parity error occurs.
5	INV	0	RW	<b>Invert Input And Output</b> Set to invert the output on LEUn_TX and input on LEUn_RX.
	Value			Description
	0			A high value on the input/output is 1, and a low value is 0.
	1			A low value on the input/output is 1, and a high value is 0.
4	STOPBITS	0	RW	<b>Stop-Bit Mode</b> Determines the number of stop-bits used. Only used when transmitting data. The receiver only verifies that one stop bit is present.
	Value	Mode		Description
	0	ONE		One stop-bit is transmitted with every frame
	1	TWO		Two stop-bits are transmitted with every frame
3:2	PARITY	0x0	RW	<b>Parity-Bit Mode</b> Determines whether parity bits are enabled, and whether even or odd parity should be used.
	Value	Mode		Description
	0	NONE		Parity bits are not used
	2	EVEN		Even parity are used. Parity bits are automatically generated and checked by hardware.
	3	ODD		Odd parity is used. Parity bits are automatically generated and checked by hardware.
1	DATABITS	0	RW	<b>Data-Bit Mode</b> This register sets the number of data bits.

Bit	Name	Reset	Access	Description
	Value	Mode		Description
	0	EIGHT		Each frame contains 8 data bits
	1	NINE		Each frame contains 9 data bits
0	AUTOTRI	0	RW	<b>Automatic Transmitter Tristate</b> When set, LEUn_TX is tristated whenever the transmitter is inactive.
	Value			Description
	0			LEUn_TX is held high when the transmitter is inactive. INV inverts the inactive state.
	1			LEUn_TX is tristated when the transmitter is inactive

### 19.5.2 LEUARTn\_CMD - Command Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

For more information about Registers, please see <a href="#">the Access to Low Energy Peripherals (Peripherals Registers)</a> .

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7	CLEARRX	0	W1	<b>Clear RX</b> Set to clear receive buffer and the RX shift register.
6	CLEARTX	0	W1	<b>Clear TX</b> Set to clear transmit buffer and the TX shift register.
5	RXBLOCKDIS	0	W1	<b>Receiver Block Disable</b> Set to clear RXBLOCK, resulting in all incoming frames being loaded into the receive buffer.
4	RXBLOCKEN	0	W1	<b>Receiver Block Enable</b> Set to set RXBLOCK, resulting in all incoming frames being discarded.
3	TXDIS	0	W1	<b>Transmitter Disable</b> Set to disable transmission.
2	TXEN	0	W1	<b>Transmitter Enable</b> Set to enable data transmission.
1	RXDIS	0	W1	<b>Receiver Disable</b> Set to disable data reception. If a frame is under reception when the receiver is disabled, the incoming frame is discarded.
0	RXEN	0	W1	<b>Receiver Enable</b> Set to activate data reception on LEUn_RX.

### 19.5.3 LEUARTn\_STATUS - Status Register

Offset	Bit Position																																	
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Access																									R	R	R	R	R	R	R	R	R	R
Name																									TXIDLE	RXDATAV	TXBL	TXC	RXBLOCK	TXENS	RXENS			

Bit	Name	Reset	Access	Description
31:7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6	TXIDLE	1	R	<b>TX Idle</b> Set when TX is idle
5	RXDATAV	0	R	<b>RX Data Valid</b> Set when data is available in the receive buffer. Cleared when the receive buffer is empty.
4	TXBL	1	R	<b>TX Buffer Level</b> Indicates the level of the transmit buffer. Set when the transmit buffer is empty, and cleared when it is full.
3	TXC	0	R	<b>TX Complete</b> Set when a transmission has completed and no more data is available in the transmit buffer. Cleared when a new transmission starts.
2	RXBLOCK	0	R	<b>Block Incoming Data</b> When set, the receiver discards incoming frames. An incoming frame will not be loaded into the receive buffer if this bit is set at the instant the frame has been completely received.
1	TXENS	0	R	<b>Transmitter Enable Status</b> Set when the transmitter is enabled.
0	RXENS	0	R	<b>Receiver Enable Status</b> Set when the receiver is enabled. The receiver must be enabled for start frames, signal frames, and multi-processor address bit detection.

### 19.5.4 LEUARTn\_CLKDIV - Clock Control Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

For more information about Registers please see [the Access to Low Energy peripherals \(Peripheral Registers\)](#).

Offset	Bit Position																																	
0x00C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Name																	RXENAT	TXDISAT	TXBREAK									TXDATA				

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15	RXENAT	0	W	<b>Enable RX After Transmission</b> Set to enable reception after transmission.
	Value	Description		
	0	The receiver is not enabled after the frame has been transmitted		
	1	The receiver is enabled (setting RXENS) after the frame has been transmitted		
14	TXDISAT	0	W	<b>Disable TX After Transmission</b> Set to disable transmitter directly after transmission has completed.
	Value	Description		
	0	The transmitter is not disabled after the frame has been transmitted		
	1	The transmitter is disabled (clearing TXENS) after the frame has been transmitted		
13	TXBREAK	0	W	<b>Transmit Data As Break</b> Set to send data as a break. Recipient will see a framing error or a break condition depending on its configuration and the value of TXDATA.
	Value	Description		
	0	The specified number of stop-bits are transmitted		
	1	Instead of the ordinary stop-bits, 0 is transmitted to generate a break. A single stop-bit is generated after the break to allow the receiver to detect the start of the next frame		
12:9	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
8:0	TXDATA	0x000	W	<b>TX Data</b> Use this register to write data to the LEUART. If the transmitter is enabled, a transfer will be initiated at the first opportunity.

19.5.11 LEUARTn\_TXDATA - Transmit Buffer Data Register (Async Reg)

## 20. TIMER - Timer/Counter

### Quick Facts

#### What?

The TIMER (Timer/Counter) keeps track of timing and counts events, generates output waveforms and triggers timed actions in other peripherals.

#### Why?

Most applications have activities that need to be timed accurately with as little CPU intervention and energy consumption as possible.

#### How?

The flexible 16-bit timer can be configured to provide PWM waveforms with optional dead-time insertion (e.g. motor control) or work as a frequency generator. The timer can also count events and control other peripherals through the PRS, which offloads the CPU and reduces energy consumption.

### 20.1 Introduction

The 16-bit general purpose timer has 3 or 4 compare/capture channels for input capture and compare/Pulse-Width Modulation (PWM) output. TIMER0 also includes a Dead-Time Insertion module suitable for motor control applications.

## 20.2 Features

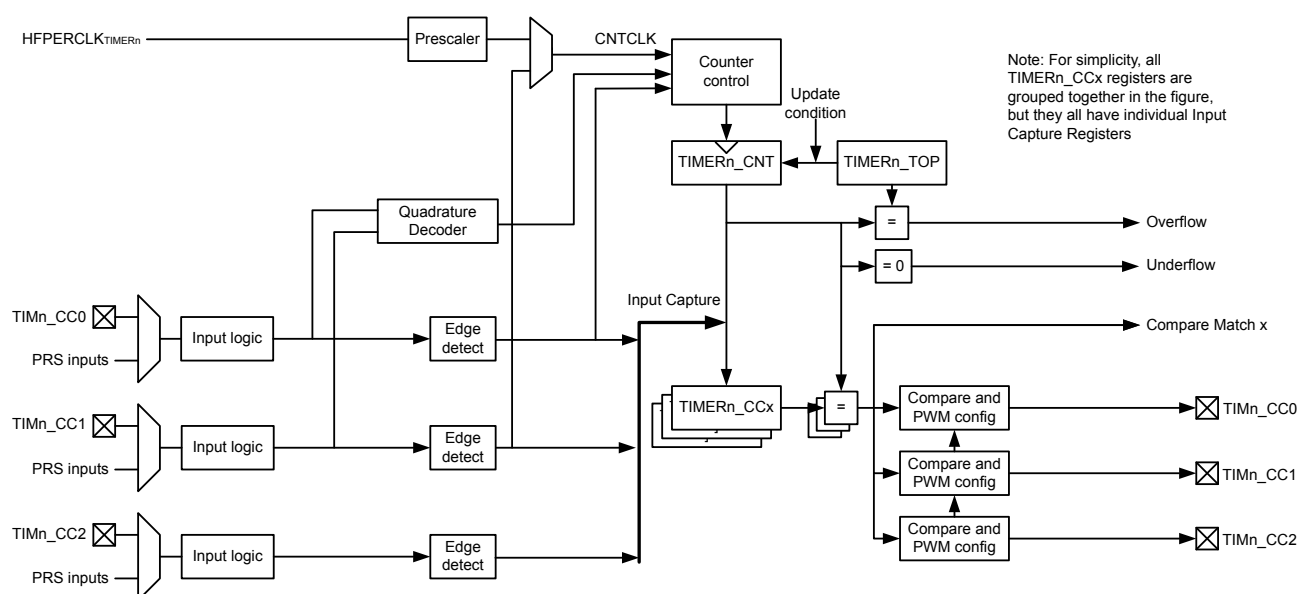

- 16-bit auto reload up/down counter
  - Dedicated 16-bit reload register which serves as counter maximum
- 3 or 4 Compare/Capture channels
  - Individually configurable as either input capture or output compare/PWM
- Multiple Counter modes
  - Count up
  - Count down
  - Count up/down
  - Quadrature Decoder
  - Direction and count from external pins
- 2x Count Mode
- Counter control from PRS or external pin
  - Start
  - Stop
  - Reload and start
- Inter-Timer connection
  - Allows 32-bit counter mode
  - Start/stop synchronization between several timers
- Input Capture
  - Period measurement
  - Pulse width measurement
  - Two capture registers for each capture channel
    - Capture on either positive or negative edge
    - Capture on both edges
  - Optional digital noise filtering on capture inputs
- Output Compare
  - Compare output toggle/pulse on compare match
  - Immediate update of compare registers
- PWM
  - Up-count PWM
  - Up/down-count PWM
  - Predictable initial PWM output state (configured by SW)
  - Buffered compare register to ensure glitch-free update of compare values
- Clock sources
  - HFPERCLK<sub>TIMERn</sub>
    - 10-bit Prescaler
  - External pin
  - Peripheral Reflex System
- Debug mode
  - Configurable to either run or stop when processor is stopped (halt/breakpoint)
- Interrupts, PRS output and/or DMA request on:
  - Underflow
  - Overflow
  - Compare/Capture event
- Dead-Time Insertion Unit (TIMER0 only)
  - Complementary PWM outputs with programmable dead-time
    - Dead-time is specified independently for rising and falling edge
      - 10-bit prescaler
      - 6-bit time value
  - Outputs have configurable polarity
  - Outputs can be set inactive individually by software.
  - Configurable action on fault

- Set outputs inactive
- Clear output
- Tristate output
- Individual fault sources
  - One or two PRS signals
  - Debugger
    - Support for automatic restart
  - Core lockup
- Configuration lock

## 20.3 Functional Description

An overview of the TIMER module is shown in [Figure 20.1 TIMER Block Overview on page 616](#) and it consists of a 16 bit up/down counter with 3 Compare/Capture channels connected to pins TIMn\_CC0, TIMn\_CC1, and TIMn\_CC2.

**Figure 20.1. TIMER Block Overview**

### 20.3.1 Counter Modes

The timer consists of a counter that can be configured to the following modes:

1. Up-count: Counter counts up until it reaches the value in TIMERN\_TOP, where it is reset to 0 before counting up again.
2. Down-count: The counter starts at the value in TIMERN\_TOP and counts down. When it reaches 0, it is reloaded with the value in TIMERN\_TOP.
3. Up/Down-count: The counter starts at 0 and counts up. When it reaches the value in TIMERN\_TOP, it counts down until it reaches 0 and starts counting up again.
4. Quadrature Decoder: Two input channels where one determines the count direction, while the other pin triggers a clock event.

In addition, to the TIMER modes listed above, the TIMER also supports a 2x Count Mode. In this mode the counter increments/decrements by 2. The 2x Count Mode intended use is to generate 2x PWM frequency when the Compare/Capture channel is put in PWM mode. The 2x Count Mode can be enabled by setting the X2CNT bitfield in the TIMERN\_CTRL register.

The counter value can be read or written by software at any time by accessing the CNT field in TIMERN\_CNT.

### 20.3.1.1 Events

Overflow is set when the counter value shifts from `TIMERN_TOP` to the next value when counting up. In up-count mode and Quadrature Decoder mode the next value is 0. In up/down-count mode, the next value is `TIMERN_TOP-1`.

Underflow is set when the counter value shifts from 0 to the next value when counting down. In down-count mode and Quadrature Decoder mode, the next value is `TIMERN_TOP`. In up/down-count mode the next value is 1.

An update event occurs on overflow in up-count mode and on underflow in down-count or up/down count mode. Additionally, an update event also occurs on overflow and underflow in Quadrature Decoder Mode. This event is used to time updates of buffered values.

### 20.3.1.2 Operation

Figure 20.2 **TIMER Hardware Timer/Counter Control** on page 617 shows the hardware Timer/Counter control. Software can start or stop the counter by setting the START or STOP bits in `TIMERN_CMD`. The counter value (CNT in `TIMERN_CNT`) can always be written by software to any 16-bit value.

It is also possible to control the counter through either an external pin or PRS input. This is done through the input logic for the Compare/Capture Channel 0. The Timer/Counter allows individual actions (start, stop, reload) to be taken for rising and falling input edges. This is configured in the `RISEA` and `FALLA` fields in `TIMERN_CTRL`. The reload value is 0 in up-count and up/down-count mode and `TOP` in down-count mode.

The `RUNNING` bit in `TIMERN_STATUS` indicates if the timer is running or not. If the `SYNC` bit in `TIMERN_CTRL` is set, the timer is started/stopped/reloaded (external pin or PRS) when any of the other timers are started/stopped/reloaded.

The `DIR` bit in `TIMERN_STATUS` indicates the counting direction of the timer at any given time. The counter value can be read or written by software through the `CNT` field in `TIMERN_CNT`. In Up/Down-Count mode the count direction will be set to up if the `CNT` value is written by software.

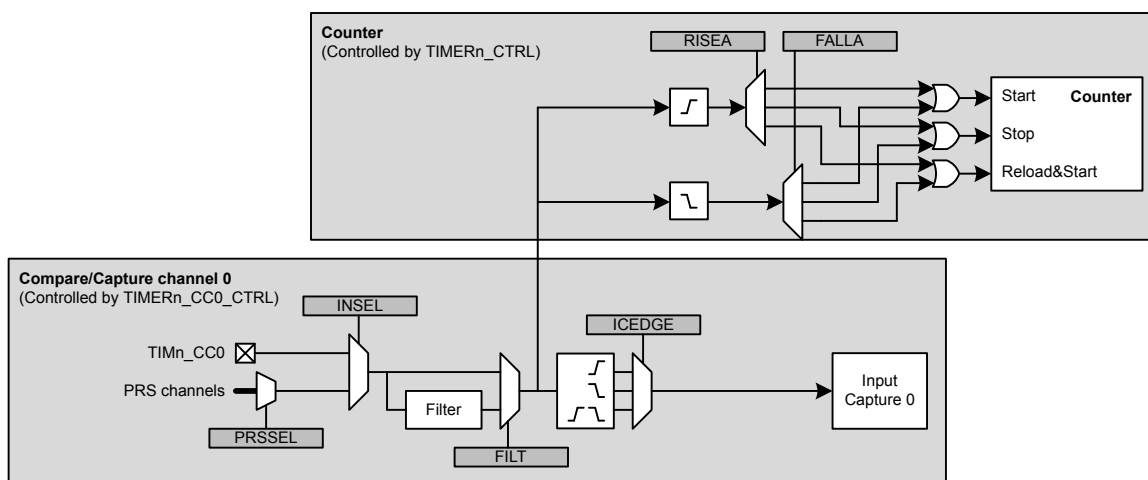

Figure 20.2. TIMER Hardware Timer/Counter Control

### 20.3.1.3 Clock Source

The counter can be clocked from several sources, which are all synchronized with the peripheral clock (HFPERCLK). See [Figure 20.3 TIMER Clock Selection on page 618](#).

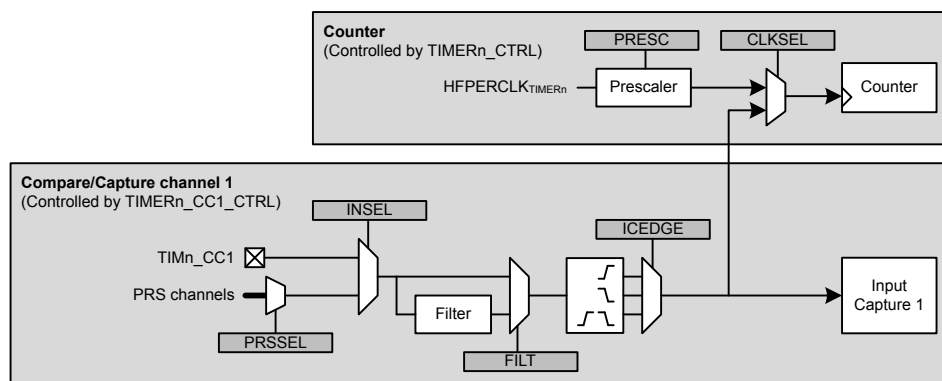

Figure 20.3. TIMER Clock Selection

### 20.3.1.4 Peripheral Clock (HFPERCLK)

The peripheral clock (HFPERCLK) can be used as a source with a configurable prescale factor of  $2^{\text{PRESC}}$ , where PRESC is an integer between 0 and 10, which is set in PRESC in TIMERN\_CTRL. However, if 2x Count Mode is enabled and the Compare/Capture channels are put in PWM mode, the CC output is updated on both clock edges so prescaling the peripheral clock will produce an incorrect result. The prescaler is stopped and reset when the timer is stopped.

### 20.3.1.5 Compare/ Capture Channel 1 Input

The timer can also be clocked by positive and/or negative edges on the Compare/Capture channel 1 input. This input can either come from the TIMn\_CC1 pin or one of the PRS channels. The input signal must not have a higher frequency than  $f_{\text{HFPERCLK}}/3$  when running from a pin input or a PRS input with FILT enabled in TIMERN\_CCx\_CTRL. When running from PRS without FILT, the frequency can be as high as  $f_{\text{HFPERCLK}}$ . Note that when clocking the timer from the same pulse that triggers a start (through RISEA/FALLA in TIMERN\_CTRL), the starting pulse will not update the Counter Value.

### 20.3.1.6 Underflow/Overflow from Neighboring Timer

All timers are linked together (see [Figure 20.4 TIMER Connections on page 618](#)), allowing timers to count on overflow/underflow from the lower numbered neighbouring timers to form a 32-bit or 48-bit timer. Note that all timers must be set to same count direction and less significant timer(s) can only be set to count up or down.

Figure 20.4. TIMER Connections

### 20.3.1.7 One-Shot Mode

By default, the counter counts continuously until it is stopped. If the OSMEN bit is set in the TIMERN\_CTRL register, however, the counter is disabled by hardware on the first *update event* (see [20.3.1.1 Events](#)). Note that when the counter is running with CC1 as clock source (0b01 in CLKSEL in TIMERN\_CTRL) and OSMEN is set, a CC1 capture event will not take place on the *update event* (CC1 rising edge) that stops the timer.

### 20.3.1.8 Top Value Buffer

The TIMERN\_TOP register can be altered either by writing it directly or by writing to the TIMER\_TOPB (buffer) register. When writing to the buffer register the TIMERN\_TOPB register will be written to TIMERN\_TOP on the next *update event*. Buffering ensures that the TOP value is not set below the actual count value. The TOPBV flag in TIMERN\_STATUS indicates whether the TIMERN\_TOPB register contains data that has not yet been written to the TIMERN\_TOP register (see [Figure 20.5 TIMER TOP Value Update Functionality on page 619](#)).

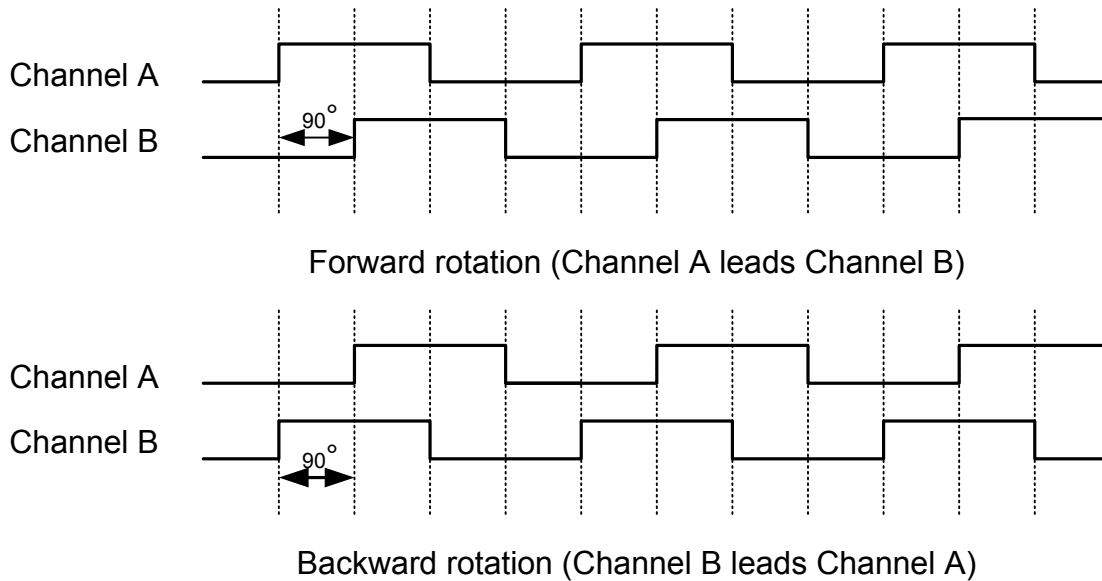

**Note:** When writing to TIMERN\_TOP register directly, the TIMERN\_TOPB register value will be invalidated and the TOPBV flag will be cleared. This prevents TIMERN\_TOP register from being immediately updated by an existing valid TIMERN\_TOPB value during the next *update event*.

**Figure 20.5. TIMER TOP Value Update Functionality**

### 20.3.1.9 Quadrature Decoder

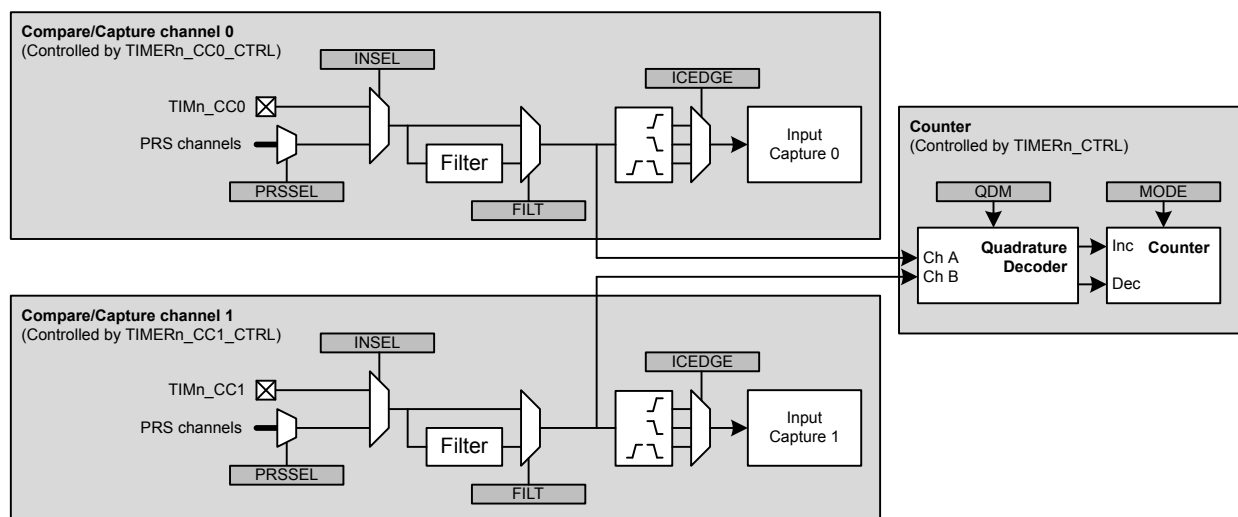

Quadrature Decoding mode is used to track motion and determine both rotation direction and position. The Quadrature Decoder uses two input channels that are 90 degrees out of phase (see [Figure 20.6 TIMER Quadrature Encoded Inputs on page 620](#)).

**Figure 20.6. TIMER Quadrature Encoded Inputs**

In the timer these inputs are tapped from the Compare/Capture channel 0 (Channel A) and 1 (Channel B) inputs before edge detection. The Timer/Counter then increments or decrements the counter, based on the phase relation between the two inputs. The Quadrature Decoder Mode supports two channels, but if a third channel (Z-terminal) is available, this can be connected to an external interrupt and trigger a counter reset from the interrupt service routine. By connecting a periodic signal from another timer as input capture on Compare/Capture Channel 2, it is also possible to calculate speed and acceleration.

**Note:** In Quadrature Decoder mode, overflow and underflow triggers an *update event*

**Figure 20.7. TIMER Quadrature Decoder Configuration**

The Quadrature Decoder can be set in either X2 or X4 mode, which is configured in the QDM bit in TIMERN\_CTRL. See [Figure 20.7 TIMER Quadrature Decoder Configuration on page 620](#)

### 20.3.1.10 X2 Decoding Mode

In X2 Decoding mode, the counter increments or decrements on every edge of Channel A, see [Table 20.1 TIMER Counter Response in X2 Decoding Mode on page 621](#) and [Figure 20.8 TIMER X2 Decoding Mode on page 621](#).

**Table 20.1. TIMER Counter Response in X2 Decoding Mode**

Channel B	Channel A	
	Rising	Falling
0	Increment	Decrement
1	Decrement	Increment

**Figure 20.8. TIMER X2 Decoding Mode**

### 20.3.1.11 X4 Decoding Mode

In X4 Decoding mode, the counter increments or decrements on every edge of Channel A and Channel B, see [Figure 20.9 TIMER X4 Decoding Mode on page 621](#) and [Table 20.2 TIMER Counter Response in X4 Decoding Mode on page 621](#).

**Table 20.2. TIMER Counter Response in X4 Decoding Mode**

Opposite Channel	Channel A		Channel B	
	Rising	Falling	Rising	Falling
Channel A = 0			Decrement	Increment
Channel A = 1			Increment	Decrement
Channel B = 0	Increment	Decrement		
Channel B = 1	Decrement	Increment		

**Figure 20.9. TIMER X4 Decoding Mode**

### 20.3.1.12 TIMER Rotational Position

To calculate a position [Figure 20.10 TIMER Rotational Position Equation on page 622](#) can be used.

$$\text{pos}^\circ = (\text{CNT}/X \times N) \times 360^\circ$$

**Figure 20.10. TIMER Rotational Position Equation**

where X = Encoding type and N = Number of pulses per revolution.

### 20.3.2 Compare/Capture Channels

The timer contains 3 Compare/Capture channels, which can be configured in the following modes:

1. Input Capture
2. Output Compare
3. PWM

#### 20.3.2.1 Input Pin Logic

Each Compare/Capture channel can be configured as an input source for the Capture Unit or as external clock source for the timer (see [Figure 20.11 TIMER Input Pin Logic on page 622](#)). Compare/Capture channels 0 and 1 are the inputs for the Quadrature Decoder Mode. The input channel can be filtered before it is used, which requires the input to remain stable for 5 cycles in a row before the input is propagated to the output.

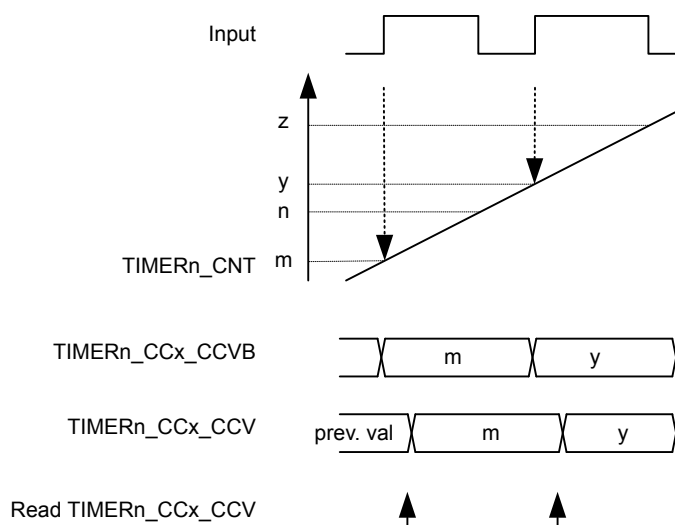

**Figure 20.11. TIMER Input Pin Logic**

#### 20.3.2.2 Compare/Capture Registers

The Compare/Capture channel registers are prefixed with TIMERN\_CCx\_, where the x stands for the channel number. Since the Compare/Capture channels serve three functions (input capture, compare, PWM), the behavior of the Compare/Capture registers (TIMERN\_CCx\_CCV) and buffer registers (TIMERN\_CCx\_CCVB) change depending on the mode the channel is set in.

### 20.3.2.3 Input Capture

In Input Capture Mode, the counter value (TIMERN\_CNT) can be captured in the Compare/Capture Register (TIMERN\_CCx\_CCV) (see [Figure 20.12 TIMER Input Capture on page 623](#)). The CCPOL bits in TIMERN\_STATUS indicate the polarity of the edge that triggered the capture in TIMERN\_CCx\_CCV.

**Figure 20.12. TIMER Input Capture**

The Compare/Capture Buffer Register (TIMERN\_CCx\_CCVB) and the TIMERN\_CCx\_CCV register form double-buffered capture registers allowing two subsequent capture events to take place before a read-out is required. The first capture can always be read from TIMERN\_CCx\_CCV, and reading this address will load the next capture value into TIMERN\_CCx\_CCV from TIMERN\_CCx\_CCVB if it contains valid data. The CC value can be read without altering the FIFO contents by reading TIMERN\_CCx\_CCV. TIMERN\_CCx\_CCVB can also be read without altering the FIFO contents. The ICV flag in TIMERN\_STATUS indicates if there is a valid unread capture in TIMERN\_CCx\_CCV. In this mode, TIMERN\_CCx\_CCV is read-only.

In the case where a capture is triggered while both TIMERN\_CCx\_CCV and TIMERN\_CCx\_CCVB contain unread capture values, the buffer overflow interrupt flag (ICBOF in TIMERN\_IF) will be set. On overflow new capture values will overwrite the value in TIMERN\_CCx\_CCVB and the value of TIMERN\_CCx\_CCV will remain unchanged. TIMERN\_CCx\_CCV will always contain the oldest unread value and TIMERN\_CCx\_CCVB will always contain the newest value.

**Note:** In input capture mode, the timer will only trigger interrupts when it is running.

### 20.3.2.4 Period/Pulse-Width Capture

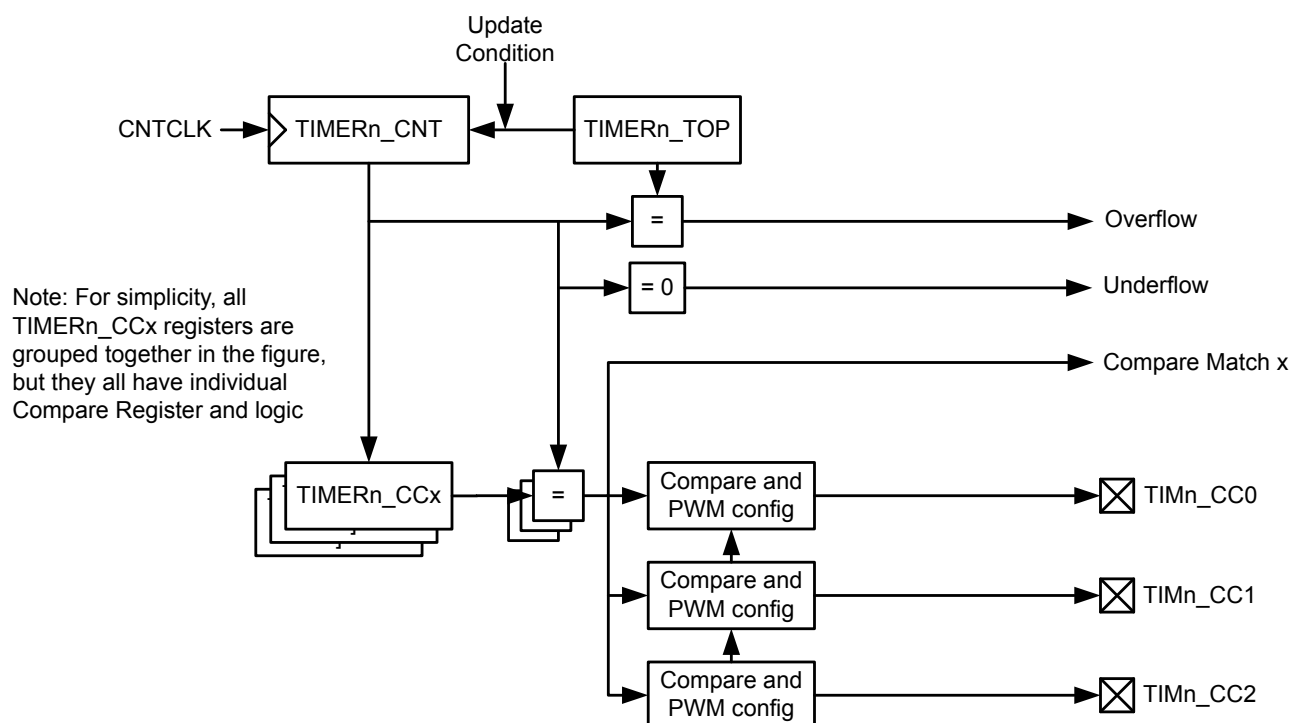

Period and/or pulse-width capture can only be possible with Channel 0 (CC0), because this is the only channel that can start and stop the timer. This can be done by setting the RISEA field in TIMERN\_CTRL to Clear&Start, and select the wanted input from either external pin or PRS, see [Figure 20.13 TIMER Period and/or Pulse width Capture on page 624](#). For period capture, the Compare/Capture Channel should then be set to input capture on a rising edge of the same input signal. To capture the width of a high pulse, the Compare/Capture Channel should be set to capture on a falling edge of the input signal. To measure the low pulse-width of a signal, opposite polarities should be chosen.

**Figure 20.13. TIMER Period and/or Pulse width Capture**

### 20.3.2.5 Compare

Each Compare/Capture channel contains a comparator which outputs a compare match if the contents of `TIMERN_CCx_CCV` matches the counter value, see [Figure 20.14 TIMER Block Diagram Showing Comparison Functionality on page 625](#). In compare mode, each compare channel can be configured to either set, clear or toggle the output on an event (compare match, overflow or underflow). The output from each channel is represented as an alternative function on the port it is connected to, which needs to be enabled for the CC outputs to propagate to the pins.

**Figure 20.14. TIMER Block Diagram Showing Comparison Functionality**

The compare output is delayed by one cycle to allow for full 0% to 100% PWM generation. Each example contains a high detail diagram which specifies the exact timing of events during Compare or PWM operation. If occurring in the same cycle, match action will have priority over overflow or underflow action.

The input selected (through `PRSEL`, `INSEL` and `FILTSEL` in `TIMERN_CCx_CTRL`) for the CC channel will also be sampled on compare match and the result is found in the `CCPOL` bits in `TIMERN_STATUS`. It is also possible to configure the `CCPOL` to always track the inputs by setting `ATI` in `TIMERN_CTRL`.

The `COIST` bit in `TIMERN_CCx_CTRL` is the initial state of the compare/PWM output. The `COIST` bit can also be used as an initial value to the compare outputs on a reload-start when `RSSCOIST` is set in `TIMERN_CTRL`. Also the resulting output can be inverted by setting `OUTINV` in `TIMERN_CCx_CTRL`. It is recommended to turn off the CC channel before configuring the output state to avoid any pulses on the output. The CC channel can be turned off by setting `MODE` to `OFF` in `TIMERN_CCx_CTRL`.

**Figure 20.15. TIMER Output Logic**

### 20.3.2.6 Compare Mode Registers

When running in Output Compare or PWM mode, the value in `TIMERN_CCx_CCV` will be compared against the count value. In Compare mode the output can be configured to toggle, clear or set on compare match, overflow, and underflow through the `CMOA`, `COFOA` and `CUFOA` fields in `TIMERN_CCx_CTRL`. `TIMERN_CCx_CCV` can be accessed directly or through the buffer register `TIMERN_CCx_CCVB`, see [Figure 20.16 TIMER Output Compare/PWM Buffer Functionality Detail on page 626](#). When writing to the buffer register, the value in `TIMERN_CCx_CCVB` will be written to `TIMERN_CCx_CCV` on the next *update event*. This functionality ensures glitch free PWM outputs. The `CCVBV` flag in `TIMERN_STATUS` indicates whether the `TIMERN_CCx_CCVB` register contains data that has not yet been written to the `TIMERN_CCx_CCV` register. Note that when writing 0 to `TIMERN_CCx_CCVB` in up-down count mode the `CCV` value is updated when the timer counts from 0 to 1. Thus, the compare match for the next period will not happen until the timer reaches 0 again on the way down.

Figure 20.16. TIMER Output Compare/PWM Buffer Functionality Detail

### 20.3.2.7 Frequency Generation (FRG)

Frequency generation (see [Figure 20.17 TIMER Up-count Frequency Generation on page 627](#)) can be achieved in compare mode by:

- Setting the counter in up-count mode
- Enabling buffering of the TOP value.
- Setting the CC channels overflow action to toggle

**Figure 20.17. TIMER Up-count Frequency Generation**

The output frequency is given by [Figure 20.18 TIMER Up-count Frequency Generation Equation on page 627](#)

$$f_{FRG} = f_{HPERCLK} / (2^{(PRESC + 1)} \times (TOP + 1) \times 2)$$

**Figure 20.18. TIMER Up-count Frequency Generation Equation**

The figure below provides cycle accurate timing and event generation information for frequency generation.

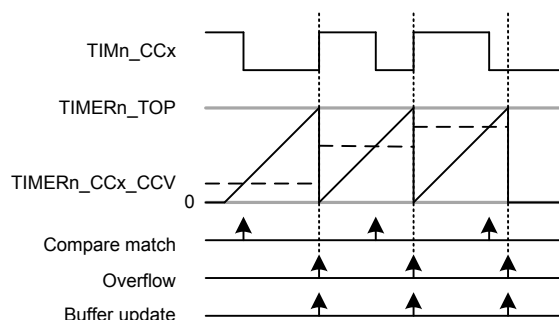

**Figure 20.19. TIMER Up-count Frequency Generation Detail**

### 20.3.2.8 Pulse-Width Modulation (PWM)

In PWM mode, TIMERN\_CCx\_CCV is buffered to avoid glitches in the output. The settings in the Compare Output Action configuration bits are ignored in PWM mode and PWM generation is only supported for up-count and up/down-count mode.

### 20.3.2.9 Up-count (Single-slope) PWM

If the counter is set to up-count and the Compare/Capture channel is put in PWM mode, single slope PWM output will be generated (see [Figure 20.20 TIMER Up-count PWM Generation on page 628](#)). In up-count mode the PWM period is TOP+1 cycles and the PWM output will be high for a number of cycles equal to TIMERN\_CCx\_CCV. This means that a constant high output is achieved by setting TIMER\_CCx to TOP+1 or higher. The PWM resolution (in bits) is then given by [Figure 20.21 TIMER Up-count PWM Resolution Equation on page 628](#).

**Figure 20.20. TIMER Up-count PWM Generation**

$$R_{PWM_{up}} = \log(TOP+1)/\log(2)$$

**Figure 20.21. TIMER Up-count PWM Resolution Equation**

The PWM frequency is given by [Figure 20.22 TIMER Up-count PWM Frequency Equation on page 628](#):

$$f_{PWM_{up/down}} = f_{HCLK} / (2^{\text{PRESC}} \times (TOP + 1))$$

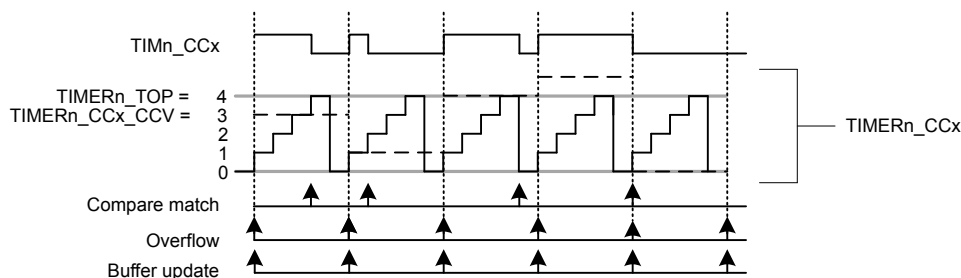

**Figure 20.22. TIMER Up-count PWM Frequency Equation**

The high duty cycle is given by [Figure 20.23 TIMER Up-count Duty Cycle Equation on page 628](#)

$$DS_{up} = CCVx/(TOP+1)$$

**Figure 20.23. TIMER Up-count Duty Cycle Equation**

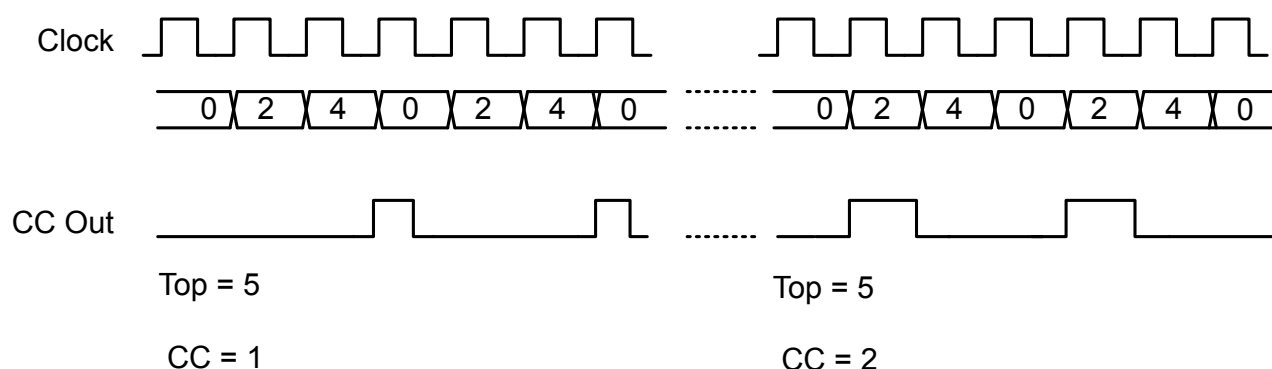

The figure below provides cycle accurate timing and event generation information for up-count mode.

**Figure 20.24. TIMER Up-count PWM Generation Detail**

### 20.3.2.10 2x Count Mode

When the timer is set in 2x mode, the TIMER will count up by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in [Figure 20.25 TIMER CC out in 2x mode on page 629](#)

**Figure 20.25. TIMER CC out in 2x mode**

[Figure 20.26 TIMER 2x PWM Resolution Equation on page 629.](#)

$$R_{PWM_{2xmode}} = \log(TOP/2+1)/\log(2)$$

**Figure 20.26. TIMER 2x PWM Resolution Equation**

The PWM frequency is given by [Figure 20.27 TIMER 2x Mode PWM Frequency Equation\( Up-count\) on page 629](#):

$$f_{PWM_{2xmode}} = f_{HCLK} / \text{floor}(TOP/2)+1$$

**Figure 20.27. TIMER 2x Mode PWM Frequency Equation( Up-count)**

The high duty cycle is given by [Figure 20.28 TIMER 2x Mode Duty Cycle Equation on page 629](#)

$$DS_{2xmode} = CCVx/((\text{floor}(TOP/2)+1)*2)$$

**Figure 20.28. TIMER 2x Mode Duty Cycle Equation**

If the counter is set to up-down count and the Compare/Capture channel is put in PWM mode, dual slope PWM output will be generated by [Figure 20.29 TIMER Up/Down-count PWM Generation on page 630](#). The resolution (in bits) is given by [Figure 20.30 TIMER Up/Down-count PWM Resolution Equation on page 630](#).

$$R_{\text{PWM}_{\text{up/down}}} = \log(\text{TOP}+1)/\log(2)$$

The PWM frequency is given by [Figure 20.31 TIMER Up/Down-count PWM Frequency Equation on page 630](#):

$$f_{\text{PWM}_{\text{up/down}}} = f_{\text{HFPERCLK}} / (2^{(\text{PRESC}+1)} \times \text{TOP}))$$

The high duty cycle is given by [Figure 20.32 TIMER Up/Down-count Duty Cycle Equation on page 630](#)

$$DS_{up/down} = CCVx/TOP$$

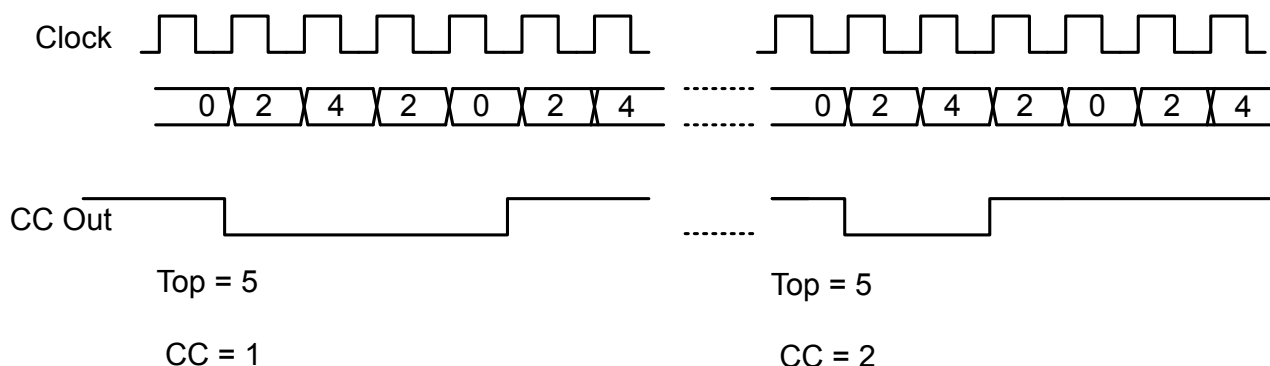

The figure below provides cycle accurate timing and event generation information for up-count mode.

**Figure 20.33. TIMER Up/Down-count PWM Generation**

### 20.3.2.12 2x Count Mode

When the timer is set in 2x mode, the TIMER will count up/down by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in [Figure 20.34 TIMER CC out in 2x mode on page 631](#)

**Figure 20.34. TIMER CC out in 2x mode**

[Figure 20.35 TIMER 2x PWM Resolution Equation on page 631.](#)

$$R_{PWM_{2xmode}} = \log(TOP/2+1)/\log(2)$$

**Figure 20.35. TIMER 2x PWM Resolution Equation**

The PWM frequency is given by [Figure 20.36 TIMER 2x Mode PWM Frequency Equation\( Up/Down-count\) on page 631:](#)

$$f_{PWM_{2xmode}} = f_{HCLK} / (\text{floor}(TOP/2)*2)$$

**Figure 20.36. TIMER 2x Mode PWM Frequency Equation( Up/Down-count)**

The high duty cycle is given by two equations based on the CCVx values. [Figure 20.37 TIMER 2x Mode Duty Cycle Equation for CCVx = 1 or CCVx = even on page 631](#) and [Figure 20.38 TIMER 2x Mode Duty Cycle Equation for all other CCVx = odd values on page 631](#)

$$DS_{2xmode} = (CCVx*2)/(\text{floor}(TOP/2)*4)$$

**Figure 20.37. TIMER 2x Mode Duty Cycle Equation for CCVx = 1 or CCVx = even**

$$DS_{2xmode} = (CCVx*2 - CCVx)/(\text{floor}(TOP/2)*4)$$

**Figure 20.38. TIMER 2x Mode Duty Cycle Equation for all other CCVx = odd values**

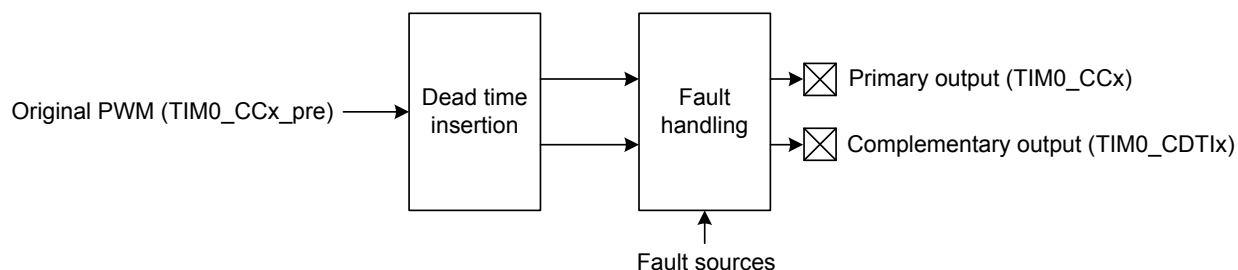

### 20.3.2.13 Timer Configuration Lock

To prevent software errors from making changes to the timer configuration, a configuration lock is available similar to DTI configuration Lock. Writing any value but 0xCE80 to LOCKKEY in TIMERN\_LOCK results in TIMERN\_CTRL, TIMERN\_CMD, TIMERN\_TOP, TIMERN\_CNT, TIMERN\_CCx\_CTRL and TIMERN\_CCx\_CCV being locked from writing. To unlock the registers, write 0xCE80 to LOCKKEY in TIMERN\_LOCK. The value of TIMERN\_LOCK is 1 when the lock is active, and 0 when the registers are unlocked.

### 20.3.3 Dead-Time Insertion Unit (TIMER0 only)

The Dead-Time Insertion Unit aims to make control of brushless DC (BLDC) motors safer and more efficient by introducing complementary PWM outputs with dead-time insertion and fault handling, see [Figure 20.39 TIMER Dead-Time Insertion Unit Overview on page 632](#).

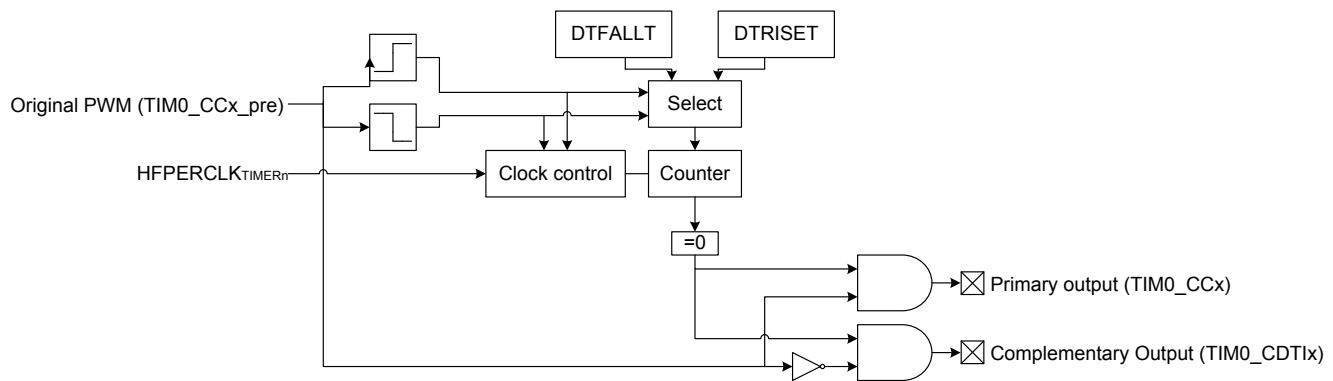

**Figure 20.39. TIMER Dead-Time Insertion Unit Overview**

When used for motor control, the PWM outputs TIM0\_CC0, TIM0\_CC1 and TIM0\_CC2 are often connected to the high-side transistors of a triple half-bridge setup (UH, VH and WH), and the complementary outputs connected to the respective low-side transistors (UL, VL, WL shown in [Figure 20.40 TIMER Triple Half-Bridge on page 632](#)). Transistors used in such a bridge often do not open/close instantaneously, and using the exact complementary inputs for the high and low side of a half-bridge may result in situations where both gates are open. This can give unnecessary current-draw and short circuit the power supply. The DTI unit provides dead-time insertion to deal with this problem.

**Figure 20.40. TIMER Triple Half-Bridge**

For each of the 3 compare-match outputs of TIMER0, an additional complementary output is provided by the DTI unit. These outputs, named TIM0\_CDTI0, TIM0\_CDTI1 and TIM0\_CDTI2 are provided to make control of e.g. 3-channel BLDC or permanent magnet AC (PMAC) motors possible using only a single timer, see [Figure 20.41 TIMER Overview of Dead-Time Insertion Block for a Single PWM channel on page 633](#).

**Figure 20.41. TIMER Overview of Dead-Time Insertion Block for a Single PWM channel**

The DTI unit is enabled by setting DTEN in TIMERO\_DTCTRL. In addition to providing the complementary outputs, the DTI unit then also overrides the compare match outputs from the timer.

The DTI unit gives the rising edges of the PWM outputs and the rising edges of the complementary PWM outputs a configurable time delay. By doing this, the DTI unit introduces a dead-time where both the primary and complementary outputs in a pair are inactive as seen in [Figure 20.42 TIMER Polarity of Both Signals are Set as Active-High on page 633](#).

**Figure 20.42. TIMER Polarity of Both Signals are Set as Active-High**

Dead-time is specified individually for the rising and falling edge of the original PWM. These values are shared across all the three PWM channels of the DTI unit. A single prescaler value is provided for the DTI unit, meaning that both the rising and falling edge dead-times share prescaler value. The prescaler divides the  $HFPERCLK_{TIMERn}$  by a configurable factor between 1 and 1024, which is set in the DTPRESC field in TIMERO\_DTTIME. The rising and falling edge dead-times are configured in DTRISSET and DTFALLT in TIMERO\_DTTIME to any number between 1-64  $HFPERCLK_{TIMER0}$  cycles.

The DTAR and DTFATS bits in TIMERO\_DTCTRL control the DTI output behavior when the timer stops. By default the DTI block stops when the timer is stopped. Setting the DTAR bit will cause the DTI to output on channel 0 to continue when the timer is stopped. DTAR effects only channel 0. See [20.3.3.2 PRS Channel as a Source](#) for an example of when this can be used. While in this mode the undivided  $HFPERCLK_{TIMER0}$  (DTPRESC=0) is always used regardless of programmed DTPRESC value in TIMERO\_DTTIME. This means that rise and fall dead times are calculated assuming DTPRESC = 0.

When the timer stops DTI outputs are frozen by default, preserving their last state. To allow the outputs to go to a safe state as programmed in the DTFA field of TIMERO\_DTFC register and set the DTFATS bitfield in the TIMERO\_DTCTRL reg. Note that when DTAR is also set, DTAR has priority over DTFATS for DTI channel 0 output.

**Table 20.3. DTI output when timer halted**

DTAR	DTFATS	State
0	0	frozen
0	1	safe
1	0	running
1	1	running

### 20.3.3.1 Output Polarity

The value of the primary and complementary outputs in a pair will never be set active at the same time by the DTI unit. The polarity of the outputs can be changed however, if this is required by the application. The active values of the primary and complementary outputs are set by the DTIPOL and DTCINV bits in the `TIMER0_DTCTRL` register. The DTIPOL bit of this register specifies the base polarity. If DTIPOL = 0, then the outputs are active-high, and if DTIPOL = 1 they are active-low. The relative phase of the primary and complementary outputs is not changed by DTIPOL, as the polarity of both outputs is changed, see [Figure 20.45 TIMER Output Polarities on page 635](#)

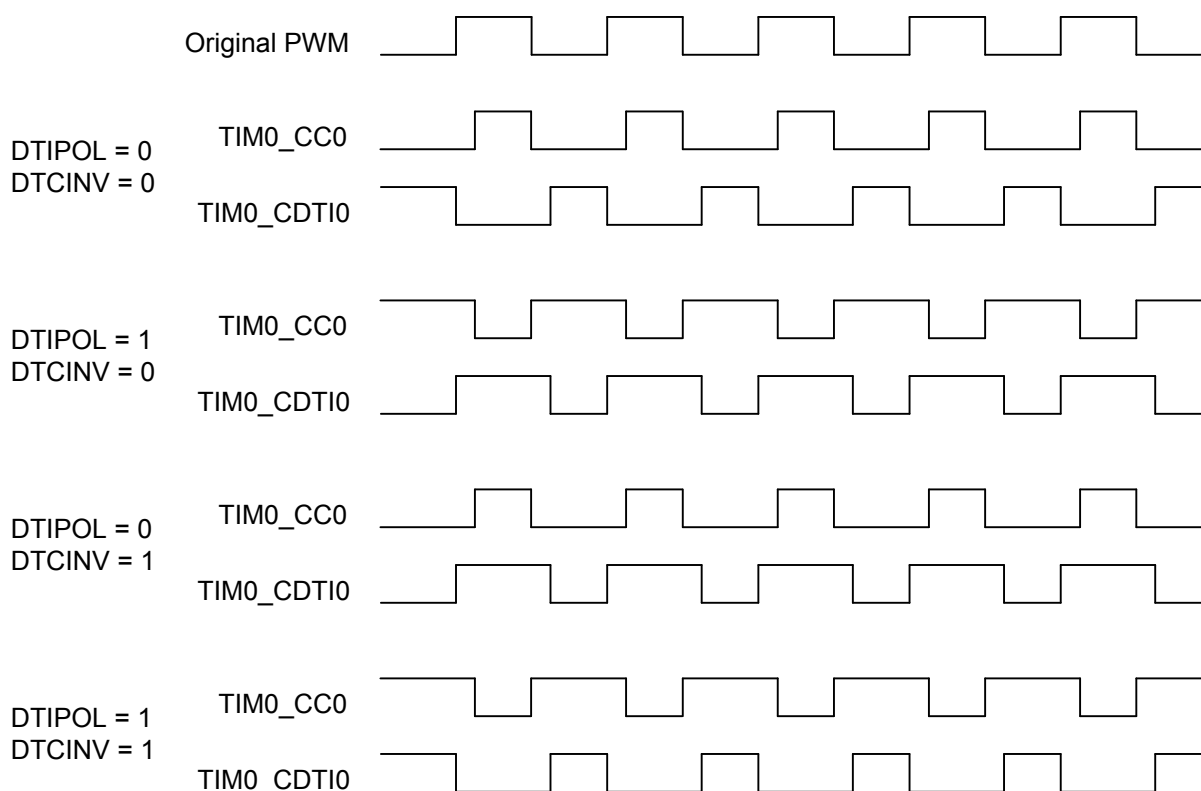

In some applications, it may be required that the primary outputs are active-high, while the complementary outputs are active-low. This can be accomplished by manipulating the DTCINV bit of the `TIMER0_DTCTRL` register, which inverts the polarity of the complementary outputs relative to the primary outputs.

DTIPOL = 0 and DTCINV = 0 results in outputs with opposite phase and active-high states.

**Figure 20.43. TIMER DTI Example 1**

DTIPOL = 1 and DTCINV = 1 results in outputs with equal phase. The primary output will be active-high, while the complementary will be active-low

**Figure 20.44. TIMER DTI Example 2**

**Figure 20.45. TIMER Output Polarities**

Output generation on the individual DTI outputs can be disabled by configuring `TIMER0_DTOGEN`. When output generation on an output is disabled that output will go to and stay in its inactive state.

### 20.3.3.2 PRS Channel as a Source

A PRS channel can be used as input to the DTI module instead of the PWM output from the timer for DTI channel 0. Setting DTPRSEN in `TIMER0_DTCTRL` will override the source of the first DTI channel, driving `TIM0_CC0` and `TIM0_CDTI0`, with the value on the PRS channel. The rest of the DTI channels will continue to be driven by the PWM output from the timer. The input PRS channel is chosen by configuring `DTPRSSEL` in `TIMER0_DTCTRL`. Note that the timer must be running even when PRS is used as DTI source. However, if it is required to keep the DTI channel 0 running even when the timer is stopped, set `DTAR` in `TIMER0_DTCTRL`. When this bit is set, it uses `DTPRESC=0` regardless of the value programmed in `DTPRESC` in `TIMER0_DTIME`.

The DTI prescaler, set by `DTPRESC` in `TIMER0_DTIME` determines the accuracy with which the DTI can insert dead-time into a PRS signal. The maximum dead-time error equals  $2^{DTPRESC}$  clock cycles. With zero prescaling, the inserted dead-times are therefore accurate, but they may be inaccurate for larger prescaler settings.

### 20.3.3.3 Fault Handling

The fault handling system of the DTI unit allows the outputs of the DTI unit to be put in a well-defined state in case of a fault. This hardware fault handling system enables a fast reaction to faults, reducing the possibility of damage to the system.

The fault sources which trigger a fault in the DTI module are determined by the bitfields of `TIMER0_DTFC` register. Any combination of the available error sources can be selected:

- PRS source 0, determined by `DTPRS0FSEL` in `TIMER0_DTFC`
- PRS source 1, determined by `DTPRS1FSEL` in `TIMER0_DTFC`
- Debugger
- Core Lockup

One or two PRS channels can be used as an error source. When PRS source 0 is selected as an error source, `DTPRS0FSEL` determines which PRS channel is used for this source. `DTPRS1FSEL` determines which PRS channel is selected as PRS source 1. Please note that for Core Lockup, the `LOCKUPRDIS` in `RMU_CTRL` must be set. Otherwise this will generate a full reset of the chip.

### 20.3.3.4 Action on Fault

When a fault occurs, the bit representing the fault source is set in `TIMER0_DTFault` register, and the outputs from the DTI unit are set to a well-defined state. The following options are available, and can be enabled by configuring `DTFACT` in `TIMER0_DTFC`:

- Set outputs to inactive level
- Clear outputs
- Tristate outputs

With the first option enabled, the output state in case of a fault depends on the polarity settings for the individual outputs. An output set to be active high will be set low if a fault is detected, while an output set to be active low will be driven high.

When a fault occurs, the fault source(s) can be read out from `TIMER0_DTFault` register.

Additionally a fault action can also be triggered when the timer stops if `DTFATS` in `TIMER0_DTCTRL` is set. This allows the DTI output to go to safe state programmed in `DTFACT` in `TIMER0_DTFC` when timer stops. When `DTAR` and `DTFATS` in `TIMER0_DTCTRL` are both set, DTI channel 0 keeps running even when the timer stops. This is useful when DTI channel 0 has an input coming from PRS.

### 20.3.3.5 Exiting Fault State

When a fault is triggered by the PRS system, software intervention is required to re-enable the outputs of the DTI unit. This is done by manually clearing bits in `TIMER0_DTFault` register. If the fault source as determined by checking `TIMER0_DEFAULT` is the debugger alone, the outputs can be automatically restarted when the debugger exits. To enable automatic restart set `DTDAS` in `TIMER0_DCTRL`. When an automatic restart occurs the `DTDBGF` bit in `TIMER0_DTFault` will be automatically cleared by hardware. If any other bits in the `TIMER0_DTFault` register are set when the hardware clears `DTDBGF` the DTI module will not exit the fault state.

### 20.3.3.6 DTI Configuration Lock

To prevent software errors from making changes to the DTI configuration, a configuration lock is available. Writing any value but `0xCE80` to `LOCKKEY` in `TIMER0_DTLOCK` results in `TIMER0_DTFC`, `TIMER0_DTCTRL`, `TIMER0_DTIME` and `TIMER0_ROUTE` being locked from writing. To unlock the registers, write `0xCE80` to `LOCKKEY` in `TIMER0_DTLOCK`. The value of `TIMER0_DTLOCK` is 1 when the lock is active, and 0 when the registers are unlocked.

## 20.3.4 Debug Mode

When the CPU is halted in debug mode, the timer can be configured to either continue to run or to be frozen. This is configured in `DEBUGRUN` in `TIMERn_CTRL`.

### 20.3.5 Interrupts, DMA and PRS Output

The timer has 3 different types of output events:

- Counter Underflow
- Counter Overflow
- Compare match or input capture (one per Compare/Capture channel)

Each of the events has its own interrupt flag. Also, there is one interrupt flag for each Compare/Capture channel which is set on buffer overflow in capture mode. Buffer overflow happens when a new capture pushes an old unread capture out of the `TIMERN_CCx_CCV/TIMERN_CCx_CCVB` register pair.

If the interrupt flags are set and the corresponding interrupt enable bits in `TIMERN_IEN` are set high, the timer will send out an interrupt request. Each of the events will also lead to a one `HPPERCLKTIMERN` cycle high pulse on individual PRS outputs. Setting `PRSOCNF` to `LEVEL` in `TIMERN_CCx_CTRL` will make the compare match PRS output follow the compare match output, instead of outputting one `HPPERCLKTIMERN` cycle high pulse. Interrupts are cleared by setting the corresponding bit in the `TIMERN_IFC` register.

Each of the events will also set a DMA request when they occur. The different DMA requests are cleared when certain acknowledge conditions are met, see [Table 20.4 TIMER DMA Events on page 637](#). Events which clear the DMA requests do not clear interrupt flags. Software must still manually clear the interrupt flag if interrupts are in use.

If `DMACLRACT` is set in `TIMERN_CTRL`, the DMA request is cleared when the triggered DMA channel is active, without having to access any timer registers. This is useful in cases where a timer event is used to trigger a DMA transfer that does not target the CCV or CCVB register.

**Table 20.4. TIMER DMA Events**

Event	Acknowledge/Clear
Underflow/Overflow	Read or write to <code>TIMERN_CNT</code> or <code>TIMERN_TOPB</code>
CC 0	Read or write to <code>TIMERN_CC0_CCV</code> or <code>TIMERN_CC0_CCVB</code>
CC 1	Read or write to <code>TIMERN_CC1_CCV</code> or <code>TIMERN_CC1_CCVB</code>
CC 2	Read or write to <code>TIMERN_CC2_CCV</code> or <code>TIMERN_CC2_CCVB</code>

### 20.3.6 GPIO Input/Output

The `TIMn_CCx` inputs/outputs and `TIM0_CDTIx` outputs are accessible as alternate functions through GPIO. Each pin connection can be enabled/disabled separately by setting the corresponding `CCxPEN` or `CDTIxPEN` bits in `TIMERN_ROUTE`. The `LOCATION` bits in the same register can be used to move all enabled pins to alternate pins. See the device datasheet for the mapping between block locations (`LOC0`, `LOC1`, etc.) and actual device pins (`PA0`, `PA1`, etc.).

## 20.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	TIMERN_CTRL	RW	Control Register
0x004	TIMERN_CMD	W1	Command Register
0x008	TIMERN_STATUS	R	Status Register
0x00C	TIMERN_IF	R	Interrupt Flag Register
0x010	TIMERN_IFS	W1	Interrupt Flag Set Register
0x014	TIMERN_IFC	(R)W1	Interrupt Flag Clear Register
0x018	TIMERN_IEN	RW	Interrupt Enable Register
0x01C	TIMERN_TOP	RWH	Counter Top Value Register
0x020	TIMERN_TOPB	RW	Counter Top Value Buffer Register

Access			RW	RW		RW									RW				RW			RW		RW	RW	RW	RW	RW	RW	RW			RW	
Name			RSSCOIST	ATI		PRESC									CLKSEL				X2CNT			FALLA		RISEA		DMACLRACT	DEBUGRUN	QDM	OSMEN	SYNC			MODE	

Bit	Name	Reset	Access	Description
31:30	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
29	RSSCOIST	0	RW	<b>Reload-Start Sets Compare Ouput initial State</b> When set, compare output is set to COIST value at Reload-Start event
28	ATI	0	RW	<b>Always Track Inputs</b> when set, makes CCPOL always track the polarity of the inputs
27:24	PRESC	0x0	RW	<b>Prescaler Setting</b> These bits select the prescaling factor.
	Value	Mode	Description	
	0	DIV1	The HFPERCLK is undivided	
	1	DIV2	The HFPERCLK is divided by 2	
	2	DIV4	The HFPERCLK is divided by 4	
	3	DIV8	The HFPERCLK is divided by 8	
	4	DIV16	The HFPERCLK is divided by 16	
	5	DIV32	The HFPERCLK is divided by 32	
	6	DIV64	The HFPERCLK is divided by 64	
	7	DIV128	The HFPERCLK is divided by 128	
	8	DIV256	The HFPERCLK is divided by 256	
	9	DIV512	The HFPERCLK is divided by 512	
	10	DIV1024	The HFPERCLK is divided by 1024	
23:18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17:16	CLKSEL	0x0	RW	<b>Clock Source Select</b> These bits select the clock source for the timer.
	Value	Mode	Description	
	0	PRESCHFPERCLK	Prescaled HFPERCLK	
	1	CC1	Compare/Capture Channel 1 Input	
	2	TIMEROUF	Timer is clocked by underflow(down-count) or overflow(up-count) in the lower numbered neighbor Timer	
15:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13	X2CNT	0	RW	<b>2x Count Mode</b> Enable 2x count mode
12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11:10	FALLA	0x0	RW	<b>Timer Falling Input Edge Action</b> These bits select the action taken in the counter when a falling edge occurs on the input.
	Value	Mode	Description	

Bit	Name	Reset	Access	Description
	0	NONE		No action
	1	START		Start counter without reload
	2	STOP		Stop counter without reload
	3	RELOADSTART		Reload and start counter
9:8	RISEA	0x0	RW	<b>Timer Rising Input Edge Action</b> These bits select the action taken in the counter when a rising edge occurs on the input.
	Value	Mode		Description
	0	NONE		No action
	1	START		Start counter without reload
	2	STOP		Stop counter without reload
	3	RELOADSTART		Reload and start counter
7	DMACLRACT	0	RW	<b>DMA Request Clear on Active</b> When this bit is set, the DMA requests are cleared when the corresponding DMA channel is active. This enables the timer DMA requests to be cleared without accessing the timer.
6	DEBUGRUN	0	RW	<b>Debug Mode Run Enable</b> Set this bit to enable timer to run in debug mode.
	Value			Description
	0			Timer is frozen in debug mode
	1			Timer is running in debug mode
5	QDM	0	RW	<b>Quadrature Decoder Mode Selection</b> This bit sets the mode for the quadrature decoder.
	Value	Mode		Description
	0	X2		X2 mode selected
	1	X4		X4 mode selected
4	OSMEN	0	RW	<b>One-shot Mode Enable</b> Enable/disable one shot mode.
3	SYNC	0	RW	<b>Timer Start/Stop/Reload Synchronization</b> When this bit is set, the Timer is started/stopped/reloaded by start/stop/reload commands in the other timers
	Value			Description
	0			Timer is not started/stopped/reloaded by other timers
	1			Timer is started/stopped/reloaded by other timers
2	<i>Reserved</i>	<i>To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a></i>		
1:0	MODE	0x0	RW	<b>Timer Mode</b> These bit set the counting mode for the Timer. Note, when Quadrature Decoder Mode is selected (MODE = 'b11), the CLKSEL is don't care. The Timer is clocked by the Decoder Mode clock output.

Bit	Name	Reset	Access	Description
	Value	Mode		Description
0		UP		Up-count mode
1		DOWN		Down-count mode
2		UPDOWN		Up/down-count mode
3		QDEC		Quadrature decoder mode

### 20.5.2 TIMERN\_CMD - Command Register

9	CCVBV1	0	R	<b>CC1 CCVB Valid</b>						

Bit	Name	Reset	Access	Description
	This field indicates that the TIMERN_CC1_CCVB registers contain data which have not been written to TIMERN_CC1_CCV. These bits are only used in output compare/PWM mode and are cleared when CCMODE is written to 0b00 (Off).			
	Value	Description		
	0	TIMERN_CC1_CCVB does not contain valid data		
	1	TIMERN_CC1_CCVB contains valid data which will be written to TIMERN_CC1_CCV on the next update event		
8	CCVBV0	0	R	<b>CC0 CCVB Valid</b>
	This field indicates that the TIMERN_CC0_CCVB registers contain data which have not been written to TIMERN_CC0_CCV. These bits are only used in output compare/PWM mode and are cleared when CCMODE is written to 0b00 (Off).			
	Value	Description		
	0	TIMERN_CC0_CCVB does not contain valid data		
	1	TIMERN_CC0_CCVB contains valid data which will be written to TIMERN_CC0_CCV on the next update event		
7:3	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
2	TOPBV	0	R	<b>TOPB Valid</b>
	This indicates that TIMERN_TOPB contains valid data that has not been written to TIMERN_TOP. This bit is also cleared when TIMERN_TOP is written.			
	Value	Description		
	0	TIMERN_TOPB does not contain valid data		
	1	TIMERN_TOPB contains valid data which will be written to TIMERN_TOP on the next update event		
1	DIR	0	R	<b>Direction</b>
	Indicates count direction.			
	Value	Mode	Description	
	0	UP	Counting up	
	1	DOWN	Counting down	
0	RUNNING	0	R	<b>Running</b>
	Indicates if timer is running or not.			

## 20.5.6 TIMERN\_IFC - Interrupt Flag Clear Register

Offset	Bit Position

Name		FILT	INSEL	PRSCONF	ICEVCTRL		ICEDGE							PRSSEL					CUFOA		COFOA		CMOA					COIST		OUTINV		MODE

Bit	Name	Reset	Access	Description
31	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
30	FILT	0	RW	<b>Digital Filter</b> Enable digital filter.
	Value	Mode		Description
	0	DISABLE		Digital filter disabled
	1	ENABLE		Digital filter enabled
29	INSEL	0	RW	<b>Input Selection</b> Select Compare/Capture channel input.
	Value	Mode		Description
	0	PIN		TIMERNCCx pin is selected
	1	PRS		PRS input (selected by PRSSEL) is selected
28	PRSCONF	0	RW	<b>PRS Configuration</b> Select PRS pulse or level.
	Value	Mode		Description
	0	PULSE		Each CC event will generate a one HPERCLK cycle high pulse
	1	LEVEL		The PRS channel will follow CC out
27:26	ICEVCTRL	0x0	RW	<b>Input Capture Event Control</b> These bits control when a Compare/Capture PRS output pulse and interrupt flag is set. DMA request however is set on every capture.
	Value	Mode		Description
	0	EVERYEDGE		PRS output pulse and interrupt flag set on every capture
	1	EVERYSECONDEDGE		PRS output pulse and interrupt flag set on every second capture
	2	RISING		PRS output pulse and interrupt flag set on rising edge only (if ICEDGE = BOTH)
	3	FALLING		PRS output pulse and interrupt flag set on falling edge only (if ICEDGE = BOTH)
25:24	ICEDGE	0x0	RW	<b>Input Capture Edge Select</b> These bits control which edges the edge detector triggers on. The output is used for input capture and external clock input.
	Value	Mode		Description
	0	RISING		Rising edges detected
	1	FALLING		Falling edges detected
	2	BOTH		Both edges detected
	3	NONE		No edge detection, signal is left as it is
23:20	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

Bit	Name	Reset	Access	Description
19:16	PRSEL	0x0	RW	<b>Compare/Capture Channel PRS Input Channel Selection</b> Select PRS input channel for Compare/Capture channel.
	Value	Mode		Description
	0	PRSCH0		PRS Channel 0 selected as input
	1	PRSCH1		PRS Channel 1 selected as input
	2	PRSCH2		PRS Channel 2 selected as input
	3	PRSCH3		PRS Channel 3 selected as input
	4	PRSCH4		PRS Channel 4 selected as input
	5	PRSCH5		PRS Channel 5 selected as input
	6	PRSCH6		PRS Channel 6 selected as input
	7	PRSCH7		PRS Channel 7 selected as input
	8	PRSCH8		PRS Channel 8 selected as input
	9	PRSCH9		PRS Channel 9 selected as input
	10	PRSCH10		PRS Channel 10 selected as input
	11	PRSCH11		PRS Channel 11 selected as input
15:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13:12	CUFOA	0x0	RW	<b>Counter Underflow Output Action</b> Select output action on counter underflow.
	Value	Mode		Description
	0	NONE		No action on counter underflow
	1	TOGGLE		Toggle output on counter underflow
	2	CLEAR		Clear output on counter underflow
	3	SET		Set output on counter underflow
11:10	COFOA	0x0	RW	<b>Counter Overflow Output Action</b> Select output action on counter overflow.
	Value	Mode		Description
	0	NONE		No action on counter overflow
	1	TOGGLE		Toggle output on counter overflow
	2	CLEAR		Clear output on counter overflow
	3	SET		Set output on counter overflow
9:8	CMOA	0x0	RW	<b>Compare Match Output Action</b> Select output action on compare match.
	Value	Mode		Description
	0	NONE		No action on compare match
	1	TOGGLE		Toggle output on compare match

Bit	Name	Reset	Access	Description
	2	CLEAR		Clear output on compare match
	3	SET		Set output on compare match
7:5	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
4	COIST	0	RW	<b>Compare Output Initial State</b>  This bit is only used in Output Compare and PWM mode. When this bit is set in Compare or PWM mode, the output is set high when the counter is disabled. When counting resumes, this value will represent the initial value for the output. If the bit is cleared, the output will be cleared when the counter is disabled.
3	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
2	OUTINV	0	RW	<b>Output Invert</b>  Setting this bit inverts the output from the CC channel (Output compare, PWM).
1:0	MODE	0x0	RW	<b>CC Channel Mode</b>  These bits select the mode for Compare/Capture channel.
	Value	Mode	Description	
	0	OFF	Compare/Capture channel turned off	
	1	INPUTCAPTURE	Input capture	
	2	OUTPUTCOMPARE	Output compare	
	3	PWM	Pulse-Width Modulation	

#### 20.5.16 TIMERN\_CCx\_CCV - CC Channel Value Register (Actionable Reads)

Offset	Bit Position																															
0x064	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x0000															
Access																	RWH															
Name																	CCV															

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:0	CCV	0x0000	RWH	<b>CC Channel Value</b>  In input capture mode, this field holds the first unread capture value. When reading this register in input capture mode, the contents of the TIMERN_CCx_CCVB register will be written to TIMERN_CCx_CCV in the next cycle. In compare mode, this field holds the compare value.

**20.5.17 TIMERN\_CCx\_CCVP - CC Channel Value Peek Register**

Offset	Bit Position																															
0x068	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x0000															
Access																	R															
Name																	CCVP															

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:0	CCVP	0x0000	R	<b>CC Channel Value Peek</b>  This field is used to read the CC value without pulling data through the FIFO in capture mode.

**20.5.18 TIMERN\_CCx\_CCVB - CC Channel Buffer Register**

Offset	Bit Position																															
0x06C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x0000															
Access																	RWH															
Name																	CCVB															

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:0	CCVB	0x0000	RWH	<b>CC Channel Value Buffer</b>  In Input Capture mode, this field holds the last capture value if the TIMERN_CCx_CCV register already contains an earlier unread capture value. In Output Compare or PWM mode, this field holds the CC buffer value which will be written to TIMERN_CCx_CCV on an update event if TIMERN_CCx_CCVB contains valid data.

## 20.5.19 TIMERN\_DTCTRL - DTI Control Register

Offset	Bit Position																			
0x0A0	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12

## 21. LETIMER - Low Energy Timer

### Quick Facts

#### What?

The LETIMER is a down-counter that can keep track of time and output configurable waveforms. Running on a 32.768 Hz, clock the LETIMER is available in EM2 DeepSleep.

#### Why?

The LETIMER can be used to provide repeatable waveforms to external components while remaining in EM2 DeepSleep. It is well suited for applications such as metering systems or to provide more compare values than available in the RTC.

#### How?

With buffered repeat and top value registers, the LETIMER can provide glitch-free waveforms at frequencies up to 16 kHz. It can be coupled with RTC using PRS, allowing advanced time-keeping and wake-up functions in EM2 DeepSleep.

### 21.1 Introduction

The unique LETIMER™, the Low Energy Timer, is a 16-bit timer that is available in energy mode EM2 DeepSleep EM1 Sleep, and EM0 Active. Because of this, it can be used for timing and output generation when most of the device is powered down, allowing simple tasks to be performed while the power consumption of the system is kept at an absolute minimum.

The LETIMER can be used to output a variety of waveforms with minimal software intervention. It can also be connected to the Real Time Counter (RTC) using PRS, and can be configured to start counting on compare matches from the RTC.

### 21.2 Features

- 16-bit down count timer
- 2 Compare match registers
- Compare register 0 can be top timer top value
- Compare registers can be double buffered
- Double buffered 8-bit Repeat Register
- Same clock source as the Real Time Counter
- LETIMER can be triggered (started) by an RTC event via PRS or by software
- LETIMER can be started, stopped, and/or cleared by PRS
- 2 output pins can optionally be configured to provide different waveforms on timer underflow:
  - Toggle output pin
  - Apply a positive pulse (pulse width of one  $LFACLK_{LETIMER}$  period)
  - PWM
- Interrupt on:
  - Compare matches
  - Timer underflow
  - Repeat done
- Optionally runs during debug
- PRS Output

## 21.3 Functional Description

An overview of the LETIMER module is shown in [Figure 21.1 LETIMER Overview on page 681](#). The LETIMER is a 16-bit down-counter with two compare registers, LETIMERn\_COMP0 and LETIMERn\_COMP1. The LETIMERn\_COMP0 register can optionally act as a top value for the counter. The repeat counter LETIMERn\_REP0 allows the timer to count a specified number of times before it stops. Both the LETIMERn\_COMP0 and LETIMERn\_REP0 registers can be double buffered by the LETIMERn\_COMP1 and LETIMERn\_REP1 registers to allow continuous operation. The timer can generate a single pin output, or two linked outputs.

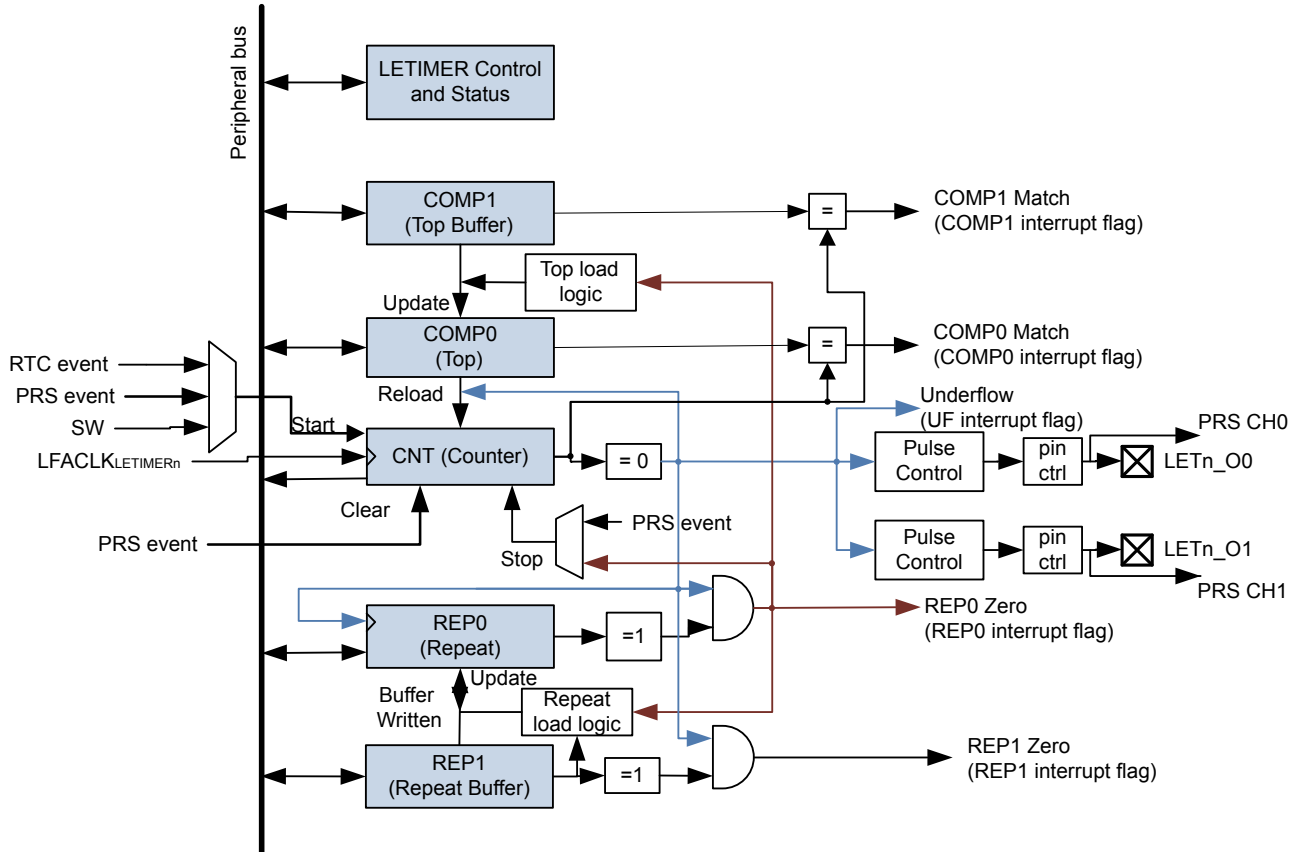

Figure 21.1. LETIMER Overview

### 21.3.1 Timer

The timer is started by setting command bit START in LETIMERn\_CMD, and stopped by setting the STOP command bit in the same register. RUNNING in LETIMERn\_STATUS is set as long as the timer is running. The timer can also be started on external signals, such as a compare match from the Real Time Counter. If START and STOP are set at the same time, STOP has priority, and the timer will be stopped.

The timer value can be read using the LETIMERn\_CNT register. The value can be written, and it can also be cleared by setting the CLEAR command bit in LETIMERn\_CMD. If the CLEAR and START commands are issued at the same time, the timer will be cleared, then start counting at the top value.

### 21.3.2 Compare Registers

The LETIMER has two compare match registers, LETIMERn\_COMP0 and LETIMERn\_COMP1. Each of these compare registers are capable of generating an interrupt when the counter value LETIMERn\_CNT becomes equal to their value. When LETIMERn\_CNT becomes equal to the value of LETIMERn\_COMP0, the interrupt flag COMP0 in LETIMERn\_IF is set, and when LETIMERn\_CNT becomes equal to the value of LETIMERn\_COMP1, the interrupt flag COMP1 in LETIMERn\_IF is set.

### 21.3.3 Top Value

If COMP0TOP in LETIMERn\_CTRL is set, the value of LETIMERn\_COMP0 acts as the top value of the timer, and LETIMERn\_COMP0 is loaded into LETIMERn\_CNT on timer underflow. If COMP0TOP is cleared to 0, the timer wraps around to 0xFFFF. The underflow interrupt flag UF in LETIMERn\_IF is set when the timer reaches zero.

#### 21.3.3.1 Buffered Top Value

If BUFTOP in LETIMERn\_CTRL is set, the value of LETIMERn\_COMP0 is buffered by LETIMERn\_COMP1. In this mode, the value of LETIMERn\_COMP1 is loaded into LETIMERn\_COMP0 every time LETIMERn\_REP0 is about to decrement to 0. This can for instance be used in conjunction with the buffered repeat mode to generate continually changing output waveforms.

Write operations to LETIMERn\_COMP0 have priority over buffer loads.

#### 21.3.3.2 Repeat Modes

By default, the timer wraps around to the top value or 0xFFFF on each underflow, and continues counting. The repeat counters can be used to get more control of the operation of the timer, including defining the number of times the counter should wrap around. Four different repeat modes are available, see [Table 21.1 LETIMER Repeat Modes on page 682](#).

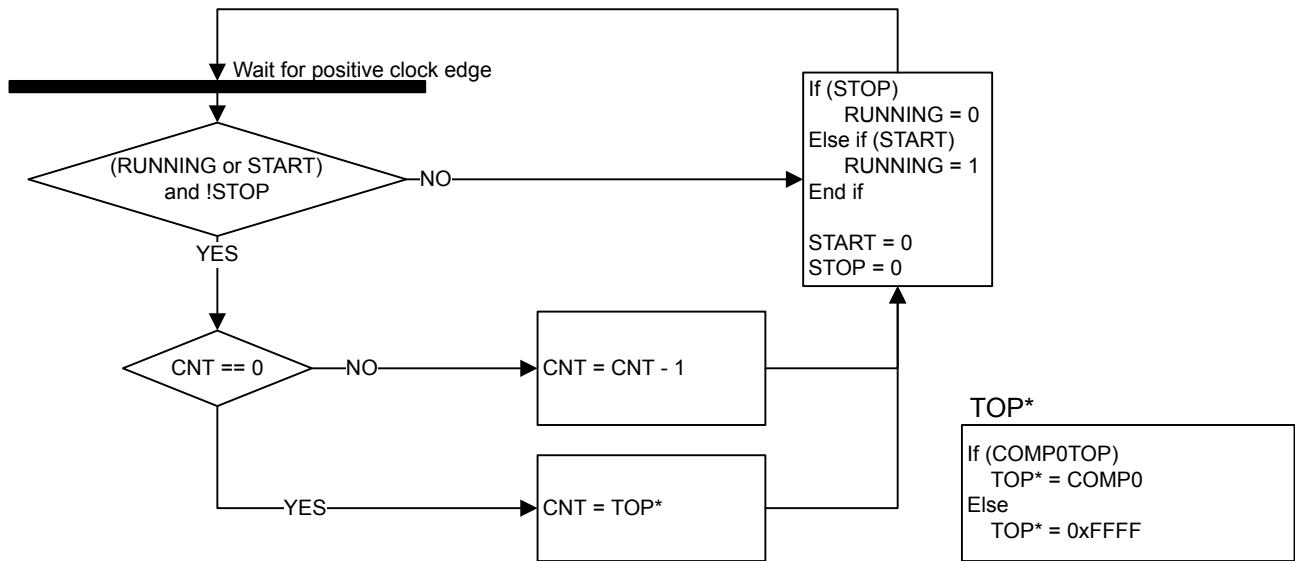

**Table 21.1. LETIMER Repeat Modes**

REPMODE	Mode	Description
0b00	Free-running	The timer runs until it is stopped.
0b01	One-shot	The timer runs as long as LETIMERn_REP0 != 0. LETIMERn_REP0 is decremented at each timer underflow.
0b10	Buffered	The timer runs as long as LETIMERn_REP0 != 0. LETIMERn_REP0 is decremented on each timer underflow. If LETIMERn_REP1 has been written, it is loaded into LETIMERn_REP0 when LETIMERn_REP0 is about to be decremented to 0.
0b11	Double	The timer runs as long as LETIMERn_REP0 != 0 or LETIMERn_REP1 != 0. Both LETIMERn_REP0 and LETIMERn_REP1 are decremented at each timer underflow.

The interrupt flags REP0 and REP1 in LETIMERn\_IF are set whenever LETIMERn\_REP0 or LETIMERn\_REP1 are decremented to 0 respectively. REP0 is also set when the value of LETIMERn\_REP1 is loaded into LETIMERn\_REP0 in buffered mode.

### 21.3.3.3 Free-Running Mode

In free-running mode, the LETIMER acts as a regular timer and the repeat counter is disabled. When started, the timer runs until it is stopped using the STOP command bit in LETIMERn\_CMD. A state machine for this mode is shown in [Figure 21.2 LETIMER State Machine for Free-running Mode on page 683](#).

**Figure 21.2. LETIMER State Machine for Free-running Mode**

Note that the CLEAR command bit in LETIMERn\_CMD always has priority over other changes to LETIMERn\_CNT. When the clear command is used, LETIMERn\_CNT is set to 0 and an underflow event will not be generated when LETIMERn\_CNT wraps around to the top value or 0xFFFF. Since no underflow event is generated, no output action is performed. LETIMERn\_REP0, LETIMERn\_REP1, LETIMERn\_COMP0 and LETIMERn\_COMP1 are also left untouched.

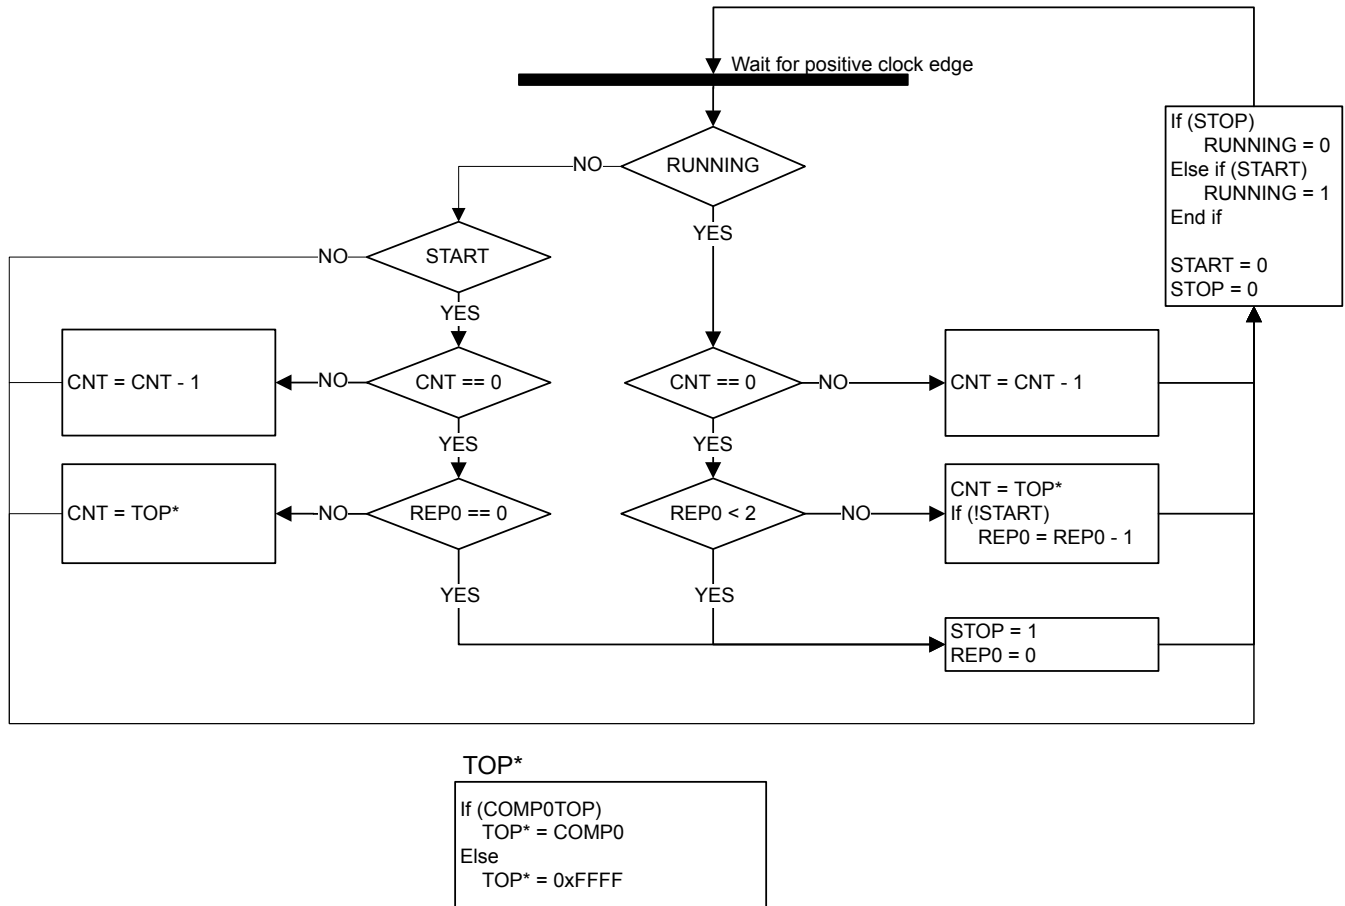

### 21.3.3.4 One-shot Mode

The one-shot repeat mode is the most basic repeat mode. In this mode, the repeat register LETIMERn\_REP0 is decremented every time the timer underflows, and the timer stops when LETIMERn\_REP0 goes from 1 to 0. In this mode, the timer counts down LETIMERn\_REP0 times, i.e. the timer underflows LETIMERn\_REP0 times.

#### Note:

Note that write operations to LETIMERn\_REP0 have priority over the timer decrement event. If LETIMERn\_REP0 is assigned a new value in the same cycle as a timer decrement event occurs, the timer decrement will not occur and the new value is assigned.

LETIMERn\_REP0 can be written while the timer is running to allow the timer to run for longer periods at a time without stopping. [Figure 21.3 LETIMER One-shot Repeat State Machine on page 684](#).

**Figure 21.3. LETIMER One-shot Repeat State Machine**

### 21.3.3.5 Buffered Mode

The Buffered repeat mode allows buffered timer operation. When started, the timer runs LETIMERN\_REP0 number of times. If LETIMERN\_REP1 has been written since the last time it was used and it is nonzero, LETIMERN\_REP1 is then loaded into LETIMERN\_REP0, and counting continues the new number of times. The timer keeps going as long as LETIMERN\_REP1 is updated with a nonzero value before LETIMERN\_REP0 is finished counting down. The timer top value (LETIMERN\_COMP0) may also optionally be buffered by setting BUFTOP in LETIMERN\_CTRL.

If the timer is started when both LETIMERN\_CNT and LETIMERN\_REP0 are zero but LETIMERN\_REP1 is non-zero, LETIMERN\_REP1 is loaded into LETIMERN\_REP0, and the counter counts the loaded number of times.

Used in conjunction with a buffered top value, both the top and repeat values of the timer may be buffered, and the timer can for instance be set to run 4 times with period 7 (top value 6), 6 times with period 200, then 3 times with period 50.

A state machine for the buffered repeat mode is shown in [Figure 21.4 LETIMER Buffered Repeat State Machine on page 685](#). REP1<sub>USED</sub> shown in the state machine is an internal variable that keeps track of whether the value in LETIMERN\_REP1 has been loaded into LETIMERN\_REP0 or not. The purpose of this is that a value written to LETIMERN\_REP1 should only be counted once. REP1<sub>USED</sub> is cleared whenever LETIMERN\_REP1 is written.

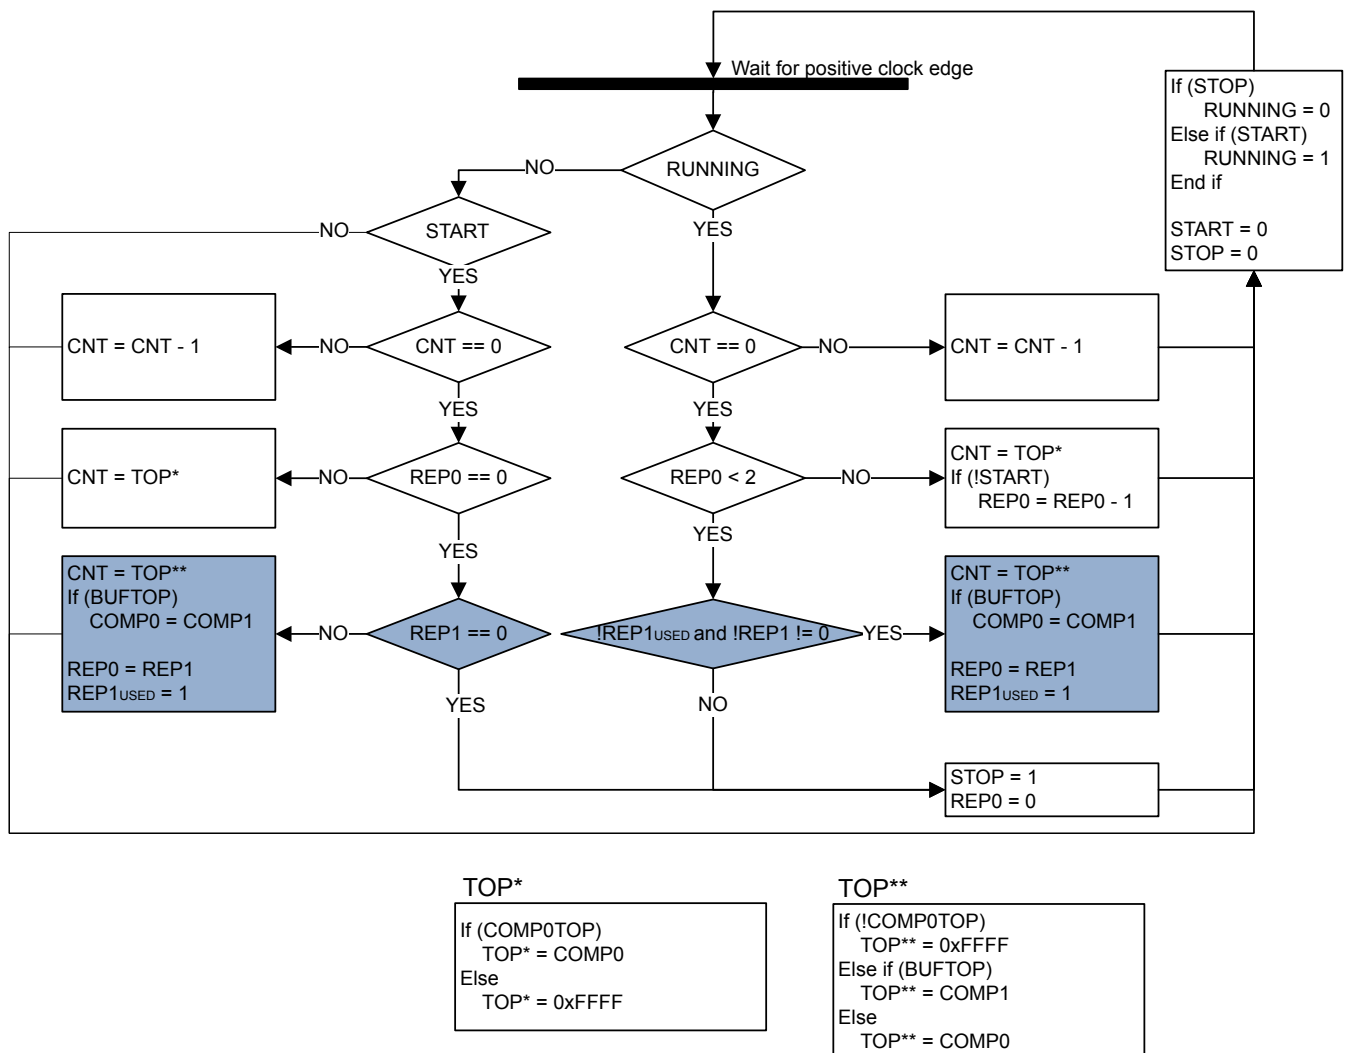

Figure 21.4. LETIMER Buffered Repeat State Machine

### 21.3.3.6 Double Mode

The Double repeat mode works much like the one-shot repeat mode. The difference is that, where the one-shot mode counts as long as LETIMERn\_REP0 is larger than 0, the double mode counts as long as either LETIMERn\_REP0 or LETIMERn\_REP1 is larger than 0. As an example, say LETIMERn\_REP0 is 3 and LETIMERn\_REP1 is 10 when the timer is started. If no further interaction is done with the timer, LETIMERn\_REP0 will now be decremented 3 times, and LETIMERn\_REP1 will be decremented 10 times. The timer counts a total of 10 times, and LETIMERn\_REP0 is 0 after the first three timer underflows and stays at 0. LETIMERn\_REP0 and LETIMERn\_REP1 can be written at any time. After a write to either of these, the timer is guaranteed to underflow at least the written number of times if the timer is running. Use the Double repeat mode to generate output on both the LETIMER outputs at the same time. The state machine for this repeat mode can be seen in [Figure 21.5 LETIMER Double Repeat State Machine on page 686](#).

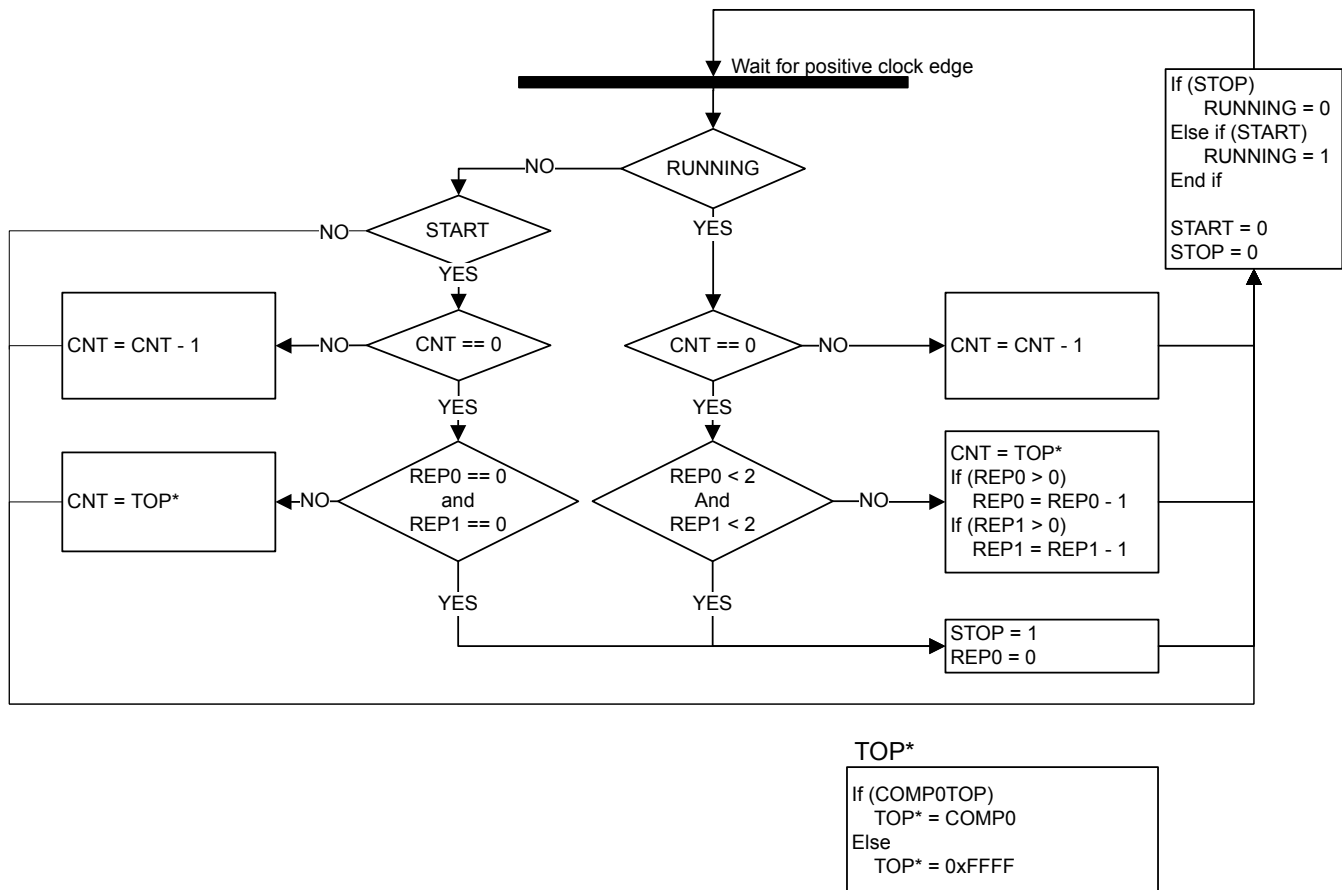

Figure 21.5. LETIMER Double Repeat State Machine

### 21.3.3.7 Clock Source

The LETIMER clock source and its prescaler value are defined in the Clock Management Unit (CMU). The LFACLK<sub>LETIMERn</sub> has a frequency given by [Figure 21.6 LETIMER Clock Frequency on page 686](#).

$$f_{\text{LFACLK\_LETIMERn}} = 32.768 / 2^{\text{LETIMERn}}$$

Figure 21.6. LETIMER Clock Frequency

where the exponent LETIMERn is a 4 bit value in the CMU\_LFAPRESC0 register.

To use this module, the LE interface clock must be enabled in CMU\_HFCORECLKEN0, in addition to the module clock.

### 21.3.3.8 PRS Input Triggers

The LETIMER can be configured to start, stop, and/or clear based on PRS inputs. The diagram showing the functions of the PRS input triggers is shown in [Figure 21.7 LETIMER PRS input triggers. on page 687](#).

There are 12 PRS inputs to the LETIMER. PRSSTARTEN, PRSSTOPEN, and PRSCLEAREN are used to enable starting, stopping, and/or clearing the LETIMER through the PRS inputs. PRSSTARTSEL, PRSSTOPSEL, and PRSCLEARSEL selects which PRS inputs are used to start, stop, and/or clear the LETIMER. Finally, PRSSTARTMODE, PRSSTOPMODE, and PRSCLEARMODE select which edge or edge(s) can trigger the start, stop, and/or clear action.

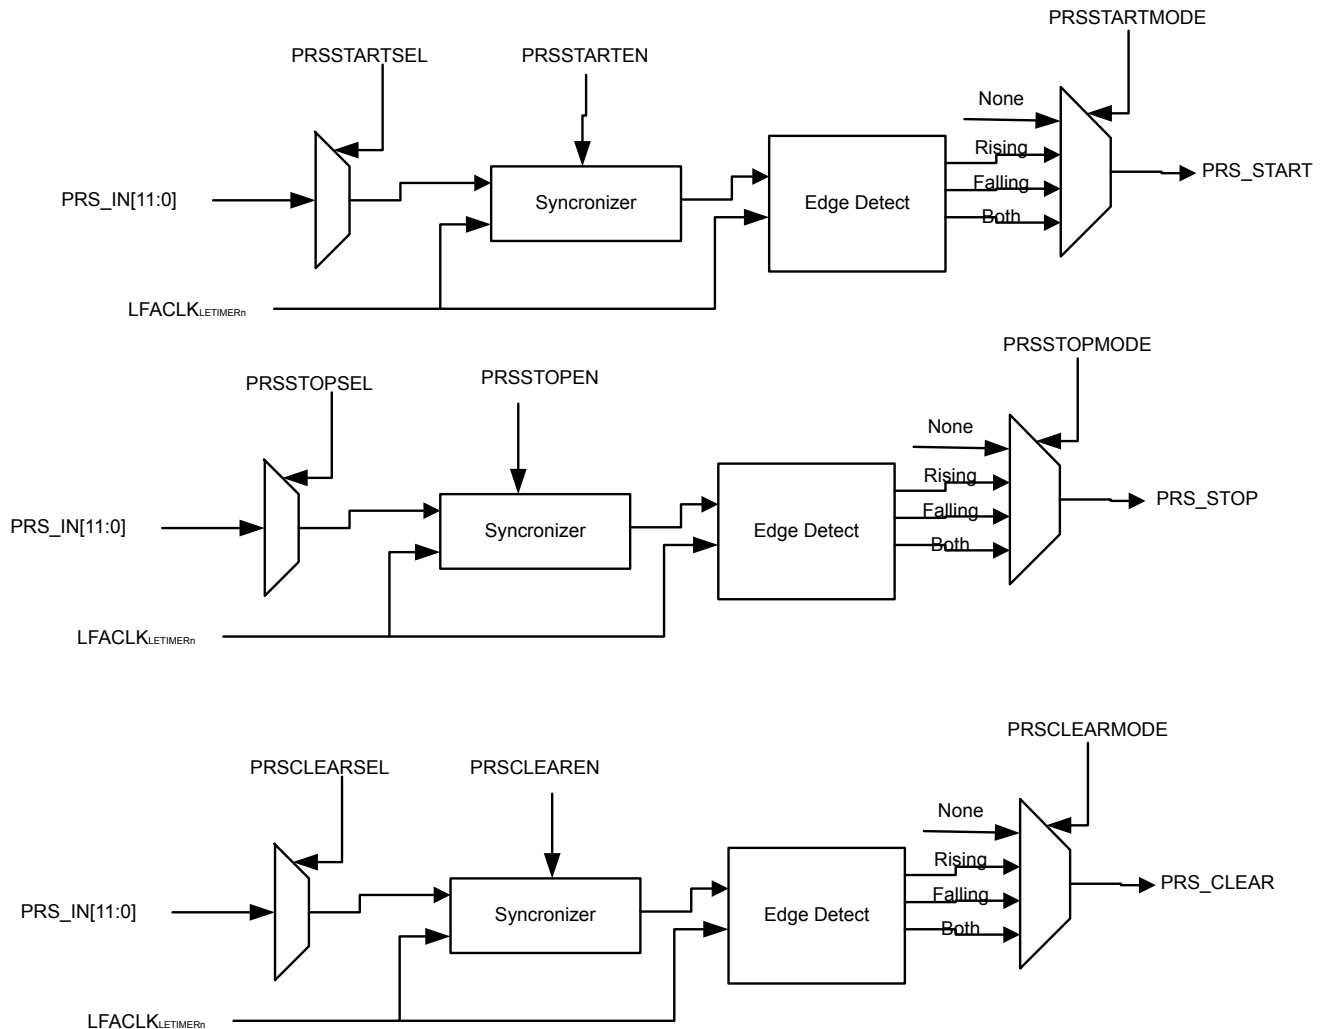

Figure 21.7. LETIMER PRS input triggers.

### 21.3.3.9 Debug

If DEBUGRUN in LETIMERn\_CTRL is cleared, the LETIMER automatically stops counting when the CPU is halted during a debug session, and resumes operation when the CPU continues. Because of synchronization, the LETIMER is halted two clock cycles after the CPU is halted, and continues running two clock cycles after the CPU continues. RUNNING in LETIMERn\_STATUS is not cleared when the LETIMER stops because of a debug-session.

Set DEBUGRUN in LETIMERn\_CTRL to allow the LETIMER to continue counting even when the CPU is halted in debug mode.

### 21.3.4 Underflow Output Action

For each of the repeat registers, an underflow output action can be set. The configured output action is performed every time the counter underflows while the respective repeat register is nonzero. In PWM mode, the output is similarly only changed on COMP1 match if the repeat register is nonzero. As an example, the timer will perform 7 output actions if LETIMERN\_REP0 is set to 7 when starting the timer in one-shot mode and leaving it untouched.

The output actions can be set by configuring UFOA0 and UFOA1 in LETIMERN\_CTRL. UFOA0 defines the action on output 0, and is connected to LETIMERN\_REP0, while UFOA1 defines the action on output 1 and is connected to LETIMERN\_REP1. The possible actions are defined in [Table 21.2 LETIMER Underflow Output Actions on page 688](#).

**Table 21.2. LETIMER Underflow Output Actions**

UF0A0/UF0A1	Mode	Description
0b00	Idle	The output is held at its idle value
0b01	Toggle	The output is toggled on LETIMERN_CNT underflow if LEIMERN_REPx is nonzero
0b10	Pulse	The output is held active for one clock cycle on LETIMERN_CNT underflow if LETIMERN_REPx is nonzero. It then returns to its idle value
0b11	PWM	The output is set idle on LETIMERN_CNT underflow and active on compare match with LETIMERN_COMP1 if LETIMERN_REPx is nonzero.

**Note:**

For the Pulse and PWM modes, the outputs will return to their idle states regardless of the state of the corresponding LETIMERN\_REPx registers. They will only be set active if the LETIMERN\_REPx registers are nonzero however.

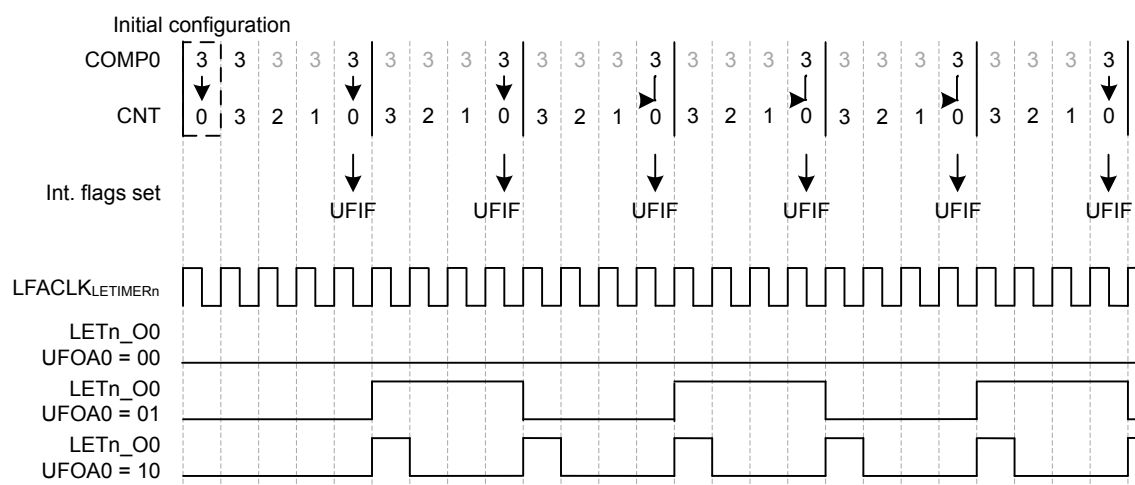

**Note:**

For free-running mode, LETIMERN\_REP0 != 0 for output generation to be enabled.

The polarity of the outputs can be set individually by configuring OPOL0 and OPOL1 in LETIMERN\_CTRL. When these are cleared, their respective outputs have a low idle value and a high active value. When they are set, the idle value is high, and the active value is low.

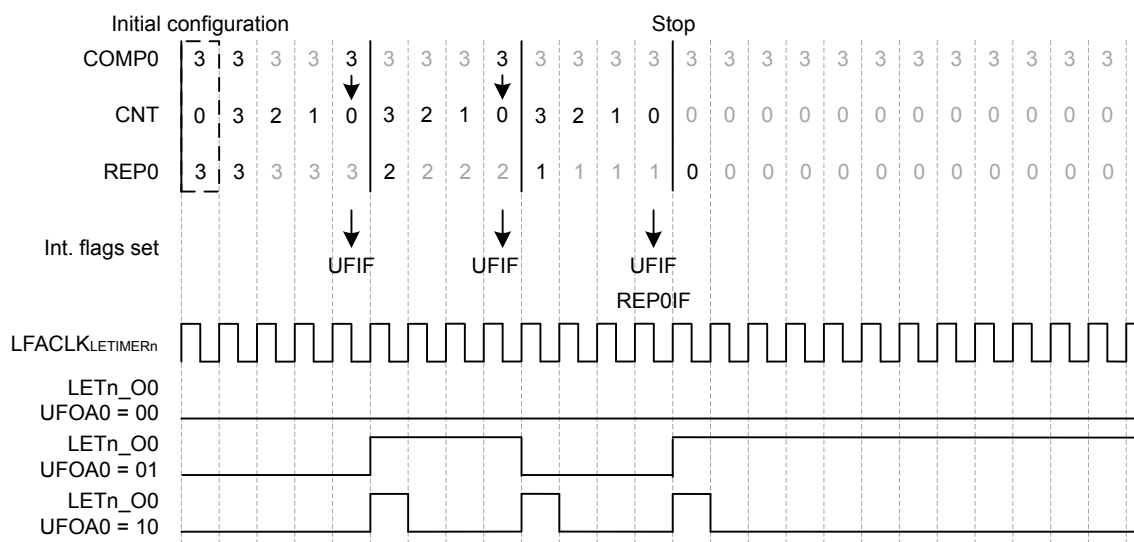

When using the toggle action, the outputs can be driven to their idle values by setting their respective CTO0/CTO1 command bits in LETIMERN\_CTRL. This can be used to put the output in a well-defined state before beginning to generate toggle output, which may be important in some applications. The command bit can also be used while the timer is running.

Some simple waveforms generated with the different output modes are shown in [Figure 21.8 LETIMER Simple Waveforms Output on page 689](#). For the example, REPMODE in LETIMERN\_CTRL has been cleared, COMP0TOP also in LETIMERN\_CTRL has been set and LETIMERN\_COMP0 has been written to 3. As seen in the figure, LETIMERN\_COMP0 now decides the length of the signal periods. For the toggle mode, the period of the output signal is  $2(\text{LETIMERN\_COMP0} + 1)$ , and for the pulse modes, the periods of the output signals are LETIMERN\_COMP0+1. Note that the pulse outputs are delayed by one period relative to the toggle output. The pulses come at the end of their periods.

**Figure 21.8. LETIMER Simple Waveforms Output**

For the example in [Figure 21.9 LETIMER Repeated Counting on page 689](#), the One-shot repeat mode has been selected, and LETIMERn\_REP0 has been written to 3. The resulting behavior is pretty similar to that shown in Figure 6, but in this case, the timer stops after counting to zero LETIMERn\_REP0 times. By using LETIMERn\_REP0 the user has full control of the number of pulses/toggles generated on the output.

### Figure 21.9. LETIMER Repeated Counting

Using the Double repeat mode, output can be generated on both the LETIMER outputs. [Figure 21.10 LETIMER Dual Output on page 690](#) shows an example of this. UFOA0 and UFOA1 in LETIMERn\_CTRL are configured for pulse output and the outputs are configured for low idle polarity. As seen in the figure, the number written to the repeat registers determine the number of pulses generated on each of the outputs.

**Figure 21.10. LETIMER Dual Output**

### 21.3.5 PRS Output

The LETIMER outputs can be routed out onto the PRS system. LETn\_O0 can be routed to PRS channel 0, and LETn\_O1 can be routed to PRS channel 1. Enabling the PRS connection can be done by setting SOURCESEL to LETIMERx and SIGSEL to LETIMERxCHn in PRS\_CHx\_CTRL. The PRS register description can be found in [15.5 Register Description](#)

### 21.3.6 Examples

This section presents a couple of usage examples for the LETIMER.

### 21.3.6.1 Triggered Output Generation

If both LETIMERN\_CNT and LETIMERN\_REP0 are 0 in buffered mode, and COMP0TOP and BUFTOP in LETIMERN\_CTRL are set, the values of LETIMERN\_COMP1 and LETIMERN\_REP1 are loaded into LETIMERN\_CNT and LETIMERN\_REP0 respectively when the timer is started. If no additional writes to LETIMERN\_REP1 are done before the timer stops, LETIMERN\_REP1 determines the number of pulses/toggles generated on the output, and LETIMERN\_COMP1 determines the period lengths.

As the RTC can be used via PRS to start the LETIMER, the RTC and LETIMER can thus be combined to generate specific pulse-trains at given intervals. Software can update LETIMERN\_COMP1 and LETIMERN\_REP1 to change the number of pulses and pulse-period in each train, but if changes are not required, software does not have to update the registers between each pulse train.

For the example in [Figure 21.11 LETIMER Triggered Operation on page 691](#), the initial values cause the LETIMER to generate two pulses with 3 cycle periods, or a single pulse 3 cycles wide every time the LETIMER is started. After the output has been generated, the LETIMER stops, and is ready to be triggered again.

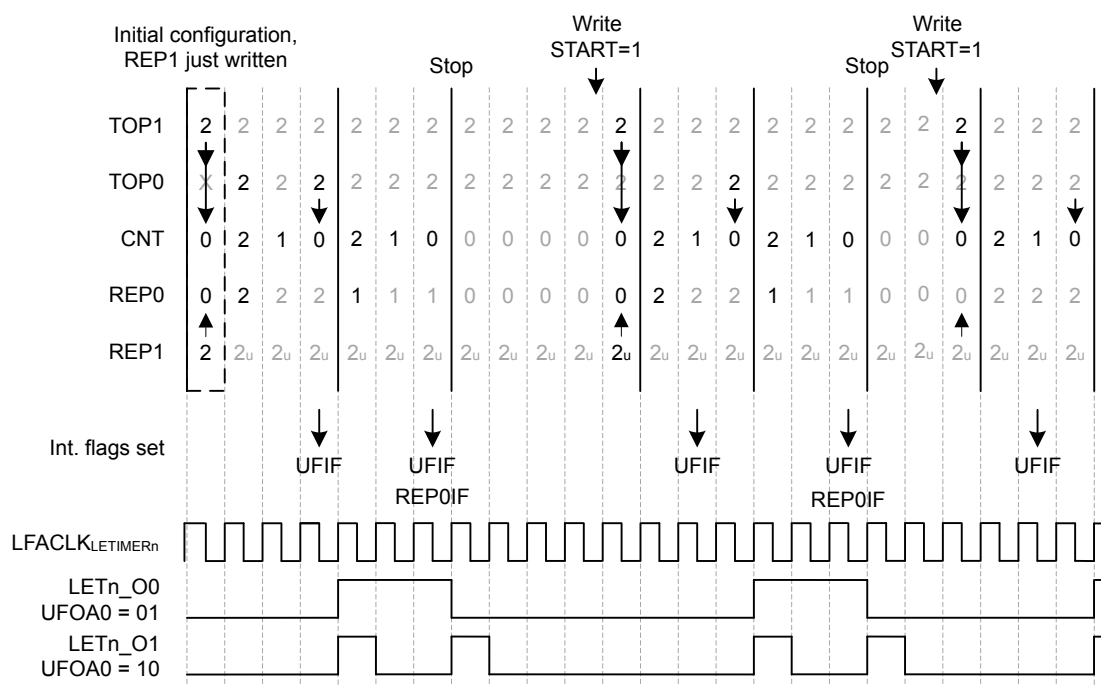

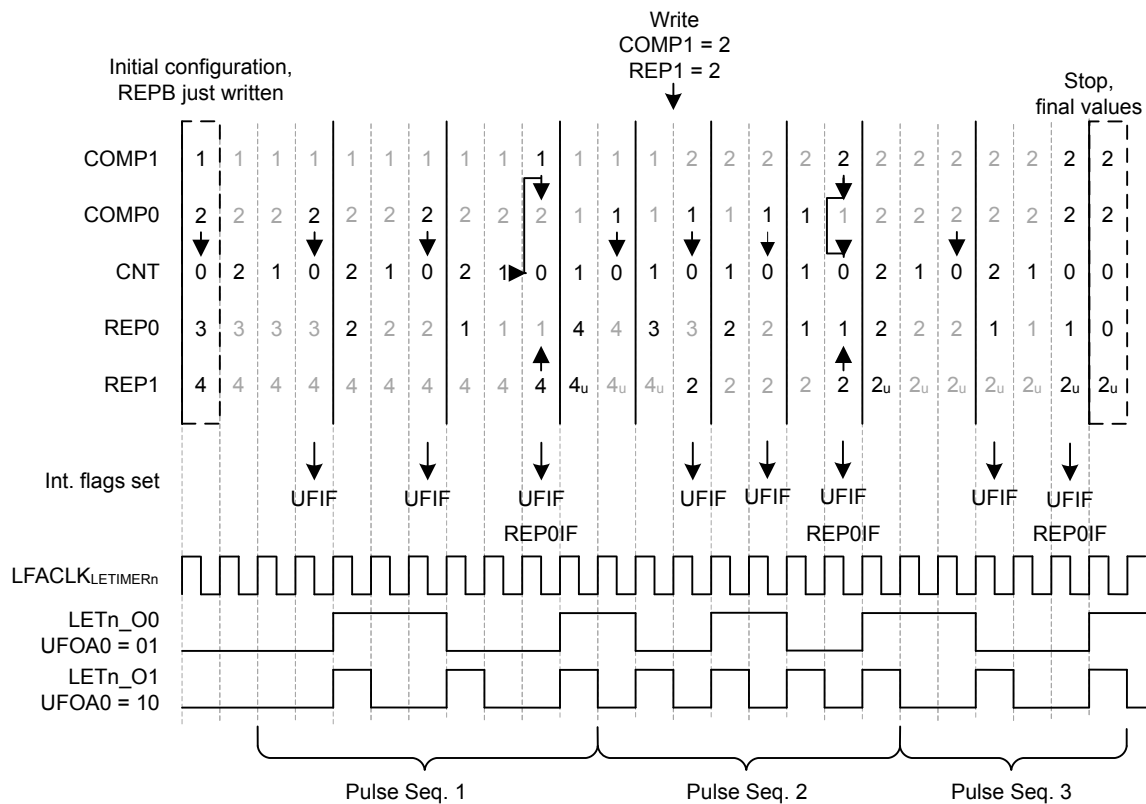

Figure 21.11. LETIMER Triggered Operation

### 21.3.6.2 Continuous Output Generation

In some scenarios, it might be desired to make LETIMER generate a continuous waveform. Very simple constant waveforms can be generated without the repeat counter as shown in [Figure 21.8 LETIMER Simple Waveforms Output on page 689](#), but to generate changing waveforms, using the repeat counter and buffer registers can prove advantageous.

For the example in [Figure 21.12 LETIMER Continuous Operation on page 692](#), the goal is to produce a pulse train consisting of 3 sequences with the following properties:

- 3 pulses with periods of 3 cycles
- 4 pulses with periods of 2 cycles
- 2 pulses with periods of 3 cycles

### Figure 21.12. LETIMER Continuous Operation

The first two sequences are loaded into the LETIMER before the timer is started.

LETIMERN\_COMP0 is set to 2 (cycles – 1), and LETIMERN\_REP0 is set to 3 for the first sequence, and the second sequence is loaded into the buffer registers, i.e. COMP1 is set to 1 and LETIMERN\_REP1 is set to 4.

The LETIMER is set to trigger an interrupt when LETIMERn\_REP0 is done by setting REP0 in LETIMERn\_IEN. This interrupt is a good place to update the values of the buffers. Last but not least REPMODE in LETIMERn\_CTRL is set to buffered mode, and the timer is started.

In the interrupt routine the buffers are updated with the values for the third sequence. If this had not been done, the timer would have stopped after the second sequence.

The final result is shown in [Figure 21.12 LETIMER Continuous Operation on page 692](#). The pulse output is grouped to show which sequence generated which output. Toggle output is also shown in the figure. Note that the toggle output is not aligned with the pulse outputs.

#### Note:

Multiple LETIMER cycles are required to write a value to the LETIMER registers. The example in [Figure 21.12 LETIMER Continuous Operation on page 692](#) assumes that writes are done in advance so they arrive in the LETIMER as described in the figure.

[Figure 21.13 LETIMER LETIMERn\\_CNT Not Initialized to 0 on page 693](#) shows an example where the LETIMER is started while LETIMERn\_CNT is nonzero. In this case the length of the first repetition is given by the value in LETIMERn\_CNT.

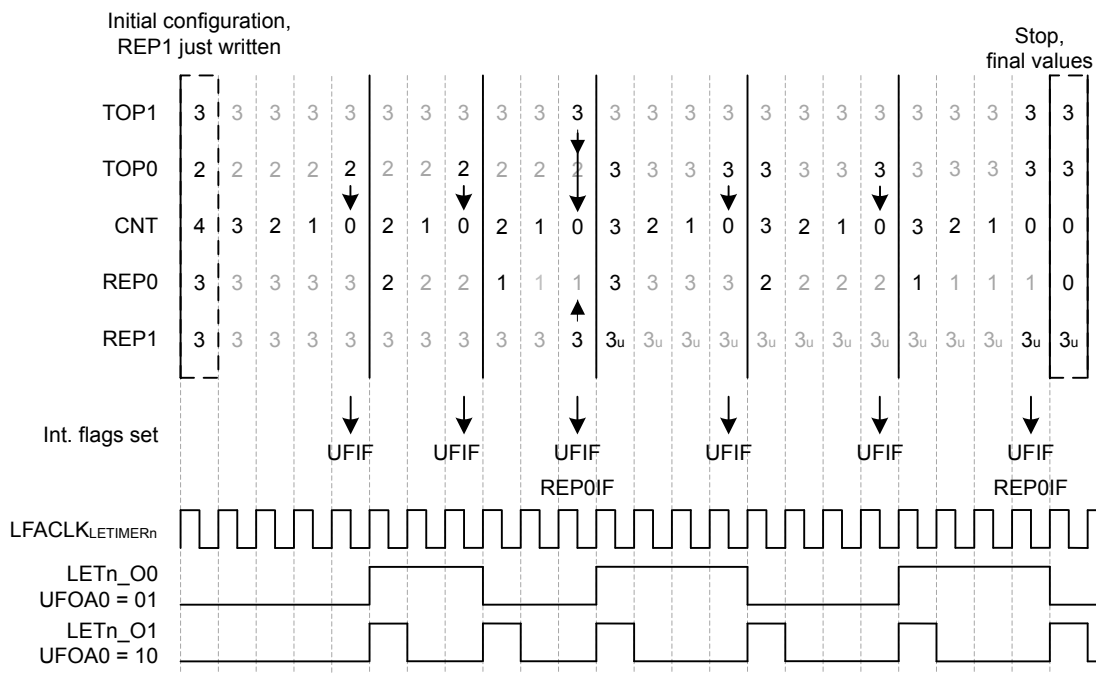

Figure 21.13. LETIMER LETIMERn\_CNT Not Initialized to 0

#### 21.3.6.3 PWM Output

There are several ways of generating PWM output with the LETIMER, but the most straight-forward way is using the PWM output mode. This mode is enabled by setting UFOA0 or UFOA1 in LETIMERn\_CTRL to 3. In PWM mode, the output is set idle on timer underflow, and active on LETIMERn\_COMP1 match, so if for instance COMP0TOP = 1 and OPOL0 = 0 in LETIMERn\_CTRL, LETIMERn\_COMP0 determines the PWM period, and LETIMERn\_COMP1 determines the active period.

The PWM period in PWM mode is LETIMERn\_COMP0 + 1. There is no special handling of the case where LETIMERn\_COMP1 > LETIMERn\_COMP0, so if LETIMERn\_COMP1 > LETIMERn\_COMP0, the PWM output is given by the idle output value. This means that for OPOLx = 0 in LETIMERn\_CTRL, the PWM output will always be 0 for at least one clock cycle, and for OPOLx = 1 LETIMERn\_CTRL, the PWM output will always be 1 for at least one clock cycle.

To generate a PWM signal using the full PWM range, invert OPOLx when LETIMERn\_COMP1 is set to a value larger than LETIMERn\_COMP0.

#### 21.3.6.4 Interrupts

The interrupts generated by the LETIMER are combined into one interrupt vector. If the interrupt for the LETIMER is enabled, an interrupt will be made if one or more of the interrupt flags in LETIMERn\_IF and their corresponding bits in LETIMER\_IEN are set.

### 21.3.7 Register access

This module is a Low Energy Peripheral, and supports immediate synchronization. For description regarding immediate synchronization, the reader is referred to [4.3.1 Writing](#).

### 21.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	LETIMERn_CTRL	RW	Control Register
0x004	LETIMERn_CMD	W1	Command Register
0x008	LETIMERn_STATUS	R	Status Register
0x00C	LETIMERn_CNT	RWH	Counter Value Register
0x010	LETIMERn_COMP0	RWH	Compare Value Register 0
0x014	LETIMERn_COMP1	RW	Compare Value Register 1
0x018	LETIMERn_REP0	RWH	Repeat Counter Register 0
0x01C	LETIMERn_REP1	RWH	Repeat Counter Register 1
0x020	LETIMERn_IF	R	Interrupt Flag Register
0x024	LETIMERn_IFS	W1	Interrupt Flag Set Register
0x028	LETIMERn_IFC	(R)W1	Interrupt Flag Clear Register
0x02C	LETIMERn_IEN	RW	Interrupt Enable Register
0x034	LETIMERn_SYNCBUSY	R	Synchronization Busy Register
0x040	LETIMERn_ROUTEPEN	RW	I/O Routing Pin Enable Register
0x044	LETIMERn_ROUTELOC0	RW	I/O Routing Location Register
0x050	LETIMERn_PRSEL	RW	PRS Input Select Register

## 21.5 Register Description

### 21.5.1 LETIMERn\_CTRL - Control Register (Async Reg)

For More information about Registers please see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

For more information about Registers please see [4.5 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

Value		Mode	Description	
0		NONE	LETn_O1 is held at its idle value as defined by OPOL1.	
1		TOGGLE	LETn_O1 is toggled on CNT underflow.	
2		PULSE	LETn_O1 is held active for one LFACLK <sub>LETIMER0</sub> clock cycle on CNT underflow. The output then returns to its idle value as defined by OPOL1.	
3		PWM	LETn_O1 is set idle on CNT underflow, and active on compare match with COMP1	
3:2	UFOA0	0x0	RW	<b>Underflow Output Action 0</b> Defines the action on LETn_O0 on a LETIMER underflow.
Value		Mode	Description	
0		NONE	LETn_O0 is held at its idle value as defined by OPOL0.	

Bit	Name	Reset	Access	Description
	1	TOGGLE		LETn_O0 is toggled on CNT underflow.
	2	PULSE		LETn_O0 is held active for one LFACLK <sub>LETIMER0</sub> clock cycle on CNT underflow. The output then returns to its idle value as defined by OPOL0.
	3	PWM		LETn_O0 is set idle on CNT underflow, and active on compare match with COMP1
1:0	REPMODE	0x0	RW	<b>Repeat Mode</b> Allows the repeat counter to be enabled and disabled.
	Value	Mode		Description
	0	FREE		When started, the LETIMER counts down until it is stopped by software.
	1	ONESHOT		The counter counts REP0 times. When REP0 reaches zero, the counter stops.
	2	BUFFERED		The counter counts REP0 times. If REP1 has been written, it is loaded into REP0 when REP0 reaches zero. Else the counter stops
	3	DOUBLE		Both REP0 and REP1 are decremented when the LETIMER wraps around. The LETIMER counts until both REP0 and REP1 are zero

22. CRYOTIMER - Ultra Low Energy Timer/Counter

Quick Facts

**What?**

The CRYOTIMER is a timer capable of providing wakeup events/interrupts after deterministic intervals in all energy modes, including EM4.

**Why?**

The CRYOTIMER enables the chip to remain in the lowest energy modes for long durations, while keeping track of time and being able to wake up at regular intervals, all with an absolute minimum current consumption.

**How?**

Using a counter running on a prescaled Low Frequency Oscillator, the CRYOTIMER can provide periodic wakeup events with a very wide period range.

22.1 Introduction

The CRYOTIMER is a 32 bit counter which operates on a low frequency oscillator, and is capable of running in all Energy Modes. It can provide periodic Wakeup events and PRS signals which can be used to wake up peripherals from any energy mode. The CRYOTIMER provides a very wide range of periods for the interrupts facilitating flexible ultra-low energy operation.

Because of its simplicity, the CRYOTIMER is a lower energy solution for periodically waking up the MCU compared to the RTCC.

22.2 Features

- 32 bit Counter
- Works in all the energy modes
- Only External and Power-On resets reset the CRYOTIMER
- Interrupt/wake up event after deterministic intervals
- PRS Output
- Debug mode
  - Configurable to either run or stop when processor is stopped (break)

22.3 Functional Description

22.3.1 Block Diagram

An overview of the CRYOTIMER is shown in [Figure 22.1 CRYOTIMER Block Overview on page 714](#).

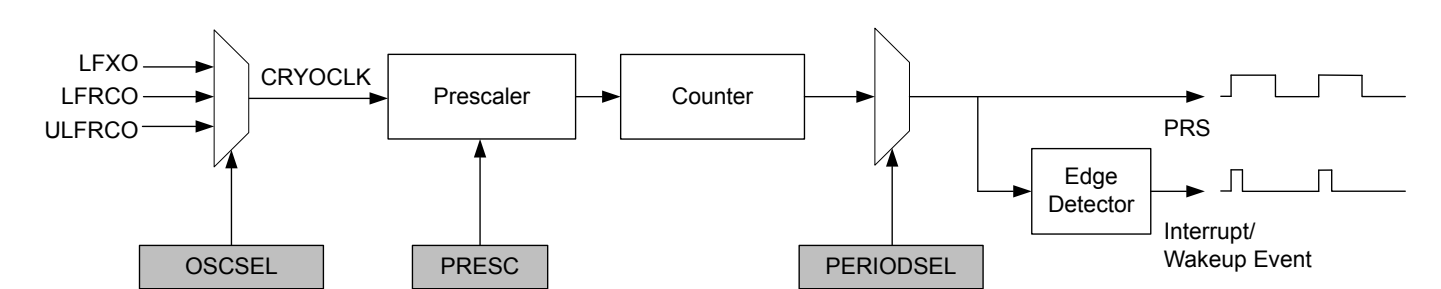

Figure 22.1. CRYOTIMER Block Overview

22.3.2 Operation

The desired low frequency oscillator for the CRYOTIMER operation can be selected by using OSCSEL in CRYOTIMER\_CTRL. The selection must be made before enabling the CRYOTIMER, and it must be ensured that the selected oscillator is ready. This can be checked by observing LFXORDY or LFRCORDY (depending upon the oscillator selection) in CMU\_STATUS. Note that the ULFRCO is always ready.

By default the CRYOTIMER is held in reset. It can be started by setting EN in CRYOTIMER\_CTRL. The CRYOTIMER, when running, is reset by clearing EN.

The timer counts at a frequency determined by PRESC in CRYOTIMER\_CTRL. This value should be set before the CRYOTIMER is enabled. Setting PRESC to 0 gives the maximum resolution, while higher values allow longer periods, see [Table 22.1 CRYOTIMER Resolution vs Maximum Wakeup event/Interrupt period](#),  $F_{CRYOCLK} = 32768 \text{ Hz}$  on [page 715](#).

The 32-bit Counter provides 32 different options for selecting the duration between the Wakeup events. The selected duration is specified by CRYOTIMER\_PERIODSEL. It should be configured before the CRYOTIMER is enabled.

$$T_{WU} = (2^{PRESC} \times 2^{PERIODSEL})/f_{CRYOCLK}$$

Figure 22.2. Duration between the CRYOTIMER Wakeup events in seconds

Table 22.1. CRYOTIMER Resolution vs Maximum Wakeup event/Interrupt period,  $F_{CRYOCLK} = 32768 \text{ Hz}$

CRYOTIMER_CTRL_PRESC	Resolution, $2^{PRESC}/f_{CRYOCLK}$	Maximum Wakeup event/Interrupt Period

DIV64	1.95 ms	97 days
DIV128	3.91 ms	194 days

The 32-bit counter value of the CRYOTIMER can be read using the CRYOTIMER\_CNT register.

The PRS output pulses of the CRYOTIMER are 1 CRYOCLK clock cycle wide. However, if the PRESC and PERIODSEL are both set to 0, the width of these pulses will be half CRYOCLK time period.

The CRYOTIMER wakeup events set the flag in the CRYOTIMER\_IF. Interrupt on this event can be enabled by using the CRYOTIMER\_IEN register.

The CRYOTIMER is always reset by the External Pin and Power-On resets. Additionally, by using EMU\_CTRL, it can also be configured to reset by Watchdog, lockup, and system request resets.

**Note:** The CRYOTIMER configuration bits/registers should only be changed when EN in CRYOTIMER\_CTRL is cleared.

22.3.3 Debug Mode

When the CPU is halted in debug mode, the CRYOTIMER can be configured to either continue to run or to be frozen. This is configured using DEBUGRUN in CRYOTIMER\_CTRL.

22.3.4 Energy Mode availability

The CRYOTIMER is available in all Energy Modes. Wakeup from EM2 DeepSleep and EM3 Stop to EM0 Active can be performed using the regular interrupt as discussed in [22.3.2 Operation](#). To generate wakeup events during EM4 Hibernate/Shutoff, EM4WU in CRYOTIMER\_EM4WUEN must be set to 1. Refer to [11. EMU - Energy Management Unit](#) for details on how to configure the EMU.

## 22.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	CRYOTIMER_CTRL	RW	Control Register
0x004	CRYOTIMER_PERIODSEL	RW	Interrupt Duration

## 23. ACMP - Analog Comparator

### Quick Facts

#### What?

The ACMP (Analog Comparator) compares two analog signals and returns a digital value telling which is greater.

#### Why?

Applications often do not need to know the exact value of an analog signal, only if it has passed a certain threshold. Often the voltage must be monitored continuously, which requires extremely low power consumption.

#### How?

Available down to Energy Mode 3 and using as little as 100 nA, the ACMP can wake up the system when input signals pass the threshold. The analog comparator can compare two analog signals or one analog signal and a highly configurable internal reference.

### 23.1 Introduction

The Analog Comparator compares the voltage of two analog inputs and outputs a digital signal indicating which input voltage is higher. Inputs can either be from internal references or from external pins. Response time, and thereby the current consumption, can be configured by altering the current supply to the comparator.

### 23.2 Features

- Up to 144 selectable external I/O inputs for both positive and negative inputs
  - Up to 48 I/O can be used as a dividable reference
- Voltage supply monitoring
- Low power mode for internal  $V_{DD}$  and bandgap references
- Selectable hysteresis
  - 8 values
  - Values can be positive or negative
  - Divideable references have scale for both both output values, allowing for even larger hysteresis
- Selectable response time
- Asynchronous interrupt generation on selectable edges
  - Rising edge
  - Falling edge
  - Both edges
- Operational in EM0 Active down to EM3 Stop
- Dedicated capacitive sense mode with up to 80 inputs
  - Adjustable internal resistor
- Configurable output when inactive
- Comparator output direct on PRS
- Comparator output on GPIO through alternate functionality
  - Output inversion available

An overview of the ACMP is shown in [Figure 23.1 ACMP Overview on page 724](#).

The output of the comparator can be read in the `ACMPOUT` bit in `ACMPn_STATUS`. It is possible to switch inputs while the comparator is enabled, but all other configuration should only be changed while the comparator is disabled.

### 23.3.1 Warm-up Time

The analog comparator is enabled by setting the EN bit in ACMPn\_CTRL. The comparator requires some time to stabilize after it is enabled. This time period is called the warm-up time. The warm-up period is self-timed and will complete within 5 $\mu$ s after EN is set.

During warm-up and when the comparator is disabled, the output level of the comparator is set to the value of the INACTVAL bit in ACMPn\_CTRL. When the warm-up time is over, the ACMPACT bit in ACMPn\_STATUS is set to 1 to indicate that the comparator is active.

An edge interrupt will be generated if the edge interrupt is enabled and the value set in INACTVAL differs from ACMPOUT when the comparator transitions from warm-up to active.

Software should wait until the warm-up period is over before entering EM2 or EM3, otherwise no comparator interrupts will be detected. EM1 can still be entered during warm-up. After the warm-up period is completed, interrupts will be detected in EM2 and EM3.

### 23.3.2 Response Time

There is a delay from when the input voltage changes polarity to when the output toggles. This delay is called the response time and can be altered by increasing or decreasing the bias current to the comparator through the BIASPROG and FULLBIAS fields in the ACMPn\_CTRL register. The current and speed of the circuit increase as the values of FULLBIAS and BIASPROG are increased from their minimum setting of FULLBIAS=0 BIASPROG=0b00000 to the maximum setting FULLBIAS=1 BIASPROG=0b11111 (maximum). The setting of FULLBIAS has a greater affect on current and speed than the setting of BIASPROG. See the part datasheet for specific current and response times related to the setting of these fields.

If FULLBIAS is set, to avoid glitches the highest hysteresis level should be used.

### 23.3.3 Hysteresis

When the hysteresis level is set to a non-zero value, the digital output will not toggle until the positive input voltage is at a voltage equal to the hysteresis level above or below the negative input voltage (see [Figure 23.3 Hysteresis on page 726](#) ). This feature can be used to avoid continual comparator output changes due to noise when the positive and negative inputs are nearly equal by requiring the input difference to exceed the hysteresis threshold.

In the analog comparator, hysteresis can be configured to 8 different levels. Level 0 is no hysteresis. Hysteresis is configured through the HYST field in ACMPn\_HYSTERSIS0 and ACMPn\_HYSTERSIS1 registers. The hysteresis value can be positive or negative. The comparator will output a 1 if:

$$\text{POSSEL} - \text{NEGSEL} > \text{HYST}$$

There are two hysteresis registers, ACMPn\_HYSTERSIS0 and ACMPn\_HYSTERSIS1, as the ACMP supports asymmetric hysteresis. ACMPn\_HYSTERSIS0 are the hysteresis values used when the comparator output is 0; ACMPn\_HYSTERSIS1 are the values used when the comparator output is 1. The user must set both registers to the same values if symmetric hysteresis is desired.

Along with the HYST field, the ACMPn\_HYSTERSIS0/1 registers include the DIVVA and DIVVB fields. This allows the user to implement even larger hysteresis when comparing against VADIV or VBDIV, as the reference voltage can vary with the comparator output, also.

Figure 23.3. Hysteresis

### 23.3.4 Input Selection

The POSSEL and NEGSEL fields in ACMPn\_INPUTSEL control the input connections to the positive and negative inputs of the comparator. The user can select external GPIO pins on the chip, or select a number of internal chip voltages. Pins are selected by configuring channels on APORT buses. Not all selectable channels are available on a given device, as different devices within a family may not implement or bring out all of the I/O defined for that family.

The mapping for external I/O connections to ACMP0 and ACMP1 inputs is shown in [Table 23.1 ACMP0 and ACMP1 Bus and Pin Mapping on page 727](#). Note that this table shows the mapping for an entire family of devices. Refer to the Pin Definition and the APORT Client Map in the device datasheet for specific details on which I/O are available for each family and package configuration.

**Table 23.1. ACMP0 and ACMP1 Bus and Pin Mapping**

ACMP Port	APORT0		APORT1		APORT2		APORT3		APORT4	
Polarity	X	Y	X	Y	X	Y	X	Y	X	Y

CH3								PD11	PD11	
CH2							PD10			PD10
CH1										
CH0										

There are limitations on the POSSEL and NEGSEL connections than can be made. The user cannot select an X-bus for both POSSEL and NEGSEL simultaneously, nor a Y-bus for both POSSEL and NEGSEL simultaneously. The second limitation is that when using the feedback resistor only X-bus selections can be made for POSSEL. (The resistor only physically exists on the positive input of the comparator).

Refer to [Table 23.1 ACMP0 and ACMP1 Bus and Pin Mapping on page 727](#) for specific I/O pin connection options. Note that the same I/O pin may appear in multiple locations. Enumerations for the POSSEL and NEGSEL fields can be determined by finding the desired pin connection in the table and then combining the ACMP Port, polarity and channel identifier. For example, pin PF7 is listed as CH23 on APORT2, polarity X. The enumeration would be APORT2XCH23. PF7 is also available on CH23 of APORT1, polarity Y, so APORT1YCH23 also selects PF7.

The user may also select from a number of internal voltages. VADIV and VBDIV are two dividable voltages. VADIV can be VDD divided, or the user can choose to select inputs from a number of APORT buses. VBDIV consists of two dividable band-gap references of either 1.25V or 2.5V. Each of these voltages have dividers in the ACMPn\_HYSTERESIS0/1 registers. The formula for the division of these voltages is:

$$VADIV = VA \times (DIVVA+1) / 64$$

**Figure 23.3. VA Voltage Division**

$$VBDIV = VB \times (DIVVB+1) / 64$$

**Figure 23.4. VB Voltage Division**

Either VADIV and VBDIV can also be used as an input to a lower power reference: VLP. Which of the two is used is configured via the VLPSEL field in ACMPn\_INPUTSEL. If the user selects VLP as an input source, then VADIV or VBDIV cannot be used as the source for the other input.

ACMP can be configured to operate with a selected level of accuracy depending on the setting of ACCURACY in ACMPn\_CTRL. The default is low-accuracy mode where ACMP operates with lower accuracy but consumes less current. When higher accuracy is needed the user can set ACCURACY=1 at the cost of higher current consumption.

The ACMP block has dedicated inputs APORT0X and APORT0Y to facilitate direct connection of the ACMP to chip pins. Currently, no part in this family uses these analog buses.

### 23.3.5 Capacitive Sense Mode

The analog comparator includes specialized hardware for capacitive sensing of passive push buttons. Such buttons are traces on the PCB laid out in a way that creates a parasitic capacitor between the button and the ground node. Because a human finger will have a small intrinsic capacitance to ground, the capacitance of the button will increase when the button is touched. The capacitance is measured by including the capacitor in a free-running RC oscillator (see [Figure 23.5 Capacitive Sensing Setup on page 730](#)). The frequency produced will decrease when the button is touched compared to when it is not touched. By measuring the output frequency with a timer (via the PRS), the change in capacitance can be detected.

The analog comparator contains a feedback loop including an optional internal resistor. This resistor is enabled by setting the CSRESEN bit in ACMPn\_INPUTSEL. The resistance can be set to any of 8 values by configuring the CSRESSEL bits in ACMPn\_INPUTSEL. The source for VADIV is set to VDD by setting field VASEL=0 in ACMPn\_INPUTSEL. The oscillation rails are defined by the VADIV fields in registers ACMPn\_HYSTERESIS0/1. The user should select VADIV as the source for NEGSEL, and APORTXCHc for POSSEL in ACMPn\_INPUTSEL. When enabled, the comparator output will oscillate between the rails defined by VADIV in ACMPn\_HYSTERESIS0/1.

**Figure 23.5. Capacitive Sensing Setup**

### 23.3.6 Interrupts and PRS Output

The analog comparator includes an edge triggered interrupt flag (EDGE in ACMPn\_IF). If either IRISE and/or IFALL in ACMPn\_CTRL is set, the EDGE interrupt flag will be set on rising and/or falling edge of the comparator output respectively. An interrupt request will be sent if the EDGE interrupt flag in ACMPn\_IF is set and enabled through the EDGE bit in ACMPn\_IEN. The edge interrupt can also be used to wake up the device from EM3 Stop-EM1 Sleep.

The analog comparator includes the interrupt flag WARMUP in ACMPn\_IF which is set when a warm-up sequence has finished. An interrupt request will be sent if the WARMUP interrupt flag in ACMPn\_IF is set and enabled through the WARMUP bit in ACMPn\_IEN.

The analog comparator can also generate an interrupt if a bus conflict occurs. An interrupt request will be sent if the APORTCONFLICT interrupt flag in ACMPn\_IF is set and enabled through the APORTCONFLICT bit in ACMPn\_IEN.

The synchronized comparator output is also available as a PRS output signal.

### 23.3.7 Output to GPIO

The output from the comparator and the capacitive sense output are available as alternate functions to the GPIO pins. Set the ACMP-PEN bit in ACMPn\_ROUTE to enable the output to a pin and the LOCATION bits to select the output location. The GPIO-pin must also be set as output. The output to the GPIO can be inverted by setting the GPIOINV bit in ACMPn\_CTRL.

### 23.3.8 APORT Conflicts

The analog comparator connects to chip pins through APORT buses. It is possible that another APORT client is using a given APORT bus. To help debugging over-utilization of APORT resources the ACMP provides a number of status registers. The ACMPn\_APOR-TREQ gives the user visibility into what APORT buses the ACMP is requesting given the setting of registers ACMPn\_INPUTSEL and ACMPn\_CTRL. ACMPn\_APORTCONFLICT indicates if any of the selections are in conflict, internally or externally.

For example, if the user selects APORT1XCH0 for POSSEL and APORT3XCH1 for NEGSEL, then bits APORT1XCONFLICT and APORT3XCONFLICT would be 1 in register ACMPn\_APORTCONFLICT, as it is illegal for POSSEL and NEGSEL to both select an X-bus simultaneously.

If the user wishes the ACMP to monitor the same pin as another APORT client within the system, the ACMP can be configured to not attempt to control the switches on an APORT bus via the fields APORTXMASTERDIS, APORXYMASTERDIS, and APORTVMAS-TERDIS in ACMPn\_CTRL. APORTXMASTERDIS and APORXYMASTERDIS control if the X or Y bus selected via POSSEL or NEGSEL is mastered or not. APORTVMAS-TERDIS controls if either the X or Y bus selection of VASEL is mastered or not. When bus mastering is disabled, it is the other APORT client that determines which pin is connected to the APORT bus.

### 23.3.9 Supply Voltage Monitoring

The ACMP can be used to monitor supply voltages. The ACMP can select which voltage it uses via PWRSEL in ACMPn\_CTRL. This voltage can be selected for VADIV using VASEL=0 in ACMPn\_INPUTSEL and divided to a voltage with the band-gap reference range using DIVVA in registers ACMPn\_HYSTERESIS0/1. The band-gap reference voltage can also be scaled via DIVVB in registers ACMPn\_HYSTERESIS0/1 to provide a voltage higher or lower than the scaled VA voltage for comparison.

## 23.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	ACMPn_CTRL	RW	Control Register
0x004	ACMPn_INPUTSEL	RW	Input Selection Register
0x008	ACMPn_STATUS	R	Status Register
0x00C	ACMPn_IF	R	Interrupt Flag Register
0x010	ACMPn_IFS	W1	Interrupt Flag Set Register

## 24. ADC - Analog to Digital Converter

### Quick Facts

#### What?

The ADC is used to convert analog signals into a digital representation and features low-power, autonomous operation.

#### Why?

In many applications there is a need to measure analog signals and record them in a digital representation, without exhausting the energy source.

#### How?

A low power ADC samples up to 32 input channels in a programmable sequence. With the help of PRS and DMA, the ADC can operate without CPU intervention in EM2 and EM3, minimizing the number of powered up resources. The ADC can further be duty-cycled to reduce the energy consumption.

### 24.1 Introduction

The ADC uses a Successive Approximation Register (SAR) architecture, with a resolution of up to 12 bits at up to one million samples per second (1 Msps). The integrated input multiplexer can select from external I/Os and 11 internal signals.

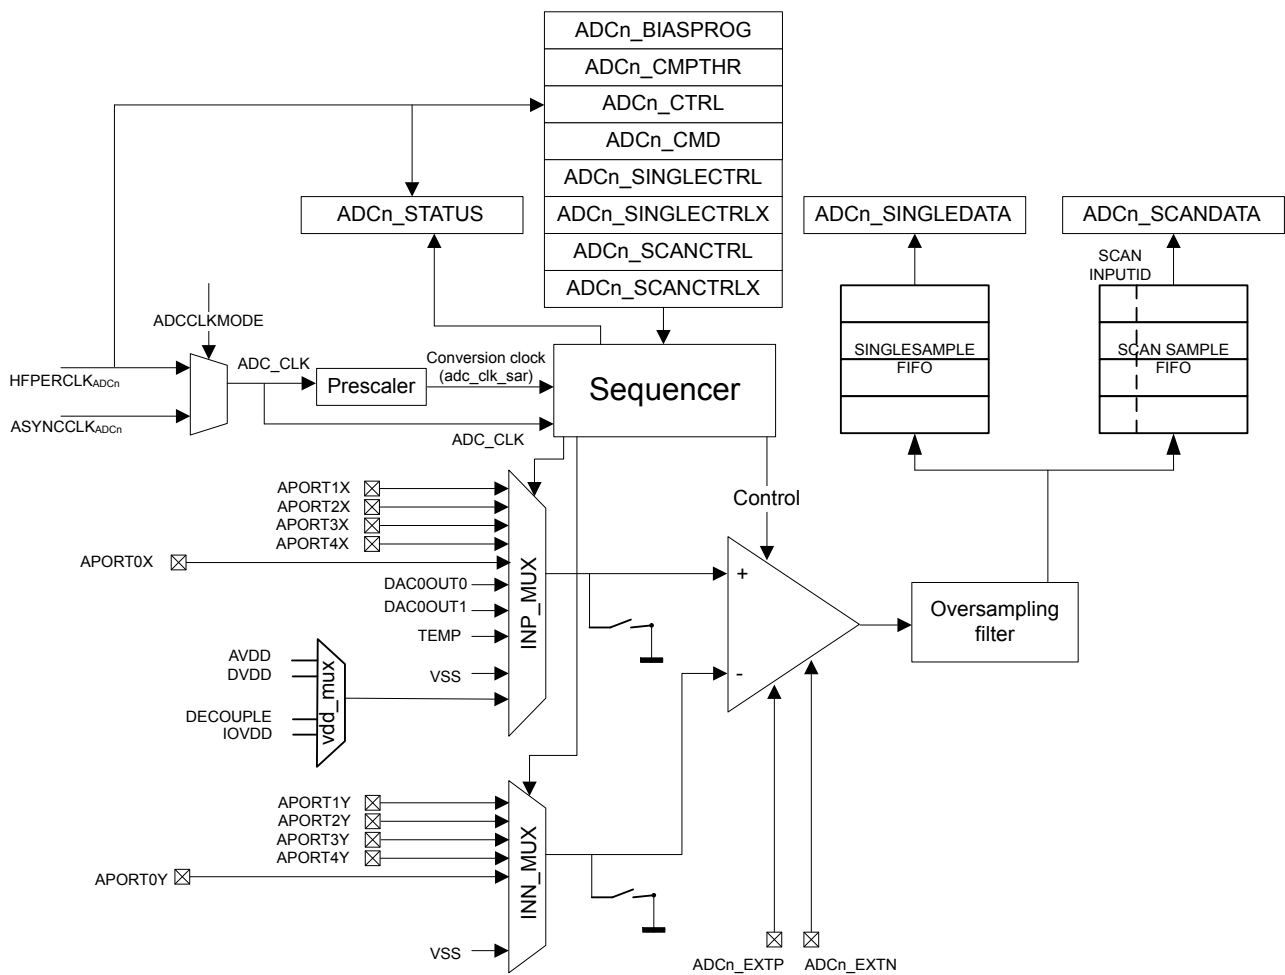

## 24.2 Features

- Programmable resolution (6/8/12-bit)
  - 13 conversion clock cycles for a 12-bit conversion
  - Maximum 1 Msps @ 12-bit
  - Maximum 1.6 Msps @ 6-bit
- Configurable acquisition time
- Externally controllable conversion start time using PRS in TIMED mode
- Integrated prescaler for conversion clock generation
  - Selectable clock division factor from 1 to 128
- Wide conversion clock range: 32 kHz to 16 MHz
- Can be run during EM2 and EM3, waking up the system upon various enabled interrupts
- Can be run during EM2 and EM3 with DMA enabled to pull data from the FIFOs without waking up the system
- Automated clock gating to save power when not converting
- Supports up to 144 external input channels and 11 internal inputs
  - Includes temperature sensor and random number generator function
- Left or right adjusted results
  - Results in 2's complement representation
  - Differential results sign extended to 32-bits results
- Programmable scan sequence
  - Up to 32 configurable samples in scan sequence
  - Mask to select which pins are included in the sequence
  - Triggered by software or PRS input
  - One shot or repetitive mode
  - Oversampling available
  - Four deep FIFO to store conversion data along with channel ID and option to overwrite old data when full
  - Programmable watermark (DVL) to generate SCAN interrupt
  - Supports overflow and underflow interrupt generation
  - Supports window compare function
  - Conversion tailgating support for predictable periodic scans
- Programmable single channel conversion
  - Triggered by software or PRS input
  - Can be interleaved between two scan sequences
  - One shot or repetitive mode
  - Oversampling available
  - Four deep FIFO to store conversion data with option to overwrite old data when full
  - programmable watermark (DVL) to generate SINGLE interrupt
  - Supports overflow and underflow interrupt generation
  - Supports window compare function
- Hardware oversampling support
  - 1st order accumulate and dump filter
  - From 2 to 4096 oversampling ratio (OSR)
  - Results in 16-bit representation
  - Enabled individually for scan sequence and single channel mode
  - Common OSR select
- Programmable and preset input full scale (peak-to-peak) range (VFS) with selectable reference sources
  - VFS=1.25 V using internal VBGR reference
  - VFS=2.5 V using internal VBGR reference
  - VFS=AVDD with AVDD as reference source
  - VFS=5 V with internal VBGR reference
  - Single ended external reference
  - Differential external reference
  - VFS=2xAVDD with AVDD as reference source
  - User-programmable dividers for flexible VFS options from internal, external or supply voltage reference sources

- Support for offset and gain calibration
- Interrupt generation and/or DMA request when
  - Programmable number of converted data available in the single FIFO (also generates DMA request)
  - Programmable number of converted data available in the scan FIFO (also generates DMA request)
  - Single FIFO overflow or underflow
  - Scan FIFO overflow or underflow
  - Latest Single conversion tripped compare logic
  - Latest Scan conversion tripped compare logic
  - Analog over-voltage interrupt
  - Programming Error interrupt due to APORT Bus Request conflict or NEGSEL programming error

### 24.3 Functional Description

An overview of the ADC is shown in [Figure 24.1 ADC Overview on page 755](#).

**Figure 24.1. ADC Overview**

### 24.3.1 Clock Selection

The ADC logic is partitioned into two clock domains: HUPERCLK and ADC\_CLK. The HUPERCLK domain contains the register interface logic, APORT request logic and portions of FIFO read logic. The HUPERCLK is the default clock for the ADC peripheral. The rest of the ADC is clocked by the ADC\_CLK domain. The ADC\_CLK is chosen by ADCCLKMODE bit in the ADCn\_CTRL register.

The ADC\_CLK is the main clock for the ADC engine. If the ADCCLKMODE is set to SYNC, the ADC\_CLK is equal to the HUPERCLK and the ADC operates in synchronous mode. If the ADCCLKMODE is set to ASYNC, the ADC\_CLK is ASYNCCLK and the ADC operates in asynchronous mode. This distinction is important to understand as there are additional system restrictions and benefits to running the ADC in asynchronous mode detailed in [24.3.13 ASYNC ADC\\_CLK Usage Restrictions and Benefits](#).

The ADC has an internal clock prescaler, controlled by PRESC bits in ADCn\_CTRL, which can divide the ADC\_CLK by any factor between 1 and 128 to generate the conversion clock (adc\_clk\_sar) for the ADC. This adc\_clk\_sar is also used to generate acquisition timing. Note that the maximum clock frequency for adc\_clk\_sar is 16 MHz. The ADC warmup time is determined by ADC\_CLK and not by adc\_clk\_sar.

ASYNCCLK is a clock source from the CMU which is considered asynchronous to HUPERCLK. The CMU\_ADCCTRL register can be programmed to request and use ASYNCCLK. It has multiple choices for its source, including AUXHFRCO, HFXO and HFSRCCLK, and can optionally be inverted. If the chosen source for ASYNCCLK is not active at the time of request, the CMU enables the source oscillator upon receiving the request, and shuts down the oscillator when the ADC stops requesting the clock. Consult the CMU chapter for details of how to program the clock sources for the ASYNCCLK and oscillator start-up time details.

Software may choose a clock request generation scheme by programming the ASYNCCLKEN and WARMMODE of the ADCn\_CTRL register. If the ASYNCCLKEN is set to ASNEEDED with WARMMODE set to NORMAL, the ADC requests ASYNCCLK only when a conversion trigger is activated. The ASYNCCLK request is withdrawn after the conversion is complete. All other options keep the ASYNCCLK request "ON" until software programs these fields otherwise or changes the ADCCLKMODE to SYNC.

For EM2 or EM3 operation of the ADC, the ADC\_CLK must be configured for AUXHFRCO as this is the only available option during EM2 or EM3. The ADC\_CLK source should not be changed as the system enters or exits various energy modes, otherwise measurement inaccuracies will result.

### 24.3.2 Conversions

A conversion consists of two phases: acquisition and approximation. The input is sampled in the acquisition phase before it is converted to digital representation during the approximation phase. The acquisition time can be configured independently for scan sequence and single channel conversions (see [24.3.3 ADC Modes](#)) by setting AT in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The acquisition times can be set to 1, 2, 3 or any integer power of 2 from 4 to 256 adc\_clk\_sar cycles.

#### Note:

For high impedance sources the acquisition time should be adjusted to allow enough time for the internal sample capacitor to fully charge. The minimum acquisition time for sampling at 1 Msps and typical input loading is 187.5 ns.

The ADC uses one adc\_clk\_sar cycle per output bit in the approximation phase plus 1 extra adc\_clk\_sar cycle.

$$T_{\text{conv}} = (T_{\text{acq}} + (N + 1) \times T_{\text{adc\_clk\_sar}}) \times \text{OVSSEL}$$

Where  $T_{\text{acq}}$  is the acquisition time set by the AT bit field, N is the resolution (in bits), and OVSSEL is the oversampling ratio according to the OVSSEL field in ADCn\_CTRL when oversampling is enabled (see [24.3.8.6 Oversampling](#)).

**Figure 24.2. ADC Total Conversion Time Per Output**

**Figure 24.3. ADC Conversion Timing**

### 24.3.3 ADC Modes

The ADC contains two programmable modes: single channel mode and scan mode. Both modes have separate configuration registers and a four-deep FIFO for conversion results. Both modes may be set up to run only once per trigger or to automatically repeat after each operation. The scan mode has priority over the single channel mode. However by default, if scan sequence is running, a triggered single channel conversion will be interleaved between two scan samples.

#### 24.3.3.1 Single Channel Mode

Single channel mode can be used to convert a single channel either once per trigger or repetitively. The configuration of single channel mode is done using the `ADCn_SINGLECTRL` and `ADCn_SINGLECTRLX` registers and the result FIFO can be read through the `ADCn_SINGLEDATA` register. The `DVL` field of the `ADCn_SINGLECTRLX` controls the FIFO watermark crossing which sets the `SINGLEDV` bit in `ADCn_STATUS` high and is cleared when the data is read and the number of unread data samples falls below the `DVL` threshold. The user can choose to throw out new samples or overwrite the old samples when the FIFO becomes full by programming the `FIFOFACT` field of the `ADCn_SINGLECTRLX` register. Single channel results can also be read through `ADCn_SINGLEDATAP` without popping the FIFO, returning its latest element. The `DIFF` field in `ADCn_SINGLECTRL` selects whether differential or single ended inputs are used and `POSSEL` and `NEGSEL` selects the input signal(s). The `CMPEN` bit in the `ADCn_SINGLECTRL` register enables the window compare function, and the latest converted data is compared against values programmed into the `ADGT` and `ADLT` fields of the `ADCn_CMPTHR` register and generates `SINGLECMP` interrupts if enabled. The window compare function allows for compare triggering both within (if `ADGT` less than `ADLT`) or out of (if `ADGT` greater than `ADLT`) window.

#### 24.3.3.2 Scan Mode

Scan mode is used to perform conversions across multiple channels, sweeping a set of selected inputs in a sequence. The configuration of scan mode is done in the `ADCn_SCANCTRL` and `ADCn_SCANCTRLX` registers. It has similar controls and data read mechanisms to single channel mode. There are two key differences between single channel mode and scan mode: the input sequence is programmed differently, and it has additional information in the result to indicate the channel on which the conversion was acquired. [24.3.5 Input Selection](#) explains how the input sequence is chosen. When the scan sequence is triggered, the ADC samples all inputs that are included in the mask (`ADCn_SCANMASK`), starting at the lowest pin number. `DIFF` in `ADCn_SCANCTRL` selects whether single ended or differential inputs are used. The FIFO data is tagged with `SCANINPUTID` and can be read along with the scan data using `ADCn_SCANDATAX` register. The `ADCn_SCANDATAXP` can be used to read the latest valid entry from the scan FIFO without popping it. There is also a `ADCn_SCANDATA` register that contains results without the `SCANINPUTID` appended.

### 24.3.4 Warm-up Time

After power-on, the ADC requires some time for internal bias currents and references to settle prior to starting a conversion. This time period is called the warm-up time. Warm-up timing is performed by hardware. Software must program the number of ADC\_CLK cycles required to count at least 1  $\mu$ s in the TIMEBASE field of the ADCn\_CTRL register. TIMEBASE only affects the timing of the warm-up sequence and is not dependent on adc\_clk\_sar. When enabling the ADC or changing references between samples, the ADC is automatically warmed up for 5  $\mu$ s (5 times the period indicated by TIMEBASE).

Normally, the ADC will be warmed up only when samples are requested and is shut off when there are no more samples waiting. However, if lower latency is needed, configuring the WARMUPMODE field in ADCn\_CTRL allows the ADC and/or reference to stay warm between samples, reducing the warm-up time or eliminating it altogether. [Figure 24.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 759](#) shows the effects on analog power consumption in scenarios using different WARMUPMODE settings.

Only the reference for scan-mode can be kept warm. Thus, if the single-mode reference setting is different than scan-mode, the single mode conversion will first warmup its reference for 5  $\mu$ s before a conversion begins. If the ADC is used only in single conversion mode, it is important to configure both the ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX and ADCn\_SCANCTRL, ADCn\_SCANCTRLX registers with the same reference to avoid this extra warm-up time.

Various warmup modes are described here:

- **NORMAL:** This is the lowest power option for general-purpose use and low sampling rates (below 35 ksp/s). The ADC and references are shut off when there are no samples waiting. The ADC does not consume any power when it is shut down. A 5  $\mu$ s warmup time will be initiated prior to every conversion. Figure a in [Figure 24.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 759](#) shows this mode.
- **KEEPINSTANDBY:** This mode is suitable for infrequent sampling of lower impedance inputs, and is the lowest power option for sampling rates between about 35 and 125 ksp/s. It may also be useful for lower sampling rates where latency is important. The reference selected for scan mode is kept warm, but the ADC is powered down. The ADC will initiate a 1  $\mu$ s warmup period before a conversion begins. Because the reference is kept warm, the ADC will consume a small amount of standby current when it is not converting. Figure b in [Figure 24.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 759](#) shows this mode.
- **KEEPINSLOWACC:** This mode is useful for high-impedance inputs which are sampled infrequently. It is similar to KEEPINSTANDBY, but continuously tracks the input, keeping the input multiplexer connected to the APORT bus. This mode consumes little more power than KEEPINSTANDBY mode (about 2  $\mu$ A extra) when a conversion is not in progress. This allows the user to avoid programming long acquisition time that would otherwise be necessary for high-impedance inputs when ADC wakes up to full power mode, thereby reducing the total current consumption per conversion.
- **KEEPADCWARM:** This mode provides the lowest latency and allows for maximum sampling rates. The ADC and reference circuitry remain powered on even when conversions are not in progress. Figure c in [Figure 24.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 759](#) shows this mode. This mode consumes the most power, but as soon as a trigger event occurs, the acquisition and conversion begin with no warm-up time.

When KEEPADCWARM is chosen, ADC is termed as being in continuous operation. When any other warmup mode is chosen, ADC is termed to be in duty-cycled operation.

When entering EM2 or EM3, if the ADC is not going to be used, it should be returned to an idle state and WARMUPMODE in ADCn\_CTRL written to 0. Refer to [24.3.15 ADC Programming Model](#) for more information on placing the ADC in an idle state. If the ADC is going to be used in these low energy modes, the user can use any of the WARMUPMODE settings, but should be mindful of the power consumption that comes along with the different mode settings. For EM2 or EM3 operation, the ADC clock source must be configured to use AUXHFRCO.

**Figure 24.4. ADC Analog Power Consumption With Different WARMUPMODE Settings**

**Note:**

When using any warm-up mode other than **NORMAL**, always switch back to the **NORMAL** mode before switching to another warm-up mode.

### 24.3.5 Input Selection

The ADC samples and converts the analog voltage differential at its positive and negative voltage inputs. The input multiplexers of the ADC can connect these inputs to one of several internal nodes (e.g., temperature sensor) or to external signals via analog ports (APORT0, APORT1, APORT2, APORT3 or APORT4).

The analog ports APORT1, APORT2, APORT3, and APORT4 connect to external pins via analog buses (BUSAX, BUSAY, BUSBX, etc.) which are shared among other analog peripherals on the device. APORT1 through APORT4 are each 32 channels wide with connections to two sub-buses: a 16-channel X bus and a 16-channel Y bus. In the ADC module, all X buses connect to the INP\_MUX and all Y buses connect to the INN\_MUX as shown in [Figure 24.5 APORT connection to the ADC on page 760](#). Connections to the X and Y sub-buses alternate channels on the APORT. On APORT1 and APORT3, even-numbered channels connect to the X bus, and odd-numbered channels connect to the Y bus. On APORT2 and APORT4, even-numbered channels connect to the X bus and odd-numbered channels connect to the Y bus.

Unlike APORT1 through APORT4, APORT0 is not a shared resource. It consists of a 16-channel X bus and a 16-channel Y bus, each with dedicated I/O pin connections. Note that APORT0 is not available on all device families.

**Figure 24.5. APORT connection to the ADC**

For differential measurements, one input must be chosen from an X bus and the other from a Y bus. Choosing both inputs from an X bus or both from a Y bus will generate a PROGERR interrupt (if enabled) of NEGSELCONF type. The PROGERR type can be checked in the ADCn\_STATUS register.

The mapping for external I/O connections to ADC0 inputs is shown in [Table 24.1 ADC0 Bus and Pin Mapping on page 761](#). Note that this table shows the mapping for an entire family of devices. Refer to the Pin Definition and the APORT Client Map in the device datasheet for specific details on which I/O are available for each family and package configuration.

**Table 24.1. ADC0 Bus and Pin Mapping**

ADC Port	APORT0		APORT1		APORT2		APORT3		APORT4

CH1										
CH0										

Multiple peripherals may request the same shared system bus (BUSAX, BUSAY, BUSBX, etc.). When this happens, a conflict status is generated and that bus is kept floating. If this happens with the ADC, the PROGERR field in ADCn\_STATUS is set to BUSCONF, and an interrupt may be generated (if enabled). When connecting dedicated I/Os through APORT0, all inputs are available to APORT0X and APORT0Y and no bus conflict is possible. Refer to [24.3.5.3 APORT Conflicts](#) for more information on identifying and resolving bus conflicts.

**Note:** The internal inputs can only be sampled in single channel, single-ended mode. NEGSEL should be fixed to VSS for these conversions.

#### 24.3.5.1 Configuring ADC Inputs in Single Channel Mode

In single channel mode, the ADCn\_SINGLECTRL register provides the POSSEL and NEGSEL selection for positive and negative channel selection of the ADC. The APORT Client Map provides external pin to internal bus channel mapping enumeration for a particular device. Software can also choose internal nodes for POSSEL.

For all single-ended conversions, VSS must be selected in NEGSEL.

Note that in both the POSSEL and NEGSEL fields, it is possible to choose inputs from both X and Y buses, even though X channels are physically connected to the positive mux (INP\_MUX) and Y channels are physically connected to the negative mux (INN\_MUX). For single-ended operation (DIFF = 0), if the positive input is chosen from a Y channel the ADC performs a negative single ended conversion and automatically inverts the result at the end, producing a positive result. For differential conversions (DIFF = 1), if a Y channel is chosen for the positive input and an X channel is chosen for the negative input, the ADC result will be inverted to produce the correct polarity.

Refer to [Table 24.1 ADC0 Bus and Pin Mapping on page 761](#) for specific pin connection options. Note that the same I/O pin may appear in multiple locations. Enumerations for the POSSEL and NEGSEL fields can be determined by finding the desired pin connection in the table and then combining the ADC Port, polarity and channel identifier. For example, pin PF7 is listed as CH23 on APORT2, polarity X. The enumeration would be APORT2XCH23. PF7 is also available on CH23 of APORT1, polarity Y, so APORT1YCH23 also selects PF7.

### 24.3.5.2 Configuring ADC Inputs in Scan Mode

In scan mode, the ADC can sample and convert up to 32 external channels on each conversion trigger. Internal channels are not available in scan mode. The ADC's scanner logic automatically changes the input mux settings between conversions, eliminating the need for firmware intervention.

The ADC scanner logic is controlled by a set of 32 logical channels called SCANINPUTIDs. The 32 SCANINPUTIDs are arranged in four groups of 8 channels each. Each channel group can point to a predefined series of 8 sequential channels on any of the available APORTs. The ADCn\_SCANINPUTSEL register is used to configure which group of physical APORT channels each of the SCANINPUTID channel groups map to. For example, selecting APORT1CH16TOCH23 in the INPUT7TO0SEL field selects APORT1CH16 for SCANINPUTID0, APORT1CH17 for SCANINPUTID1, APORT1CH18 for SCANINPUTID2, and so on.

The four SCANINPUTID groups are fully independent and may be selected from any APORT in any combination. It is possible also to repeat the same selection in multiple groups. For example, the user may select APORT2CH0TOCH7 for all four of the SCANINPUTID groups.

In many cases, the user application will not require all 32 channels of the scanner to be converted. Each of the scanner channels may be individually enabled according to the needs of the system. The ADCn\_SCANMASK register is used to enable and disable individual SCANINPUTIDs. The bits in the ADCn\_SCANMASK register correspond one-to-one with the SCANINPUTID channel numbers. During a scan operation, the ADC scanner logic will convert only the enabled SCANINPUTIDs, in order from lowest to highest.

In single-ended mode, all conversions performed by the ADC will be relative to VSS. For any enabled SCANINPUTID, the selected APORT channel will be connected to the ADC with the opposite ADC input terminal connected to VSS. Note that the channel groups selected in ADCn\_SCANINPUTSEL point to a block of 8 channels on an APORT, which includes both X and Y channels. Depending on the channels enabled by ADCn\_SCANMASK, the ADC may perform conversions on the X or the Y bus associated with that APORT.

Figure 24.6 ADC Single-ended Scan Mode Example on page 763 shows an example of a single-ended scan configuration. In this example, ADCn\_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn\_SCANMASK selects six of these channels for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of six single-ended ADC conversions: PF0, PF3, PA5, PA5, PF7, and PF4.

**Figure 24.6. ADC Single-ended Scan Mode Example**

In differential mode, the default operation of the ADC scanner is to perform a differential measurement between the selected APORT channel and the next channel on that APORT. For example, if the enabled SCANINPUTID points to APORT1CH6, the ADC will perform a differential conversion between APORT1CH6 and APORT1CH7.

There are two exceptions to this rule, listed in order of precedence:

1. When converting SCANINPUTID15, the differential conversion will be performed between the channel selected by SCANINPUTID15 and the channel selected by SCANINPUTID8.
2. When APORTnCH31 is the selected input, the differential conversion will be performed between APORTnCH31 and APORTnCH0.

Figure 24.7 ADC Differential Scan Mode Example on page 764 shows an example of a differential scan configuration. In this example, ADCn\_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn\_SCANMASK selects three channels pairs for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of three differential ADC conversions: PF0-PF1, PF2-PF3, and PA4-PA5.

**Figure 24.7. ADC Differential Scan Mode Example**

In certain applications it may be desirable to perform differential conversions on several channels against a common voltage. The ADCn\_SCANNEGSEL register allows eight of the SCANINPUTIDs to re-map the negative terminal of a differential conversion to a common channel. In the first ADCn\_SCANINPUTSEL group, the negative input for SCANINPUT 0, 2, 4, and 6 may be re-mapped to any of the odd-numbered channels in that group (SCANINPUT 1, 3, 5, or 7). Likewise, in the second ADCn\_SCANINPUTSEL group, the negative input for SCANINPUT 9, 11, 13, and 15 may be re-mapped to any of the even-numbered channels in that group (SCANINPUT 8, 10, 12, or 14).

Figure 24.8 ADC Differential Scan Mode Re-mapping Negative Input Selections on page 764 shows the effects of the ADCn\_SCANNEGSEL register on the re-mappable inputs. The left side of the figure shows the default channel mapping, and the right side of the figure shows how ADCn\_SCANNEGSEL can be programmed to map the same negative input on up to four channels.

### 24.3.5.3 APORT Conflicts

The ADC shares common analog buses connected to its APORTs (1-4) with other analog peripherals (see [Table 24.1 ADC0 Bus and Pin Mapping on page 761](#)). As the ADC performs single or scan conversions, it requests the shared buses and sends selections for the control switches to connect the desired I/O pins. If another analog peripheral requests the same shared bus at the same time, there will be a collision and none of the peripherals will be granted control of that bus.

To help debug over-utilization of APORT resources, the ADC hardware provides status information in local registers. The ADCn\_APOR-TREQ register gives the user visibility into which APORT(s) the ADC is requesting given the setting of the input selection registers. ADCn\_APORTCONFLICT reports any conflicts that occur. If PROGERR in ADCn\_IEN is set, any conflict generates an interrupt. The PROGERR field in the ADCn\_STATUS register indicates whether the programming error happened as a result of an APORT bus conflict (BUSCONF) or from a negative-input selection conflict (NEGSELCONF). If the PROGERR interrupt occurred due to a negative selection conflict, then the interrupt can be cleared by software only after correcting the conflict. If a software clear is attempted without correcting the configuration, the interrupt will be cleared for one clock cycle but then it will trigger again as the invalid configuration still persists.

**Note:** The ADC requests shared bus connections as soon as that bus is selected in the input select registers, even if the ADC is not performing any conversions. This means that by using the APORT request, the ADC will acquire the associated shared analog bus, preventing other peripherals from using it. The bus will be released only when the input select registers are changed.

It is possible for the ADC to passively monitor shared bus signals without controlling the switches and creating bus conflicts. This can be done by setting the ADCn\_APORTMASTERDIS register. When ADCn\_APORTMASTERDIS is used, channel selection defers to the peripheral acting as the bus master for that shared bus, and no bus conflict will occur. The ADC will connect its input to the shared bus, but the specific channel will be controlled by the peripheral designated as the bus master.

### 24.3.6 Reference Selection and Input Range Definition

The full scale voltage (VFS) of the ADC is defined as the full input range, from the lowest possible input voltage to the highest. For single-ended conversions, the input range on the selected positive input is from 0 to VFS. For differential conversions, the input to the converter is the difference between the positive and negative input selections. This can range from -VFS/2 to +VFS/2.

VFS for the converter is determined by a combination of the selected voltage reference (VREF) and programmable divider circuits on the ADC input and voltage reference paths. Users have full control over the VREF and divider selections, offering a very flexible and wide selection of VFS values. In most applications however, it is not necessary to adjust VFS beyond a set of common pre-defined choices. For the simplest VFS configuration, refer to [24.3.6.1 Basic Full-Scale Voltage Configuration](#). If the application requires a VFS configuration not available in the pre-defined choices, [24.3.6.2 Advanced Full-Scale Voltage Configuration](#) covers additional configuration options.

#### 24.3.6.1 Basic Full-Scale Voltage Configuration

Basic configuration of the VFS (full scale voltage) for the converter is done by programming the REF bitfield in ADCn\_SINGLECTRL (for single channel mode) or ADCn\_SCANCTRL (for scan mode) to any of the pre-defined options. The list of available pre-defined VFS options is:

- VFS = 1.25 V using internal VBGR as the reference source
- VFS = 2.5 V using internal VBGR as the reference source
- VFS = AVDD using AVDD as the reference source ( $AVDD \leq 3.6$  V)
- VFS = 5 V using internal VBGR as the reference source
- VFS = ADCn\_EXTP external pin as a single-ended reference source (1.2 V - 3.6 V)
- VFS = ADCn\_EXTP - ADCn\_EXTN external pins as a differential reference source. (1.2 V - 3.6 V difference)
- VFS = 2 x AVDD using AVDD as the reference source ( $AVDD \leq 3.6$  V)

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the supply voltages. If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in ADCn\_BIASPROG should be cleared to 0. This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software should set GPBIASACC in ADCn\_BIASPROG to 1 to conserve energy.

If the pre-defined VFS options do not suit the particular application, refer to [24.3.6.2 Advanced Full-Scale Voltage Configuration](#) for more advanced VFS options.

### 24.3.6.2 Advanced Full-Scale Voltage Configuration

For most applications, the pre-defined VFS options described in [24.3.6.1 Basic Full-Scale Voltage Configuration](#) are suitable. Advanced VFS configurations are also possible by programming the REF bitfield in ADCn\_SINGLECTRL or ADCn\_SCANCTRL to the CONF option. Programming the REF bitfield to CONF allows the user to select the specific VREF source and adjust the programmable input and reference divider options directly.

The general procedure for programming an advanced VFS configuration is as follows:

1. Select the voltage reference source using VREFSEL.
2. Configure VREFATTFIX and VREFATT so that the reference voltage at the ADC is between 0.7 and 1.05 V.
3. Configure VINATT to achieve the desired full-scale voltage.

The VREFSEL field in ADCn\_SINGLECTRLX or ADCn\_SCANCTRLX selects the voltage reference source. The ADC can choose from the following voltage reference (VREF) sources:

- VBGR: An internal 0.83 V bandgap reference voltage. This is the most precise internal reference source available.
- VDDXWATT: An attenuated version of the AVDD supply voltage. The attenuation factor is determined by the VREFATTFIX and/or VREFATT bit fields.
- VREFPWATT: An external reference source applied to the ADCn\_EXTP pin, and attenuated by the attenuation factor (determined by the VREFATTFIX and/or VREFATT bit fields). This is the appropriate choice for external reference inputs greater than 1.05 V.
- VREFP: An external reference source applied to the ADCn\_EXTP pin, without any attenuation. This is the appropriate choice for external reference inputs between 0.7 V and 1.05 V.
- VENTROPY: A very low internal reference voltage (approx. 0.1 V). This option is intended to be used only with the ADC inputs tied internally to VSS, for generating random noise at the ADC output.
- VREFPNWATT: A differential version of VREFPWATT, with the reference source applied to the ADCn\_EXTP and ADCn\_EXTN pins and attenuated. This is the appropriate choice where a differential reference of greater than 1.05 V is required.
- VREFPN: A differential version of VREFP, with the reference source applied to the ADCn\_EXTP and ADCn\_EXTN pins and no attenuation. This is the appropriate choice where a differential reference of between 0.7 V and 1.05 V is required.
- VBGRLOW: An internal 0.78 V bandgap reference voltage.

The ADC reference voltage should be attenuated to a lower voltage when using AVDD or the external reference source. A simple method for a wide range of reference sources is to set VREFATTFIX to 1. The VREF attenuation factor ( $ATT_{VREF}$ ) can then be selected between 1/3 (when VREFATT is greater than 0), and 1/4 (when VREFATT is equal to 0). For reference sources between 1.2 V and 3.6 V,  $ATT_{VREF} = 1/3$  is the best choice.  $ATT_{VREF} = 1/4$  can be used with references from 1.6 V to 3.8 V, with slight performance degradation.

Finer granularity on  $ATT_{VREF}$  is possible as well, by clearing VREFATTFIX to 0, and setting the VREFATT field. For optimal performance with VREFATTFIX = 0, the attenuated ADC reference input should be limited to between 0.7 V and 1.05 V. When VREFATTFIX is cleared to 0,  $ATT_{VREF}$  is set according to the equation:

$$ATT_{VREF} = (VREFATT + 6) / 24 \text{ for } VREFATT < 13, \text{ and } (VREFATT - 3) / 12 \text{ for } VREFATT \geq 13$$

**Figure 24.9.  $ATT_{VREF}$ : VREF Attenuation Factor**

The ADC input also includes a programmable attenuator. The VIN attenuator is used to widen the available input range of the ADC beyond the reference source. The VIN attenuation factor ( $ATT_{VIN}$ ) is determined by the VINATT field according to the equation:

$$ATT_{VIN} = VINATT / 12 \text{ for } VINATT \geq 3 \text{ (settings 0, 1, and 2 are not allowable values for VINATT)}$$

**Figure 24.10.  $ATT_{VIN}$ : VIN Attenuation Factor**

VFS can be calculated by the formula given below for any given VREF source, VREF attenuation, and VIN attenuation:

$$VFS = 2 \times VREF \times ATT_{VREF} / ATT_{VIN}$$

VREF is selected in the VREFSEL bitfield, and

$ATT_{VREF}$  is the VREF attenuation factor, determined by VREFATT or VREFATTFIX

$ATT_{VIN}$  is the VIN attenuation factor, determined by VINATT

**Figure 24.11. VFS: Full-Scale Input Range**

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the supply voltages. If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in ADCn\_BIASPROG should be cleared to 0. This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software should set GPBIASACC in ADCn\_BIASPROG to 1 to conserve energy.

The combination of VREF, ATT<sub>VREF</sub> and ATT<sub>VIN</sub> can produce a wide range of full-scale voltage options for the converter. [Table 24.2 Advanced VFS Configuration: VREF = AVDD on page 767](#) shows some example VFS configurations using AVDD as a reference source.

**Table 24.2. Advanced VFS Configuration: VREF = AVDD**

AVDD Voltage	VREF Attenuation Settings	Reference Voltage at ADC	VIN Attenuation Settings	VFS
1.85 V	VREFATTFIX = 0 VREFATT = 6 <b>ATT<sub>VREF</sub> = 1/2</b>	0.925 V	VINATT = 12 <b>ATT<sub>VIN</sub> = 1</b>	1.85 V (+/-0.925 V differential)
3.0 V	VREFATTFIX = 0 VREFATT = 2 <b>ATT<sub>VREF</sub> = 1/3</b>	1.0 V	VINATT = 8 <b>ATT<sub>VIN</sub> = 2/3</b>	3.0 V (+/-1.5 V differential)
3.0 V	VREFATTFIX = 0 VREFATT = 2 <b>ATT<sub>VREF</sub> = 1/3</b>	1.0 V	VINATT = 4 <b>ATT<sub>VIN</sub> = 1/3</b>	6.0 V (+/-3.0 V differential)
3.6 V	VREFATTFIX = 1 VREFATT = 0 <b>ATT<sub>VREF</sub> = 1/4</b>	0.9 V	VINATT = 6 <b>ATT<sub>VIN</sub> = 1/2</b>	3.6 V (+/-1.8 V differential)

### 24.3.7 Programming of Bias Current

The ADC uses a chip-level bias generator to provide bias current for its operation. The ADC's internal bias can be scaled by ADCBIASPROG field of the ADCn\_BIASPROG register. At lower conversion speeds, the ADCBIASPROG can be used to lower active power. Some commonly used settings are given in the ADCBIASPROG register description. For proper operation, the ADC conversion speed must be scaled accordingly. The scale factor is calculated as:

$$\text{Bias scale factor} = (1 - \text{ADCBIASPROG}[2:0]/8) / (1 + 3 \times \text{ADCBIASPROG}[3])$$

**Figure 24.12. Bias scale factor**

The bias programming register also includes the VFAULTCLR bit field. If VREFOF interrupt is enabled and it is triggered, then the user needs to set this bit in the ISR before clearing the interrupt flag. This bit then needs to be reset after the interrupt flag is cleared in order to enable the VREFOV flag to trigger on the next VREFOV condition.

The bias current settings should only be changed while the ADC is disabled (i.e. in NORMAL warm-up mode and no conversion in progress).

### 24.3.8 Feature Set

The following sections explain different ADC features.

### 24.3.8.1 Conversion Tailgating

Scan conversions have priority over single channel conversions. This means that if scan and single triggers are received simultaneously, or even if the scan is received later when ADC is being warmed up for performing a single conversion, the scan conversion will have priority and will be done before the single conversion. However, a scan trigger will not interrupt in the middle of a single conversion, i.e., if the single conversion is in the acquisition or approximation phase, then the scan will have to wait for the single conversion to complete. If a scan sequence is triggered by a timer on a periodic basis, single channel conversion that started just before a scan trigger can delay the start of the scan sequence, thus causing jitter in sample rate. To solve this, conversion tailgating can be chosen by setting TAILGATE in ADCn\_CTRL. When this bit is set, any triggered single channels will wait for the next scan sequence to finish before activating (see [Figure 24.13 ADC Conversion Tailgating on page 768](#)). The single channel will then follow immediately after the scan sequence. In this way, the scan sequence will always start immediately when triggered, provided that the period between the scan triggers is big enough to allow the single sample conversion that was triggered to finish before the next scan trigger arrives. Note that if tailgating is set and a single channel conversion is triggered, it will indefinitely wait for a scan conversion before starting the single channel conversion.

Figure 24.13. ADC Conversion Tailgating

### 24.3.8.2 Repetitive Mode

Both single channel and scan mode can be run as a one shot conversion or in repetitive mode. The REP bitfield in ADCn\_SINGLECTRL/ADCn\_SCANCTRL registers can be used to activate the repetitive mode for single and scan respectively. In order to achieve the maximum sampling rate of 1 Msps, repetitive mode should be used.

### 24.3.8.3 Conversion Trigger

The conversion modes can be activated by writing a 1 to the SINGLESTART or SCANSTART bit in the ADCn\_CMD register. The conversions can be stopped by writing a 1 to the SINGLESTOP or SCANSTOP bit in the ADCn\_CMD register. A START command will have priority over a STOP command. When the ADC is stopped in the middle of a conversion, the result buffer is cleared (the FIFO contents for any prior conversions are still intact). Every time a STOP command is issued, the user should wait for the corresponding status flag (SINGLEACT/SCANACT) to go low and then either read all the data in the FIFO or send the corresponding FIFOCLEAR command. The SINGLEACT and SCANACT bits in ADCn\_STATUS are set high when the modes are actively converting or have pending conversions.

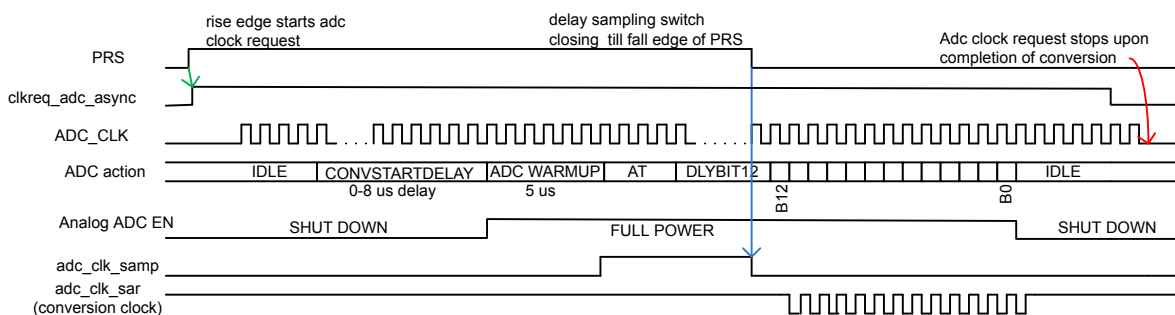

It is also possible to trigger conversions from PRS signals. The PRS is treated as an asynchronous trigger. Setting PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL enables triggering from PRS input. Which PRS channel to listen to is defined by PRSSEL in ADCn\_SINGLECTRLX/ADCn\_SCANCTRLX. When PRS trigger is selected, it is still possible to trigger a conversion from software. Please refer to the PRS chapter for more information on how to set up the PRS channels. When the conversions are triggered using the ADCn\_CMD register, then the SINGLEACT and SCANACT bits in the ADCn\_STATUS are set as soon as the START command is written to the register. When the conversion is triggered using PRS, it takes some cycles from the time PRS trigger is received until the SINGLEACT and SCANACT bits are set due to the synchronization requirement. If SINGLEACT is already high then sending a new START command or a new PRS trigger for a single conversion will not have any impact as ADC already has a single conversion ongoing or a single conversion pending (single conversion can be pending if ADC is busy running a scan sequence). The same rules apply for SCANACT and SCAN START and PRS triggers. When software issues a SINGLE/SCAN STOP command, it must wait until SINGLEACT/SCANACT flag goes low before issuing a new START.

The PRS may trigger the ADC in two possible ways, configured by PRSMODE in ADCn\_SINGLECTRLX/ADCn\_SCANCTRLX. In PULSED mode, a PRS pulse triggers the ADC to start the ADC\_CLK (if not already enabled), warm up (if not already warm), start the acquisition period, and perform the conversion. This is identical to issuing a START command from software. In this mode, the input sampling finishes at the end of the acquisition period (AT).

If the ADC\_CLK and the source of the trigger (START command or PRS pulse) are not synchronous, the frequency of the input sampling (FS), will experience a  $1\frac{1}{2}$  to  $2\frac{1}{2}$  ADC\_CLK cycle jitter due to synchronization requirements.

To precisely control the sample frequency, the PRSMODE can be set to TIMED mode. In this mode, a long PRS pulse is expected to trigger the ADC and its negative edge directly finishes input sampling and starts the approximation phase, giving precise sampling frequency management. The restriction is that the PRS pulse has to be long enough to start the ADC\_CLK (if not already enabled), and finish the acquisition period based on the AT field in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The PRS pulse needs to be high when AT event finishes. If it is not high when AT finishes, then it is ignored and input sampling finishes after AT event has ended (a two cycle latency is added to the conversion in this scenario).

If the PRS pulse is too long (e.g., FS = 32kHz), the analog ADC start can be delayed to save power. The CONVSTARTDELAY along with its EN in the ADCn\_SINGLECTRLX or ADCn\_SCANCTRLX can be programmed to implement a 0 to 8 microseconds delay. The microsecond tick is counted by TIMEBASE with ADC\_CLK similar to warmup case. This saves power as the ADC is not enabled until the last possible microsecond before the fall edge of the PRS arrives to open the sampling switch and to start the approximation phase. [Figure 24.14 ADC PRS Timed mode with ASNEEDED ADC\\_CLK request on page 769](#) shows PRS Timed mode triggering with CONVSTARTDELAY and ASNEEDED ADC\_CLK request. See that power is saved by both delaying the ADC EN and by requesting the ADC\_CLK only during ADC operation. This is especially useful in saving power when running the ADC in EM2 or EM3 power mode with low sampling frequency.

**Figure 24.14. ADC PRS Timed mode with ASNEEDED ADC\_CLK request**

When a PRS pulse is received, if the ADC\_CLK is not running (ASNEEDED mode), then the ADC requests the clock by setting clkreq\_adc\_async high. If the chosen clock source (HF XO/ HFSRCCLK/ AUXHFRCO) is already running, then it takes 5 ADC\_CLK cycles after the clock request is asserted for the ADC\_CLK to start. HF XO and HFSRCCLK (if chosen as ADC clock source) need to be

already running before ADC sends out the clock request. If AUXHFRCO is chosen as the ADC clock source, and it is not already running, then the CMU automatically turns it on when the ADC sends a clock request. In such a case, it takes (7 ADC\_CLK cycles + the oscillator startup time) for the ADC\_CLK to start. The oscillator startup time can be found in the device datasheet.

When triggering repeat mode using PRS and then stopping the triggered mode using STOP command, ensure that the PRS pulse used to generate the repeat mode has gone low by the time the STOP command is issued. If the PRS pulse continues to stay high after ADC has stopped the ongoing conversion, then it will be picked as a new trigger to start a new conversion.

**Note:**

The conversion settings should not be changed while the ADC is running. Doing so may lead to unpredictable behavior.

The adc\_clk\_sar phase is always reset by a conversion trigger as long as a conversion is not in progress. This gives predictable latency from the time of the trigger to the time the conversion starts, regardless of when in the trigger occurs.

Software should not trigger conversions if PRS Timed mode is selected and PRSEN is set to 1 in the ADCn\_SINGLECTRL/ADCn\_SCANCTRL register.

If the PRS Timed mode is being used, the acquisition time (AT) must be set greater than 0.

#### 24.3.8.4 Output Results

ADC output results are presented in 2's complement form and the format for single ended and differential conversions are given in [Table 24.3 ADC Single Ended Conversion on page 770](#) and [Table 24.4 ADC Differential Conversion on page 770](#), respectively. If differential mode is selected, the results are sign extended up to 32-bits (shown in [Table 24.6 ADC Results Representation on page 772](#)).

**Table 24.3. ADC Single Ended Conversion**

Input Voltage	Output Results	
	Binary	Hex value
$4095/4096 \times VFS$	1111111111	FFF
$0.5 \times VFS$	100000000000	800
$1/4096 \times VFS$	000000000001	001
0	000000000000	000

**Table 24.4. ADC Differential Conversion**

Input	Output Results	
	Binary	Hex value
$2047/4096 \times VFS$	0111111111	7FF
$0.25 \times VFS$	010000000000	400
$1/4096 \times VFS$	000000000001	001
0	000000000000	000
$-1/4096 \times VFS$	1111111111	FFF
$-0.25 \times VFS$	110000000000	C00
$-0.5 \times VFS$	100000000000	800

### 24.3.8.5 Resolution

The ADC performs 12-bit conversions by default. However, if full 12-bit resolution is not needed, it is possible to speed up the conversion by selecting a lower resolution (6 or 8 bits). For more information on the accuracy of the ADC, the reader is referred to the electrical characteristics section for the device.

### 24.3.8.6 Oversampling

To achieve higher accuracy, hardware oversampling can be enabled individually for each mode (Set RES in ADCn\_SINGLECTRL/ADCn\_SCANCTRL to 0x3). The oversampling rate (OVSSEL in ADCn\_CTRL) can be set to any integer power of 2 from 2 to 4096 and the configuration is shared between the scan and single channel mode (OVSSEL field in ADCn\_CTRL).

With oversampling, each input is sampled at 12-bits of resolution a number of times (given by OVSSEL), and the results are filtered by a first order accumulate and dump filter to form the end result. The data presented in the ADCn\_SINGLEDATA and ADCn\_SCANDATA registers are the direct contents of the accumulation register (sum of samples). However, if the oversampling ratio is set higher than 16x, the accumulated results are shifted to fit the MSB in bit 15 as shown in [Table 24.5 Oversampling Result Shifting and Resolution on page 771](#).

**Table 24.5. Oversampling Result Shifting and Resolution**

Oversampling setting	# right shifts	Result Resolution # bits
2x	0	13
4x	0	14
8x	0	15
16x	0	16
32x	1	16
64x	2	16
128x	3	16
256x	4	16
512x	5	16
1024x	6	16
2048x	7	16
4096x	8	16

### 24.3.8.7 Adjustment

By default, all results are right adjusted, with the LSB of the result in bit position 0 (zero). In differential mode the signed bit is extended up to bit 31, but in single ended mode the bits above the result are read as 0. By setting ADJ in ADCn\_SINGLECTRL/ADCn\_SCANCTRL, the results are left adjusted as shown in [Table 24.6 ADC Results Representation on page 772](#). When left adjusted, the MSB is always placed on bit 15 and sign extended to bit 31. All bits below the conversion result are read as 0 (zero).

**Table 24.6. ADC Results Representation**

Adjustment	Resolution	Bits																
		31 ... 16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Right	12	11 ... 11	11	11	11	11	11	10	9	8	7	6	5	4	3	2	1	0
	8	7 ... 7	7	7	7	7	7	7	7	7	7	6	5	4	3	2	1	0
	6	5 ... 5	5	5	5	5	5	5	5	5	5	5	5	4	3	2	1	0
	OVS	15 ... 15	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Left	12	11 ... 11	11	10	9	8	7	6	5	4	3	2	1	0	-	-	-	-
	8	7 ... 7	7	6	5	4	3	2	1	0	-	-	-	-	-	-	-	-
	6	5 ... 5	5	4	3	2	1	0	-	-	-	-	-	-	-	-	-	-
	OVS	15 ... 15	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 24.3.8.8 Channel Connection

The inputs are connected to the analog ADC at the beginning of the acquisition phase and are disconnected at the end of the acquisition phase. The time when the APORT switches are closed (for the next input to be converted) can be controlled by the CHCONMODE bitfield in the ADCn\_CTRL register. By default, this field is set to the MAXSETTLE option. For MAXSETTLE, APORT switches are closed on the next input as soon as the acquisition phase for the current conversion is complete. This means that the APORT switches are closed approximately 12 adc\_clk\_sar cycles (assuming 12 bit resolution) before the acquisition phase of the current conversion starts, giving APORT switches maximum time to settle. The time for which APORT switches should be closed before the acquisition phase starts, should be the same for all inputs in order to get consistent results. This means that if the ADC is warmed up with CHCONREFWARMIDLE set to 0 (scan reference warmed up and the APORT switches for the first scan channel closed) and a single trigger comes in, the single conversion will have to wait 12 adc\_clk\_sar cycles before it can start (even if single is using the same reference as scan). In this case, it might be more suitable to switch to the MAXRESP option in the CHCONMODE bitfield. In MAXRESP, the APORT switches for the upcoming conversion are closed just before the acquisition phase starts. This gives less settling time to the APORT switches but removes the extra waiting time before a conversion can start (which could be the case with MAXSETTLE as discussed above).

### 24.3.8.9 Temperature Measurement

The ADC includes an internal temperature sensor. This sensor is measured during production test and the temperature readout from the ADC at production temperature, ADC0CAL3\_TEMPREAD1V25, is given in the Device Information (DI) page. The production temperature, CAL\_TEMP, is also given in this page. The temperature sensor slope, V\_TS\_SLOPE (mV/degree Celsius), for the sensor is found in the data sheet for the device. Using the 1.25V VFS option and 12-bit resolution, the temperature can be calculated according to the following formula (VFS in the formula is 1250 mV) :

$$T_{\text{CELSIUS}} = \text{CAL\_TEMP} - (\text{ADC0CAL3\_TEMPREAD1V25} - \text{ADC\_result}) \times \text{VFS} / (4096 \times \text{V\_TS\_SLOPE})$$

**Figure 24.15. ADC Temperature Measurement**

When reading the temperature sensor, the GPBIASACC bit in ADCn\_BIASPROG should be set to 1 to keep the bias in LOWACC mode.

**Note:** The minimum acquisition time for the temperature reference is found in the electrical characteristics for the device. If using the 1.25V reference, extra acquisition time is required. In this case the AT field of ADCn\_SINGLECTRL or ADCn\_SCANCTRL should be set to a value of 9 or higher.

### 24.3.8.10 ADC as a Random Number Generator

The ADC can be used as a random number generator. This is done by:

1. Choose the REF in the ADCn\_SINGLECTRL as CONF, setting the VREFSEL in the ADCn\_SINGLECTRLX as VENTROPY and VINATT in the same register to its maximum value of 15.
2. Set DIFF to 1 and RES to 0 in the ADCn\_SINGLECTRL register.
3. Trigger a single channel conversion and then read ADCn\_SINGLEDATA register when the conversion finishes.

The LSB[2:0] of each sample will be a random number. In this mode, the POSSEL or NEGSEL in ADCn\_SINGLECTRL can be connected to VSS or any other noisy input.

### 24.3.9 Interrupts, PRS Output

The single and scan modes have separate SINGLE and SCAN interrupt flags indicating whether corresponding FIFO contains DVL # of valid conversion data. Corresponding interrupt enable bit has to be set in ADCn\_IEN in order to generate interrupts. For these interrupts, there is no software clear mechanism by writing to ADCn\_IFC. The user needs to read enough data from the interrupted FIFO to ensure it contains less than DVL # of elements. The ADCn\_SINGLEFIFOCOUNT/ADCn\_SCANFIFOCOUNT can provide number of valid elements remaining in corresponding FIFO. The FIFO can also be cleared by ADCn\_SINGLEFIFOCLEAR/ADCn\_SCANFIFOCLEAR, but any existing data will be lost by this operation.

In addition to the SINGLE and SCAN interrupt flags, there is separate scan and single channel result overflow interrupt flag which signals that a result from a scan or single channel FIFO has been overwritten before being read. There is also separate scan and single channel result underflow interrupt flag which signals that a FIFO read was issued when the FIFO was empty.

There is separate scan and single compare interrupt flag which signals a compare match with latest sample if the CMPEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL is enabled.

ADC has two separate PRS outputs, one for single channel and one for scan sequence. A finished conversion results in a one ADC\_CLK cycle pulse, which is output to the Peripheral Reflex System (PRS). Note that the PRS pulse for scan is generated once after every channel conversion in the scan sequence.

### 24.3.10 DMA Request

The ADC has two DMA request lines, SINGLEREQ and SCANREQ, which are set when a single or scan FIFO receives DVL# of samples. The requests are cleared when the corresponding single or scan result register is read and corresponding FIFO count reaches lower than DVL. It also has two additional DMA Single request lines, SINGLESREQ and SCANSREQ, that are set when the corresponding FIFO is not empty.

### 24.3.11 Calibration

The ADC supports offset and gain calibration to correct errors due to process and temperature variations. This must be done individually for each reference used. For each reference, it needs to be repeated for single-ended, negative single-ended (see [24.3.5 Input Selection](#) for details) and differential measurement. The ADC calibration (ADCn\_CAL) register contains register fields for calibrating offset and gain for both single and scan mode. The gain and offset calibration are done in single channel mode, but the resulting calibration values can be used for both single and scan mode.

Gain and offset for various references and modes are calibrated during production and the calibration values for these can be found in the Device Information page. During reset, the gain and offset calibration registers are loaded with the production calibration values for the 1V25 reference. Others can be loaded as needed or the user can perform calibration on the fly using the particular reference and mode to be used and write the result in the ADCn\_CAL before starting the ADC conversion with them.

### 24.3.11.1 Offset Calibration

Offset calibration must be performed prior to gain calibration. Follow these steps for the offset calibration in single mode:

1. Select the desired full scale configuration by setting the REF bit field of the ADCn\_SINGLECTRL register.
2. Set the AT bit field of the ADCn\_SINGLECTRL register to 16CYCLES.
3. Set the POSSEL and NEGSEL of the ADCn\_SINGLECTRL register to VSS, and set the DIFF to 1 for enabling differential input if calibrating for DIFF measurement. During calibration, the ADC samples represent the code coming out of the analog. Thus, since the input voltage is 0, the expected ADC output is 0b100000000000 in differential mode, 0b000000000000 in single-ended mode and 0b111111111111 in negative single-ended mode.
4. A binary search is used to find the offset calibration value. Set the CALEN to 1, and OFFSETINVMODE to 1 (if calibrating for negative single-ended conversion) in the ADCn\_CAL register. If user is performing negative single-ended calibration, the SINGLEOFFSETINV provides the offset else SINGLEOFFSET bit provides the offset (for both single-ended and differential offset calibration). Start with 0b0000 (or 0b1111 if doing calibration for differential mode) in SINGLEOFFSET or with 0b1000 in SINGLEOFFSETINV (if calibrating for negative single-ended conversion). Set the SINGLESTART bit in the ADCn\_CMD register to perform a 12-bit conversion and read the ADCn\_SINGLEDATA register. The offset is (ADCn\_SINGLEDATA - expected ADC output). Calculate this and write [3:0] of the result into SINGLEOFFSET or SCANOFFSETINV (if doing negative single-ended conversion). The user repeats till ADCn\_SINGLEDATA matches expected ADC output. The ADC has a 8LSB built in negative offset to allow for negative offset correction. So, with default offset value, which corrects for the negative offset, the converted ADCn\_SINGLEDATA would match expected ADC output if there were no offset. To get better noise immunity, the sampling phase can be repeated with Oversampling enabled. The result of the binary search is written to the SINGLEOFFSET (or SINGLEOFFSETINV) field of the ADCn\_CAL register.

### 24.3.11.2 Gain Calibration

Offset calibration must be performed prior to gain calibration. The Gain Calibration is done in the following manner:

1. Select an external ADC channel for single channel conversion (a differential channel can also be used).
2. Apply an external voltage on the selected ADC input channel. This voltage should correspond to the top of the ADC input range for the selected reference.
3. Set SINGLEGAIN[6:0] to 64 in the ADCn\_CAL and measure gain, repeat gain calibration walking the 1 in SINGLEGAIN[6] to SINGLEGAIN[0] till sampled ADCn\_SINGLEDATA matches expected value. This is done by setting CALEN in ADCn\_CAL set to 1 and performing single channel, reading in the raw ADC code from the ADCn\_SINGLEDATA and comparing it with expected code, i.e. 0b111111111111 for single-ended or differential conversion, and 0b000000000000 for negative single-ended conversion. The target value is ideally the top of the ADC input range, but it is recommended to use a value a couple of LSBs below in order to avoid overshooting. The result of the binary search is written to the SINGLEGAIN field of the ADCn\_CAL register.

For the VDD reference and external reference, there is no hardware gain calibration. Calibration can be done by software after taking a sample.

### 24.3.12 EM2 or EM3 Operation

The ADC can operate in EM2 or EM3 mode. For EM2 or EM3 operation the ADC\_CLK must be selected as AUXHFRCO. The section [24.3.1 Clock Selection](#) describes how to choose AUXHFRCO as the ADC\_CLK. The AUXHFRCO can be kept on for as long as sample conversion is needed or it can be requested by trigger event and after the conversion is done, the AUXHFRCO can be shut down. The second option saves power at the expense of the delay to start the AUXHFRCO oscillator. All the trigger modes are available in EM2 or EM3 as well.

While in EM2 or EM3, the ADC can wake the system to EM0 on enabled interrupts, (i.e., compare interrupt or SCAN or SINGLE interrupt indicating the corresponding FIFO has reached the DVL watermark). The ADC can also work with the DMA so that the system does not have to wake up to consume data. This can happen if the SCAN or SINGLE interrupt is disabled and the SINGLEDMAWU or SCANDMAWU in the ADCn\_CTRL is set. The DMA will be triggered by the ADC when DVL samples become available in the corresponding FIFO. The DMA will then pop all the elements of the corresponding FIFO and put the system back into the low power state. A system-level wake up will occur upon the DMA done interrupt. Note that other enabled ADC interrupts can still wake up the system when operating with the DMA. For example, the user can configure the window compare function to trip when the result reaches a certain threshold while gathering ADC data in EM2 or EM3.

The ADC works with the EMU to wake up the system or the DMA. It takes 2us from the time the ADC request a wakeup to start of the peripheral clocks. In this ASYNC mode of ADC\_CLK, it takes 6 HPERCLK cycles to read a single entry from the single or scan FIFO. So, with a 20MHz HPERCLK, it takes about 4us per DMA wakeup to empty a full FIFO (4 entries). This restricts the sampling rate to no more than 400 ksps in EM2 or EM3 in order to avoid FIFO overflows.

The AUXHFRCO power can be reduced by reducing the clock speed, and the user may adjust the ADCBIASPROG field in the ADCn\_BIASPROG register to reduce active power of the ADC during the conversions, thus reducing power even more in EM2/EM3. Please refer to the data sheet for relevant power consumption numbers.

If the ADC is not to be used in EM2 or EM3, then the user should ensure that the ADC is not busy before going to the low power mode. [24.3.15 ADC Programming Model](#) explains how to ensure the ADC is not busy. If the chip enters EM2 or EM3 when ADC is busy without using AUXHFRCO, then the ADC clock will stop but the ADC will stay on, resulting in higher supply current.

### 24.3.13 ASYNC ADC\_CLK Usage Restrictions and Benefits

When the ADC\_CLK is chosen to come from ASYNCCLK, (ADCCLKMODE is set to ASYNC), the ADC\_CLK and the ADC peripheral clock are considered asynchronous and this adds some restrictions:

- Due to a synchronization delay, accessing the following registers takes extra time (up to additional 7 HPERCLK cycles): ADCn\_SINGLEDATA, ADCn\_SCANDATA, ADCn\_SINGLEDATAP, ADCn\_SCANDATAP, ADCn\_SCANDATAX, ADCn\_SCANDATAXP, ADCn\_SINGLEFIFOCOUNT, ADCn\_SCANFIFOCOUNT, ADCn\_SINGLEFIFOCLEAR, ADCn\_SCANFIFOCLEAR.
- The safe time to change the ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX, ADCn\_SCANCTRL, ADCn\_SCANCTRLx, ADCn\_SCANINPUTSEL, ADCn\_SCANNEGSEL or ADCn\_SCANMASK register is when SINGLEACT/SCANACT in the ADCn\_STATUS is 0 with no pending trigger event. The user can enforce this by writing the SINGLESTOP or SCANSTOP in the ADCn\_CMD register and ensuring no trigger event can come before modifying the registers.
- When the ADC needs to run in EM2 or EM3, only AUXHFRCO can provide the ADC\_CLK to the ADC. Thus the user needs to set ASYNC mode of ADCCLKMODE and setup the CMU to provide the AUXHFRCO clock as ASYNCCLK.
- If the ADC needs to run on a particular adc\_clk\_sar frequency to achieve a sample rate and the HPERCLK is not a proper multiple for such clock frequency, a higher frequency system clock, HFRCO, can be chosen to be ADC\_CLK using ASYNC mode. This allows HPERCLK to be set to an optimum value from a system view point.
- ASYNC mode can also help with digital noise mitigation as this clock is asynchronous (not balanced) with the system clock. Moreover, the user can use the invert option to invert the source of ASYNCCLK helping in noise mitigation further.
- With ASNEEDED setting for ASYNCCLK request, the ADC\_CLK power can be reduced.

### 24.3.14 Window Compare Function

The ADC supports a window compare function on both the latest single and scan outputs. The compare thresholds, ADGT and ADLT, are defined in the ADCn\_CMPTHR register. These are 16-bit values and their format must match the type of conversion (single-ended or differential) the user is trying to compare with. For example, a 12-bit differential conversion is sign extended to 16 bits while a 12-bit single-ended conversion result would get zero padded to 16-bit result before comparing with ADGT and ADLT. If over-sampling is enabled, the conversion result could grow to 16-bits. There is a single set of ADLT and ADGT threshold for both single and scan compare. The user can however enable single or scan compare logic individually by enabling CMPEN in ADCn\_SINGLECTRL or ADCn\_SCANCTRL register.

The user can perform comparison both within or outside of the window defined by the ADGT and ADLT. If the ADLT is greater than ADGT, the ADC compares if the current sample is within the window. Otherwise, the ADC compares if the current sample is outside of the window.

### 24.3.15 ADC Programming Model

The ADC configuration registers are considered static and can only be updated when (1) ADC is in SYNC mode and (2) ADC is idle. ADC is considered busy when it is doing conversions (either the SINGLEACT or SCANACT status flag is high) or when it is warmed up (one of the following status flags is high: WARM, SINGLEREFWARM, SCANREFWARM). The following registers are considered ADC configuration registers: CMU\_ADCCTRL, ADCn\_CTRL, ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX, ADCn\_SCANCTRL, ADCn\_SCANCTRLX, ADCn\_SCANINPUTSEL, ADCn\_SCANNEGSEL, ADCn\_IEN, ADCn\_BIASPROG, ADCn\_SCANMASK, ADCn\_CAL and ADCn\_CMPTHR.

From reset, the ADC is in SYNC mode by default. The user can program the configuration registers as needed. If PRS is to be used, PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL should be set after all other configuration is complete. Once configuration is complete, the ADC is ready to receive triggers.

After the ADC has been used to perform conversions, the user must ensure that the ADC is idle before updating the configuration registers. The first step is to ensure that no new triggers (PRS) are being issued. It can take a few cycles from when a trigger is received to when SINGLEACT/SCANACT flags go high due to synchronization requirement. If it is unclear when the triggers were issued and if those are under synchronization or not, the user should add a small delay before checking the status flags. If the SINGLEACT/SCANACT status flags are high, the corresponding STOP command should be issued and the user should wait until the SINGLEACT/SCANACT flags go low. If the ADC was warmed up, then the WARMUPMODE should be changed to NORMAL and then the user should wait on WARM, SINGLEREFWARM and SCANREFWARM flags until those go low. Now the ADC is idle.

**Note:**

When switching ADCCLKMODE in the ADCn\_CTRL register, use the appropriate sequence below:

- SYNC to ASYNC:
  1. Disable ADC interrupts
  2. Clear the FIFOs
  3. Switch the ADCCLKMODE
- ASYNC TO SYNC:
  1. Disable ADC interrupts
  2. Switch the ADCCLKMODE
  3. Clear the FIFOs

The FIFOs are cleared by writing 1 to the ADCn\_SCANFIFOCLEAR and ADCn\_SINGLEFIFOCLEAR registers.

When switching from ASYNC to SYNC, ensure that the ASYNC clock is turned off before doing the switch.

## 24.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	ADCn_CTRL	RW	Control Register
0x008	ADCn_CMD	W1	Command Register
0x00C	ADCn_STATUS	R	Status Register
0x010	ADCn_SINGLECTRL	RW	Single Channel Control Register
0x014	ADCn_SINGLECTRLX	RW	Single Channel Control Register continued
0x018	ADCn_SCANCTRL	RW	Scan Control Register
0x01C	ADCn_SCANCTRLX	RW	Scan Control Register continued
0x020	ADCn_SCANMASK	RW	Scan Sequence Input Mask Register
0x024	ADCn_SCANINPUTSEL	RW	Input Selection register for Scan mode
0x028	ADCn_SCANNEGSEL	RW	Negative Input select register for Scan
0x02C	ADCn_CMPTHR	RW	Compare Threshold Register
0x030	ADCn_BIASPROG	RW	Bias Programming Register for various analog blocks used in ADC operation.
0x034	ADCn_CAL	RW	Calibration Register
0x038	ADCn_IF	R	Interrupt Flag Register
0x03C	ADCn_IFS	W1	Interrupt Flag Set Register
0x040	ADCn_IFC	(R)W1	Interrupt Flag Clear Register
0x044	ADCn_IEN	RW	Interrupt Enable Register
0x048	ADCn_SINGLEDATA	R(a)	Single Conversion Result Data
0x04C	ADCn_SCANDATA	R(a)	Scan Conversion Result Data
0x050	ADCn_SINGLEDATAP	R	Single Conversion Result Data Peek Register
0x054	ADCn_SCANDATAP	R	Scan Sequence Result Data Peek Register
0x068	ADCn_SCANDATAAX	R(a)	Scan Sequence Result Data + Data Source Register
0x06C	ADCn_SCANDATAAXP	R	Scan Sequence Result Data + Data Source Peek Register
0x07C	ADCn_APORTREQ	R	APORT Request Status Register
0x080	ADCn_APORTCONFLICT	R	APORT Conflict Status Register
0x084	ADCn_SINGLEFIFOCOUNT	R	Single FIFO Count Register
0x088	ADCn_SCANFIFOCOUNT	R	Scan FIFO Count Register
0x08C	ADCn_SINGLEFIFOCLEAR	W1	Single FIFO Clear Register
0x090	ADCn_SCANFIFOCLEAR	W1	Scan FIFO Clear Register
0x094	ADCn_APORTMASTERDIS	RW	APORT Bus Master Disable Register

24.5 Register Description

24.5.1 ADCn\_CTRL - Control Register

Offset	Bit Position

	10	X2048	2048 samples for each conversion result	
	11	X4096	4096 samples for each conversion result	
23	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
22:16	TIMEBASE	0x1F	RW	<b>1us Time Base</b> Sets the time base used for the ADC warm up sequence based on ADC_CLK. The TIMEBASE field should be set equal to produce timing of 1us or greater.
	Value	Description		
	TIMEBASE	ADC STANDBY/SLOWACC mode warm-up is set to 1 x (TIMEBASE + 1) ADC_CLK cycles and NORMAL mode warm-up is set to 5 x (TIMEBASE + 1) ADC_CLK cycles.		
15	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
14:8	PRESC	0x00	RW	<b>Prescaler Setting for ADC Sample and Conversion clock</b> Sets the prescale factor to generate the ADC conversion clock (adc_sar_clk) from ADC_CLK.

Bit	Name	Reset	Access	Description
	Value			Description
	PRESC			Clock prescale factor. ADC_CLK is divided by (PRESC+1) to produce adc_clk_sar.
7	ADCCLKMODE	0	RW	<b>ADC Clock Mode</b> Selects ADC_CLK source as synchronous or asynchronous - with respect to the Peripheral Clock (HFPERCLK).
	Value	Mode		Description
	0	SYNC		Synchronous clocking. Uses HFPERCLK to generate ADC_CLK, ADC will not be available in EM2 in this mode.
	1	ASYNC		Asynchronous clocking. Uses clk_adc_async coming from CMU to generate ADC_CLK. ADC might be available in EM2 in this mode if the CLK_ADC_ASYNC is available in EM2
6	ASYNCCLKEN	0	RW	<b>Selects ASYNC CLK enable mode when ADCCLKMODE=1</b> Write a 1 to keep ASYNC CLK always enabled.
	Value	Mode		Description
	0	ASNEEDED		ASYNC CLK is enabled only during ADC Conversion.
	1	ALWAYSON		ASYNC CLK is always enabled.
5	<i>Reserved</i>	<i>To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a></i>		
4	TAILGATE	0	RW	<b>Conversion Tailgating</b> Enable/disable conversion tailgating. Single channel conversions wait for a scan sequence to finish before starting.
	Value			Description
	0			Scan sequence has priority, but can be delayed by ongoing single channels.
	1			Scan sequence has priority and single channels will only start immediately after completion of a scan sequence.
3	SCANDMAWU	0	RW	<b>SCANFIFO DMA Wakeup</b> Selects whether to wakeup the DMA controller when in EM2 and DVL is reached in SCANFIFO
	Value			Description
	0			While in EM2, the DMA controller will not get requests about DVL reached in SCANFIFO
	1			DMA is available in EM2 for processing SCANFIFO DVL request
2	SINGLEDMAWU	0	RW	<b>SINGLEFIFO DMA Wakeup</b> Selects whether to wakeup the DMA controller when in EM2 and DVL is reached in SINGLEFIFO
	Value			Description
	0			While in EM2, the DMA controller will not get requests about Data Valid Level (DVL) reached in SINGLEFIFO
	1			DMA is available in EM2 for processing SINGLEFIFO DVL request
1:0	WARMUPMODE	0x0	RW	<b>Warm-up Mode</b>

Bit	Name	Reset	Access	Description
Select Warm-up Mode for ADC				
	Value	Mode		Description
	0	NORMAL		ADC is shut down after each conversion. 5us warmup time is used before each conversion.
	1	KEEPINSTANDBY		ADC is kept in standby mode between conversions. 1us warmup time is used before each conversion.
	2	KEEPINSLOWACC		ADC is kept in slow acquisition mode between conversions. 1us warmup time is used before each conversion.
	3	KEEPADCWARM		ADC is kept on after conversions, allowing for continuous conversion.

## 24.5.2 ADCn\_CMD - Command Register

#### 15:8 POSSEL 0xFF RW **Single Channel Positive Input Selection**

Selects the positive input to the ADC for single channel operation. Software can choose any of the 32 channels of any BUS as positive input. In DIFF mode POSSEL and NEGSEL need to be chosen from different resources (X or Y). If an X BUS is connected to POSSEL, only a Y BUS can connect to NEGSEL, and vice-versa. The user can also select some internal nodes as positive input for single-ended sampling. These internal nodes cannot be sampled differentially.

Bit	Name	Reset	Access	Description
31:0	SCANINPUTEN	0x00000000	RW	<b>Scan Sequence Input Mask</b>
Set one or more bits in this mask to select which inputs are included in scan sequence in either single ended or differential mode. This works with SCANINPUTSEL register. The SCANINPUTSEL chooses 32 possible channels for single-ended or 32 pairs of possible channels for differential scanning from BUSES. These chosen channels are referred as ADCn_INPUTx in the description. Four even inputs from first group of 8 ADCn_INPUTx and four odd inputs from second group of 8 ADCn_INPUTx have programmable NEGSEL, defined in SCANNEGSEL register. If the SCANMASK is set to 0 and scan conversion is triggered, ADC will do a conversion with garbage results since no inputs were enabled for conversion.				
Mode		Value	Description	
DIFF = 0				
INPUT0		xxxxxxxxxxxxxxxxxxxx1	ADCn_INPUT0 included in mask

Access	RW																RW															
Name	ADGT																ADLT															

Bit	Name	Reset	Access	Description
31:16	ADGT	0x0000	RW	<b>Greater Than Compare Threshold</b> Compare threshold value for greater-than comparison. Must match the conversion data representation chosen.
15:0	ADLT	0x0000	RW	<b>Less Than Compare Threshold</b> Compare threshold value for less-than comparison. Must match the conversion data representation chosen.

**24.5.12 ADCn\_BIASPROG - Bias Programming Register for various analog blocks used in ADC operation.**

Offset	Bit Position																																			
0x030	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Reset																	0					0													0x0	
Access																	RW					RW													RW	
Name																	GPB/ASACC					VFAULTCLR													ADCBIASPROG	

Bit	Name	Reset	Access	Description
31:17	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
16	GPBIASACC	0	RW	<b>Accuracy setting for the system bias during ADC operation</b> Select bias accuracy mode for ADC operation.
	Value	Mode	Description	
	0	HIGHACC	High accuracy setting. Use when configured for an internal VBGR reference source.	
	1	LOWACC	Low accuracy setting. Can be used for all references other than VBGR to conserve energy.	
15:13	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
12	VFAULTCLR	0	RW	<b>Clear VREFOF flag</b> Use this bit to request clearing of the VREFOF flag. If VREFOF irq is enabled and is triggered, the user must set this bit in the ISR to clear VREFOF. The user needs to reset this bit to enable VREFOF to trigger further IRQs upon VREF overflow conditions.
11:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3:0	ADCBIASPROG	0x0	RW	<b>Bias Programming Value of analog ADC block</b> These bits are used to adjust the bias current in ADC analog block.
	Value	Mode	Description	
	0	NORMAL	Normal power (use for 1Msps operation)	
	4	SCALE2	Scaling bias to 1/2	
	8	SCALE4	Scaling bias to 1/4	
	12	SCALE8	Scaling bias to 1/8	
	14	SCALE16	Scaling bias to 1/16	
	15	SCALE32	Scaling bias to 1/32	

24.5.13 ADCn\_CAL - Calibration Register

Offset	Bit Position																																											
0x034	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0												
Reset	0	0x40							0x7							0x8							0	0x40							0x7							0x8						
Access	RW	RW							RW							RW							RW	RW							RW							RW						
Name	CALEN	SCANGAIN							SCANOFFSETINV							SCANOFFSET							OFFSETINVMODE	SINGLEGAIN							SINGLEOFFSETINV							SINGLEOFFSET						

Bit	Name	Reset	Access	Description
31	CALEN	0	RW	<b>Calibration mode is enabled</b>  When enabled, the adc performs conversion and sends raw data to the ADC fifos. This can also be used to debug the adc data conversion
30:24	SCANGAIN	0x40	RW	<b>Scan Mode Gain Calibration Value</b>  This register contains the gain calibration value used with scan conversions. This field is set to the production gain calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is unsigned. Higher values lead to higher ADC results.
23:20	SCANOFFSETINV	0x7	RW	<b>Scan Mode Offset Calibration Value for negative single-ended mode</b>  This register contains the offset calibration value used with scan conversions for negative single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.
19:16	SCANOFFSET	0x8	RW	<b>Scan Mode Offset Calibration Value for differential or positive single-ended mode</b>  This register contains the offset calibration value used with scan conversions for differential or positive single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.
15	OFFSETINVMODE	0	RW	<b>Negative single-ended offset calibration is enabled</b>  When enabled, along with CALEN bit, the ADC performs negative singled ended conversion. When not enabled, if CALEN is set, DIFF bit of SINGLECTRL register decides whether to do positive single-ended or differential conversion.
14:8	SINGLEGAIN	0x40	RW	<b>Single Mode Gain Calibration Value</b>  This register contains the gain calibration value used with single conversions. This field is set to the production gain calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is unsigned. Higher values lead to higher ADC results.
7:4	SINGLEOFFSETINV	0x7	RW	<b>Single Mode Offset Calibration Value for negative single-ended mode</b>  This register contains the offset calibration value used with single conversions for negative single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.
3:0	SINGLEOFFSET	0x8	RW	<b>Single Mode Offset Calibration Value for differential or positive single-ended mode</b>  This register contains the offset calibration value used with single conversions for differential or positive single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.

24.5.14 ADCn\_IF - Interrupt Flag Register

Offset	Bit Position																																	
0x038	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset							0	0							0	0							0	0	0	0							0	0
Access							R	R							R	R							R	R	R	R							R	R
Name							PROGERR	VREFOV							SCANCMP	SINGLECMP							SCANUF	SINGLEUF	SCANOF	SINGLEOF							SCAN	SINGLE

Bit	Name	Reset	Access	Description
31:26	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
25	PROGERR	0	R	<b>Programming Error Interrupt Flag</b> Indicates that a programming error has occurred. Read the STATUS register for cause.
24	VREFOV	0	R	<b>VREF Over Voltage Interrupt Flag</b> Indicates that attenuated vref is greater than 1.3V when this bit is set. The ADC stops converting and disconnects the reference when this happens to protect the internal low-voltage circuits.
23:18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17	SCANCMP	0	R	<b>Scan Result Compare Match Interrupt Flag</b> Indicates scan result compare matched the window conditions when this bit is set.
16	SINGLECMP	0	R	<b>Single Result Compare Match Interrupt Flag</b> Indicates single result compare matched the window conditions when this bit is set.
15:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11	SCANUF	0	R	<b>Scan FIFO Underflow Interrupt Flag</b> Indicates scan result FIFO underflow when this bit is set. An underflow occurs if the FIFO is read and there is no data available.
10	SINGLEUF	0	R	<b>Single FIFO Underflow Interrupt Flag</b> Indicates single result FIFO underflow when this bit is set. An underflow occurs if the FIFO is read and there is no data available.
9	SCANOF	0	R	<b>Scan FIFO Overflow Interrupt Flag</b> Indicates scan result FIFO overflow when this bit is set. An overflow occurs if there is not room in the FIFO to store a new result.
8	SINGLEOF	0	R	<b>Single FIFO Overflow Interrupt Flag</b> Indicates single result FIFO overflow when this bit is set. An overflow occurs if there is not room in the FIFO to store a new result.
7:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	SCAN	0	R	<b>Scan Conversion Complete Interrupt Flag</b> Indicates (DVL+1) number of scan channel results are available in the Scan FIFO.
0	SINGLE	0	R	<b>Single Conversion Complete Interrupt Flag</b> Indicates (DVL+1) number of single channel results are available in the Single FIFO.

## 24.5.15 ADCn\_IFS - Interrupt Flag Set Register

Offset	Bit Position

## 25. IDAC - Current Digital to Analog Converter

### Quick Facts

#### What?

The IDAC can sink or source a configurable constant current.

#### Why?

The IDAC can be used to bias external circuits or (in conjunction with the ADC) measure capacitance by injecting a controlled current into a component.

#### How?

In addition to providing a constant current, the IDAC can be switched on and off with a PRS signal all the way down to EM3.

### 25.1 Introduction

The current digital to analog converter (IDAC) can source or sink a configurable constant current from a pin or the ADC. The current is configurable with several ranges of various step sizes.

### 25.2 Features

- Can source and sink current
- Programmable constant output current
  - Selectable current range between 0.05  $\mu\text{A}$  and 64  $\mu\text{A}$
  - Each range is linearly programmable in 32 steps
  - Support for current calibration
- Can charge ADC channels
- Support for manual and PRS triggered output enable
- Available in EM0-EM3

25.3 Functional Description

An overview of the IDAC module is shown in [Figure 25.1 IDAC Overview on page 827](#). The IDAC is designed to source or sink a programmable current which can be controlled by setting the range and the step in the RANGESEL and STEPSEL bitfields in IDAC\_CURRPROG register. The IDAC output enable to APORT can be controlled by software or PRS. Output enable to APORT is controlled by software by setting APORTOUTEN, or by PRS by setting APORTOUTENPRS in IDAC\_CTRL. The APORTOUTSEL bit-field in IDAC\_CTRL selects which APORT channel to route to pin. The IDAC is enabled by setting EN in IDAC\_CTRL.

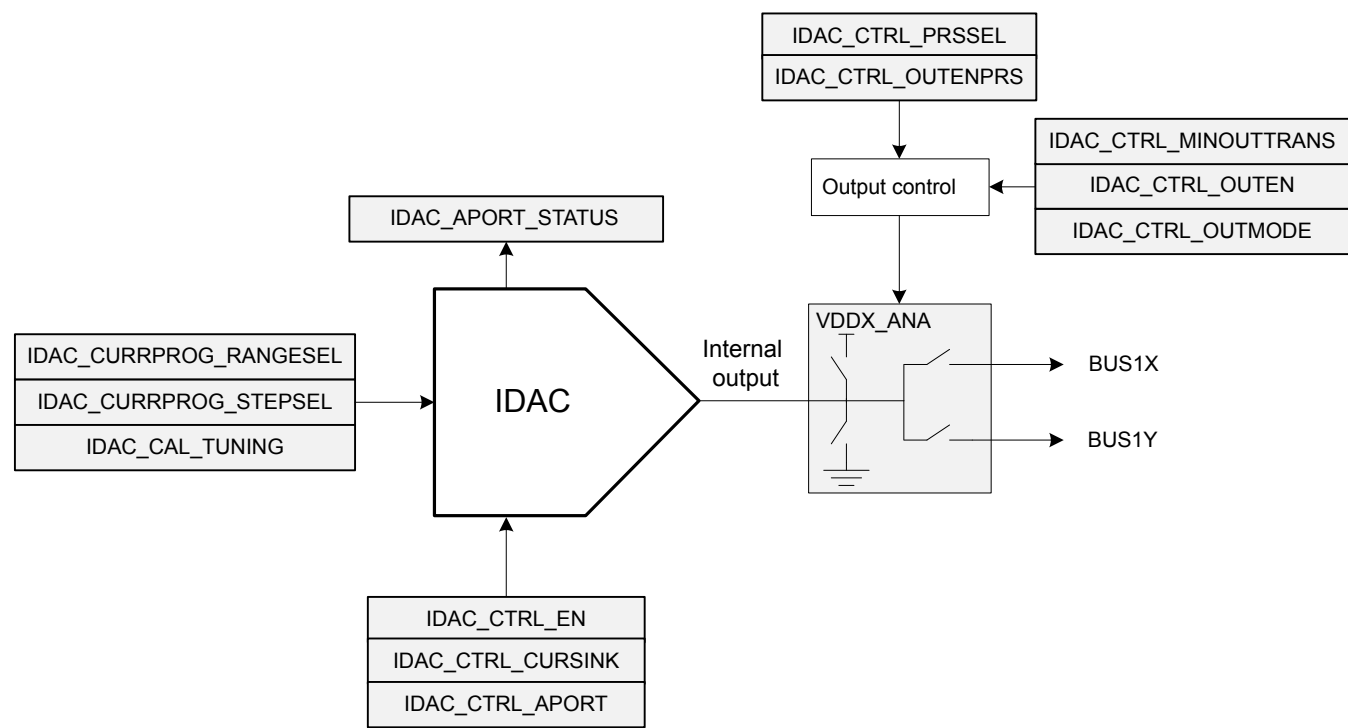

Figure 25.1. IDAC Overview

25.3.1 Current Programming

The four different current ranges can be selected by configuring the RANGESEL bitfield in IDAC\_CURRPROG. The current output in each range is linearly programmable in 32 steps, and is controlled by the STEPSEL bitfield in IDAC\_CURRPROG. These current ranges and their step sizes are shown in [Table 25.1 Range Selection on page 827](#).

Table 25.1. Range Selection

Range Select	Range Value [μA]	Step Size [nA]	Step Counts
0	0.05 - 1.6	50	32
1	1.6 - 4.7	100	32
2	0.5 - 16	500	32
3	2 - 64	2000	32

25.3.2 IDAC Enable and Warm-up

The IDAC is enabled by setting the EN bit in IDAC\_CTRL. When this bit is set, the IDAC must stabilize before its output current is stable.

It is important to wait until the IDAC is warmed up, or until any current programming is complete and the output current is stabilized, before entering EM1, EM2, or EM3.

### 25.3.3 Output Control

The IDAC output to APORT can be controlled either by software or PRS. After configuring the desired output mode, set APORTOUTENPRS in IDAC\_CTRL to enable PRS control over the output, or set APORTOUTEN in IDAC\_CTRL to enable the output via software.

### 25.3.4 Output Modes

The IDAC can output current to a pin through the APORT bus system. The IDAC is connected to APORT bus 1x and 1y (channel 0-31). The IDAC output is enabled by first configuring APORTOUTSEL in IDAC\_CTRL to the desired APORT channel and then setting APORTOUTEN in IDAC\_CTRL. For details regarding setting up the APORT see [25.3.5 APORT Configuration](#).

### 25.3.5 APORT Configuration

The IDAC output is routed to a pin through the APORT system. The IDAC can be in either master or slave mode when connecting to the APORT. By default the IDAC is in master mode and will drive the channel selected. To enable slave mode, set APORTMASTERDIS in IDAC\_CTRL. An APORT channel can be requested by configuring APORTOUTSEL to APORT1XCHx/APORT1YCHx in IDAC\_CTRL. The APORT1XREQ and APORT1YREQ bitfields in IDAC\_APORTREQ will indicate if the access was granted by the APORT. If the IDAC is in master mode, and another module is currently driving the requested channel, the APORTCONFLICT bitfield in IDAC\_STATUS will be set together with APORT1XCONFLICT or APORT1YCONFLICT in IDAC\_APORTCONFLICT. The APORTCONFLICT can also be configured to trigger an interrupt, see [25.3.6 Interrupts](#) for details. The IDAC will stop driving/listening (or stop requesting) the APORT channel by clearing APORTOUTEN in IDAC\_CTRL.

The mapping for IDAC0 outputs to external I/O connections is shown in [Table 25.2 IDAC0 Bus and Pin Mapping on page 829](#). Note that this table shows the mapping for an entire family of devices. Enumerations for the APORTOUTSEL field can be determined by finding the desired pin connection in the table and then combining the IDAC Port, polarity and channel identifier. For example, pin PB14 is listed as CH30 on APORT1, polarity X. The enumeration would be APORT1XCH30. Refer to the Pin Definition and the APORT Client Map in the device datasheet for specific details on which I/O are available for each family and package configuration.

**Table 25.2. IDAC0 Bus and Pin Mapping**

CH5		PD13
CH4	PD12	
CH3		PD11
CH2	PD10	
CH1		
CH0		

### 25.3.6 Interrupts

The APORTCONFLICT interrupt flag in the IDAC\_IF register indicates that a conflict has occurred when requesting a channel from the APORT. The APORTCONFLICT interrupt can be enabled by setting the APORTCONFLICT bit in IDAC\_IEN, or cleared by setting the APORTCONFLICT bit in IDAC\_IFC.

### 25.3.7 Minimizing Output Transition

If the internal output of the IDAC differs from the voltage at the output pin, enabling the output can cause an unwanted transition. To minimize this transition, it is possible to charge or discharge the internal output node before enabling the output to the pin. Setting MINOUTTRANS in IDAC\_CTRL when the IDAC is sourcing current connects the internal node to GND. Alternatively, setting MINOUTTRANS when the IDAC is sinking current connects the internal output node to VDD. Setting APORTOUTEN when MINOUTTRANS is set will halt the charge/discharge until either APORTOUTEN is cleared or MINOUTTRANS is cleared.

### 25.3.8 Duty Cycle Configuration

The references for the IDAC can be duty-cycled, meaning that it can source current at very low overhead current consumption at the cost of response time and accuracy. By default duty-cycling is enabled in EM2 and EM3 and disabled in EM0 and EM1. Setting EM2DUTYCYCLEDIS in IDAC\_DUTYCONFIG will disable duty cycling in EM2 and EM3. Note that sinking current can not be done with duty-cycled references so measures needs to be taken to always disable duty-cycling while sinking current.

### 25.3.9 Calibration

The IDAC can be calibrated to accurately compensate for process, supply voltage and temperature variations. During the production test, the middle step of each range is calibrated at room temperature. The TUNING bitfield in the IDAC\_CAL register can be used to do further calibration of each step with an external resistor connected to IDAC\_OUT. The calibrated tuning value for each band can be read from the Device Information (DI) page.

### 25.3.10 PRS Input

The IDAC can be configured to control the APORT output enable directly from the PRS channel by setting APORTOUTENPRS in IDAC\_CTRL, once the desired output mode is configured in IDAC\_CTRL. The PRS channel is selected using PRSSEL in the IDAC\_CTRL register.

### 25.3.11 PRS Triggered Charge Injection

The amount of charge sourced or sunk by the IDAC can be controlled by the PRS (e.g., using a timer as producer) via the output switch. [Figure 25.2 IDAC Charge Injection Example on page 831](#) shows a case where the IDAC is configured to periodically supply charge using the PRS. The amount of charge injected is proportional to the the period the IDAC is on. The total charge injected is the current multiplied by the time the output switch is enabled.

The PRS system is enabled by setting APORTOUTENPRS in IDAC\_CTRL, and the PRS channel is selected by PRSSEL in IDAC\_CTRL. To generate the periodic control signal, the TIMER module can be used, by configuring for example a CC channel to compare match with PRSLEVEL selected.

**Figure 25.2. IDAC Charge Injection Example**

## 25.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description

1:0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

## 26. GPCRC - General Purpose Cyclic Redundancy Check

### Quick Facts

#### What?

The GPCRC is an error-detecting module commonly used in digital networks and storage systems to detect accidental changes to data.

#### Why?

The GPCRC module can detect errors in data, giving a higher system reliability and robustness.

#### How?

Blocks of data entering GPCRC module can have a short checksum, based on the remainder of a polynomial division of their contents; on retrieval the calculation is repeated, and corrective action can be taken against presumed data corruption if the check values do not match.

### 26.1 Introduction

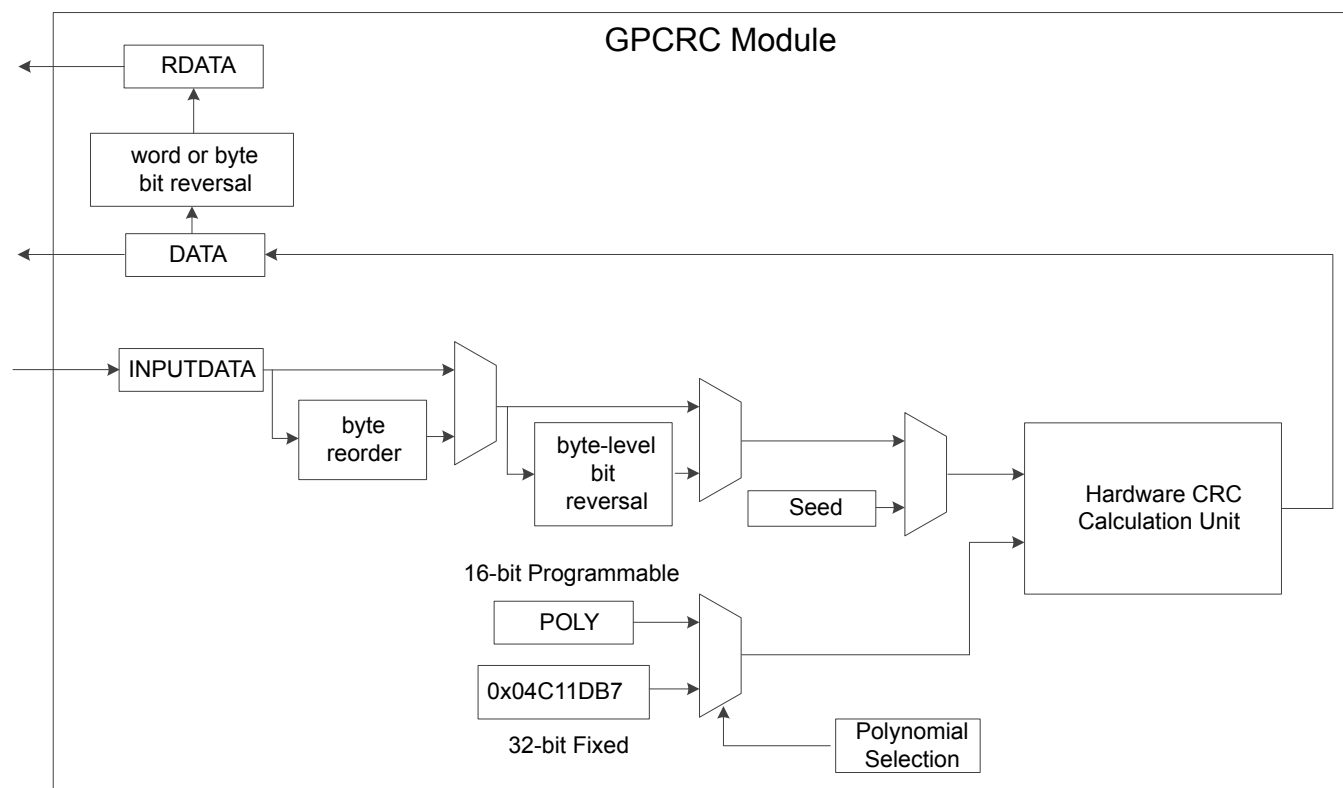

The GPCRC module is a slave peripheral that implements a Cyclic Redundancy Check (CRC) function. It supports both 32-bit and 16-bit polynomials. The supported 32-bit polynomial is 0x04C11DB7(IEEE 802.3), while the 16-bit polynomial can be programmed to any value, depending on the needs of the application. Common 16-bit polynomials are 0x1021 (CCITT-16), 0x3D65 (IEC16-MBus), and 0x8005 (ZigBee, 802.15.4, and USB).

### 26.2 Features

- Programmable 16-bit polynomial, fixed 32-bit polynomial
- Byte-level bit reversal for the CRC input
- Byte-order reorientation for the CRC input
- Word or half-word bit reversal of the CRC result
- Ability to configure and seed an operation in a single register write
- Single-cycle CRC computation for 32-, 16-, or 8-bit blocks
- DMA operation

### 26.3 Functional Description

An overview of the GPCRC module is shown in [Figure 26.1 GPCRC Overview on page 841](#).

**Figure 26.1. GPCRC Overview**

### 26.3.1 Polynomial Specification

POLYSEL in GPCRC\_CTRL selects between 32-bit and 16-bit polynomial functions. When a 32-bit polynomial is selected, the fixed IEEE 802.3 polynomial(0x04C11DB7) is used. When a 16-bit polynomial is selected, any valid polynomial can be defined by the user in GPCRC\_POLY.

A valid 16-bit CRC polynomial must have an  $x^{16}$  term and an  $x^0$  term. Theoretically, a 16-bit polynomial has 17 terms total. The convention used is to omit the  $x^{16}$  term. The polynomial should be written in **reversed** (little endian) bit order. The most significant bit corresponds to the lowest order term. Thus, the most significant bit in CRC\_POLY represents the  $x^0$  term, and the least significant bit in CRC\_POLY represents the  $x^{15}$  term. The highest significant bit of CRC\_POLY should always set to 1. The polynomial representation for the CRC-16-CCIT polynomial  $x^{16} + x^{12} + x^5 + 1$ , or 0x8408 in reversed order, is shown in [Figure 26.2 Polynomial Representation on page 842](#).

CRC-16-CCITT Normal: 0x1021 Reversed: 0x8408

Figure 26.2. Polynomial Representation

### 26.3.2 Input and Output Specification

The CRC input data can be written to the GPCRC\_INPUTDATA, GPCRC\_INPUTDATAWORD or GPCRC\_INPUTDATABYTE register via the APB bus based on different data size. If BYTEMODE in GPCRC\_CTRL is set, only the least significant byte of the data word will be used for the CRC calculation no matter which input register is written. There are also three output registers for different ordering. Reading from GPCRC\_DATA will get the result based on the polynomial in reversed order, while reading from GPCRC\_DATAREV will get the result based on the polynomial in normal order. The CRC calculation needs one clock cycle, reading from GPCRC\_DATA, GPCRC\_DATAREV or GPCRC\_DATABYTEREV register or writing to GPCRC\_CMD register is halted while the calculation is in progress.

### 26.3.3 Automatic Initialization

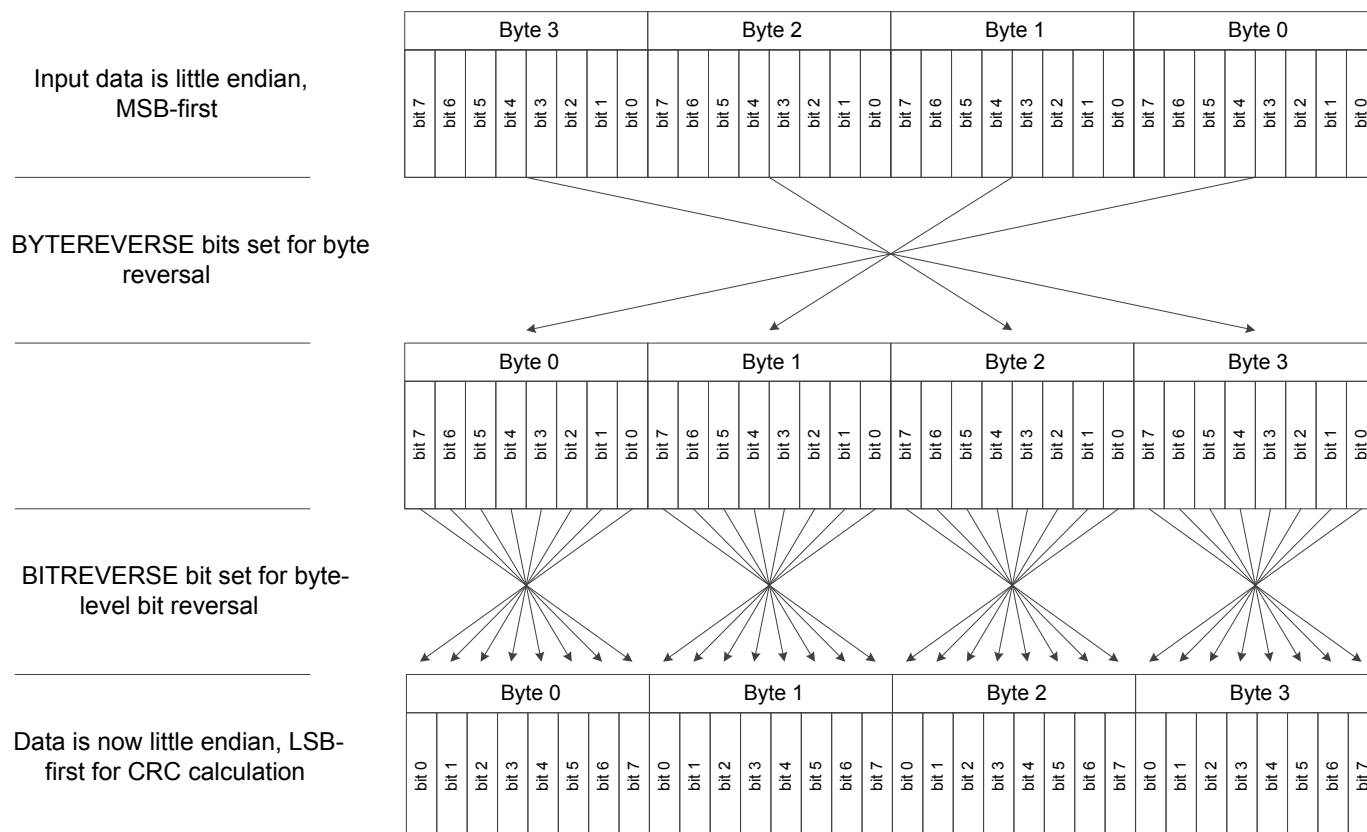

The CRC can be pre-loaded or re-initialized by first writing a 32-bit programmable init value to INIT in GPCRC\_INIT and then setting INIT in GPCRC\_CMD. It can also be re-initialized automatically when read from DATA, DATAREV or DATABYTEREV provided that AUTINIT in GPCRC\_CTRL is set, the CRC would be re-initialized with the stored init value.

### 26.3.4 DMA Usage

A DMA channel may be used to transfer data into the CRC engine. All bytes and half-word writes must be word-aligned. The recommended DMA usage model is to use the DMA to transfer all available words of data and use software writes to capture any remaining bytes.

### 26.3.5 Byte-Level Bit Reversal and Byte Reordering

The byte-level bit reversal and byte reordering operations occur before the data is used in the CRC calculation. Byte reordering can occur on words or half words. The hardware ignores the BYTEREVERSE field with any byte writes or operations with byte mode enabled (BYTEMODE = 1), but the bit reversal settings (BITREVERSE) are still applied to the byte. 32-bit little endian MSB-first data can be treated like 32-bit little endian LSB-first data, as shown in [Figure 26.3 Data Ordering Example - 32-bit MSB-first to LSB-first on page 843](#). In this example, 32-bit data is written to GPCRC\_INPUTDATA, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

**Figure 26.3. Data Ordering Example - 32-bit MSB-first to LSB-first**

When handling 16-bit data, the byte reordering function only swap the two lowest bytes and clear the two highest bytes, as shown in [Figure 26.4 Data Ordering Example - 16-bit MSB-first to LSB-first on page 844](#). In this example, 16-bit data is written to GPCRC\_INPUTDATAWORD, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

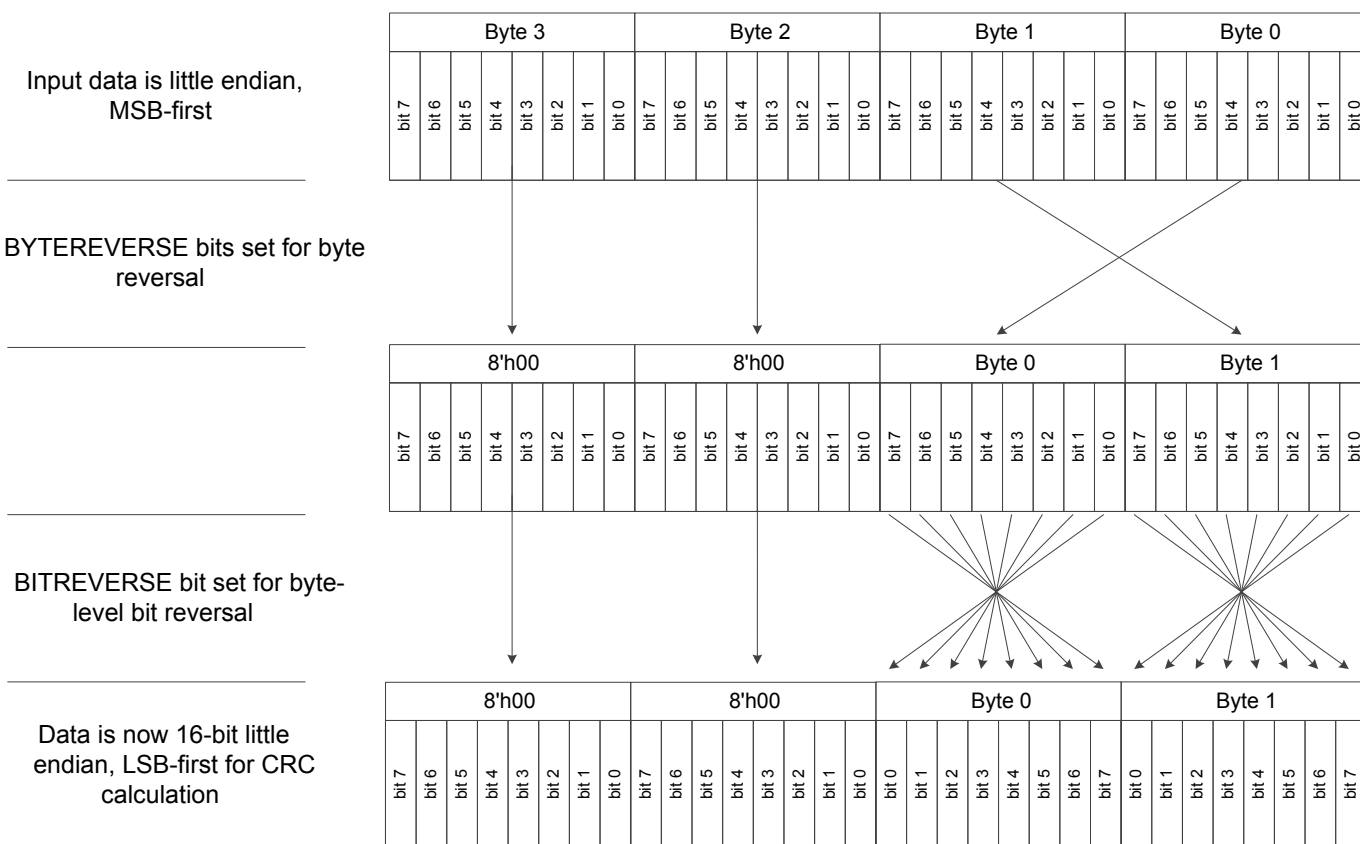

Figure 26.4. Data Ordering Example - 16-bit MSB -first to LSB-first

Assuming a word input byte order of B3 B2 B1 B0, the values used in the CRC calculation for the various settings of the byte-level bit reversal and byte reordering are shown in [Table 26.1 Byte-Level Bit Reversal and Byte Reordering Results \(B3 B2 B1 B0 Input Order\)](#) on page 844.

Table 26.1. Byte-Level Bit Reversal and Byte Reordering Results (B3 B2 B1 B0 Input Order)

Original CRC Calculation Method			Equivalent Settings		Input to CRC calculation
Polynomial Width(bits)	Byte Order	Bit Order(MSB/LSB first)	BYTEVERSE Setting	BITREVERSE Setting	
32	little endian	LSB	0	0	B3 B2 B1 B0
32	little endian	MSB	1	1	'B0 'B1 'B2 'B3
32	big endian	LSB	1	0	B0 B1 B2 B3
32	big endian	MSB	0	1	'B3 'B2 'B1 'B0
16	little endian	LSB	0	0	XX XX B1 B0
16	little endian	MSB	1	1	XX XX 'B0 'B1
16	big endian	LSB	1	0	XX XX B0 B1
16	big endian	MSB	0	1	XX XX 'B1 'B0
8	-	LSB	-	0	XX XX XX XX B0
8	-	MSB	-	1	XX XX XX XX 'B0

Original CRC Calculation Method			Equivalent Settings		Input to CRC calculation
Polynomial Width(bits)	Byte Order	Bit Order(MSB/LSB first)	BYTEREVERSE Setting	BITREVERSE Setting	
Notes: 1. X indicates a "don't care". 2. Bn is the byte field within the word. 3. 'Bn is the bit-reversed byte field within the word.					

## 26.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	GPCRC_CTRL	RW	Control Register
0x004	GPCRC_CMD	W1	Command Register
0x008	GPCRC_INIT	RWH	CRC Init Value
0x00C	GPCRC_POLY	RW	CRC Polynomial Value
0x010	GPCRC_INPUTDATA	W	Input 32-bit Data Register
0x014	GPCRC_INPUTDATAHWORD	W	Input 16-bit Data Register
0x018	GPCRC_INPUTDATABYTE	W	Input 8-bit Data Register
0x01C	GPCRC_DATA	R	CRC Data Register
0x020	GPCRC_DATAREV	R	CRC Data Reverse Register
0x024	GPCRC_DATABYTEREV	R	CRC Data Byte Reverse Register

26.5 Register Description

26.5.1 GPCRC\_CTRL - Control Register

Offset	Bit Position																																		
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reset																				0			0	0	0			0			0				
Access																				RW			RW	RW	RW			RW			RW			RW	0
Name																				AUTOINIT			BYTEVERSE	BITREVERSE	BYTEMODE			POLYSEL			EN				

Bit	Name	Reset	Access	Description
31:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13	AUTOINIT	0	RW	<b>Auto Init Enable</b>  Enables auto init by re-seeding the CRC result based on the value in INIT after reading of DATA, DATAREV or DATABYTEREV.
12:11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
10	BYTEREVERSE	0	RW	<b>Byte Reverse Mode</b>  Allows byte level reverse of bytes B3, B2, B1, B0 within the 32-bit data word
	Value	Mode	Description	
	0	NORMAL	No reverse: B3, B2, B1, B0	
	1	REVERSED	Reverse byte order. For 32-bit: B0, B1, B2, B3; For 16-bit: 0, 0, B0, B1	
9	BITREVERSE	0	RW	<b>Byte-level Bit Reverse Enable</b>  Reverses bits within each byte of the 32-bit data word
	Value	Mode	Description	
	0	NORMAL	No reverse	
	1	REVERSED	Reverse bit order in each byte	
8	BYTEMODE	0	RW	<b>Byte Mode Enable</b>  Treats all writes as bytes. Only the least significant byte of the data-word will be used for CRC calculation for all writes
7:5	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
4	POLYSEL	0	RW	<b>Polynomial Select</b>  Selects 16-bit CRC programmable polynomial or 32-bit CRC fixed polynomial
	Value	Mode	Description	
	0	CRC32	CRC-32 (0x04C11DB7) polynomial selected	
	1	16	16-bit CRC programmable polynomial selected	
3:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	EN	0	RW	<b>CRC Functionality Enable</b>  Enables CRC functionality.
	Value	Mode	Description	
	0	DISABLE	Disable CRC function. Reordering function is available, only BITREVERSE and BYTEREVERSE bits are configurable in this mode	
	1	ENABLE	Writes to inputdata registers result in CRC operations	

26.5.2 GPCRC\_CMD - Command Register

Offset	Bit Position																																
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31:0	DATABYTEREV	0x00000000	R	<b>Data Byte Reverse Value</b>  Byte reversed version of CRC Data register. When a 32-bit CRC polynomial is selected, the bytes are swizzled to {B0, B1, B2, B3}. When a 16-bit CRC polynomial is selected, the bytes are swizzled to {B2, B3, B1, B0}.

## 27. CRYPTO - Crypto Accelerator

### Quick Facts

#### What?

A fast and energy efficient autonomous hardware accelerator for AES encryption and decryption with 128- or 256-bit keys, ECC over prime and binary Galois finite fields, SHA-1, SHA-224 and SHA-256.

#### Why?

Efficient cryptography with little or no CPU intervention helps to meet the speed and energy demands of the application. Hardware implementations are generally more secure against side-channel attacks than software implementations.

#### How?

Programmable sequences of instructions on big numbers allow fast processing with little CPU intervention. Furthermore, CRYPTO is linked to the Buffer Controller (BUFC), thus enabling fast and efficient autonomous cipher operations on data buffer content.

### 27.1 Introduction

The CRYPTO module allows efficient acceleration of common cryptographic operations and allows these to be used efficiently with a low CPU load. Operations performed by CRYPTO can be set up as a sequence of instructions on a set of 128-bit, 256-bit or 512-bit registers to implement or accelerate Elliptic Curve Cryptography (ECC), SHA-1, SHA-224, SHA-256, and various block cipher modes based on the Advanced Encryption Standard, also known as AES (FIPS-197).

CRYPTO is capable of autonomously fetching data, performing cipher operations and storing data across multiple blocks. When the source data is not a multiple of 16 bytes (128 bits), Zero-padding can be included in the last block. Block operations such as Counter Mode (CTR), Electronic Code Book (ECB), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB) are easily implemented. Block Cipher modes of operation such as Electronic Code Book (ECB), Counter Mode (CTR), Cipher Block Chaining (CBC), CBC-MAC (CBC Message Authentication Code), CCM, (Counter with CBC-MAC) and GCM (Galois Counter mode) are easily implemented.

CRYPTO is delivered with an extensive software library in Simplicity Studio that implements all major cryptographic algorithms, including but not limited to AES, SHA-1, SHA-2, ECC, and legacy algorithms DES, 3DES, MD4, MD5 and RC4. The implementation accelerates the algorithms using CRYPTO when possible.

## 27.2 Features

- Efficient AES core
  - Encryption/decryption using 128-bit key (54 clock cycles) or 256-bit key (75 clock cycles)
  - Key buffer
  - Supports autonomous cipher block modes (e.g. ECB, CTR, CBC, PCBC, CFB, CBC-MAC, GMAC, CCM, CCM\* and GCM) across multiple blocks
- Accelerated SHA-1, SHA-224 and SHA-256
- Accelerated Elliptic Curve Cryptography (ECC)
  - Binary and Prime fields
  - Supports NIST recommended curves: P-192, P-224, P-256, K-163, K-233, B-163, and B-233
- Galois/Counter Mode (GCM)
  - ALU operations on GCM  $GF(2^{128})$  field
- Flexible 256-bit ALU and sequencer
  - 5 general purpose 256-bit registers
  - Supports ADD, SUB, MUL, shift, XOR, etc.
  - Up to 20 instructions can be chained to implement various block cipher modes
- Efficient operation
  - Automatic data loading and storing from registers (through BUFC, the buffer controller)
  - DMA request signals for data read and write
  - Optional XOR Data write
  - Interrupt on finished operations
- Extensive software support
  - Extensive software library in Simplicity Studio
  - Implements all major cryptographic algorithms: AES, SHA-1, SHA-2, and ECC
  - Implements legacy algorithms: DES, 3DES, MD4, MD5, and RC4
  - Hardware accelerated when possible

## 27.3 Usage and Programming Interface

Many security systems fail due to mistakes in the implementation. Therefore implementations should be left to experts in cryptographic algorithms.

To solve this, the module is supported by an hardened cryptography software library and API delivered through Silicon Labs' Simplicity Studio. The software API is a frontend for performing all supported cryptographic operations both for radio-protocols and applications, and must be used to receive prompt support.

27.4 Functional Description

A block diagram of the CRYPTO module is shown in [Figure 27.1 CRYPTO Overview on page 855](#).

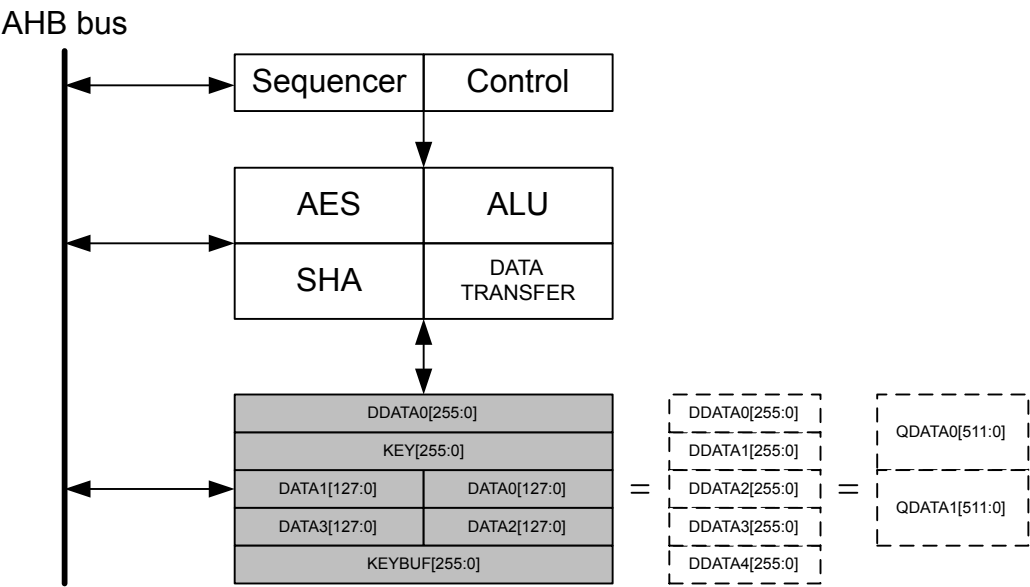

Figure 27.1. CRYPTO Overview

### 27.4.1 Data and Key Registers

The CRYPTO module contains five 256-bit registers. Accelerators are implemented through instructions operating on these registers, either by copying data between registers and external components like the BUFC or through DMA, or by executing instructions on the registers.

Depending on the instruction, the registers can be accessed as 128-bit, 256-bit or 512-bit registers. The registers can also be accessed through different interface registers to achieve different results.

When writing to and reading from the CRYPTO\_DATAx, CRYPTO\_KEY, CRYPTO\_KEYBUF, CRYPTO\_DDATAx and CRYPTO\_QDATAx registers, the least significant part is accessed first and the most significant part last, see [Figure 27.2 CRYPTO Data and Key Register Operation on page 857](#). The same is the case for the XOR and byte-access registers for DATA0 and DATA1. It is important to note that some of the 256-bit registers are composed of the 128-bit registers, and both the 512-bit registers are composed of the 256-bit registers.

**Note:** From here on, the 128, 256 and 512-bit registers are named DATAx, DDATAx, QDATAx, etc. And the access-points to these registers are named CRYPTO\_DATAx, CRYPTO\_DDATAx, CRYPTO\_QDATAx, etc.

DATA0 can be accessed through CRYPTO\_DATA0 (32-bit), CRYPTO\_DATA0XOR (32-bit), CRYPTO\_DATA0BYTE (8-bit) and CRYPTO\_DATA0XORBYTE (8-bit). Direct access to bytes 12 - 15 is available through CRYPTO\_DATA0BYTE12-15 (8-bit). The DATA0XOR (in CRYPTO\_DATA0XOR) is used for XOR'ing a value with the current value in DATA0. This is used in a large variety of block cipher modes. All of these registers operate on DATA0.

DATA1 can be accessed through CRYPTO\_DATA1 (32-bit) and CRYPTO\_DATA1BYTE (8-bit).

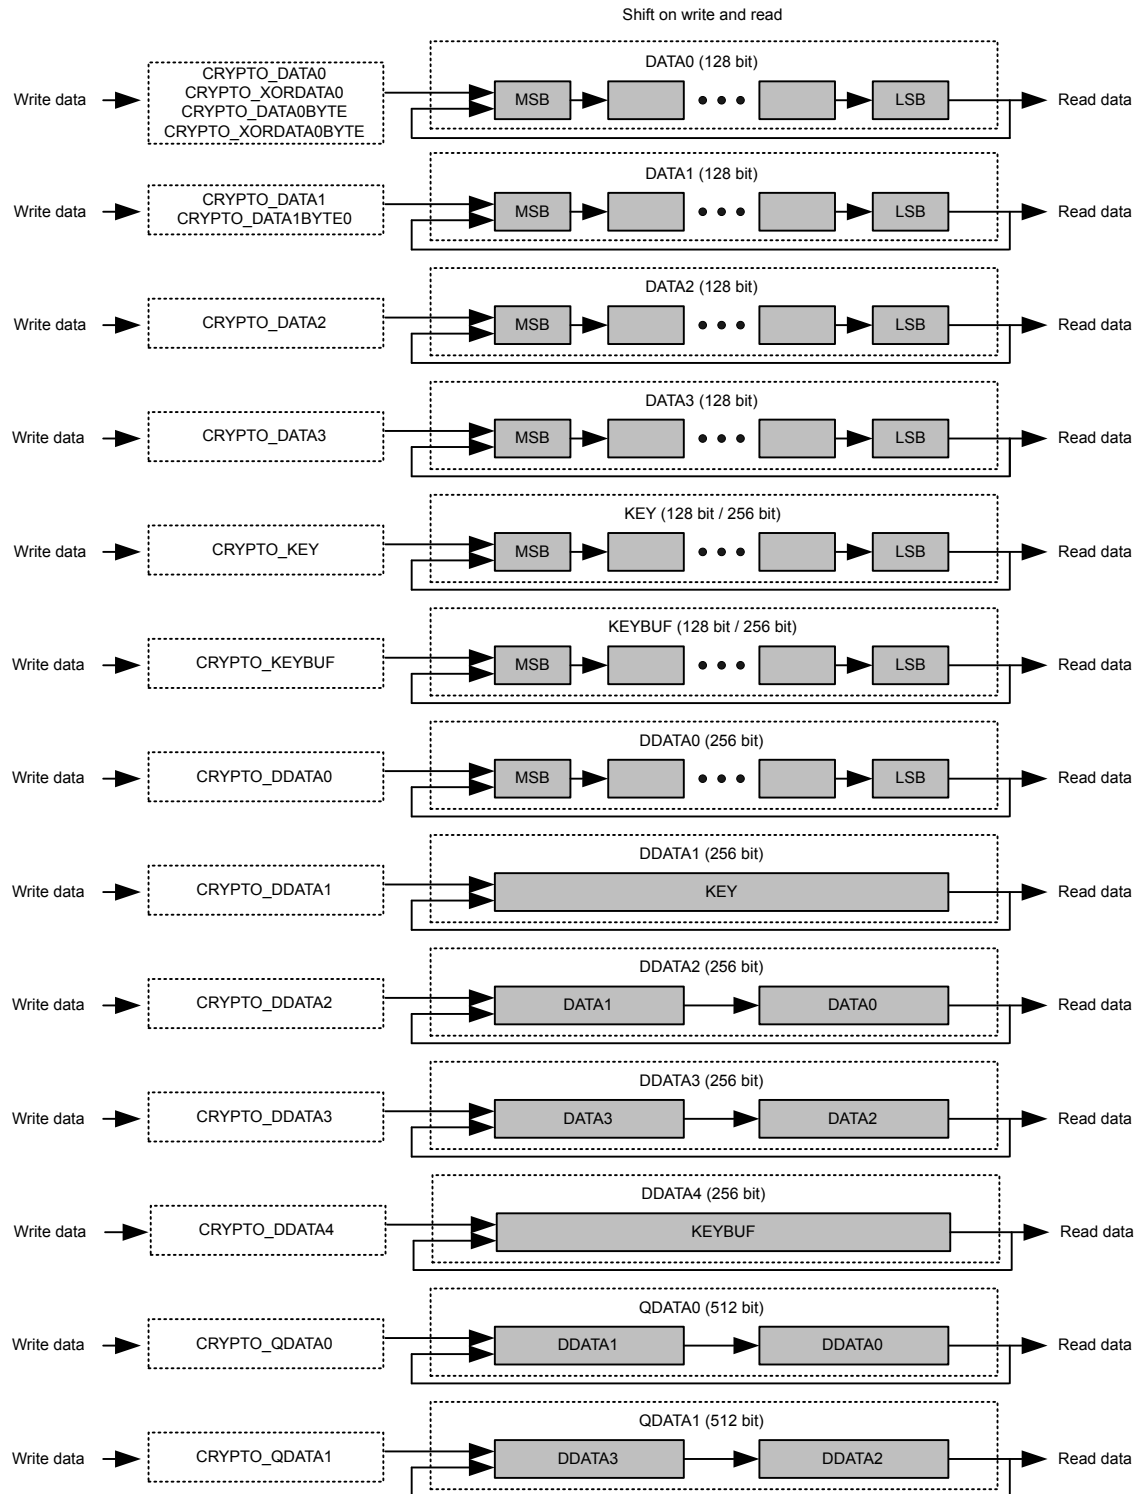

The remaining data registers have regular 32-bit access through their respective registers. Note that all data registers require a full read or write to be fully accessed. This means that the 128-bit registers need four 32-bit reads/writes, the 256-bit registers need 8 reads/writes and the 512-bit registers need 16 reads/writes. For a read, if all read accesses are not done, the register will end up as a shifted version of the original value.

**Note:** For byte-wise data accesses (DDATAxBYTE, DATAxBYTE, etc.), all reads and writes must be performed in groups of 4, due to internal buffering and shifting of 32 bits at a time. Accessing a number of bytes that is not a multiple of four can cause data incoherency in all of the data registers.

The KEY and KEYBUF registers are 256 bit wide when AES256 is set in CRYPTO\_CTRL. Else they are 128 bit wide. When used as a part of DDATAx and QDATAx, they are always 256 bit wide.

The registers DDATA0BIG and QDATA1BIG produce byte-swapped versions of DDATA0 and QDATA1 respectively. These may be used when a computation requires byte-swapping. An example of this is SHA computation, where data needs to be changed to big endian before CRYPTO can work with it. Little endian data is then loaded in through QDATA1BIG and the resulting little endian hash can be read out from DDATA0BIG, see [27.4.5 SHA](#).

Except for KEYBUF, the contents of all data registers are lost when going to EM2.

**Figure 27.2. CRYPTO Data and Key Register Operation**

#### 27.4.1.1 DATA0 Zero

DATA0ZERO in CRYPTO\_DSTATUS contains status flags indicating if any 32-bit blocks within DATA0 is 0. E.g. if DATA0[95:64] is equal to 0x00000000, ZERO64TO95 is set.

### 27.4.1.2 DDATA0 and DDATA1 Quick Observation

DDATA0LSBS in CRYPTO\_DSTATUS shows the 4 least significant bits in DDATA0. DDATA0MSBS in CRYPTO\_DSTATUS shows the 4 most significant bits of DDATA0, while DDATA1MSB in CRYPTO\_DSTATUS shows the msb of DDATA1. These observation bitfields are useful for determining the sign of the value in the data registers without having to read out the full register data register values

The 4 bits observed by DDATA0MSBS will change depending on RESULTWIDTH in CRYPTO\_WAC. When using 260-bit results, DDATA0MSBS shows bits 259-256, when using 256-bit results, it is bits 255-252, and for 128-bit results, bits 127-124 can be observed. When RESULTWIDTH is 260 bits, the 4 most significant bits, e.g. bits 259-256 are also available in CRYPTO\_DDATA0BYTE32, where they can also be written. Using this register is the only way of inputting the upper 4 bits of a 260-bit number to CRYPTO.

### 27.4.1.3 Result Width

RESULTWIDTH in CRYPTO\_WAC determines the width of the operation when performing arithmetic/shift instructions with CRYPTO. Using less wide results will reduce the current consumption of the CRYPTO module. The higher-order bits that are beyond the selected result width are ignored in the computation of arithmetic/shift operations, however, these higher-order bits will be undefined in the result of such instructions.

When RESULTWIDTH=260BIT, all DDATA registers effectively become 260 bits wide, so that the upper 4 bits are not lost when transferring data from DDATA0 to the other DDATA registers. Likewise, the arithmetic/shift instructions shall consider the full 260-bit values of DDATA0-DDATA4 when used as operation inputs. Note that DDATA0 is the only 260-bit register of which MSBs can be observed/written. The upper 4 bits are observed through DDATA0MSBS in CRYPTO\_DSTATUS or through CRYPTO\_DDATA0BYTE32. For all DDATAx registers, the extra MSBs are cleared when DDATAx is written. Furthermore, for a particular x, a write to DDATAx or any of its aliased registers will cause DDATAx MSBs to be cleared. Note, writing to KEY/KEYBUF will only clear MSBs of DDATA1/DDATA4 when AES256 mode is set. Likewise, writing to DATA0/DATA2 will not clear DDATA2/DDATA3 MSBs.

Since the DATA0-DATA3 registers are always 128-bit, all bit positions greater than 128 are interpreted as 0 when RESULTWIDTH is greater than 128 bits. However, the assignment instructions DATAxTODDATAy will not zero-out the upper 128 bits of the DDATAy target. Instead, those upper words become undefined after such operations.

## 27.4.2 Instructions and Execution

The CRYPTO module implements a set of instructions in order to load and manipulate data effectively. These instructions are grouped into four types:

- ALU instructions - arithmetic and logical bitwise operations
- Transfer instructions - moving data between registers and external peripherals like DMA and the BUFC
- Conditional instructions - conditionally execute instructions based on context
- Special instructions - various crypto and support instructions

A single instruction can be executed by writing INSTR in CRYPTO\_CMD. This will execute the instruction, and the interface of CRYPTO will be locked until the execution has completed. Multiple commands can safely be issued after each other by the CPU as long as NOBUSYSTALL in CRYPTO\_CTRL is not set. If CRYPTO gets a new command or a data access request while busy it will then stall the bus, and execute the new command as soon as it is done with the previous one. Note, there are some exceptions to this rule. For example, see [27.4.8 DMA](#).

Stalling of the bus can be disabled by setting NOBUSYSTALL in CRYPTO\_CTRL, however manipulating (reading or writing) registers while running a sequence will result in undefined behaviour. Additionally, if NOBUSYSTALL=0 and a new command or data access request is made while the Crypto is simultaneously performing a data transfer sequence, it is possible for system lockup due to bus stalling loops. The safest approach is to always check if an instruction is running by looking at INSTRRUNNING in CRYPTO\_STATUS.

### 27.4.2.1 Sequences

For executing a set of instructions it is however more efficient to load them into the CRYPTO module and run them as a sequence. This is done by writing the instructions into CRYPTO\_SEQ0-CRYPTO\_SEQ4, and marking the end of the instruction sequence with either an END or an EXEC instruction. The END simply means end-of-instructions, while writing EXEC means end-of-instructions and execute immediately.

The five registers allow up to 20 instructions to be loaded. To start execution, either end the instructions with an EXEC instruction, or set SEQSTART in CRYPTO\_CMD. CRYPTO will then execute the instructions, starting in CRYPTO\_SEQ0, and ending at the first END instruction. SEQRUNNING in CRYPTO\_STATUS is set while the sequence is running, and the interrupt flag SEQDONE in CRYPTO\_IF will be set when the sequence has completed.

A sequence can be stopped by issuing the SEQSTOP command in the CRYPTO\_CMD register. This command also clears the state of ongoing CRYPTO instructions including DMA and BUFC access. Check SEQRUNNING in CRYPTO\_STATUS after issuing the SEQSTOP command flag to make sure any ongoing sequence/transfer has completed before accessing data registers again.

### 27.4.2.2 Available Instructions

The available ALU instructions are listed in [Table 27.1 ALU Instructions on page 859](#), data transfer instructions are listed in [Table 27.2 Transfer Instructions on page 860](#), conditional instructions are listed in [Table 27.3 Conditional Instructions on page 861](#) and special instructions are listed in [Table 27.4 Special Instructions on page 861](#). The tables explain the side-effects of the instructions and shows which registers are affected. For instructions involving BUFC, the BUFC Buffers are defined by READBUFSEL and WRITEBUFSEL in CRYPTO\_CTRL for BUFC reads and writes respectively. V0 and V1 in the instructions descriptions can be any of the DDATAx registers and a selection of the DATAx registers. They can be selected using the SELDDATAxDDATAy, SELDATAxDDATAy, SELDDATAxDATAy and SELDATAxDATAy instructions. The first register in the instruction will be selected for V0, and the second for V1. This configuration stays even when the sequence is complete, and can also be set up front. The currently selected V0 and V1 can be read V0 and V1 in CRYPTO\_CSTATUS.

**Table 27.1. ALU Instructions**

Instruction	Description	Constraints/Notes
ADD	$DDATA0 = V0 + V1$	If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$
ADDO	$DDATA0 = V0 + V1$	Carry is only set, not cleared If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$
ADDC	$DDATA0 = V0 + V1 + \text{carry}$	If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$
ADDIC	$DDATA0 = V0 + V1 + \text{carry} \ll 128$	If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$ If resultwidth is 128b, then carry is undefined
MADD	$DDATA0 = (V0 + V1) \bmod P$	If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$
MADD32	$DDATA0[i] = V0[i] + V1[i]$ Word-wise addition	carry is not modified If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$
SUB	$DDATA0 = V0 - V1$	$V1 \neq DDATA0$ If $V1$ is 128b and resultwidth > 128b, then upper 128b are unknown
SUBC	$DDATA0 = V0 - V1 - \text{carry}$	$V1 \neq DDATA0$ If $V1$ is 128b and resultwidth > 128b, then upper 128b are unknown
MSUB	$DDATA0 = (V0 - V1) \bmod P$	$V1 \neq DDATA0$ If $V1$ is 128b and resultwidth > 128b, then upper 128b are unknown
MUL	$DDATA0 = DDATA1 * V1$ See <a href="#">27.4.2.3 MULx details</a>	$V1 \neq DDATA0, DDATA1$
MULC	$DDATA0 = DDATA1 * V1 + (DDATA0 \ll \text{MULWIDTH})$ See <a href="#">27.4.2.3 MULx details</a>	$V1 \neq DDATA0, DDATA1$
MMUL	$DDATA0 = (DDATA1 * V1) \bmod P$	$V1 \neq DDATA0, DDATA1$
MULO	$DDATA0 = DDATA1 * V1$ See <a href="#">27.4.2.3 MULx details</a>	$V1 \neq DDATA0, DDATA1$ . Carry is only set, not cleared
SHL	$DDATA0 = V0 \ll 1$	If $V0$ is 128b and resultwidth is 260b, then upper 4b are unknown
SHLC	$DDATA0 = V0 \ll 1 \mid \text{carry}$	If $V0$ is 128b and resultwidth is 260b, then upper 4b are unknown
SHLB	$DDATA0 = V0 \ll 1 \mid V0[\text{resultwidth}-1]$	If $V0$ is 128b and resultwidth is 260b, then upper 4b are unknown
SHL1	$DDATA0 = V0 \ll 1 \mid 1$	If $V0$ is 128b and resultwidth is 260b, then upper 4b are unknown
SHR	$DDATA0 = V0 \gg 1$	
SHRC	$DDATA0 = V0 \gg 1 \mid \text{carry} \ll \text{resultwidth}-1$	
SHRB	$DDATA0 = V0 \gg 1 \mid V0[0] \ll \text{resultwidth}-1$	
SHR1	$DDATA0 = V0 \gg 1 \mid 1 \ll \text{resultwidth}-1$	

Instruction	Description	Constraints/Notes
SHRA	$DDATA0 = V0 \gg 1 \mid V0[resultwidth-1] \ll resultwidth-1$	
CLR	$DDATA0 = 0$	
XOR	$DDATA0 = V0 \wedge V1$	If $V0 \neq DDATA0$ , then $V1 \neq DDATA0$
INV	$DDATA0 = \sim V0$	
CSET	$CARRY = 1$	
CCLR	$CARRY = 0$	
BBSWAP128	$DDATA0[127:0] = bbswap(V0[127:0])$	See <a href="#">27.4.2.5 BBSWAP128 instruction</a>
INC	$DDATA0 = DDATA0 + 1$	
DEC	$DDATA0 = DDATA0 - 1$	

**Table 27.2. Transfer Instructions**

Instruction	Operation	Constraints/Notes
DATAxTOBUF	$BUFC = DATAx$	$x = 0,1$ . BUFC buffer defined by WRITE-BUFSEL
DATAxXORBUF	$BUFC = BUFC \wedge DATAx$	$x = 0,1$ . BUFC buffer defined by WRITE-BUFSEL
BUFTODATAx	$DATAx = BUFC$	$x = 0,1$ . BUFC buffer defined by READ-BUFSEL
BUFDATA0XOR	$DATA0 = DATA0 \wedge BUFC$	BUFC buffer defined by READBUFSEL
DATATODMA0	$DMA = DATAx$ , DMA request DMA0RD	$DATAx = DATA0$ , $DDATA0$ , $DDATA0BIG$ , $QDATA0$ as defined by DMA0RSEL
DMA0TODATA	$DATAx = DMA$ , DMA request DATA0WR	$DATAx = DATA0$ , $DDATA0$ , $DDATA0BIG$ , $QDATA0$
DMA0TODATAxor	$DATA0 = DATA0 \wedge DMA$ , DMA request DATA0XORWR	
DATATODMA1	$DMA = DATAx$ , DMA request DMA1RD	$DATAx = DATA1$ , $DDATA1$ , $QDATA1$ , $QDATA1BIG$ as defined by DMA1RSEL
DMA1TODATA	$DATAx = DMA$ , DMA request DATA0WR	$DATAx = DATA1$ , $DDATA1$ , $QDATA1$ , $QDATA1BIG$
DATAxTODATAy	$DATAy = DATAx$	
DATAxTODATA0XOR	$DATA0 = DATA0 \wedge DATAx$	If resultwidth is 128b, then carry is undefined
DATAxTODATA0XORLEN	$DATA0 = DATA0 \wedge (DATAx \& (2^{**LENGTH}-1))$	LENGTH is LENGTHA or LENGTHB depending on active part of sequencelf resultwidth is 128b, then carry is undefined
DDATAxTODDATAy	$DDATAy = DDATAx$	
DDATAxHTODATA1	$DATA1 = DDATAx[255:128]$	Bits $DDATA2[259:256]$ become undefined
DDATAxLTODATAy	$DATAy = DDATAx[127:0]$	
SELDDATAxDDATAy	Use DDATAx as V0, DDATAy as V1	$x = 0,1,2,3,4$ ; $y = 0,1,2,3,4$
SELDATAxDDATAy	Use DATAx as V0, DDATAy as V1	$x = 0,1,2$ ; $y = 0,1,2,3,4$
SELDDATAxDATAy	Use DDATAx as V0, DATAy as V1	$x = 0,1,2,3,4$ ; $y = 0,1$

Instruction	Operation	Constraints/Notes
SELDATAxDATAy	Use DATAx as V0, DATAy as V1	x = 0,1,2; y = 0,1

**Table 27.3. Conditional Instructions**

Instruction	Operation	Constraints
EXECIFA	Execute following instructions if in part A of sequence	
EXECIFB	Execute following instructions if in part B of sequence	
EXECIFNLAST	Execute following instructions if not in last iteration of sequence	
EXECIFLAST	Execute following instructions if in last iteration of sequence	
EXECIFCARRY	Execute following instructions if carry bit is set	
EXECIFNCARRY	Execute following instructions if carry bit not is set	
EXECALWAYS	Always execute following instructions	

**Table 27.4. Special Instructions**

Instruction	Operation	Constraints
END	Ends execution.	
EXEC	When written to CRYPTO_SEQx register, automatically triggers execution of all instruction up to this point.	
AESENC	DATA0 = AESENC(DATA0)	
AESDEC	DATA0 = AESDEC(DATA0)	
SHA	DDATA0 = SHA(Q1)	
DATA1INC	DATA1 = inc(DATA1)See <a href="#">27.4.2.4 DATA1INC and DATA1INCCLR instructions</a>	
DATA1INCCLR	DATA1 = clearinc(DATA1)See <a href="#">27.4.2.4 DATA1INC and DATA1INCCLR instructions</a>	

### 27.4.2.3 MULx details

For the MULx instructions (not MMUL), MULWIDTH in CRYPTO\_WAC specifies the width of operands DDATA1 (and sometimes V1). This is useful in order to optimize performance because multiplications take the same number of cycles as the bits in the operands plus a couple of cycles for setup.

As for the other ALU instructions, RESULTWIDTH limits the width of the final result of the MULx and MMUL instructions.

### 27.4.2.4 DATA1INC and DATA1INCCLR instructions

DATA1INC and DATA1INCCLR operate on the 1, 2, 3 or 4 most significant bytes in DATA1, depending on INCWIDTH in CRYPTO\_CTRL. DATA1INC increments these bytes in big endian, while DATA1INCCLR clears the bytes.

### 27.4.2.5 BBSWAP128 instruction

The BBSWAP128 instruction copies the contents of the V0 operand to DDATA0 while swapping the bits of the lower 16 bytes. The operand is not changed. This operation is required for GCM. See [27.4.7 GCM and GMAC](#)

### 27.4.2.6 Carry

The carry output from most instructions can be observed through CARRY in CRYPTO\_DSTATUS. Shift-instructions set CARRY to the value that is shifted out of the register, addition and multiplication set it on register overflow, and subtraction sets it on borrow, e.g. underflow.

In addition to generating carry information, some instructions also use the current value of CARRY. ADDC, SUBC, SHLC and SHRC all use carry to generate the result. For all of these instructions, carry allows a program to chain instructions together to operate on bigger numbers than allowed by CRYPTO. E.g. by chaining first an ADD, and then an ADDC which uses the carry from the ADD operation, one can add two 512-bit numbers. By chaining more instructions, even larger numbers can be manipulated.

Other uses of CARRY include observation. To check if a register is 0, one can subtract 1 using the DEC instruction, and check if goes negative by checking the CARRY bit. CARRY can be set manually and in CRYPTO programs using the CSET and CCLR instructions, which set and clear the CARRY bit.

The MULC instruction does not use CARRY like the other C(arry) instructions, but rather preserves the old contents of the multiplication register

## 27.4.3 Repeated Sequence

To maximize efficiency, it is desirable to be able to run a set of instructions over multiple blocks of data autonomously. To repeat a sequence over a larger set of data, set LENGTHA in CRYPTO\_SEQCTRL to the number of bytes in the set, and BLOCKSIZE to the size of the blocks in the set. The sequence will then be repeated N times, where N is LENGTHA / BLOCKSIZE if LENGTHA is a multiple of BLOCKSIZE, or ceiling( LENGTHA / BLOCKSIZE ) if not. In the latter case, data written by DMA or received from BUFC will be zero-padded up to BLOCKSIZE if it is written to a register which has a size equal to BLOCKSIZE. One notable exception is when LENGTHA is 0. In this case the sequence will still execute once, but the block transfer instructions will not execute.

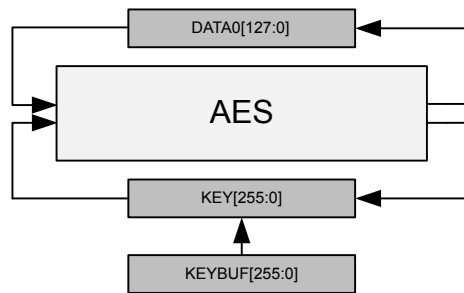

**Note:** If DMAxRSEL in CRYPTO\_CTRL selects a register that is smaller than the specified blocksize, DATATODMAx/DMAxTODATA instructions will not use the full blocksize, but will only transfer enough data to empty/fill the register once. For example, if BLOCKSIZE is set to 64B and DMA0RSEL=DDATA0, the instruction DATATODMA0 will only read 32B instead of 64B. The processing of LENGTHA/B will continue as if all 64B had been transferred.

A repeated sequence can also be made do slightly different operations on different parts of the data set. A sequence can be divided into two parts; part A, and part B. By configuring LENGTHA in CRYPTO\_SEQCTRL to the length of part A, and LENGTHB in CRYPTO\_SEQCTRLB to the length of part B, CRYPTO will first run iterations over part A, knowing it is A, and then part B, knowing it is part B. By using the conditional instructions listed in [Table 27.3 Conditional Instructions on page 861](#), a program can execute different instructions depending on whether it is in part A or part B.

#### 27.4.4 AES

The AES core operates on data in the 128-bit register DATA0 using the either a 128-bit or 256-bit key from the KEY register. The key width is specified by AES256 in CRYPTO\_CTRL. AES operations are implemented as the AESENC and AESDEC instructions, for AES encryption and AES decryption respectively. An overview of the AES functionality is shown in [Figure 27.3 CRYPTO AES Overview on page 863](#).

AES encryption and decryption enables various block cipher modes like ECB, CTR, CBC, PCBC, CFB, OFB, CBC-MAC, GMAC, CCM, CCM\*, and GCM.

**Figure 27.3. CRYPTO AES Overview**

The input data before encryption is called the PlainText and output from the encryption is called CipherText. For encryption, the key is called PlainKey. After encryption, the resulting key in the KEY registers is the CipherKey. This key must be loaded into the KEY registers prior to the decryption. After one decryption, the resulting key will be the PlainKey. The resulting PlainKey/CipherKey is only dependent on the value in the KEY registers before encryption/decryption. The resulting keys and data are shown in [Figure 27.4 CRYPTO Key and Data Definitions on page 863](#).

**Figure 27.4. CRYPTO Key and Data Definitions**

The KEY is by default loaded from KEYBUF prior to each AESENC or AESDEC instruction. If the KEY is not to be overwritten, key buffering should be disabled (KEYBUFDIS in CRYPTO\_CTRL). Disabling key buffering also allows the use of key loading through DMA.

The data and key orientation in the CRYPTO registers are shown in [Figure 27.5 CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard on page 864](#).

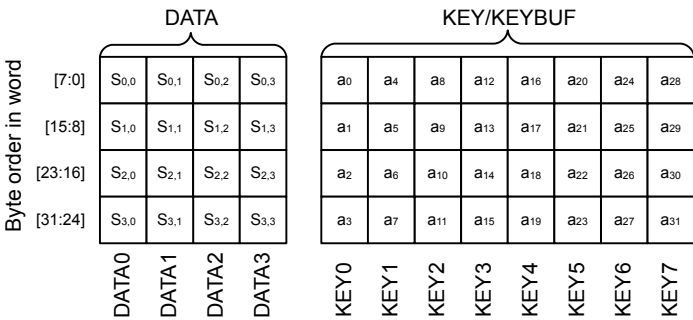

Figure 27.5. CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard

### 27.4.5 SHA

The CRYPTO SHA instruction implements SHA-1 with a 160-bit digest or SHA-2 with a 224-bit digest (SHA-224) or 256-bit digest (SHA-256). Depending on SHAMODE in CRYPTO\_CTRL, SHA-1, SHA-224 or SHA-256 will be run on the data in QDATA1, and the result will be put on DDATA0. The contents in QDATA1 will be destroyed in the process.

To run SHA on a dataset, it must first be pre-processed by appending a bit '1' to the message, then padding the data with '0' bits until the message length in bits modulo 512 is 448. Then append the length of the message before pre-processing as a 64-bit big-endian integer. This pre-processing is known as MD-strengthening, and must be done by software before processing with the CRYPTO module.

The pre-processed data can now be run through the CRYPTO module. Begin by writing the values listed in [Table 27.5 SHA Init Values on page 865](#) to CRYPTO\_DDATA1 from top to bottom, then execute the instructions listed in [Table 27.6 SHA Preparations on page 865](#).

**Table 27.5. SHA Init Values**

SHA-1	SHA-224	SHA-256
0x67452301	0xC1059ED8	0x6A09E667
0xEFCDAB89	0x367CD507	0xBB67AE85
0x98BADCFE	0x3070DD17	0x3C6EF372
0x10325476	0xF70E5939	0xA54FF53A
0xC3D2E1F0	0xFFC00B31	0x510E527F
0x00000000	0x68581511	0x9B05688C
0x00000000	0x64F98FA7	0x1F83D9AB
0x00000000	0xBEFA4FA4	0x5BE0CD19

**Table 27.6. SHA Preparations**

STEP	ACTION	Description
STEP0	DDATA1TODDATA0	Copy init data to DDATA0
STEP1	SELDDATA0DDATA1	Select DDATA0 and DDATA1 as operands for SHA instruction

Then, for each 512-bit block, write the block to CRYPTO\_QDATA1BIG, execute the instructions listed in [Table 27.7 SHA for 512-bit Block on page 865](#).

**Table 27.7. SHA for 512-bit Block**

STEP	ACTION	Description
STEP0	SHA	Perform SHA operation on data in QDATA1
STEP1	MADD32	Accumulate with previous data in DDATA1
STEP2	DDATA0TODDATA1	Copy hash to DDATA1

After the last iteration, the resulting hash can be read out from CRYPTO\_DDATA0BIG.

### 27.4.6 ECC

The CRYPTO module implements support for Elliptic Curve Cryptography through the modular instructions MADD, MMUL and MSUB, which perform modular addition, multiplication and subtraction respectively. The instructions can operate on a set of both prime fields GF(p) and binary fields GF(2<sup>m</sup>).

The type of modular arithmetic used and the modulus for the modular operations are specified by MODOP and MODULUS in CRYPTO\_WAC respectively. Changing these in the middle of an operation leads to undefined behaviour.

### 27.4.7 GCM and GMAC

CRYPTO implements support for Galois/Counter Mode (GCM), and also Galois Message Authentication Code (GMAC), by providing AES instructions and allowing multiplication on the field  $GF(2^{128})$  defined by the polynomial  $x^{128} + x^7 + x^2 + x + 1$ .

**Note:** BBSWAP128 needs to be applied to both operands and the result of the MMUL instruction when using it for GCM and GMAC

Efficient sequencer programs can be set up to perform GCM authentication and encryption/decryption on data from either BUFC, DMA, or CPU. To achieve a single-pass solution, LENGTHA in CRYPTO\_SEQCTRL is set to the length of the authentication part, and LENGTHB is set to the length of the rest of the message. Conditional instructions can then be used to make sure the two parts of the message are processed correctly. A similar approach is used to implement CCM.

### 27.4.8 DMA

The CRYPTO module has 5 DMA request signals (see [Table 27.8 DMA Signals on page 866](#)) split over 2 internal DMA channels: DMA0 and DMA1. These DMA channels are not associated with channel 0 and 1 of the system DMA, and any system DMA channel can serve any of the 5 DMA requests. See the DMA chapter for information on how to configure the system DMA.

The DMA signals are set through the use of DMA oriented instructions, and cleared by reading or writing the respective CRYPTO data registers.

**Table 27.8. DMA Signals**

Name	Set on	Cleared on
DMA0WR	Instruction DMA0TODATA, and DMA0TODATA XOR if COMBDMA0WEREQ in CRYPTO_CTRL is set.	Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 write, or CRYPTO_DDATA0XOR if COMBDMA0WEDMAREQ in CRYPTO_CTRL is set.
DMA0XORWR	Instruction DMA0TODATA XOR	Full CRYPTO_DATA0XOR write
DMA0RD	Instructions DATATODMA0	Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 read, depending on DMA0MODE in CRYPTO_CTRL
DMA1WR	Instructions DMA1TODATA	Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG write
DMA1RD	Instructions DATATODMA1	Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG read, depending on DMA1MODE in CRYPTO_CTRL

**Note:** DMAxRSEL in CRYPTO\_CTRL has to be set to the data registers that are to be read using the respective DMA channels on a DATATODMAx instruction. As an important note, DMAxRSEL in CRYPTO\_CTRL selects what is read from **any** of the selectable read registers during an ongoing DATATODMAx transfer (verify for accuracy).

When a DMA oriented CRYPTO instruction is used (either through a STEP in a Sequence or through CRYPTO\_CMD), the corresponding DMA signal is set. The instruction is complete when the entire source/destination is read/written (e.g. if DMA0TODATA is used, the operation is complete when a total of 128 valid bits have been written through the CRYPTO\_DATA0 register). DMAACTIVE in CRYPTO\_STATUS is set while CRYPTO is working on a DMA-related instruction, e.g. waiting for the DMA to read or write data to CRYPTO (see [27.4.8.1 DMA Initial Bytes Skip](#)).

Normally, when a sequence or instruction is executed, access to most CRYPTO registers will stall the CPU or DMA that is trying to access CRYPTO until the operation is done, preventing accesses to CRYPTO that could potentially interfere with an operation. During DMA operations, all non-dma registers are writeable and readable, but progress through the DMA operation will only be tracked with the registers targetted by the DMA operation. I.e. if the DMA operation is supposed to transfer 3 words to DATA0, the DMA can first choose to transfer data to e.g. DATA3, and then fulfill the transfer to DATA0.

Because the bus interface to CRYPTO is normally locked outside of DMA transfers, a wrongly set up DMA transfer, that for example transfer one byte too many might lock up the interface. One way to assist in debugging such issues can be setting NOBUSYSTALL in CRYPTO\_CTRL. This will prevent any stall on CRYPTO register accesses during sequences and instructions. Use this option with care, as modifying a register that is being used by CRYPTO can lead to undefined behavior

### 27.4.8.1 DMA Initial Bytes Skip

The DMA must be configured to use 32-bit transfer size. This normally would imply that the source data must be aligned to a 4 byte address boundary. However, it is possible to skip the initial bytes (1 to 3) when using DMA to write to DATA0 or DATA1 through a CRYPTO instruction operation. The number of bytes to skip are set in DMA0SKIP and DMA1SKIP in CRYPTO\_SEQCTRL. This implies that if DMA0SKIP is set to another value than 0, the initial DMA access will require 5 DMA transfers, even though only 4x32-bit is required.

**Note:** Any valid unused bytes from a previous DMA write will be used before new DMA data is requested. This data is invalidated by using STOP in CRYPTO\_CMD.

### 27.4.8.2 DMA Unaligned Read/Write

Except for DATA0 and DATA1, which can be loaded byte-wise using the CRYPTO\_DATA0BYTE, CRYPTO\_DATA0XORBYTE and CRYPTO\_DATA1BYTE registers, the CRYPTO data registers are loaded 32-bits at a time. In most cases this is ok, but the DMA does not directly support 32-bit unaligned accesses, so if the data buffer is not aligned to 32-bit and DMA is being used, special care must be taken.

As an example, let an in-memory 16-byte data buffer start at address  $4*N + M$  and end at the byte before  $4*N + 16 + M$ , where  $M$  is between 0 and 3 inclusive. With an  $M=0$ , we have fully aligned accesses, and everything is fine. For  $M>0$  however, the access is unaligned. If  $M=1$ , that means that the first 32-bit aligned word of the memory buffer contains 1 byte before the buffer, and 3 bytes of the buffer. Similarly, the last 32-bit aligned word of the memory buffer contains the last byte of the buffer, and three bytes after the buffer.

When doing an unaligned read, we want to only pass the 16 bytes of the buffer to the CRYPTO module. Not the  $N$  bytes before in the 32-bit aligned word, and not the  $4-N$  words at the end. To achieve this, set  $DxDMAREADMODE$  in CRYPTO\_CTRL to either UNALIGNEDFULL or UNALIGNEDLENLIMIT, and set  $DATAxDMASKIP$  in CRYPTO\_SEQCTRL equal to  $N$ . When reading in data using a DMA-oriented instruction to  $DATAx$ ,  $DDATAx$  or  $QDATAx$ , the read will now only contain the 16 bytes, and not the  $N$  bytes before or  $4-N$  words after. Note that in this case, the DMA has to be set up to transfer 5 32-bit words instead of the effective 4.

Being able to read unaligned data does not solve all cases however. If data is to be written back to the buffer after passing through CRYPTO, e.g. when doing an in-place encryption or decryption, it is very undesirable to actually modify the  $N$  bytes before and  $4-N$  bytes after the buffer. This is solved using the UAR-suffixed registers in CRYPTO when reading data out from the CRYPTO module, e.g. CRYPTO\_DATA0UAR, CRYPTO\_DATA1UAR, CRYPTO\_DDATA0UAR, CRYPTO\_DDATA1UAR, CRYPTO\_QDATA0UAR, etc. When an unaligned buffer is written to a CRYPTO buffer, CRYPTO stores the  $N$  first bytes and the  $4-N$  last bytes internally. When reading out from an UAR register, these bytes are placed back into the data if  $DATAxDMAPRES$  is set in CRYPTO\_SEQCTRL.

Note that the latter case only works if the first  $N$  and the last  $4-N$  bytes are not changed while CRYPTO works on the data. Internally CRYPTO has 2 buffers for the bytes before and after. The first one is connected to read/write of the DATA0, DDATA0 and QDATA0 registers, and the second is connected to the DATA1, DDATA1 and QDATA1 registers.

If  $DMAxRMODE$  in CRYPTO\_CTRL is set to FULL or UNALIGNEDFULL and the corresponding  $DMAxPRES$  in CRYPTO\_SEQCTRL is set, then a whole number of data buffers have to be written by the DMA. In all other cases, it is enough to write the number of 32-bit words to pass all LENGTH bits to the target CRYPTO buffer.

### 27.4.9 BUFC Data Transfer

To allow automatic encryption/decryption or other operations on radio data, CRYPTO has instructions for moving data from and to BUFC, the Buffer Controller. Both DATA0 and DATA1 can be loaded with data from the buffer selected by READBUFSEL (CRYPTO\_CTRL register) as shown in [Figure 27.6 CRYPTO BUFC Data Transfer on page 868](#). Similarly, the content of DATA0 and DATA1 can be written to the buffer selected by WRITEBUFSEL (also in the CRYPTO\_CTRL register).

**Figure 27.6. CRYPTO BUFC Data Transfer**

When reading from CRYPTO to the BUFC, the number of bytes read are determined by the DMAxRMODE configuration in CRYPTO\_CTRL. If it is set to either LENLIMIT or LENLIMITBYTE, only the number of bytes given by LENGTH in CRYPTO\_SEQCTRL are transferred. Else the full width of the last buffer is also written, e.g. a full number of 16-byte buffers are written to the BUFC.

**Note:**

The buffer selected by READBUFSEL and WRITEBUFSEL in the CRYPTO\_CTRL registers must be appropriately configured in the BUFC module prior to using instructions involving BUFC.

All BUFC reads start at the current BUFC read pointer, and move the pointer according to the number of bytes read. BUFC writes normally also work in the same way, starting at the current BUFC write pointer, and moving it the right number of positions. For BUFC XOR writes, software has the option to change this by setting either of DATAxTOBUF XORROW in CRYPTO\_CTRL. With this bit set, the BUFC write pointer will be reset to the start of the previous write before writing to the BUFC. Using this feature, BUFC data can be written with using the DATAxTOBUFC instructions, and then XOR'ed with another set of data using the DATAxTOBUFCXOR instruction.

BUFACTIVE in CRYPTO\_STATUS is set while CRYPTO is reading or writing from/to the BUFC.

#### 27.4.10 Debugging

There are multiple ways of debugging CRYPTO sequences. The most straight-forward way is to write individual instructions to INSTR in CRYPTO\_CMD. An instruction can be written, and data can be read out and examined before running another instruction.

Running individual instructions to debug a program falls short when working with repeated sequences. In these cases, a sequence is run multiple times over a set of data. This cannot be directly replicated with individual instructions.

To debug a sequence, set HALT in CRYPTO\_SEQCTRL. When set, CRYPTO requires software or the debugger to step it through each instruction in the sequence. To step through the sequence, set SEQSTEP in CRYPTO\_CMD. This will execute the current instruction, and make CRYPTO ready to execute the next one.

When stepping through a sequence, the current instruction index can be read from SEQIP in CRYPTO\_CSTATUS. SEQSKIP, also in CRYPTO\_CSTATUS, tells whether the next instruction will be executed or not, based on previous conditionals in the program. SEQPART in CRYPTO\_CSTATUS shows whether CRYPTO is currently in part A or B of a sequence. Even with NOBUSYSTALL in CRYPTO\_CTRL cleared, read and write accesses to CRYPTO will be allowed when CRYPTO is waiting to be stepped. This is to allow data registers to be inspected during debugging.

**Note:** The data registers in Crypto (those marked read-actionable) require shifting of data in order to return the result. For this reason, reading these registers will have no effect and will return unknown values during normal debugger read accesses (see [7.3.6 Debugger reads of actionable registers](#)).

#### 27.4.11 Example: Cipher Block Chaining (CBC)

In the following the setup and operation of CBC is explained and illustrated. The example can easily be adjusted to perform other cipher block modes.

### 27.4.11.1 CBC Encryption

In CBC encryption, the cipher input is the plaintext XOR'ed with the previous cipher output (an initialization vector IV is used during the first block). This mode is easily implemented using the CRYPTO instruction sequence BUFDATA0XOR, AESENC then DATA0TOBUF. The BUFDATA0XOR reads data from the buffer set by READBUFSEL and XOR's it with the content in DATA0. Then the cipher operation is performed and subsequently the DATA0TOBUF writes the content of DATA0 to the buffer set by WRITEBUFSEL (normally the same as READBUFSEL).

Prior to the operation, the initialization vector IV and key must be loaded to DATA0 and KEYBUF, respectively. Additionally, the total number of bytes to be included in the repeated sequence must be set in LENGTHA in CRYPTO\_SEQCTRL. Finally, the buffers selected by READBUFSEL and WRITEBUFSEL must be configured correctly in the BUFC. The sequence is started by issuing the SEQ-START command in CRYPTO\_CMD.

In [Figure 27.7 CBC Encryption Operation on page 870](#) the CBC encryption is illustrated and in [Table 27.9 CBC Encryption Steps on page 870](#) each step in the loop is explained.

CBC Encryption

Figure 27.7. CBC Encryption Operation

Table 27.9. CBC Encryption Steps

STEP	ACTION	Description
STEP0	BUFDATA0XOR	Move data (Plaintext, P <sub>i</sub> ) from buffer to DATA0 using XOR write.
STEP1	CIPHER	The AES Cipher Core operates on DATA0
STEP2	DATA0TOBUF	The cipher output C <sub>i</sub> is written to the buffer.

### 27.4.11.2 CBC Decryption

In CBC decryption, ciphertext ( $C_i$ ) is used as input to the Cipher Core. The output from the Cipher Core is XOR'ed with the ciphertext from the previous block  $C_{i-1}$  to form the plaintext  $P_i$  (an initialization vector IV is used as  $C_{i-1}$  during the first block).

Because each block requires both  $C_{i-1}$  and  $C_i$ , decryption is somewhat more complex than encryption. Nevertheless, CBC decryption can be performed in as a repeated sequence by having  $C_{i-1}$  from the previous block stored in DATA1 and then writing it to buffer without updating the write pointer (using the DATA1TOBUF instruction). Then the cipher output is XOR'ed with  $C_{i-1}$  in the buffer by using the DATA0TOBUF XOR instruction.

In [Figure 27.8 CBC Decryption Operation on page 871](#) the CBC decryption is illustrated and in [Table 27.10 CBC Decryption Steps on page 871](#) each step in the loop is explained.

CBC Decryption

Figure 27.8. CBC Decryption Operation

Table 27.10. CBC Decryption Steps

STEP	ACTION	Description
STEP0	BUFTODATA0	Moves data (Ciphertext, $C_i$ ) from buffer to DATA0
STEP1	DATA1TOBUF	DATA1 (Ciphertext, $C_{i-1}$ ) is moved to buffer. BUFC Write pointer is not incremented!
STEP2	DATA0TODATA1	Value of DATA0 is copied to DATA1.
STEP3	CIPHER Operation	The AES Cipher Core operates on DATA0
STEP4	DATA0TOBUF XOR	The cipher output is XOR'ed with $C_{i-1}$ (placed in the buffer at Step 2) to form the plaintext, $P_i$ .

## 27.5 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	CRYPTO_CTRL	RW	Control Register
0x004	CRYPTO_WAC	RW	Wide Arithmetic Configuration
0x008	CRYPTO_CMD	W	Command Register

	2	DDATA0BIG		
	3	QDATA0		
19:18	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
17:16	DMA0MODE	0x0	RW	<b>DMA0 Read Mode</b>  This field determines how data is read when using DMA.

Bit	Name	Reset	Access	Description
	Value	Mode		Description
	0	FULL		Target register is fully read/written during every DMA transaction
	1	LENLIMIT		Length Limited. When the current length, i.e. LENGTHA or LENGTHB indicates that there are less bytes available than the register size, only length + necessary zero padding is read. Zero padding is automatically added when writing.
	2	FULLBYTE		Target register is fully read/written during every DMA transaction. Byte-wise DMA.
	3	LENLIMITBYTE		Length Limited. When the current length, i.e. LENGTHA or LENGTHB indicates that there are less bytes available than the register size, only length + necessary zero padding is read. Byte-wise DMA. Zero padding is automatically added when writing.
15:14	INCWIDTH	0x0	RW	<b>Increment Width</b> This field determines the number of bytes used for the increment function in data1.
	Value	Mode		Description
	0	INCWIDTH1		Byte 15 in DATA1 is used for the increment function.
	1	INCWIDTH2		Bytes 14 and 15 in DATA1 are used for the increment function.
	2	INCWIDTH3		Bytes 13 to 15 in DATA1 are used for the increment function.
	3	INCWIDTH4		Bytes 12 to 15 in DATA1 are used for the increment function.
13:11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
10	NOBUSYSTALL	0	RW	<b>No Stalling of Bus When Busy</b> When set, bus accesses will not be stalled on access during an operation
9:3	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
2	SHA	0	RW	<b>SHA Mode</b> Select SHA-1 or SHA-2 mode.
	Value	Mode		Description
	0	SHA1		SHA-1 mode
	1	SHA2		SHA-2 mode (SHA-224 or SHA-256)
1	KEYBUFDIS	0	RW	<b>Key Buffer Disable</b> Set to Disable key buffering.
0	AES	0	RW	<b>AES Mode</b> Select AES mode
	Value	Mode		Description
	0	AES128		AES-128 mode
	1	AES256		AES-256 mode

27.6.2 CRYPTO\_WAC - Wide Arithmetic Configuration

Offset	Bit Position																			
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12
Reset													11	10	9	8	7	6	5	4
Access													RW	RW	RW					0
Name													RESULTWIDTH		MULWIDTH					MODOP
																				MODULUS

Bit	Name	Reset	Access	Description
31:12	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
11:10	RESULTWIDTH	0x0	RW	<b>Result Width</b> Result-size for non-modulus instructions
	Value	Mode	Description	
	0	256BIT	Results have 256 bits	
	1	128BIT	Results have 128 bits	
	2	260BIT	Results have 260 bits. Upper bits of result can be read through DDA-TA0MSBS in CRYPTO_STATUS	
9:8	MULWIDTH	0x0	RW	<b>Multiply Width</b> Number of bits to multiply on non-modulus multiply instruction
	Value	Mode	Description	
	0	MUL256	Multiply 256 bits	
	1	MUL128	Multiply 128 bits	
	2	MULMOD	Same number of bits as specified by MODULUS	
7:5	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
4	MODOP	0	RW	<b>Modular Operation Field Type</b> Field type used for modular operations
	Value	Mode	Description	
	0	BINARY	Modular operations use XOR as required by certain algorithms	
	1	REGULAR	Modular operations use normal modular arithmetic, not XOR	
3:0	MODULUS	0x0	RW	<b>Modular Operation Modulus</b> Modulus used for modular operations
	Value	Mode	Description	
	0	BIN256	Generic modulus. $p = 2^{256}$	
	1	BIN128	Generic modulus. $p = 2^{128}$	
	2	ECCBIN233P	Modulus for B-233 and K-233 ECC curves. $p(t) = t^{233} + t^{74} + 1$	
	3	ECCBIN163P	Modulus for B-163 and K-163 ECC curves. $p(t) = t^{163} + t^7 + t^6 + t^3 + 1$	
	4	GCMBIN128	Modulus for GCM. $P(t) = t^{128} + t^7 + t^2 + t + 1$	
	5	ECCPRIME256P	Modulus for P-256 ECC curve. $p = 2^{256} - 2^{224} + 2^{192} + 2^{96} - 1$	
	6	ECCPRIME224P	Modulus for P-224 ECC curve. $p = 2^{224} - 2^{96} - 1$	
	7	ECCPRIME192P	Modulus for P-192 ECC curve. $p = 2^{192} - 2^{64} - 1$	
	8	ECCBIN233N	P modulus for B-233 ECC curve	
	9	ECCBIN233KN	P modulus for K-233 ECC curve	
	10	ECCBIN163N	P modulus for B-163 ECC curve	

Bit	Name	Reset	Access	Description
11		ECCBIN163KN		P modulus for K-163 ECC curve
12		ECCPRIME256N		P modulus for P-256 ECC curve
13		ECCPRIME224N		P modulus for P-224 ECC curve
14		ECCPRIME192N		P modulus for P-192 ECC curve

27.6.3 CRYPTO\_CMD - Command Register

Offset	Bit Position																															
0x008	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 27.6.7 CRYPTO\_KEY - KEY Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x020	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXX																
Access																	RWH																
Name																	KEY																

Bit	Name	Reset	Access	Description
31:0	KEY	0XXXXXXXXX X	RWH	<b>Key Access</b>
				Access the KEY. 4x32bits (8x32bits if AES256 in CRYPTO_CTRL is set) read/write accesses are required to fully read/write KEY.

### 27.6.8 CRYPTO\_KEYBUF - KEY Buffer Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x024	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	KEYBUF																

Bit	Name	Reset	Access	Description
31:0	KEYBUF	0XXXXXXXXX X	RWH	<b>Key Buffer Access</b>
				Access to KEYBUF. 4x32bits (8x32bits if AES256 in CRYPTO_CTRL is set) read/write accesses are required to fully read/write KEYBUF

## 27.6.9 CRYPTO\_SEQCTRL - Sequence Control

Offset	Bit Position																																	
0x030	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reset	0		0	0	0x0		0x0				0x0									0x0000														
Access	RW		RW	RW	RWH		RWH				RW									RWH														
Name	HALT		DMA1PRESA	DMA0PRESA	DMA1SKIP		DMA0SKIP				BLOCKSIZE									LENGTHA														

Bit	Name	Reset	Access	Description
31	HALT	0	RW	<b>Halt Sequence</b> Allows stepping through CRYPTO instructions in the sequence for debugging.
30	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
29	DMA1PRESA	0	RW	<b>DMA1 Preserve A</b> Set to write skipped bytes back on next DMA1WR triggered write. Use this together with DMA1SKIP to enable in-place conversions with CRYPTO
28	DMA0PRESA	0	RW	<b>DMA0 Preserve A</b> Set to write skipped bytes back on next DMA0WR triggered write. Use this together with DMA0SKIP to enable in-place conversions with CRYPTO
27:26	DMA1SKIP	0x0	RWH	<b>DMA1 Skip</b> Set to number of bytes to exclude from data received by next DMA1RD insruction
25:24	DMA0SKIP	0x0	RWH	<b>DMA0 Skip</b> Set to number of bytes to exclude from data received by next DMA0RD insruction
23:22	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
21:20	BLOCKSIZE	0x0	RW	<b>Size of data blocks</b> Defines the width of blocks processed in each iteration of a sequence running on a dataset (see related note in )
	Value	Mode		Description
	0	16BYTES		A block is 16 bytes long
	1	32BYTES		A block is 32 bytes long
	2	64BYTES		A block is 64 bytes long
19:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13:0	LENGTHA	0x0000	RWH	<b>Buffer length A in bytes</b> This field sets the number of bytes to be handled during the repeated sequence. Set it to the exact number of bytes. If the number is not a multiple of BLOCKSIZE, the last data block is zero-padded. Format is unsigned integer.

## 27.6.10 CRYPTO\_SEQCTRLB - Sequence Control B

Offset	Bit Position																															
0x034	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset			0	0															0x0000													
Access			RW	RW															RWH													
Name			DMA1PRESB	DMA0PRESB															LENGTHB													

Bit	Name	Reset	Access	Description
31:30	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
29	DMA1PRESB	0	RW	<b>DMA1 Preserve B</b>  For unaligned sequences, set this bit along with DMA1PRESA for in-place conversions where all data is written out from CRYPTO again. If only the second part of a data-set is written, enable only this to preserve the data read in during part A
28	DMA0PRESB	0	RW	<b>DMA0 Preserve B</b>  For unaligned sequences, set this bit along with DMA0PRESA for in-place conversions where all data is written out from CRYPTO again. If only the second part of a data-set is written, enable only this to preserve the data read in during part A
27:14	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
13:0	LENGTHB	0x0000	RWH	<b>Buffer length B in bytes</b>  Sets the number of bytes to be handled in a second iteration over a programmed sequence.

## 27.6.11 CRYPTO\_IF - AES Interrupt Flags

Offset	Bit Position																																			
0x040	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Reset																																	R	0	R	0
Access																																	R		R	
Name																																	SEQDONE		INSTRDONE	

Bit	Name	Reset	Access	Description
31:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	SEQDONE	0	R	<b>Sequence Done</b>  Set when an instruction sequence has completed
0	INSTRDONE	0	R	<b>Instruction done</b>  Set when an instruction has completed

## 27.6.12 CRYPTO\_IFS - Interrupt Flag Set Register

Offset	Bit Position																											
0x044	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4
Reset																											0	0
Access																											W1	W1
Name																											BUFUF	BUFOF
																											SEQDONE	INSTRDONE

Bit	Name	Reset	Access	Description
31:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3	BUFUF	0	W1	<b>Set BUFUF Interrupt Flag</b> Write 1 to set the BUFUF interrupt flag
2	BUFOF	0	W1	<b>Set BUFOF Interrupt Flag</b> Write 1 to set the BUFOF interrupt flag
1	SEQDONE	0	W1	<b>Set SEQDONE Interrupt Flag</b> Write 1 to set the SEQDONE interrupt flag
0	INSTRDONE	0	W1	<b>Set INSTRDONE Interrupt Flag</b> Write 1 to set the INSTRDONE interrupt flag

### 27.6.13 CRYPTO\_IFC - Interrupt Flag Clear Register

Offset	Bit Position																																	
0x048	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4						
Reset																													0	3	0	2		
Access																													(R)W1	(R)W1	(R)W1	(R)W1		
Name																													BUFUF	BUFOF	SEQDONE	INSTRDONE		

Bit	Name	Reset	Access	Description
31:4	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
3	BUFUF	0	(R)W1	<b>Clear BUFUF Interrupt Flag</b>  Write 1 to clear the BUFUF interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).
2	BUFOF	0	(R)W1	<b>Clear BUFOF Interrupt Flag</b>  Write 1 to clear the BUFOF interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).
1	SEQDONE	0	(R)W1	<b>Clear SEQDONE Interrupt Flag</b>  Write 1 to clear the SEQDONE interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).
0	INSTRDONE	0	(R)W1	<b>Clear INSTRDONE Interrupt Flag</b>  Write 1 to clear the INSTRDONE interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).

### 27.6.16 CRYPTO\_SEQ1 - Sequence Register 1

Offset	Bit Position																															
0x054	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x00								0x00								0x00								0x00							
Access	RW								RW								RW								RW							
Name	INSTR7								INSTR6								INSTR5								INSTR4							

Bit	Name	Reset	Access	Description
31:24	INSTR7	0x00	RW	<b>Sequence Instruction 7</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
23:16	INSTR6	0x00	RW	<b>Sequence Instruction 6</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
15:8	INSTR5	0x00	RW	<b>Sequence Instruction 5</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
7:0	INSTR4	0x00	RW	<b>Sequence Instruction 4</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.

### 27.6.17 CRYPTO\_SEQ2 - Sequence Register 2

Offset	Bit Position																															
0x058	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x00								0x00								0x00								0x00							
Access	RW								RW								RW								RW							
Name	INSTR11								INSTR10								INSTR9								INSTR8							

Bit	Name	Reset	Access	Description
31:24	INSTR11	0x00	RW	<b>Sequence Instruction 11</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
23:16	INSTR10	0x00	RW	<b>Sequence Instruction 10</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
15:8	INSTR9	0x00	RW	<b>Sequence Instruction 9</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
7:0	INSTR8	0x00	RW	<b>Sequence Instruction 8</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.

**27.6.18 CRYPTO\_SEQ3 - Sequence Register 3**

Offset	Bit Position																															
0x05C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x00								0x00								0x00								0x00							
Access	RW								RW								RW								RW							
Name	INSTR15								INSTR14								INSTR13								INSTR12							

Bit	Name	Reset	Access	Description
31:24	INSTR15	0x00	RW	<b>Sequence Instruction 15</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
23:16	INSTR14	0x00	RW	<b>Sequence Instruction 14</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
15:8	INSTR13	0x00	RW	<b>Sequence Instruction 13</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
7:0	INSTR12	0x00	RW	<b>Sequence Instruction 12</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.

**27.6.19 CRYPTO\_SEQ4 - Sequence Register 4**

Offset	Bit Position																															
0x060	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x00								0x00								0x00								0x00							
Access	RW								RW								RW								RW							
Name	INSTR19								INSTR18								INSTR17								INSTR16							

Bit	Name	Reset	Access	Description
31:24	INSTR19	0x00	RW	<b>Sequence Instruction 19</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
23:16	INSTR18	0x00	RW	<b>Sequence Instruction 18</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
15:8	INSTR17	0x00	RW	<b>Sequence Instruction 17</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.
7:0	INSTR16	0x00	RW	<b>Sequence Instruction 16</b> Sequence instruction. See INSTR the CRYPTO_CMD for a possible values.

## 27.6.20 CRYPTO\_DATA0 - DATA0 Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x080	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DATA0																

Bit	Name	Reset	Access	Description
31:0	DATA0	0XXXXXXXXX X	RWH	<b>Data 0 Access</b>
Access to DATA0. 4x32bits read/write accesses are required to fully read/write DATA0				

## 27.6.21 CRYPTO\_DATA1 - DATA1 Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x084	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DATA1																

Bit	Name	Reset	Access	Description
31:0	DATA1	0XXXXXXXXX X	RWH	<b>Data 1 Access</b>
Access to DATA1. 4x32bits read/write accesses are required to fully read/write DATA1				

### 27.6.22 CRYPTO\_DATA2 - DATA2 Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x088	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DATA2																

Bit	Name	Reset	Access	Description
31:0	DATA2	0XXXXXXXXX X	RWH	<b>Data 2 Access</b>
Access to DATA2. 4x32bits read/write accesses are required to fully read/write DATA2.				

### 27.6.23 CRYPTO\_DATA3 - DATA3 Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x08C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DATA3																

Bit	Name	Reset	Access	Description
31:0	DATA3	0XXXXXXXXX X	RWH	<b>Data 3 Access</b>
Access to DATA3. 4x32bits read/write accesses are required to fully read/write DATA3.				

**27.6.24 CRYPTO\_DATA0XOR - DATA0XOR Register Access (No Bit Access) (Actionable Reads)**

Offset	Bit Position																																
0x0A0	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXX																
Access																	RWH																
Name																	DATA0XOR																

Bit	Name	Reset	Access	Description
31:0	DATA0XOR	0XXXXXXXXX	RWH	<b>XOR Data 0 Access</b>

Any value written to this register will be XOR'ed with the value of DATA0. The result is stored in DATA0. Reads return DATA0 directly. 4x32bits read/write accesses are required to perform a full XOR write to DATA0

**27.6.25 CRYPTO\_DATA0BYTE - DATA0 Register Byte Access (No Bit Access) (Actionable Reads)**

Offset	Bit Position																															
0x0B0	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xxx							
Access																									RWH							
Name																									DATA0BYTE							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA0BYTE	0XXX	RWH	<b>Data 0 Byte Access</b>

Access to DATA0. 16x8bits read/write accesses are required to fully read/write DATA0. Accesses must be performed in multiples of 4, or data incoherency may occur

## 27.6.26 CRYPTO\_DATA1BYTE - DATA1 Register Byte Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																															
0x0B4	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xXX							
Access																									RWH							
Name																									DATA1BYTE							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA1BYTE	0xXX	RWH	<b>Data 1 Byte Access</b> Access to DATA1. 16x8bits read/write accesses are required to fully read/write DATA1. Accesses must be performed in multiples of 4, or data incoherency may occur

## 27.6.27 CRYPTO\_DATA0XORBYTE - DATA0 Register Byte XOR Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																															
0x0BC	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xxx							
Access																									RWH							
Name																									DATA0XORBYTE							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA0XORBYTE	0xXX	RWH	<b>Data 0 XOR Byte Access</b> Access to DATA0. 16x8bits read/write accesses are required to fully read/write DATA0. Written data is XOR'ed with the already present data in DATA0. Accesses must be performed in multiples of 4, or data incoherency may occur

## 27.6.28 CRYPTO\_DATA0BYTE12 - DATA0 Register Byte 12 Access (No Bit Access)

Offset	Bit Position																															
0x0C0	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xxx							
Access																									RWH							
Name																									DATA0BYTE12							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA0BYTE12	0xxx	RWH	<b>Data 0 Byte 12 Access</b> Access to DATA0 byte 12.

## 27.6.29 CRYPTO\_DATA0BYTE13 - DATA0 Register Byte 13 Access (No Bit Access)

Offset	Bit Position																															
0x0C4	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xxx							
Access																									RWH							
Name																									DATA0BYTE13							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA0BYTE13	0xxx	RWH	<b>Data 0 Byte 13 Access</b> Access to DATA0 byte 13.

### 27.6.30 CRYPTO\_DATA0BYTE14 - DATA0 Register Byte 14 Access (No Bit Access)

Offset	Bit Position																															
0x0C8	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xXX							
Access																									RWH							
Name																									DATA0BYTE14							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA0BYTE14	0xXX	RWH	<b>Data 0 Byte 14 Access</b> Access to DATA0 byte 14.

### 27.6.31 CRYPTO\_DATA0BYTE15 - DATA0 Register Byte 15 Access (No Bit Access)

Offset	Bit Position																															
0x0CC	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0xxx							
Access																									RWH							
Name																									DATA0BYTE15							

Bit	Name	Reset	Access	Description
31:8	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
7:0	DATA0BYTE15	0xXX	RWH	<b>Data 0 Byte 15 Access</b> Access to DATA0 byte 15.

**27.6.32 CRYPTO\_DDATA0 - DDATA0 Register Access (No Bit Access) (Actionable Reads)**

Offset	Bit Position																																
0x100	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DDATA0																

Bit	Name	Reset	Access	Description
31:0	DDATA0	0XXXXXXXXX X	RWH	<b>Double Data 0 Access</b>
Access to DDATA0. 8x32bits read/write accesses are required to fully read/write DDATA0.				

**27.6.33 CRYPTO\_DDATA1 - DDATA1 Register Access (No Bit Access) (Actionable Reads)**

Offset	Bit Position																																
0x104	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DDATA1																

Bit	Name	Reset	Access	Description
31:0	DDATA1	0XXXXXXXXX X	RWH	<b>Double Data 0 Access</b>
Access to DDATA1, which is equal to the full width of KEY regardless of AES256 in CRYPTO_CTRL. 8x32bits read/write accesses are required to fully read/write DDATA1.				

**27.6.34 CRYPTO\_DDATA2 - DDATA2 Register Access (No Bit Access) (Actionable Reads)**

Offset	Bit Position																																
0x108	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DDATA2																

Bit	Name	Reset	Access	Description
31:0	DDATA2	0XXXXXXXXX	RWH	<b>Double Data 0 Access</b>
Access to DDATA2, which consists of {DATA1, DATA0}. 8x32bits read/write accesses are required to fully read/write DDATA2.				

**27.6.35 CRYPTO\_DDATA3 - DDATA3 Register Access (No Bit Access) (Actionable Reads)**

Offset	Bit Position																																
0x10C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DDATA3																

Bit	Name	Reset	Access	Description
31:0	DDATA3	0XXXXXXXXX	RWH	<b>Double Data 0 Access</b>
Access to DDATA3, which consists of {DATA3, DATA2}. 8x32bits read/write accesses are required to fully read/write DDATA3.				

### 27.6.36 CRYPTO\_DDATA4 - DDATA4 Register Access (No Bit Access) (Actionable Reads)

Offset	Bit Position																																
0x110	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset																	0XXXXXXXXXX																
Access																	RWH																
Name																	DDATA4																

Bit	Name	Reset	Access	Description
31:0	DDATA4	0XXXXXXXXX X	RWH	<b>Double Data 0 Access</b>
Access to DDATA4, which is equal to the full width of KEYBUF regardless of AES256 in CRYPTO_CTRL. 8x32bits read/write accesses are required to fully read/write DDATA4.				

### 27.6.37 CRYPTO\_DDATA0BIG - DDATA0 Register Big Endian Access (No Bit Access) (Actionable Reads)

Offset	Bit Position

## 28. GPIO - General Purpose Input/Output

### Quick Facts

#### What?

The General Purpose Input/Output (GPIO) is used for pin configuration, direct pin manipulation and sensing, as well as routing for peripheral pin connections.

#### Why?

Easy to use and highly configurable input/output pins are important to fit many communication protocols as well as minimizing software control overhead. Flexible routing of peripheral functions helps to ease PCB layout.

#### How?

Each pin on the device can be individually configured as either an input or an output with several different drive modes. Also, individual bit manipulation registers minimizes control overhead. Peripheral connections to pins can be routed to several different locations, thus solving congestion issues that may arise with multiple functions on the same pin. Fully asynchronous interrupts can also be generated from any pin.

### 28.1 Introduction

In the EFR32 devices the General Purpose Input/Output (GPIO) pins are organized into ports with up to 16 pins each. These GPIO pins can individually be configured as either an output or input. More advanced configurations like open-drain, open-source, and glitch filtering can be configured for each individual GPIO pin. The GPIO pins can also be overridden by peripheral pin connections, like Timer PWM outputs or USART communication, which can be routed to several locations on the device. The GPIO supports up to 16 asynchronous external pin interrupts, which enable interrupts from any pin on the device. Also, the input value of a pin can be routed through the Peripheral Reflex System to other peripherals.

#### Note:

To use the GPIO, the GPIO clock must first be enabled in `CMU_HFBUSCLKEN0`. Setting this bit enables the HFBUSCLK for the GPIO.

## 28.2 Features

- Individual configuration for each pin
  - Tristate (reset state)
  - Push-pull
  - Open-drain
  - Pull-up resistor
  - Pull-down resistor
  - Drive strength
    - 1 mA
    - 10 mA
  - Slewrate
  - Over Voltage Tolerance
- EM4 IO pin retention
  - Output enable
  - Output value
  - Pull enable
  - Pull direction
  - Over Voltage Tolerance
- EM4 wake-up on selected GPIO pins
- Glitch suppression input filter
- Alternate functions (e.g. peripheral outputs and inputs)
  - Routed to several locations on the device
  - Pin connections can be enabled individually
  - Output data can be overridden by peripheral
  - Output enable can be overridden by peripheral
- Toggle register for output data
- Dedicated data input register (read-only)
- Interrupts
  - 2 Interrupt lines using either levels or edges
    - EM4 wake-up pins are selectable for level interrupts
    - All GPIO pins are selectable for edge interrupts
  - Separate enable, status, set and clear registers
  - Asynchronous sensing
  - Rising, falling or both edges
  - High or low level detection
  - Wake up from EM0 Active-EM3 Stop
- Peripheral Reflex System producer
  - All GPIO pins are selectable
- Configuration lock functionality to avoid accidental changes

## 28.3 Functional Description

An overview of the GPIO module is shown in [Figure 28.1 Pin Configuration on page 913](#). The GPIO pins are grouped into 16-pin ports. Each individual GPIO pin is called Pxn where x indicates the port (A, B, C ...) and n indicates the pin number (0,1,...,15). Fewer than 16 bits may be available on some ports, depending on the total number of I/O pins on the package. After a reset, both input and output are disabled for all pins on the device, except for the Serial Wire Debug pins.

To use a pin, the Mode Register (GPIO\_Px\_MODEL/GPIO\_Px\_MODEH) must be configured for the pin to make it an input or output. These registers can also do more advanced configuration, which is covered in [28.3.1 Pin Configuration](#). When the port is configured as an input or an output, the Data In Register (GPIO\_Px\_DIN) can be used to read the level of each pin in the port (bit n in the register is connected to pin n on the port). When configured as an output, the value of the Data Out Register (GPIO\_Px\_DOUT) will be driven to the pin.

The DOUT value can be changed in 4 different ways:

- Writing to the GPIO\_Px\_DOUT register
- Writing the BITSET address of the GPIO\_Px\_DOUT register sets the DOUT bits
- Writing the BITCLEAR address of the GPIO\_Px\_DOUT register clears the DOUT bits
- Writing the GPIO\_Px\_DOUTTGL register toggles the corresponding DOUT bits

Reading the GPIO\_Px\_DOUT register will return its contents. Reading the GPIO\_Px\_DOUTTGL register will return 0.

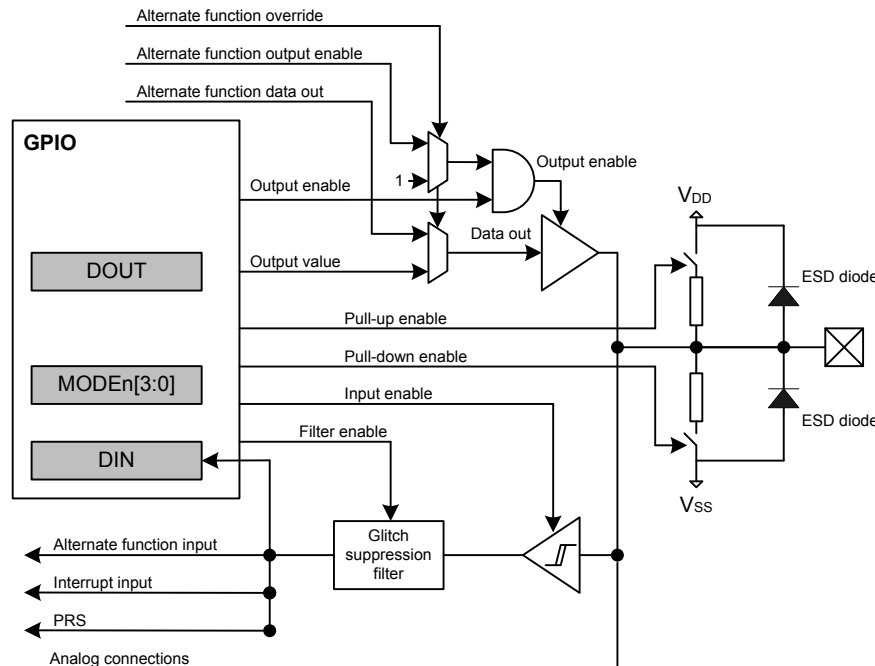

Figure 28.1. Pin Configuration

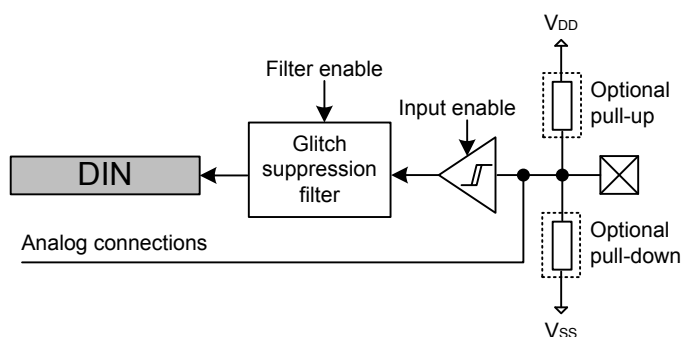

### 28.3.1 Pin Configuration

In addition to setting the pins as either outputs or inputs, the GPIO\_Px\_MODEL and GPIO\_Px\_MODEH registers can be used for more advanced configurations. GPIO\_Px\_MODEL contains 8 bit fields named MODEn (n=0,1,..7) which control pins 0-7, while GPIO\_Px\_MODEH contains 8 bit fields named MODEn (n=8,9,..15) which control pins 8-15. In some modes GPIO\_Px\_DOUT is also used for extra configurations like pull-up/down and glitch suppression filter enable. [Table 28.1 Pin Configuration on page 914](#) shows the available configurations.

**Table 28.1. Pin Configuration**

MODEn	Input	Output	DOUT	Pull-down	Pull-up	Alt Port Ctrl	Input Filter	Description	
DISABLED	Disabled	Disabled	0					Input disabled	
			1		On			Input disabled with pull-up	
INPUT	Enabled if not DINDIS		0						Input enabled
			1				On		Input enabled with filter
INPUTPULL			0	On					Input enabled with pull-down
			1		On				Input enabled with pull-up
INPUTPULLFILTER			0	On			On		Input enabled with pull-down and filter
			1		On		On		Input enabled with pull-up and filter
PUSHPULL		Push-pull	x						Push-pull
PUSHPULLALT			x			On			Push-pull with alternate port control values
WIREDOR		Open Source (Wired-OR)	x						Open-source
WIREDORPULLDOWN			x	On					Open-source with pull-down
WIREDAND		Open Drain (Wired-AND)	x						Open-drain
WIREDANDFILTER			x				On		Open-drain with filter
WIREDANDPULLUP			x		On				Open-drain with pull-up
WIREDANDPULLUPFILTER			x		On		On		Open-drain with pull-up and filter
WIREDANDALT			x			On			Open-drain with alternate port control values
WIREDANDALTFILTER			x			On	On		Open-drain with alternate port control values and filter
WIREDANDALTPULLUP			x		On	On			Open-drain with alternate port control values and pull-up
WIREDANDALTPULLUPFILTER			x		On	On	On		Open-drain with alternate port control values, pull-up and filter

MODEn determines which mode the pin is in at a given time. Setting MODEn to DISABLED disables the pin, reducing power consumption to a minimum. When the output driver, input driver and Over Voltage Tolerance is disabled, the pin can be used as a connection for an analog module. An input is enabled by setting MODEn to any value other than DISABLED while DINDIS for the given port is cleared. Set DINDIS to disable the input of a gpio port. The pull-up, pull-down and glitch filter function can optionally be applied to the input, see [Figure 28.2 Tristated Output with Optional Pull-up or Pull-down on page 915](#).

**Figure 28.2. Tristated Output with Optional Pull-up or Pull-down**

When MODEn is PUSH\_PULL or PUSH\_PULLALT, the pin operates in push-pull mode. In this mode, the pin can have alternate port control values and can be driven either high or low, dependent on the value of GPIO\_Px\_DOUT. The push-pull configuration is shown in [Figure 28.3 Push-Pull Configuration on page 915](#).

**Figure 28.3. Push-Pull Configuration**

When MODEn is WIRE\_ODR or WIRE\_ODR\_PULLEDOWN, the pin operates in open-source mode (with a pull-down resistor for WIRE\_ODR\_PULLEDOWN). When driving a high value in open-source mode, the pull-down is disconnected to save power.

When the mode is prefixed with WIRE\_ODR, the pin operates in open-drain mode as shown in [Figure 28.4 Open-drain on page 915](#). In open-drain mode, the pin can have an input filter, a pull-up, alternate port control values or any combination of these. When driving a low value in open-drain mode, the pull-up is disconnected to save power.

**Figure 28.4. Open-drain**

### 28.3.1.1 Over Voltage Tolerance

Over voltage capability is available for most pins. If available, it allows the pin to be used at either the minimum of VDDIO + 2V and 5.5V (for 5V tolerant pads) or the minimum of VDDIO + 2V and 3.8V (for non-5V tolerant pads). The datasheet specifies which pins can be used as 5V tolerant pins. Default over voltage is enabled for each pin supporting that feature. Over voltage tolerance can be disabled on a per pin basis. The over voltage tolerance feature applied to the selected pins is configured in the GPIO\_Px\_OVTDIS register. Disabling the over voltage tolerance for a pin will provide less distortion on that pin, which is useful when the pin is used as analog input.

### 28.3.1.2 Alternate Port Control

The Alternate Port Control allows for additional flexibility of port level settings. A user may setup two different port configurations (normal and alternate modes) and select which is applied on a pin by pin bases. For example you may configure half of port A to use the low drive strength setting (normal mode) while the other half uses high drive strength (alternate mode).

Alternate port control is enabled when MODEN is set to any of the ALT enumerated modes (ie. PUSH\_PULLALT). When MODEN is an alternate mode, the pin uses the alternate port control values specified in the DINDISALT, SLEWRATEALT, and DRIVESTRENGTHALT fields in GPIO\_Px\_CTRL. In all other modes, the port control values are used from the DINDIS, SLEWRATE, and DRIVESTRENGTH fields in GPIO\_Px\_CTRL.

### 28.3.1.3 Drive Strength

The drive strength can be applied to pins on a port-by-port basis. The drive strength applied to pins configured using normal MODEN settings can be controlled using the DRIVESTRENGTH field in GPIO\_Px\_CTRL. The drive strength applied to pins configured using alternate MODEN settings can be controlled using the DRIVESTRENGTHALT field.

### 28.3.1.4 Slewrate

The slewrate can be applied to pins on a port-by-port basis. The slewrate applied to pins configured using normal MODEN settings can be controlled using the SLEWRATE fields in GPIO\_Px\_CTRL. The slewrate applied to pins configured using the alternate MODEN settings can be controlled using the SLEWRATEALT field.

### 28.3.1.5 Input Disable

The pin inputs can be disabled on a port-by-port basis. The input of pins configured using the normal MODEN settings can be disabled by setting DINDIS in GPIO\_Px\_CTRL. The input of pins configured using the alternate MODEN settings can be disabled by setting DINDISALT.

### 28.3.1.6 Configuration Lock

GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_CTRL, GPIO\_Px\_PINLOCKN, GPIO\_Px\_OVTDIS, GPIO\_EXTIPSELL, GPIO\_EXTIPSELH, GPIO\_EXTIPINSELL, GPIO\_EXTIPINSELH, GPIO\_INSENSE, GPIO\_ROUTEPEL, and GPIO\_ROUTELOC0 can be locked by writing any value other than 0xA534 to GPIO\_LOCK. Writing the value 0xA534 to the GPIOx\_LOCK register unlocks the configuration registers.

In addition to configuration lock, GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_DOUT, GPIO\_Px\_DOUTTGL, and GPIO\_Px\_OVTDIS can be locked individually for each pin by clearing the corresponding bit in GPIO\_Px\_PINLOCKN. When a bit in the GPIO\_Px\_PINLOCKN register is cleared, it will stay cleared until reset.

### 28.3.2 EM4 Wake-up

It is possible to trigger a wake-up from EM4 using any of the selectable EM4WU GPIO pins. The wake-up request can be triggered through the pins by enabling the corresponding bit in the GPIO\_EM4WUEN register. When EM4 wake-up is enabled for the pin, the input filter is enabled during EM4. This is done to avoid false wake-up caused by glitches. In addition, the polarity of the EM4 wake-up request can be selected using the GPIO\_EXTILEVEL register.

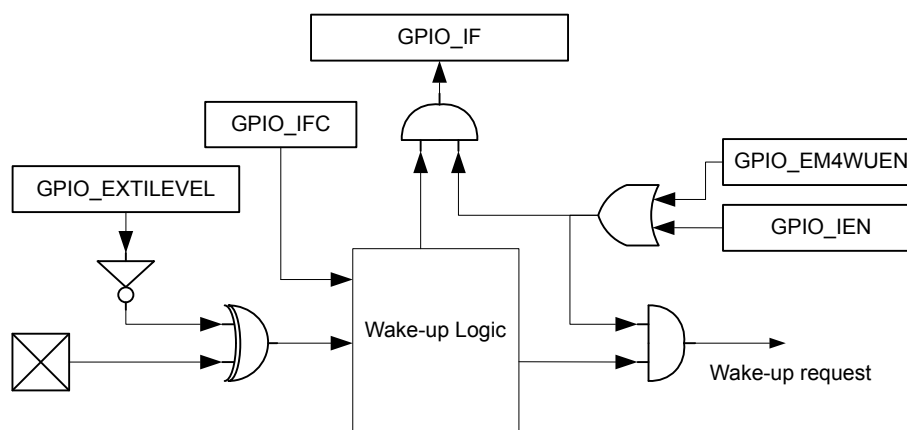

Figure 28.5. EM4 Wake-up Logic

The pins used for EM4 wake-up must be configured as inputs with glitch filters using the GPIO\_Px\_MODEL/GPIO\_Px\_MODEH register. If the input is disabled and the wakeup polarity is low, a false wakeup will occur when entering EM4. If the input is enabled, the glitch filtered is disabled, and the polarity is set low, a glitch will occur when going into EM4 that will cause an immediate wake-up. Before going down to EM4, it is important to clear the wake-up logic by setting the GPIO\_IFC bit, which clears the wake-up logic, including the GPIO\_IF register. It is possible to determine which pin caused the EM4WU by reading the GPIO\_IF register. The mapping between EM4WU pins and the bit indexes in the GPIO\_EM4WUEN, GPIO\_EXTILEVEL, GPIO\_IFC, GPIO\_IFS, GPIO\_IEN, and GPIO\_IF registers is as follows:

Table 28.2. EM4WU Register Bit Index to EM4WU pin Mapping

EM4WU Register Bit Indexes	EM4WU Pin
16	GPIO_EM4WU0
17	GPIO_EM4WU1
18	GPIO_EM4WU2
19	GPIO_EM4WU3
...	...
31	GPIO_EM4WU15

**Note:** Please see the device datasheet for actual pin location

### 28.3.3 EM4 Retention

By default GPIO pins revert back to their reset state when EM4 is entered. The GPIO pins can be configured to retain the settings for output enable, output value, pull enable, pull direction and over voltage tolerance while in EM4.

EM4 GPIO retention is controlled with the EM4IORETMODE field in the EMU\_EM4CTRL register. Setting EM4IORETMODE to EM4EXIT will cause retention to persist while in EM4 and reset the GPIO's during wakeup. Setting EM4IORETMODE to SWUNLATCH will cause the retention to persist until the EM4UNLATCH bit is written by software. When using SWUNLATCH the GPIO register values are still reset on wakeup. In order to ensure that the GPIO state does not change software must re-write the GPIO registers before setting EM4UNLATCH and ending EM4 GPIO retention. See the EMU chapter for additional documentation on its registers and the EM4UNLATCH bit.

### 28.3.4 Alternate Functions

Alternate functions are connections to pins from peripherals, i.e. Timers, USARTs, etc.. These peripherals contain route registers, where the pin connections are enabled. In addition, the route registers contain a location bit field that configures which pin an output of that peripheral will be connected to if enabled. After connecting a peripheral, the pin configuration stays as set in GPIO\_Px\_MODEL, GPIO\_Px\_MODEH and GPIO\_Px\_DOUT registers. For example, the pin configuration must be set to output enable in GPIO\_Px\_MODEL or GPIO\_Px\_MODEH for a peripheral to be able to use the pin as an output.

It is not recommended to select two or more peripherals as output on the same pin. The reader is referred to the pin map section of the device datasheet for more information on the possible locations of each alternate function.

#### 28.3.4.1 Analog Connections

When using the GPIO pin for analog functionality, it is recommended to disable the over voltage tolerance by setting the corresponding pin in the GPIO\_Px\_OVTDIS register and setting the MODEN in GPIO\_Px\_MODEL or GPIO\_Px\_MODEH equal to DISABLE to disable the input sense, output driver and pull resistors.

#### 28.3.4.2 Debug Connections

##### 28.3.4.2.1 Serial Wire Debug Connection

The SW Debug Port is routed as an alternate function and the SWDIO and SWCLK pin connections are enabled by default with internal pull up and pull down resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN and SWCLKTCKPEN bits in GPIO\_ROUTEPEN to 0.

The Serial Wire Viewer pin, SWV, can be enabled by setting the SWVPEN bit in GPIO\_ROUTEPEN. This bit can also be routed to alternate locations by configuring the SWVLOC bitfield in GPIO\_ROUTELOC0.

##### 28.3.4.2.2 JTAG Debug Connection

The JTAG Debug Port is routed as an alternate function and the TMS, TCK, TDO, and TDI pin connections are enabled by default with internal pull up, pull down, no pull, and pull up resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN, SWCLKTCKPEN, TDOPEN, and TDIPEN bits in GPIO\_ROUTEPEN to 0.

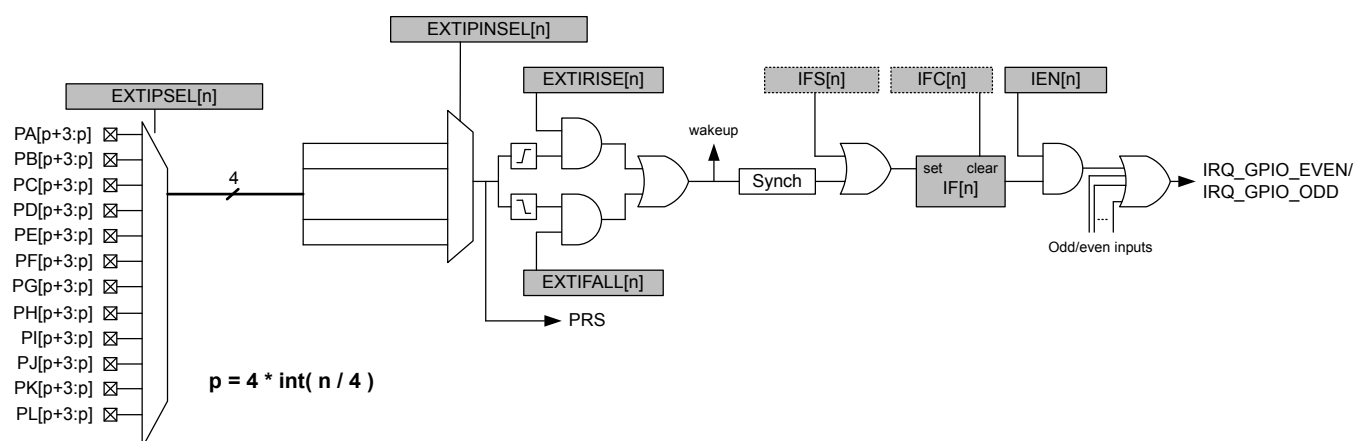

##### 28.3.4.2.3 Disabling Debug Connections

When the debug pins are disabled, the device can no longer be accessed by a debugger. A reset will set the debug pins back to their enabled default state. The GPIO\_ROUTEPEN register can only be updated when the debugger is disconnected from the system. Any attempts to modify GPIO\_ROUTEPEN when the debugger is connected will not occur. If you do disable the debug pins, make sure you have at least a 3 second timeout at the start of your program code before you disable the debug pins. This way the debugger will have time to connect to the device after a reset and before the pins are disabled.

### 28.3.5 Interrupt Generation

### 28.3.5.1 Edge Interrupt Generation

The GPIO can generate an interrupt from any edge of the input of any GPIO pin on the device. The edge interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM3 Stop, see [Figure 28.6 Pin n Interrupt Generation on page 919](#).

**Figure 28.6. Pin n Interrupt Generation**

External pin interrupts can be represented in the form of `EXTI[index]`, where `index` is the external interrupt number. For example, the `EXTI7` interrupt has an index of 7. All pins within a group of four (0-3,4-7,8-11,12-15) from all ports are grouped together to trigger one interrupt. The group of pins available to trigger an interrupt is determined by the interrupt index and calculated as  $\text{int}(\text{index}/4)$ . For example the first 4 interrupts (`EXTI0` - `EXTI3`) are triggered by pins in the first group (`Px[3:0]`) and the second 4 interrupts (`EXTI4`-`EXTI7`) are triggered by pins in the second group (`Px[7:4]`).

The `EXTIPSELn` bits in `GPIO_EXTIPSELL` or `GPIO_EXTIPSELH` select which PORT in the group will trigger the interrupt. The `EXTIPINSELn` bits in `GPIO_EXTIPINSELL` or `GPIO_EXTIPINSELH` will determine which pin inside the selected group will trigger the interrupt.

For example if `EXTIPSEL11 = PORTB` and `EXTIPINSEL11 = 0` then `PB8` will be used for `EXTI11`. `EXTI11` uses the third group ( $11/4 = 2$ ) so the list of possible pins is `Px[11:8]`. The setting of `EXTIPSEL11` further narrows the selection to `PB[11:8]`. Finally `EXTIPINSEL11` selects the first pin in that group which is `PB8`.

The `GPIO_EXTIRISE[n]` and `GPIO_EXTIFALL[n]` registers enable sensing of rising and falling edges. By setting the `EXT[n]` bit in `GPIO_IEN`, a high interrupt flag `n`, will trigger one of two interrupt lines. The even interrupt line is triggered by any enabled even numbered interrupt flag index, while the odd interrupt line is triggered by odd flag indexes. The interrupt flags can be set and cleared by software when writing the `GPIO_IFS` and `GPIO_IFC` registers. Since the external interrupts are asynchronous, they are sensitive to noise. To increase noise tolerance, the `MODEL` and `MODEH` fields in the `GPIO_Px_MODEL` and `GPIO_Px_MODEH` registers, respectively, should be set to include glitch filtering for pins that have external interrupts enabled.

28.3.5.2 Level Interrupt Generation

GPIO can generate a level interrupt using the input of any GPIO EM4 wake-up pins on the device. The interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM4.

In order to enable the level interrupt, set the EM4WU field in the GPIO\_IEN register and the EM4WUn field in the GPIO\_EXTILEVEL register. Upon a level interrupt occurring, the corresponding EM4WU index in the GPIO\_IF register will be set along with the odd or even interrupt line depending on the index inside of GPIO\_IF, see [Figure 28.7 Level Interrupt Example on page 920](#) The wake-up granularity of the level interrupts is based on the settings of the EM4WU field in the GPIO\_IEN register and the EM4WUEN field in the GPIO\_EM4WUEN register, see [Table 28.3 Level Interrupt Energy Mode Wakeup on page 920](#)

Table 28.3. Level Interrupt Energy Mode Wakeup

GPIO_IEN	GPIO_EM4WUEN	Energy Mode Wakeup
0	0	No Interrupt
0	1	EM4H,EM4S
1	0	EM1,EM2,EM3,EM4H,EM4S
1	1	EM1,EM2,EM3,EM4H,EM4S

By setting the EM4WU8 in GPIO\_EXTILEVEL and EM4WU[8] in GPIO\_IEN, the interrupt flag EM4WU[8] in GPIO\_IF will be triggered by a high level on pin EM4WU8 and a interrupt request will be sent on IRQ\_GPIO\_EVEN.

Figure 28.7. Level Interrupt Example

28.3.6 Output to PRS

All pins within a group of four(0-3,4-7,8-11,12-15) from all ports are grouped together to form one PRS producer which outputs to the PRS. The pin from which the output should be taken is selected in the same fashion as the edge interrupts.

PRS output is not effeted by the interrupt edge detction logic or gated by the IEN bits. See [Figure 28.6 Pin n Interrupt Generation on page 919](#) for an ilistration of where the PRS output signal is generated.

28.3.7 Synchronization

To avoid metastability in synchronous logic connected to the pins, all inputs are synchronized with double flip-flops. The flip-flops for the input data run on the HFBUSCLK. Consequently, when a pin changes state, the change will have propagated to GPIO\_Px\_DIN after two 2 HFBUSCLK cycles. Synchronization (also running on the HFBUSCLK) is also added for interrupt input. To save power when the external interrupts or level interrupts are not used, the synchronization flip-flops for these can be turned off by clearing INT or EM4WU,respectively, in GPIO\_INSENSE register.

## 28.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Type	Description
0x000	GPIO_PA_CTRL	RW	Port Control Register
0x004	GPIO_PA_MODEL	RW	Port Pin Mode Low Register
0x008	GPIO_PA_MODEH	RW	Port Pin Mode High Register
0x00C	GPIO_PA_DOUT	RW	Port Data Out Register
0x018	GPIO_PA_DOUTTGL	W1	Port Data Out Toggle Register
0x01C	GPIO_PA_DIN	R	Port Data In Register
0x020	GPIO_PA_PINLOCKN	RW	Port Unlocked Pins Register
0x028	GPIO_PA_OVTDIS	RW	Over Voltage Disable for all modes
...	GPIO_Px_CTRL	RW	Port Control Register
...	GPIO_Px_MODEL	RW	Port Pin Mode Low Register
...	GPIO_Px_MODEH	RW	Port Pin Mode High Register
...	GPIO_Px_DOUT	RW	Port Data Out Register
...	GPIO_Px_DOUTTGL	W1	Port Data Out Toggle Register
...	GPIO_Px_DIN	R	Port Data In Register
...	GPIO_Px_PINLOCKN	RW	Port Unlocked Pins Register
...	GPIO_Px_OVTDIS	RW	Over Voltage Disable for all modes
0x0F0	GPIO_PF_CTRL	RW	Port Control Register
0x0F4	GPIO_PF_MODEL	RW	Port Pin Mode Low Register
0x0F8	GPIO_PF_MODEH	RW	Port Pin Mode High Register
0x0FC	GPIO_PF_DOUT	RW	Port Data Out Register
0x108	GPIO_PF_DOUTTGL	W1	Port Data Out Toggle Register
0x10C	GPIO_PF_DIN	R	Port Data In Register
0x110	GPIO_PF_PINLOCKN	RW	Port Unlocked Pins Register
0x118	GPIO_PF_OVTDIS	RW	Over Voltage Disable for all modes
0x400	GPIO_EXTIPSELL	RW	External Interrupt Port Select Low Register
0x404	GPIO_EXTIPSELH	RW	External Interrupt Port Select High Register
0x408	GPIO_EXTIPINSELL	RW	External Interrupt Pin Select Low Register
0x40C	GPIO_EXTIPINSELH	RW	External Interrupt Pin Select High Register
0x410	GPIO_EXTIRISE	RW	External Interrupt Rising Edge Trigger Register
0x414	GPIO_EXTIFALL	RW	External Interrupt Falling Edge Trigger Register
0x418	GPIO_EXTILEVEL	RW	External Interrupt Level Register
0x41C	GPIO_IF	R	Interrupt Flag Register
0x420	GPIO_IFS	W1	Interrupt Flag Set Register
0x424	GPIO_IFC	(R)W1	Interrupt Flag Clear Register
0x428	GPIO_IEN	RW	Interrupt Enable Register

Offset	Name	Type	Description
0x42C	GPIO_EM4WUEN	RW	EM4 wake up Enable Register
0x440	GPIO_ROUTEPEN	RW	I/O Routing Pin Enable Register
0x444	GPIO_ROUTELOC0	RW	I/O Routing Location Register
0x450	GPIO_INSENSE	RW	Input Sense Register
0x454	GPIO_LOCK	RWH	Configuration Lock Register

28.5 Register Description

28.5.1 GPIO\_Px\_CTRL - Port Control Register

Offset	Bit Position																																							
0x000	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
Reset				0						0x5						0				0								0x5									0			
Access				RW						RW						RW				RW								RW			0x5									RW
Name				DINDISALT						SLEWRATEALT						DRIVESTRENGTHALT				DINDIS								SLEWRATE									DRIVESTRENGTH			

Bit	Name	Reset	Access	Description
31:29	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
28	DINDISALT	0	RW	<b>Alternate Data In Disable</b> Data input disable for port pins using alternate modes.
27:23	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
22:20	SLEWRATEALT	0x5	RW	<b>Alternate slewrate limit for port</b> Slewrate limit for port pins using alternate modes. Higher values represent faster slewrates.
19:17	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
16	DRIVESTRENGTH-ALT	0	RW	<b>Alternate drive strength for port</b> Drive strength setting for port pins using alternate drive strength.
Value		Mode		Description
0		STRONG		10 mA drive current
1		WEAK		1 mA drive current
15:13	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
12	DINDIS	0	RW	<b>Data In Disable</b> Data input disable for port pins not using alternate modes.
11:7	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
6:4	SLEWRATE	0x5	RW	<b>Slewrate limit for port</b> Slewrate limit for port pins not using alternate modes. Higher values represent faster slewrates.
3:1	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
0	DRIVESTRENGTH	0	RW	<b>Drive strength for port</b> Drive strength setting for port pins not using alternate modes.
Value		Mode		Description
0		STRONG		10 mA drive current
1		WEAK		1 mA drive current

28.5.2 GPIO\_Px\_MODEL - Port Pin Mode Low Register

Offset	Bit Position																															
0x004	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31:28	MODE7	0x0	RW	<b>Pin 7 Mode</b>
	Configure mode for pin 7.			
	Value	Mode	Description	
	0	DISABLED	Input disabled. Pullup if DOUT is set.	
	1	INPUT	Input enabled. Filter if DOUT is set	
	2	INPUTPULL	Input enabled. DOUT determines pull direction	
	3	INPUTPULLFILTER	Input enabled with filter. DOUT determines pull direction	
	4	PUSHPULL	Push-pull output	
	5	PUSHPULLALT	Push-pull using alternate control	
	6	WIREDOR	Wired-or output	
	7	WIREDORPULLDOWN	Wired-or output with pull-down	
	8	WIREDAND	Open-drain output	
	9	WIREDANDFILTER	Open-drain output with filter	
	10	WIREDANDPULLUP	Open-drain output with pullup	
	11	WIREDANDPULLUP-FILTER	Open-drain output with filter and pullup	
	12	WIREDANDALT	Open-drain output using alternate control	
	13	WIREDANDALTFILTER	Open-drain output using alternate control with filter	
	14	WIREDANDALTPULL-UP	Open-drain output using alternate control with pullup	
	15	WIREDANDALTPUL-LUPFILTER	Open-drain output uisng alternate control with filter and pullup	
27:24	MODE6	0x0	RW	<b>Pin 6 Mode</b>
	Configure mode for pin 6.			
	Value	Mode	Description	
	0	DISABLED	Input disabled. Pullup if DOUT is set.	
	1	INPUT	Input enabled. Filter if DOUT is set	
	2	INPUTPULL	Input enabled. DOUT determines pull direction	
	3	INPUTPULLFILTER	Input enabled with filter. DOUT determines pull direction	
	4	PUSHPULL	Push-pull output	
	5	PUSHPULLALT	Push-pull using alternate control	
	6	WIREDOR	Wired-or output	
	7	WIREDORPULLDOWN	Wired-or output with pull-down	
	8	WIREDAND	Open-drain output	
	9	WIREDANDFILTER	Open-drain output with filter	
	10	WIREDANDPULLUP	Open-drain output with pullup	
	11	WIREDANDPULLUP-FILTER	Open-drain output with filter and pullup	

Bit	Name	Reset	Access	Description
	12	WIREDANDALT		Open-drain output using alternate control
	13	WIREDANDALTFILTER		Open-drain output using alternate control with filter
	14	WIREDANDALTPULL-UP		Open-drain output using alternate control with pullup
	15	WIREDANDALTPUL-LUPFILTER		Open-drain output uisng alternate control with filter and pullup
23:20	MODE5	0x0	RW	<b>Pin 5 Mode</b> Configure mode for pin 5.
	Value	Mode		Description
	0	DISABLED		Input disabled. Pullup if DOUT is set.
	1	INPUT		Input enabled. Filter if DOUT is set
	2	INPUTPULL		Input enabled. DOUT determines pull direction
	3	INPUTPULLFILTER		Input enabled with filter. DOUT determines pull direction
	4	PUSHPULL		Push-pull output
	5	PUSHPULLALT		Push-pull using alternate control
	6	WIREDOR		Wired-or output
	7	WIREDORPULLDOWN		Wired-or output with pull-down
	8	WIREDAND		Open-drain output
	9	WIREDANDFILTER		Open-drain output with filter
	10	WIREDANDPULLUP		Open-drain output with pullup
	11	WIREDANDPULLUP-FILTER		Open-drain output with filter and pullup
	12	WIREDANDALT		Open-drain output using alternate control
	13	WIREDANDALTFILTER		Open-drain output using alternate control with filter
	14	WIREDANDALTPULL-UP		Open-drain output using alternate control with pullup
	15	WIREDANDALTPUL-LUPFILTER		Open-drain output uisng alternate control with filter and pullup
19:16	MODE4	0x0	RW	<b>Pin 4 Mode</b> Configure mode for pin 4.
	Value	Mode		Description
	0	DISABLED		Input disabled. Pullup if DOUT is set.
	1	INPUT		Input enabled. Filter if DOUT is set
	2	INPUTPULL		Input enabled. DOUT determines pull direction
	3	INPUTPULLFILTER		Input enabled with filter. DOUT determines pull direction
	4	PUSHPULL		Push-pull output
	5	PUSHPULLALT		Push-pull using alternate control
	6	WIREDOR		Wired-or output

Bit	Name	Reset	Access	Description
	7	WIREDORPULLDOWN		Wired-or output with pull-down
	8	WIREDAND		Open-drain output
	9	WIREDANDFILTER		Open-drain output with filter
	10	WIREDANDPULLUP		Open-drain output with pullup
	11	WIREDANDPULLUP-FILTER		Open-drain output with filter and pullup
	12	WIREDANDALT		Open-drain output using alternate control
	13	WIREDANDALTFILTER		Open-drain output using alternate control with filter
	14	WIREDANDALTPULL-UP		Open-drain output using alternate control with pullup
	15	WIREDANDALTPUL-LUPFILTER		Open-drain output usng alternate control with filter and pullup
15:12	MODE3	0x0	RW	<b>Pin 3 Mode</b> Configure mode for pin 3.
	Value	Mode		Description
	0	DISABLED		Input disabled. Pullup if DOUT is set.
	1	INPUT		Input enabled. Filter if DOUT is set
	2	INPUTPULL		Input enabled. DOUT determines pull direction
	3	INPUTPULLFILTER		Input enabled with filter. DOUT determines pull direction
	4	PUSHPULL		Push-pull output
	5	PUSHPULLALT		Push-pull using alternate control
	6	WIREDOR		Wired-or output
	7	WIREDORPULLDOWN		Wired-or output with pull-down
	8	WIREDAND		Open-drain output
	9	WIREDANDFILTER		Open-drain output with filter
	10	WIREDANDPULLUP		Open-drain output with pullup
	11	WIREDANDPULLUP-FILTER		Open-drain output with filter and pullup
	12	WIREDANDALT		Open-drain output using alternate control
	13	WIREDANDALTFILTER		Open-drain output using alternate control with filter
	14	WIREDANDALTPULL-UP		Open-drain output using alternate control with pullup
	15	WIREDANDALTPUL-LUPFILTER		Open-drain output usng alternate control with filter and pullup
11:8	MODE2	0x0	RW	<b>Pin 2 Mode</b> Configure mode for pin 2.
	Value	Mode		Description
	0	DISABLED		Input disabled. Pullup if DOUT is set.
	1	INPUT		Input enabled. Filter if DOUT is set

Bit	Name	Reset	Access	Description
	2	INPUTPULL		Input enabled. DOUT determines pull direction
	3	INPUTPULLFILTER		Input enabled with filter. DOUT determines pull direction
	4	PUSHPULL		Push-pull output
	5	PUSHPULLALT		Push-pull using alternate control
	6	WIREDOR		Wired-or output
	7	WIREDORPULLDOWN		Wired-or output with pull-down
	8	WIREDAND		Open-drain output
	9	WIREDANDFILTER		Open-drain output with filter
	10	WIREDANDPULLUP		Open-drain output with pullup
	11	WIREDANDPULLUP-FILTER		Open-drain output with filter and pullup
	12	WIREDANDALT		Open-drain output using alternate control
	13	WIREDANDALTFILTER		Open-drain output using alternate control with filter
	14	WIREDANDALTPULL-UP		Open-drain output using alternate control with pullup
	15	WIREDANDALTPUL-LUPFILTER		Open-drain output usng alternate control with filter and pullup
7:4	MODE1	0x0	RW	<b>Pin 1 Mode</b> Configure mode for pin 1.
	Value	Mode		Description
	0	DISABLED		Input disabled. Pullup if DOUT is set.
	1	INPUT		Input enabled. Filter if DOUT is set
	2	INPUTPULL		Input enabled. DOUT determines pull direction
	3	INPUTPULLFILTER		Input enabled with filter. DOUT determines pull direction
	4	PUSHPULL		Push-pull output
	5	PUSHPULLALT		Push-pull using alternate control
	6	WIREDOR		Wired-or output
	7	WIREDORPULLDOWN		Wired-or output with pull-down
	8	WIREDAND		Open-drain output
	9	WIREDANDFILTER		Open-drain output with filter
	10	WIREDANDPULLUP		Open-drain output with pullup
	11	WIREDANDPULLUP-FILTER		Open-drain output with filter and pullup
	12	WIREDANDALT		Open-drain output using alternate control
	13	WIREDANDALTFILTER		Open-drain output using alternate control with filter
	14	WIREDANDALTPULL-UP		Open-drain output using alternate control with pullup
	15	WIREDANDALTPUL-LUPFILTER		Open-drain output usng alternate control with filter and pullup

Bit	Name	Reset	Access	Description
3:0	MODE0	0x0	RW	<b>Pin 0 Mode</b>
Configure mode for pin 0.				
Value	Mode	Description		
0	DISABLED	Input disabled. Pullup if DOUT is set.		
1	INPUT	Input enabled. Filter if DOUT is set		
2	INPUTPULL	Input enabled. DOUT determines pull direction		
3	INPUTPULLFILTER	Input enabled with filter. DOUT determines pull direction		
4	PUSHPULL	Push-pull output		
5	PUSHPULLALT	Push-pull using alternate control

	1	Interrupt flag set		
15:0	EXT	0x0000	R	<b>External Pin Interrupt Flag</b> Pin n external interrupt flag.
	Value	Description		
	0	External interrupt flag cleared		
	1	External interrupt flag set		

## 28.5.17 GPIO\_IFS - Interrupt Flag Set Register

Offset	Bit Position																																					
0x420	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Reset	0x0000																0x0000																					
Access	W1																W1																					
Name	EM4WU																EXT																					

Bit	Name	Reset	Access	Description
31:16	EM4WU	0x0000	W1	<b>Set EM4WU Interrupt Flag</b> Write 1 to set the EM4WU interrupt flag
15:0	EXT	0x0000	W1	<b>Set EXT Interrupt Flag</b> Write 1 to set the EXT interrupt flag

**28.5.18 GPIO\_IFC - Interrupt Flag Clear Register**

Offset	Bit Position																															
0x424	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x0000																0x0000															
Access	(R)W1																(R)W1															
Name	EM4WU																EXT															

Bit	Name	Reset	Access	Description
31:16	EM4WU	0x0000	(R)W1	<b>Clear EM4WU Interrupt Flag</b>  Write 1 to clear the EM4WU interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).
15:0	EXT	0x0000	(R)W1	<b>Clear EXT Interrupt Flag</b>  Write 1 to clear the EXT interrupt flag. Reading returns the value of the IF and clears the corresponding interrupt flags (This feature must be enabled globally in MSC.).

**28.5.19 GPIO\_IEN - Interrupt Enable Register**

Offset	Bit Position																															
0x428	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x0000																0x0000															
Access	RW																RW															
Name	EM4WU																EXT															

Bit	Name	Reset	Access	Description
31:16	EM4WU	0x0000	RW	<b>EM4WU Interrupt Enable</b>  Enable/disable the EM4WU interrupt
15:0	EXT	0x0000	RW	<b>EXT Interrupt Enable</b>  Enable/disable the EXT interrupt

28.5.20 GPIO\_EM4WUEN - EM4 wake up Enable Register

Offset	Bit Position																															
0x42C	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset	0x0000																															
Access	RW																															
Name	EM4WUEN																															

Bit	Name	Reset	Access	Description
31:16	EM4WUEN	0x0000	RW	<b>EM4 wake up enable</b> Write 1 to enable EM4 wake up request, write 0 to disable EM4 wake up request.
	Value	Description		
	0	Disable EM4 wake up on pin		
	1	Enable EM4 wake up on pin		
15:0	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		

28.5.21 GPIO\_ROUTEPEN - I/O Routing Pin Enable Register

Offset	Bit Position																											
0x440	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4
Reset																											0	3
Access																											RW	RW
Name																											SWVPEN	TDIPEN
																											TDOPEN	SWDIOTMSPEN
																											SWCLKTCKPEN	

Bit	Name	Reset	Access	Description
31:5	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
4	SWVPEN	0	RW	<b>Serial Wire Viewer Output Pin Enable</b> Enable Serial Wire Viewer connection to pin.
3	TDIPEN	1	RW	<b>JTAG Test Debug Input Pin Enable</b> Enable JTAG TDI connection to pin.
2	TDOPEN	1	RW	<b>JTAG Test Debug Output Pin Enable</b> Enable JTAG TDO connection to pin.
1	SWDIOTMSPEN	1	RW	<b>Serial Wire Data and JTAG Test Mode Select Pin Enable</b> Enable Serial Wire Data and JTAG Test Mode Select connection to pin. WARNING: When this pin is disabled, the device can no longer be accessed by a debugger. A reset will set the pin back to a default state as enabled. If you disable this pin, make sure you have at least a 3 second timeout at the start of you program code before you disable the pin. This way, the debugger will have time to halt the device after a reset before the pin is disabled.
0	SWCLKTCKPEN	1	RW	<b>Serial Wire Clock and JTAG Test Clock Pin Enable</b> Enable Serial Wire and JTAG Clock connection to pin. WARNING: When this pin is disabled, the device can no longer be accessed by a debugger. A reset will set the pin back to a default state as enabled. If you disable this pin, make sure you have at least a 3 second timeout at the start of you program code before you disable the pin. This way, the debugger will have time to halt the device after a reset before the pin is disabled.

**28.5.22 GPIO\_ROUTELOC0 - I/O Routing Location Register**

Offset	Bit Position																															
0x444	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																									0x00							
Access																									RW							
Name																									SWVLOC							

Bit	Name	Reset	Access	Description
31:6	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
5:0	SWVLOC	0x00	RW	<b>I/O Location</b> Decides the location of the SWV pins.
	Value	Mode		Description
	0	LOC0		Location 0
	1	LOC1		Location 1
	2	LOC2		Location 2
	3	LOC3		Location 3

**28.5.23 GPIO\_INSENSE - Input Sense Register**

Offset	Bit Position																															
0x450	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																											1	1	0			
Access																											RW	RW	RW			
Name																											EM4WU	INT				

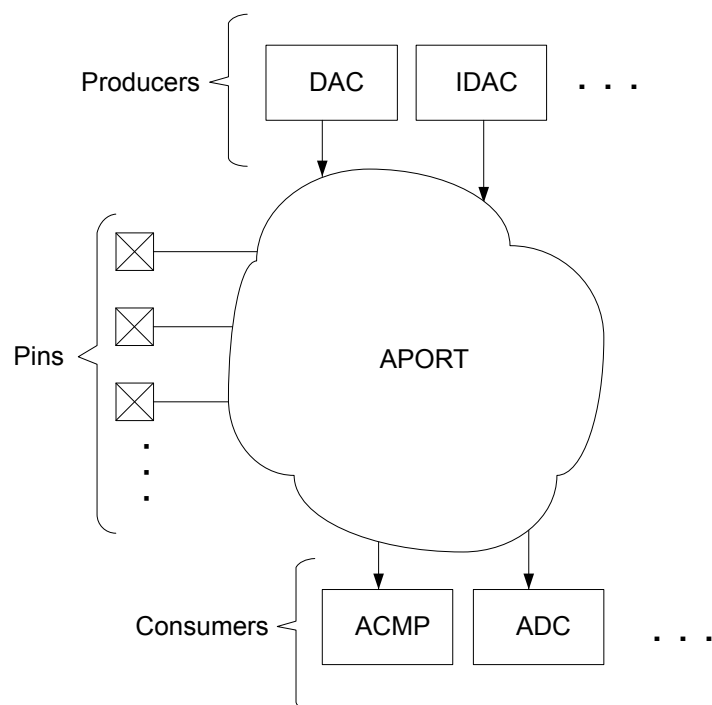

Bit	Name	Reset	Access	Description
31:2	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
1	EM4WU	1	RW	<b>EM4WU Interrupt Sense Enable</b> Set this bit to enable input sensing for EM4WU interrupts.
0	INT	1	RW	<b>Interrupt Sense Enable</b> Set this bit to enable input sensing for interrupts.

28.5.24 GPIO\_LOCK - Configuration Lock Register

Offset	Bit Position																															
0x454	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reset																	0x0000															
Access																	RWH															
Name																	LOCKKEY															

Bit	Name	Reset	Access	Description
31:16	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a>		
15:0	LOCKKEY	0x0000	RWH	<b>Configuration Lock Key</b>  Write any other value than the unlock code to lock MODEL, MODEH, CTRL, PINLOCKN, OVTDIS, EXTIPSELL, EXTIPSELH, EXTIGSELL, EXTIGSELH, INSENSE, ROUTEPEN, and ROUTELOC0 from editing. Write the unlock code to unlock. When reading the register, bit 0 is set when the lock is enabled.
Mode		Value		Description
Read Operation				
UNLOCKED		0		GPIO registers are unlocked
LOCKED		1		GPIO registers are locked
Write Operation				
LOCK		0		Lock GPIO registers
UNLOCK		0xA534		Unlock GPIO registers

## 29. APORT - Analog Port

### Quick Facts

#### What?

The Analog Port (APORT) is a set of analog buses which are used to connect I/O pins to analog peripheral signals.

#### Why?

The APORT gives on-chip analog resources access to a large number of I/O pins, and provides the system designer with a high degree of routing flexibility.

#### How?

An analog peripheral requests a pad by simply configuring its input/output to use a channel on APORT. That selection becomes an APORT request where the APORT control switches the pad and the analog signal onto a common bus.

### 29.1 Introduction

APORT consists of wires, switches, and control logic needed to route signals between analog peripherals and I/O pins. On-chip clients can be either producers or consumers. Analog producers are active devices that drive current/voltage into an APORT, such as current or voltage DACs. Consumers are passive devices that monitor or react to the current/voltage routed to them via the APORT, such as ADCs or analog comparators (ACMP).

### 29.2 Features

- Pins are typically mapped to two different APORT buses
- Arbitration and conflict status provided to each APORT client

### 29.3 Functional Description

**Figure 29.1. Analog Bus (ABUS)**

An analog bus (ABUS) consists of analog switches connected to a common wire as shown in [Figure 29.1 Analog Bus \(ABUS\) on page 960](#). An APORT consists of multiple ABUSes. Since many clients can operate differentially, buses are grouped by pairs as X and Y. If a given client uses a single ABUS (e.g. single-ended ADC), X and Y are just labels to differentiate the two buses.

When operating differentially, most APORT clients require that one input be chosen from an X bus and the other from a Y bus. For example, the ACMP block will not allow both positive and negative inputs to be chosen from X buses.

## 29.3.1 APORT ABUS Naming

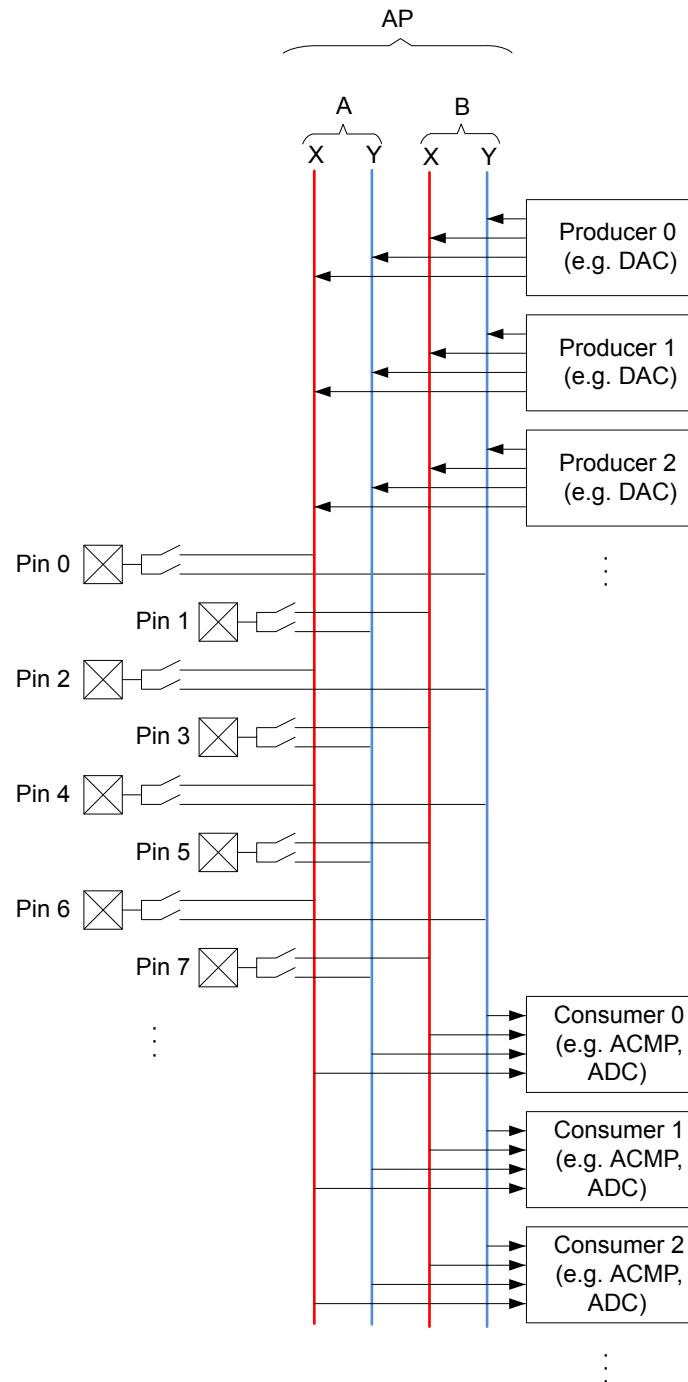

Figure 29.2. APORT Structure

APORT ABUSes are prefixed with "AP" and are grouped in pairs. Each pair is uniquely identified using a letter prefix ("A", "B", "C", etc.) followed by either a "X" or "Y" to identify the ABUS in the pair. For example, "APDX" decodes as: "AP"=APORT, "D"=pair, "X"=bus. [Figure 29.2 APORT Structure on page 961](#) illustrates this organization.

APORT clients are generally described in this reference manual. For example, the ACMP client is described once, but the device could contain multiple instances of the ACMP. Because of this, for APORT client descriptions in this reference manual, the ABUS connections are generalized with the prefix "BUS" followed by a number (instead of the "AP" followed by a letter). It is possible that different

instances of an APORT client connect to different ABUSes. For example, ACMP0 BUS1X might connect to the ABUS APAX while ACMP1 BUS1X might connect to ABUS APCX. Refer to the APORT Client Map in the device datasheet to map the generalized APORT client bus name to an actual device ABUS.

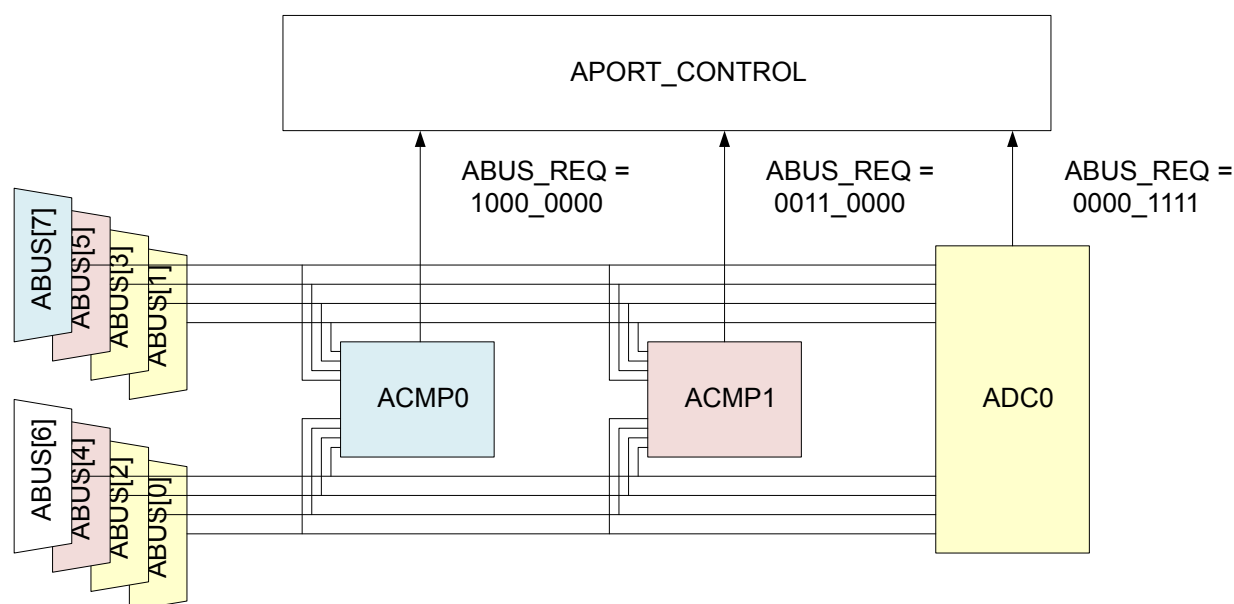

A given ABUS has multiple switches which need to be identified. The switches on a bus are specified with the bus name ID followed by a channel ID. For example, channel switch 7 on a given APORT client might be given as BUS1XCH7. Channels are not always map to an I/O for a particular device. Refer to the APORT Client Map in the device datasheet for which channels are mapped, and if mapped, to which I/O.

### 29.3.2 Managing ABUSes

The ABUSes of an APORT are shared resources. The user needs to be mindful of this in assigning I/O for different clients throughout the chip, as it is possible to have conflicts for a given ABUS. Each ABUS has an arbiter responsible for limiting the control over the ABUS to one and only one client. If multiple clients attempt to control an ABUS, the arbiter allows no client control over the ABUS and asserts a conflict signal to the clients. The user has the ability to check for such a conflict in each client's status, as well as generate an interrupt.

Having only one client control an ABUS is not the same as having only one user of an ABUS. It is possible for multiple clients to access a single ABUS, but requires all but one client to relinquish control of the ABUS. To do this, some clients have bits to disable bus master-ship which are 0 by default. One example is the BUSXMASTERDIS bit in the ACMPn\_CTRL. When set to 1, the client will not assert control of the ABUS switches, but may still connect to an ABUS that is controlled by another client.

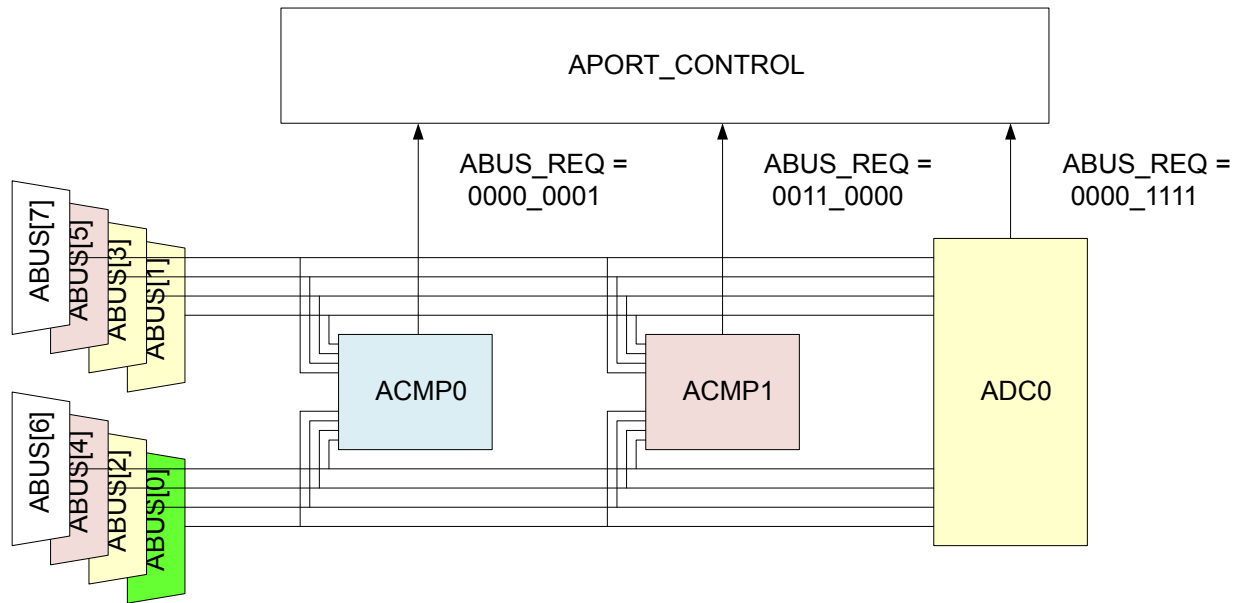

For example, if an IDAC, ADC, and ACMP all want to use the same pin on a particular ABUS the user might set the bus master disable bit to 1 for the IDAC and ACMP. The ADC is the sole master of the switch configuration on that ABUS, so switches are configured using the configuration set in the ADC.

**Figure 29.3. APORT Example 1**

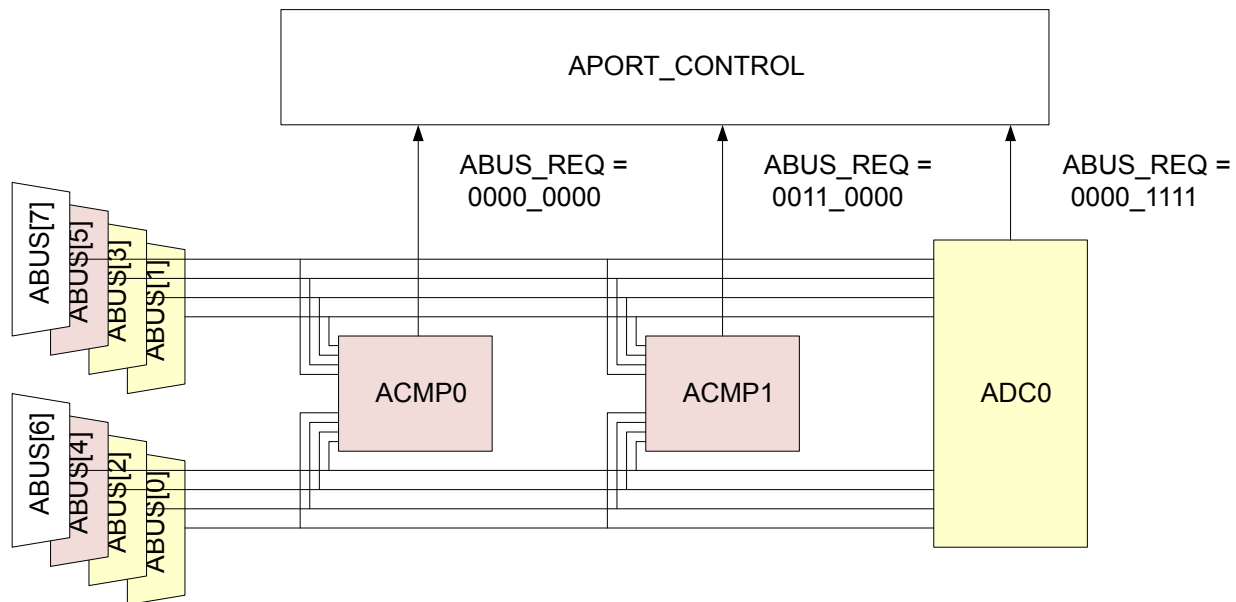

Figure 29.3 APORT Example 1 on page 963 illustrates the sharing of APORT. For illustration purposes, each ABUS is identified by a numeric index (instead of APAX, APAY, APBX, etc.). Also, the requests from all the APORT clients are packed into a bit-vector named **BUS\_REQ** to illustrate the request from the APORT Clients (instead of by name such as **BUS1XREQ**, **BUS1YREQ**, **BUS2XREQ**, etc.). In Figure 29.3 APORT Example 1 on page 963, ABUS and client are the same color if the client has been granted the ABUS.

In Figure 29.3 APORT Example 1 on page 963 ADC0 has requested ABUS[3:0], ACMP1 has requested ABUS[5:4], ACMP0 has requested ABUS[7], and ABUS[6] is unused. No APORT Client has requested the same ABUS as another, so there is no conflict.

**Figure 29.4. APORT Example 2: Bus Conflict**

In [Figure 29.4 APORT Example 2: Bus Conflict on page 964](#) is a similar example to [Figure 29.3 APORT Example 1 on page 963](#), but now both ACMP0 and ADC0 are requesting ABUS[0]. This is a configuration error, so APORT grants neither client ABUS[0]. The user must resolve the conflict before ABUS[0] is useable.

**Figure 29.5. APORT Example 3: Sharing an ABUS**

[Figure 29.5 APORT Example 3: Sharing an ABUS on page 964](#) illustrates ABUS sharing. Both ACMPs are configured identically, except ACMP0 has its BUSMASTERDIS bit-field set to 1. There is only one APORT master for ABUS[5:4], so there is no conflict.

## Appendix 1. Abbreviations

This section lists abbreviations used in this document.

**Table 1.1. Abbreviations**

Abbreviation	Description
ADC	Analog to Digital Converter
AES	Advanced Encryption Standard
AFC	Automatic Frequency Control
AGC	Automatic Gain Control
AHB	AMBA Advanced High-performance Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".
APB	AMBA Advanced Peripheral Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".
ASK	Amplitude Shift Keying
BT	Bandwidth Time product
BUFC	Buffer Controller
BR	Baud Rate
BW	Bandwidth
CBC	Cipher Block Chaining (AES mode of operation)
CBC-MAC	Cipher Block Chaining - Message Authentication Code (AES mode of operation)
CC	Compare / Capture
CCA	Clear Channel Assessment
CFB	Cipher Feedback (AES mode of operation)
CLK	Clock
CMD	Command
CMU	Clock Management Unit
CM3	ARM Cortex-M3
CM4	ARM Cortex-M4
CRC	Cyclic Redundancy Check
CTR	Counter mode (AES mode of operation)
CTRL	Control
DBG	Debug
DC	Direct Current
DEMOD	Demodulator
DSSS	Direct Sequence Spread Spectrum
ECB	Electronic Code Book (AES mode of operation)
EFR32	Wireless Gecko
EM	Energy Mode
EMU	Energy Management Unit
FEC	Forward Error Correction

Abbreviation	Description
FRC	Frame Controller
FSK	Frequency Shift Keying
GFSK	Gaussian Frequency Shift Keying
GMSK	Gaussian Minimum Shift Keying
GPIO	General Purpose Input / Output
HFRCO	High Frequency RC Oscillator
HFXO	High Frequency Crystal Oscillator
HW	Hardware
Hz	Hertz
IF	Intermediate Frequency
ISR	Interrupt Service Routine
LFRCO	Low Frequency RC Oscillator
LFXO	Low Frequency Crystal Oscillator
LO	Local Oscillator
MOD	Modulator
MODEM	Modulator and Demodulator
MSK	Minimum Shift Keying
NRZ	Non Return to Zero
NVIC	Nested Vector Interrupt Controller
OFB	Output Feedback Mode (AES mode of operation)
OOK	On Off Keying
OQPSK	Offset Quadrature Phase Shift Keying
PD	Power Down
PRS	Peripheral Reflex System
PROTIMER	Protocol Timer
PWM	Pulse Width Modulation
RAM	Random Access Memory
RF	Radio Frequency
RMU	Reset Management Unit
RSM	Radio State Machine
RSSI	Received Signal Strength Indicator
RTC	Real Time Counter
RX	Receive
SPI	Serial Peripheral Interface
SW	Software
SYNTH	Synthesiser
TX	Transmit

Abbreviation	Description
XTAL	Crystal

7.3.3.2 Device Erase	.92
7.3.3.3 System Reset	.92
7.3.3.4 System Bus Stall	.92
7.3.3.5 User Flash Page CRC.	.92
7.3.4 Debug Lock	.93
7.3.5 AAP Lock.	.93
7.3.6 Debugger reads of actionable registers.	.93
7.3.7 Debug Recovery	.94
7.4 Register Map	.94
7.5 Register Description.	.94
7.5.1 AAP_CMD - Command Register	.94
7.5.2 AAP_CMDKEY - Command Key Register	.95
7.5.3 AAP_STATUS - Status Register	.95
7.5.4 AAP_CTRL - Control Register	.96
7.5.5 AAP_CRCCMD - CRC Command Register	.96
7.5.6 AAP_CRCSTATUS - CRC Status Register	.97
7.5.7 AAP_CRCADDR - CRC Address Register	.97
7.5.8 AAP_CRCRESULT - CRC Result Register	.98
7.5.9 AAP_IDR - AAP Identification Register	.98
<b>8. MSC - Memory System Controller</b>	<b>99</b>
8.1 Introduction.	.99
8.2 Features.	100
8.3 Functional Description	101
8.3.1 User Data (UD) Page Description	101
8.3.2 Lock Bits (LB) Page Description	102
8.3.3 Device Information (DI) Page	102
8.3.4 Bootloader	102
8.3.5 Device Revision	103
8.3.6 Post-reset Behavior	103
8.3.7 Flash Startup	103
8.3.8 Wait-states	104
8.3.8.1 One Wait-state Access	104
8.3.8.2 Zero Wait-state Access	104
8.3.8.3 Operation Above	104

8.3.9	Suppressed Conditional Branch Target Prefetch (SCBTP)	104
8.3.10	Cortex-M4 If-Then Block Folding	104
8.3.11	Instruction Cache	105
8.3.12	Erase and Write Operations	106
8.3.12.1	Mass erase	106
8.4	Register Map	107
8.5	Register Description	108
8.5.1	MSC_CTRL - Memory System Control Register	108
8.5.2	MSC_READCTRL - Read Control Register	109
8.5.3	MSC_WRITECTRL - Write Control Register	111
8.5.4	MSC_WRITECMD - Write Command Register	112
8.5.5	MSC_ADDRB - Page Erase/Write Address Buffer	113
8.5.6	MSC_WDATA - Write Data Register	113
8.5.7	MSC_STATUS - Status Register	114
8.5.8	MSC_IF - Interrupt Flag Register	115
8.5.9	MSC_IFS - Interrupt Flag Set Register	116
8.5.10	MSC_IFC - Interrupt Flag Clear Register	117
8.5.11	MSC_IEN - Interrupt Enable Register	118
8.5.12	MSC_LOCK - Configuration Lock Register	119
8.5.13	MSC_CACHECMD - Flash Cache Command Register	120
8.5.14	MSC_CACHEHITS - Cache Hits Performance Counter	120
8.5.15	MSC_CACHEMISSES - Cache Misses Performance Counter	121
8.5.16	MSC_MASSLOCK - Mass Erase Lock Register	121
8.5.17	MSC_STARTUP - Startup Control	122
8.5.18	MSC_CMD - Command Register	123
<b>9.</b>	<b>LDMA - Linked DMA Controller.</b>	<b>124</b>
9.1	Introduction	124
9.1.1	Features	125
9.2	Block Diagram	126
9.3	Functional Description	127
9.3.1	Channel Descriptor	127
9.3.1.1	DMA Transfer Size	127
9.3.1.2	Source/Destination Increments	127
9.3.1.3	Block Size	127
9.3.1.4	Transfer Count	128
9.3.1.5	Descriptor List	128
9.3.1.6	Addresses	128
9.3.1.7	Addressing Modes	128
9.3.1.8	Byte Swap	129
9.3.1.9	DMA Size and Source/Destination Increment Programming	130
9.3.2	Channel Configuration	132
9.3.2.1	Address Increment/Decrement	132
9.3.2.2	Loop Counter	132
9.3.3	Channel Select Configuration	132
9.3.4	Starting a transfer	132
9.3.4.1	Peripheral Transfer Requests	133
9.3.5	Managing Transfer Errors	133
9.3.6	Arbitration	133

9.3.6.1 Arbitration Priority . . . . .	133
9.3.6.2 DMA Transfer Arbitration . . . . .	135
9.3.7 Channel descriptor data structure . . . . .	136
9.3.7.1 XFER descriptor structure . . . . .	136
9.3.7.2 SYNC descriptor structure . . . . .	137
9.3.7.3 WRI descriptor structure . . . . .	138
9.3.8 Interaction with the EMU . . . . .	138
9.3.9 Interrupts . . . . .	139
9.3.10 Debugging . . . . .	139
9.4 Examples . . . . .	139
9.4.1 Single Direct Register DMA Transfer . . . . .	139
9.4.2 Descriptor Linked List . . . . .	140
9.4.3 Single Descriptor Looped Transfer . . . . .	142
9.4.4 Descriptor List with Looping . . . . .	143
9.4.5 Simple Inter-Channel Synchronization . . . . .	144
9.4.6 2D Copy . . . . .	146
9.4.7 Ping-Pong . . . . .	148
9.4.8 Scatter-Gather . . . . .	149
9.5 Register Map . . . . .	150
9.6 Register Description . . . . .	151
9.6.1 LDMA_CTRL - DMA Control Register . . . . .	151
9.6.2 LDMA_STATUS - DMA Status Register . . . . .	152
9.6.3 LDMA_SYNC - DMA Synchronization Trigger Register (Single-Cycle RMW) . . . . .	153
9.6.4 LDMA_CHEN - DMA Channel Enable Register (Single-Cycle RMW) . . . . .	153
9.6.5 LDMA_CHBUSY - DMA Channel Busy Register . . . . .	154
9.6.6 LDMA_CHDONE - DMA Channel Linking Done Register (Single-Cycle RMW) . . . . .	154
9.6.7 LDMA_DBGHALT - DMA Channel Debug Halt Register . . . . .	155
9.6.8 LDMA_SWREQ - DMA Channel Software Transfer Request Register . . . . .	155
9.6.9 LDMA_REQDIS - DMA Channel Request Disable Register . . . . .	156
9.6.10 LDMA_REQPEND - DMA Channel Requests Pending Register . . . . .	156
9.6.11 LDMA_LINKLOAD - DMA Channel Link Load Register . . . . .	157
9.6.12 LDMA_REQCLEAR - DMA Channel Request Clear Register . . . . .	157
9.6.13 LDMA_IF - Interrupt Flag Register . . . . .	158
9.6.14 LDMA_IFS - Interrupt Flag Set Register . . . . .	158
9.6.15 LDMA_IFC - Interrupt Flag Clear Register . . . . .	159
9.6.16 LDMA_IEN - Interrupt Enable register . . . . .	159
9.6.17 LDMA_CHx_REQSEL - Channel Peripheral Request Select Register . . . . .	160
9.6.18 LDMA_CHx_CFG - Channel Configuration Register . . . . .	163
9.6.19 LDMA_CHx_LOOP - Channel Loop Counter Register . . . . .	164
9.6.20 LDMA_CHx_CTRL - Channel Descriptor Control Word Register . . . . .	165
9.6.21 LDMA_CHx_SRC - Channel Descriptor Source Data Address Register . . . . .	168
9.6.22 LDMA_CHx_DST - Channel Descriptor Destination Data Address Register . . . . .	169
9.6.23 LDMA_CHx_LINK - Channel Descriptor Link Structure Address Register . . . . .	170
<b>10. RMU - Reset Management Unit . . . . .</b>	<b>171</b>
10.1 Introduction . . . . .	171
10.2 Features . . . . .	171
10.3 Functional Description . . . . .	172

10.3.1	Reset levels	173
10.3.2	RMU_RSTCAUSE Register	174
10.3.3	Power-On Reset (POR)	175
10.3.4	Brown-Out Detector (BOD)	175
10.3.5	RESETn pin Reset	176
10.3.6	Watchdog Reset	176
10.3.7	Lockup Reset	176
10.3.8	System Reset Request	176
10.3.9	Radio Reset	176
10.3.10	Reset state	176
10.3.11	Registers with alternate reset	176
10.4	Registers with alternate reset	177
10.5	Register Map	178
10.6	Register Description	179
10.6.1	RMU_CTRL - Control Register	179
10.6.2	RMU_RSTCAUSE - Reset Cause Register	182
10.6.3	RMU_CMD - Command Register	184
10.6.4	RMU_RST - Reset Control Register	184
10.6.5	RMU_LOCK - Configuration Lock Register	185
<b>11.</b>	<b>EMU - Energy Management Unit</b>	<b>186</b>
11.1	Introduction	186
11.2	Features	186
11.3	Functional Description	187
11.3.1	Energy Modes	188
11.3.1.1	EM0 Active	189
11.3.1.2	EM1 Sleep	189
11.3.1.3	EM2 DeepSleep	190
11.3.1.4	EM3 Stop	190
11.3.1.5	EM4 Hibernate	191
11.3.1.6	EM4 Shutoff	191
11.3.2	Entering Low Energy Modes	191
11.3.2.1	Entry into EM1 Sleep	191
11.3.2.2	Entry into EM2 DeepSleep or EM3 Stop	192
11.3.2.3	Entry into EM4 Hibernate	192
11.3.3	Exiting a Low Energy Mode	193
11.3.4	Power Configurations	194
11.3.4.1	Power Configuration 0: STARTUP	195
11.3.4.2	Power Configuration 1: No DC-DC	196
11.3.4.3	Power Configuration 2: DC-DC	197
11.3.5	DC-to-DC Interface	198
11.3.5.1	Bypass Mode	198
11.3.5.2	Low Power (LP) Mode	199
11.3.5.3	Low Noise (LN) Mode	199
11.3.5.4	Analog Peripheral Power Selection	200
11.3.5.5	IOVDD Connection	200
11.3.5.6	DC-to-DC Programming Guidelines	200
11.3.6	Brown Out Detector (BOD)	200
11.3.6.1	AVDD BOD	200
11.3.6.2	DVDD and DECOUPLE BOD	200

11.3.7	Voltage Monitor (VMON)	201
11.3.8	Powering off SRAM blocks	201
11.3.9	Temperature Sensor Status	201
11.3.10	Registers latched in EM4.	201
11.3.11	Register Resets	201
11.4	Register Map	202
11.5	Register Description	203
11.5.1	EMU_CTRL - Control Register	203
11.5.2	EMU_STATUS - Status Register	204
11.5.3	EMU_LOCK - Configuration Lock Register	206
11.5.4	EMU_RAM0CTRL - Memory Control Register	207
11.5.5	EMU_CMD - Command Register	208
11.5.6	EMU_EM4CTRL - EM4 Control Register	209
11.5.7	EMU_TEMPLIMITS - Temperature limits for interrupt generation	210
11.5.8	EMU_TEMP - Value of last temperature measurement	210
11.5.9	EMU_IF - Interrupt Flag Register	211
11.5.10	EMU_IFS - Interrupt Flag Set Register	214
11.5.11	EMU_IFC - Interrupt Flag Clear Register	217
11.5.12	EMU_IEN - Interrupt Enable Register	220
11.5.13	EMU_PWRLOCK - Regulator and Supply Lock Register	222
11.5.14	EMU_PWRCFG - Power Configuration Register. This is no longer used	223
11.5.15	EMU_PWRCTRL - Power Control Register.	223
11.5.16	EMU_DCDCCTRL - DCDC Control	224
11.5.17	EMU_DCDCMISCCTRL - DCDC Miscellaneous Control Register	225
11.5.18	EMU_DCDCZDETCTRL - DCDC Power Train NFET Zero Current Detector Control Register	227
11.5.19	EMU_DCDCCLIMCTRL - DCDC Power Train PFET Current Limiter Control Register	228
11.5.20	EMU_DCDCLNVCTRL - DCDC Low Noise Voltage Register	229
11.5.21	EMU_DCDCTIMING - DCDC Controller Timing Value Register	230
11.5.22	EMU_DCDCLPVCTRL - DCDC Low Power Voltage Register	231
11.5.23	EMU_DCDCLPCTRL - DCDC Low Power Control Register	232
11.5.24	EMU_DCDCLNFREQCTRL - DCDC Low Noise Controller Frequency Control	233
11.5.25	EMU_DCDCSYNC - DCDC Read Status Register	233
11.5.26	EMU_VMONAVDDCTRL - VMON AVDD Channel Control	234
11.5.27	EMU_VMONALTAVDDCTRL - Alternate VMON AVDD Channel Control	235
11.5.28	EMU_VMONDVDDCTRL - VMON DVDD Channel Control	236
11.5.29	EMU_VMONIO0CTRL - VMON IOVDD0 Channel Control	237
11.5.30	EMU_VMONPAVDDCTRL - VMON PAVDD Channel Control	238
<b>12.</b>	<b>CMU - Clock Management Unit</b>	<b>239</b>
12.1	Introduction	239
12.2	Features	239
12.3	Functional Description	240
12.3.1	System Clocks	242
12.3.1.1	HFCLK - High Frequency Clock	242
12.3.1.2	HFCORECLK - High Frequency Core Clock	242
12.3.1.3	HFBUSCLK - High Frequency Bus Clock	242
12.3.1.4	HFPERCLK - High Frequency Peripheral Clock	242
12.3.1.5	HFRADIOCLK - High Frequency Radio Clock	243

12.3.1.6	LFACLK - Low Frequency A Clock . . . . .	243
12.3.1.7	LFBCLK - Low Frequency B Clock . . . . .	243
12.3.1.8	LFECLK - Low Frequency E Clock . . . . .	243
12.3.1.9	PCNTnCLK - Pulse Counter n Clock . . . . .	243
12.3.1.10	WDOGCLK - Watchdog Timer Clock . . . . .	244
12.3.1.11	CRYOCLK - Cryotimer Clock. . . . .	244
12.3.1.12	RFSENSECLK - RFSENSE Clock . . . . .	244
12.3.1.13	AUXCLK - Auxiliary Clock. . . . .	244
12.3.1.14	Debug Trace Clock . . . . .	244
12.3.2	Oscillators . . . . .	244
12.3.2.1	Enabling and Disabling . . . . .	245
12.3.2.2	Oscillator Start-up Time and Time-out . . . . .	248
12.3.2.3	Switching Clock Source . . . . .	249
12.3.2.4	HFXO Configuration . . . . .	251
12.3.2.5	LFXO Configuration . . . . .	254
12.3.2.6	HFRCO and AUXHFRCO Configuration . . . . .	255
12.3.2.7	LFRCO Configuration . . . . .	255
12.3.2.8	RC Oscillator Calibration . . . . .	256
12.3.2.9	Automatic HFXO Start . . . . .	258
12.3.3	Configuration For Operating Frequencies . . . . .	261
12.3.4	Energy Modes. . . . .	262
12.3.5	Clock Output on a Pin . . . . .	263
12.3.6	Clock Input from a Pin . . . . .	263
12.3.7	Clock Output on PRS . . . . .	263
12.3.8	Error Handling. . . . .	263
12.3.9	Interrupts . . . . .	263
12.3.10	Wake-up . . . . .	264
12.3.11	Protection . . . . .	264
12.4	Register Map. . . . .	265
12.5	Register Description . . . . .	267
12.5.1	CMU_CTRL - CMU Control Register . . . . .	267
12.5.2	CMU_HFRCOCTRL - HFRCO Control Register . . . . .	270
12.5.3	CMU_AUXHFRCOCTRL - AUXHFRCO Control Register . . . . .	272
12.5.4	CMU_LFRCOCTRL - LFRCO Control Register . . . . .	273
12.5.5	CMU_HFXOCTRL - HFXO Control Register . . . . .	274
12.5.6	CMU_HFXOCTRL1 - HFXO Control 1 . . . . .	277
12.5.7	CMU_HFXOSTARTUPCTRL - HFXO Startup Control . . . . .	278
12.5.8	CMU_HFXOSTEADYSTATECTRL - HFXO Steady State control . . . . .	279
12.5.9	CMU_HFXOTIMEOUTCTRL - HFXO Timeout Control . . . . .	280
12.5.10	CMU_LFXOCTRL - LFXO Control Register . . . . .	283
12.5.11	CMU_CALCTRL - Calibration Control Register . . . . .	286
12.5.12	CMU_CALCNT - Calibration Counter Register . . . . .	289
12.5.13	CMU_OSCENCMD - Oscillator Enable/Disable Command Register . . . . .	290
12.5.14	CMU_CMD - Command Register . . . . .	291
12.5.15	CMU_DBGCLKSEL - Debug Trace Clock Select . . . . .	292
12.5.16	CMU_HFCLKSEL - High Frequency Clock Select Command Register . . . . .	292
12.5.17	CMU_LFACLKSEL - Low Frequency A Clock Select Register . . . . .	293
12.5.18	CMU_LFBCLKSEL - Low Frequency B Clock Select Register . . . . .	293
12.5.19	CMU_LFECLKSEL - Low Frequency E Clock Select Register . . . . .	294
12.5.20	CMU_STATUS - Status Register . . . . .	295

12.5.21	CMU_HFCLKSTATUS - HFCLK Status Register . . . . .	297
12.5.22	CMU_HFXOTRIMSTATUS - HFXO Trim Status . . . . .	298
12.5.23	CMU_IF - Interrupt Flag Register . . . . .	299
12.5.24	CMU_IFS - Interrupt Flag Set Register . . . . .	301
12.5.25	CMU_IFC - Interrupt Flag Clear Register . . . . .	303
12.5.26	CMU_IEN - Interrupt Enable Register . . . . .	306
12.5.27	CMU_HFBUSCLKEN0 - High Frequency Bus Clock Enable Register 0 . . . . .	308
12.5.28	CMU_HFPERCLKEN0 - High Frequency Peripheral Clock Enable Register 0 . . . . .	309
12.5.29	CMU_LFACLKEN0 - Low Frequency A Clock Enable Register 0 (Async Reg) . . . . .	310
12.5.30	CMU_LFBCLKEN0 - Low Frequency B Clock Enable Register 0 (Async Reg) . . . . .	310
12.5.31	CMU_LFECLKEN0 - Low Frequency E Clock Enable Register 0 (Async Reg) . . . . .	311
12.5.32	CMU_HFPRESC - High Frequency Clock Prescaler Register . . . . .	312
12.5.33	CMU_HFCOREPRESC - High Frequency Core Clock Prescaler Register . . . . .	313
12.5.34	CMU_HFPERPRESC - High Frequency Peripheral Clock Prescaler Register . . . . .	313
12.5.35	CMU_HFEXPPRESC - High Frequency Export Clock Prescaler Register . . . . .	314
12.5.36	CMU_LFAPRESC0 - Low Frequency A Prescaler Register 0 (Async Reg) . . . . .	315
12.5.37	CMU_LFBPRESC0 - Low Frequency B Prescaler Register 0 (Async Reg) . . . . .	316
12.5.38	CMU_LFEPRESC0 - Low Frequency E Prescaler Register 0 (Async Reg). When waking up from EM4 make sure EM4UNLATCH in EMU_CMD is set for this to take effect . . . . .	316
12.5.39	CMU_SYNCBUSY - Synchronization Busy Register . . . . .	317
12.5.40	CMU_FREEZE - Freeze Register . . . . .	320
12.5.41	CMU_PCNTCTRL - PCNT Control Register . . . . .	321
12.5.42	CMU_ADCCTRL - ADC Control Register . . . . .	322
12.5.43	CMU_ROUTEPEN - I/O Routing Pin Enable Register . . . . .	323
12.5.44	CMU_ROUTELOC0 - I/O Routing Location Register . . . . .	324
12.5.45	CMU_LOCK - Configuration Lock Register . . . . .	325
<b>13.</b>	<b>RTCC - Real Time Counter and Calendar . . . . .</b>	<b>326</b>
13.1	Introduction . . . . .	326
13.2	Features . . . . .	327
13.3	Functional Description . . . . .	327
13.3.1	Counter . . . . .	328
13.3.1.1	Normal Mode . . . . .	329
13.3.1.2	Calendar Mode. . . . .	330
13.3.1.3	RTCC Initialization . . . . .	330
13.3.2	Capture/Compare Channels . . . . .	331
13.3.3	Interrupts and PRS Output . . . . .	333
13.3.3.1	Main Counter Tick PRS Output . . . . .	334
13.3.4	Energy Mode Availability . . . . .	334
13.3.5	Register Lock . . . . .	334
13.3.6	Oscillator Failure Detection . . . . .	334
13.3.7	Retention Registers . . . . .	334
13.3.8	Frame Controller Interface . . . . .	334
13.3.9	Debug Session . . . . .	334
13.4	Register Map. . . . .	335
13.5	Register Description . . . . .	336
13.5.1	RTCC_CTRL - Control Register (Async Reg) . . . . .	336
13.5.2	RTCC_PRECNT - Pre-Counter Value Register (Async Reg) . . . . .	338

13.5.3	RTCC_CNT - Counter Value Register (Async Reg)	339
13.5.4	RTCC_COMBCNT - Combined Pre-Counter and Counter Value Register	339
13.5.5	RTCC_TIME - Time of day register (Async Reg)	340
13.5.6	RTCC_DATE - Date register (Async Reg)	341
13.5.7	RTCC_IF - RTCC Interrupt Flags	342
13.5.8	RTCC_IFS - Interrupt Flag Set Register	343
13.5.9	RTCC_IFC - Interrupt Flag Clear Register	344
13.5.10	RTCC_IEN - Interrupt Enable Register	346
13.5.11	RTCC_STATUS - Status register	347
13.5.12	RTCC_CMD - Command Register	347
13.5.13	RTCC_SYNCBUSY - Synchronization Busy Register	347
13.5.14	RTCC_POWERDOWN - Retention RAM power-down register (Async Reg)	348
13.5.15	RTCC_LOCK - Configuration Lock Register (Async Reg)	348
13.5.16	RTCC_EM4WUEN - Wake Up Enable	349
13.5.17	RTCC_CCx_CTRL - CC Channel Control Register (Async Reg)	350
13.5.18	RTCC_CCx_CCV - Capture/Compare Value Register (Async Reg)	352
13.5.19	RTCC_CCx_TIME - Capture/Compare Time Register (Async Reg)	353
13.5.20	RTCC_CCx_DATE - Capture/Compare Date Register (Async Reg)	354
13.5.21	RTCC_RETx_REG - Retention register	354
<b>14.</b>	<b>WDOG - Watchdog Timer</b>	<b>355</b>
14.1	Introduction	355
14.2	Features	355
14.3	Functional Description	355
14.3.1	Clock Source	356
14.3.2	Debug Functionality	356
14.3.3	Energy Mode Handling	356
14.3.4	Register access	356
14.3.5	Warning Interrupt	356
14.3.6	Window Interrupt	357
14.3.7	PRS as Watchdog Clear	358

15.5	Register Description . . . . .	376
15.5.1	PRS_SWPULSE - Software Pulse Register . . . . .	376
15.5.2	PRS_SWLEVEL - Software Level Register . . . . .	377
15.5.3	PRS_ROUTEOPEN - I/O Routing Pin Enable Register . . . . .	378
15.5.4	PRS_ROUTELOC0 - I/O Routing Location Register . . . . .	379
15.5.5	PRS_ROUTELOC1 - I/O Routing Location Register . . . . .	382
15.5.6	PRS_ROUTELOC2 - I/O Routing Location Register . . . . .	385
15.5.7	PRS_CTRL - Control Register . . . . .	388
15.5.8	PRS_DMAREQ0 - DMA Request 0 Register . . . . .	389
15.5.9	PRS_DMAREQ1 - DMA Request 1 Register . . . . .	390
15.5.10	PRS_PEEK - PRS Channel Values . . . . .	391
15.5.11	PRS_CHx_CTRL - Channel Control Register . . . . .	392
<b>16.</b>	<b>PCNT - Pulse Counter . . . . .</b>	<b>397</b>
16.1	Introduction . . . . .	397
16.2	Features . . . . .	397
16.3	Functional Description . . . . .	398
16.3.1	Pulse Counter Modes . . . . .	398
16.3.1.1	Single Input Oversampling Mode . . . . .	398
16.3.1.2	Externally Clocked Single Input Counter Mode . . . . .	398
16.3.1.3	Quadrature decoder modes . . . . .	399
16.3.1.4	Externally Clocked Quadrature Decoder Mode . . . . .	400
16.3.1.5	Oversampling Quadrature Decoder Mode . . . . .	402
16.3.2	Hysteresis . . . . .	405
16.3.3	Auxiliary counter . . . . .	406
16.3.4	Triggered compare and clear . . . . .	407
16.3.5	Register Access . . . . .	408
16.3.6	Clock Sources . . . . .	408
16.3.7	Input Filter . . . . .	408
16.3.8	Edge Polarity . . . . .	409
16.3.9	PRS and PCNTn_S0IN,PCNTn_S1IN Inputs . . . . .	409
16.3.10	Interrupts . . . . .	409
16.3.10.1	Underflow and Overflow Interrupts . . . . .	409
16.3.10.2	Direction Change Interrupt . . . . .	410
16.3.11	Cascading Pulse Counters . . . . .	411
16.4	Register Map . . . . .	412
16.5	Register Description . . . . .	413
16.5.1	PCNTn_CTRL - Control Register (Async Reg) . . . . .	413

16.5.2	PCNTn_CMD - Command Register (Async Reg)	417
16.5.3	PCNTn_STATUS - Status Register	417
16.5.4	PCNTn_CNT - Counter Value Register	418
16.5.5	PCNTn_TOP - Top Value Register	418
16.5.6	PCNTn_TOPB - Top Value Buffer Register (Async Reg)	419
16.5.7	PCNTn_IF - Interrupt Flag Register	419
16.5.8	PCNTn_IFS - Interrupt Flag Set Register	420
16.5.9	PCNTn_IFC - Interrupt Flag Clear Register	421
16.5.10	PCNTn_IEN - Interrupt Enable Register	422
16.5.11	PCNTn_ROUTELOC0 - I/O Routing Location Register	423
16.5.12	PCNTn_FREEZE - Freeze Register	426
16.5.13	PCNTn_SYNCBUSY - Synchronization Busy Register	426
16.5.14	PCNTn_AUXCNT - Auxiliary Counter Value Register	427
16.5.15	PCNTn_INPUT - PCNT Input Register	428
16.5.16	PCNTn_OVSCFG - Oversampling Config Register (Async Reg)	430
<b>17.</b>	<b>I2C - Inter-Integrated Circuit Interface</b>	<b>431</b>

20.5.3	TIMERn_STATUS - Status Register . . . . .	643
20.5.4	TIMERn_IF - Interrupt Flag Register . . . . .	647
20.5.5	TIMERn_IFS - Interrupt Flag Set Register . . . . .	648
20.5.6	TIMERn_IFC - Interrupt Flag Clear Register . . . . .	649
20.5.7	TIMERn_IEN - Interrupt Enable Register . . . . .	651
20.5.8	TIMERn_TOP - Counter Top Value Register . . . . .	652
20.5.9	TIMERn_TOPB - Counter Top Value Buffer Register . . . . .	652
20.5.10	TIMERn_CNT - Counter Value Register . . . . .	653
20.5.11	TIMERn_LOCK - TIMER Configuration Lock Register . . . . .	653
20.5.12	TIMERn_ROUTE PEN - I/O Routing Pin Enable Register . . . . .	654
20.5.13	TIMERn_ROUTE LOC0 - I/O Routing Location Register . . . . .	655
20.5.14	TIMERn_ROUTE LOC2 - I/O Routing Location Register . . . . .	660
20.5.15	TIMERn_CCx_CTRL - CC Channel Control Register . . . . .	664
20.5.16	TIMERn_CCx_CCV - CC Channel Value Register (Actionable Reads) . . . . .	667
20.5.17	TIMERn_CCx_CCVP - CC Channel Value Peek Register . . . . .	668
20.5.18	TIMERn_CCx_CCVB - CC Channel Buffer Register . . . . .	668
20.5.19	TIMERn_DTCTRL - DTI Control Register . . . . .	669
20.5.20	TIMERn_DTTIME - DTI Time Control Register . . . . .	672
20.5.21	TIMERn_DTFC - DTI Fault Configuration Register . . . . .	673
20.5.22	TIMERn DTOGEN - DTI Output Generation Enable Register . . . . .	676
20.5.23	TIMERn_DTFAULT - DTI Fault Register . . . . .	677
20.5.24	TIMERn_DTFAULTC - DTI Fault Clear Register . . . . .	678
20.5.25	TIMERn_DTLOCK - DTI Configuration Lock Register . . . . .	679

<b>21. LETIMER - Low Energy Timer . . . . .</b>	<b>680</b>
21.1 Introduction . . . . .	680
21.2 Features . . . . .	680
21.3 Functional Description . . . . .	681
21.3.1 Timer. . . . .	681
21.3.2 Compare Registers . . . . .	681
21.3.3 Top Value . . . . .	682
21.3.3.1 Buffered Top Value . . . . .	682
21.3.3.2 Repeat Modes . . . . .	682
21.3.3.3 Free-Running Mode . . . . .	683
21.3.3.4 One-shot Mode. . . . .	684
21.3.3.5 Buffered Mode . . . . .	685
21.3.3.6 Double Mode . . . . .	686
21.3.3.7 Clock Source . . . . .	686
21.3.3.8 PRS Input Triggers . . . . .	687
21.3.3.9 Debug. . . . .	687
21.3.4 Underflow Output Action . . . . .	688
21.3.5 PRS Output . . . . .	690
21.3.6 Examples . . . . .	690
21.3.6.1 Triggered Output Generation . . . . .	691
21.3.6.2 Continuous Output Generation . . . . .	692
21.3.6.3 PWM Output . . . . .	693
21.3.6.4 Interrupts. . . . .	693
21.3.7 Register access . . . . .	694
21.4 Register Map. . . . .	694
21.5 Register Description . . . . .	695
21.5.1 LETIMERn_CTRL - Control Register (Async Reg) . . . . .	695
21.5.2 LETIMERn_CMD - Command Register . . . . .	697
21.5.3 LETIMERn_STATUS - Status Register . . . . .	698
21.5.4 LETIMERn_CNT - Counter Value Register . . . . .	698
21.5.5 LETIMERn_COMP0 - Compare Value Register 0 (Async Reg) . . . . .	699
21.5.6 LETIMERn_COMP1 - Compare Value Register 1 (Async Reg) . . . . .	699
21.5.7 LETIMERn_REP0 - Repeat Counter Register 0 (Async Reg) . . . . .	700
21.5.8 LETIMERn_REP1 - Repeat Counter Register 1 (Async Reg) . . . . .	700
21.5.9 LETIMERn_IF - Interrupt Flag Register . . . . .	701
21.5.10 LETIMERn_IFS - Interrupt Flag Set Register . . . . .	702
21.5.11 LETIMERn_IFC - Interrupt Flag Clear Register . . . . .	703
21.5.12 LETIMERn_IEN - Interrupt Enable Register . . . . .	704
21.5.13 LETIMERn_SYNCBUSY - Synchronization Busy Register . . . . .	704
21.5.14 LETIMERn_ROUTEPEN - I/O Routing Pin Enable Register . . . . .	705
21.5.15 LETIMERn_ROUTELOC0 - I/O Routing Location Register . . . . .	706
21.5.16 LETIMERn_PRSEL - PRS Input Select Register . . . . .	709
<b>22. CRYOTIMER - Ultra Low Energy Timer/Counter . . . . .</b>	<b>713</b>
22.1 Introduction . . . . .	713
22.2 Features . . . . .	713
22.3 Functional Description . . . . .	713
22.3.1 Block Diagram . . . . .	714

22.3.2	Operation	715
22.3.3	Debug Mode	715
22.3.4	Energy Mode availability	715
22.4	Register Map.	716
22.5	Register Description	717
22.5.1	CRYOTIMER_CTRL - Control Register	717
22.5.2	CRYOTIMER_PERIODSEL - Interrupt Duration	718
22.5.3	CRYOTIMER_CNT - Counter Value	720
22.5.4	CRYOTIMER_EM4WUEN - Wake Up Enable	720
22.5.5	CRYOTIMER_IF - Interrupt Flag Register	721
22.5.6	CRYOTIMER_IFS - Interrupt Flag Set Register	721
22.5.7	CRYOTIMER_IFC - Interrupt Flag Clear Register	722
22.5.8	CRYOTIMER_IEN - Interrupt Enable Register	722
<b>23.</b>	<b>ACMP - Analog Comparator</b>	<b>723</b>
23.1	Introduction	723
23.2	Features	723
23.3	Functional Description	724
23.3.1	Warm-up Time	725
23.3.2	Response Time	725
23.3.3	Hysteresis	726
23.3.4	Input Selection	727
23.3.5	Capacitive Sense Mode	729
23.3.6	Interrupts and PRS Output	730
23.3.7	Output to GPIO	731
23.3.8	APOINT Conflicts	731
23.3.9	Supply Voltage Monitoring	731
23.4	Register Map.	731
23.5	Register Description	732
23.5.1	ACMPn_CTRL - Control Register	732
23.5.2	ACMPn_INPUTSEL - Input Selection Register	736
23.5.3	ACMPn_STATUS - Status Register	741
23.5.4	ACMPn_IF - Interrupt Flag Register	742
23.5.5	ACMPn_IFS - Interrupt Flag Set Register	742
23.5.6	ACMPn_IFC - Interrupt Flag Clear Register	743
23.5.7	ACMPn_IEN - Interrupt Enable Register	744
23.5.8	ACMPn_APOINTREQ - APOINT Request Status Register	745
23.5.9	ACMPn_APOINTCONFLICT - APOINT Conflict Status Register	746
23.5.10	ACMPn_HYSTERESIS0 - Hysteresis 0 Register	748
23.5.11	ACMPn_HYSTERESIS1 - Hysteresis 1 Register	749
23.5.12	ACMPn_ROUTE PEN - I/O Routing Pine Enable Register	750
23.5.13	ACMPn_ROUTELOC0 - I/O Routing Location Register	751
<b>24.</b>	<b>ADC - Analog to Digital Converter</b>	<b>753</b>
24.1	Introduction	753
24.2	Features	754
24.3	Functional Description	755

24.3.1	Clock Selection	756
24.3.2	Conversions	756
24.3.3	ADC Modes	757
24.3.3.1	Single Channel Mode	757
24.3.3.2	Scan Mode	757
24.3.4	Warm-up Time	758
24.3.5	Input Selection	760
24.3.5.1	Configuring ADC Inputs in Single Channel Mode	762
24.3.5.2	Configuring ADC Inputs in Scan Mode	763
24.3.5.3	APORT Conflicts	765
24.3.6	Reference Selection and Input Range Definition	765
24.3.6.1	Basic Full-Scale Voltage Configuration	765
24.3.6.2	Advanced Full-Scale Voltage Configuration	766
24.3.7	Programming of Bias Current	767
24.3.8	Feature Set	767
24.3.8.1	Conversion Tailgating	768
24.3.8.2	Repetitive Mode	768
24.3.8.3	Conversion Trigger	769
24.3.8.4	Output Results	770
24.3.8.5	Resolution	771
24.3.8.6	Oversampling	771
24.3.8.7	Adjustment	772
24.3.8.8	Channel Connection	772
24.3.8.9	Temperature Measurement	772
24.3.8.10	ADC as a Random Number Generator	773
24.3.9	Interrupts, PRS Output	773
24.3.10	DMA Request	773
24.3.11	Calibration	773
24.3.11.1	Offset Calibration	774
24.3.11.2	Gain Calibration	774
24.3.12	EM2 or EM3 Operation	775
24.3.13	ASYNC ADC_CLK Usage Restrictions and Benefits	775
24.3.14	Window Compare Function	775
24.3.15	ADC Programming Model	776
24.4	Register Map	777
24.5	Register Description	778
24.5.1	ADCn_CTRL - Control Register	778
24.5.2	ADCn_CMD - Command Register	781
24.5.3	ADCn_STATUS - Status Register	782
24.5.4	ADCn_SINGLECTRL - Single Channel Control Register	783
24.5.5	ADCn_SINGLECTRLX - Single Channel Control Register continued	788
24.5.6	ADCn_SCANCTRL - Scan Control Register	791
24.5.7	ADCn_SCANCTRLX - Scan Control Register continued	794
24.5.8	ADCn_SCANMASK - Scan Sequence Input Mask Register	797
24.5.9	ADCn_SCANINPUTSEL - Input Selection register for Scan mode	800
24.5.10	ADCn_SCANNEGSEL - Negative Input select register for Scan	803
24.5.11	ADCn_CMPTHR - Compare Threshold Register	806
24.5.12	ADCn_BIASPROG - Bias Programming Register for various analog blocks used in ADC operation.	807
24.5.13	ADCn_CAL - Calibration Register	808

24.5.14	ADCn_IF - Interrupt Flag Register . . . . .	810
24.5.15	ADCn_IFS - Interrupt Flag Set Register . . . . .	812
24.5.16	ADCn_IFC - Interrupt Flag Clear Register . . . . .	813
24.5.17	ADCn_IEN - Interrupt Enable Register . . . . .	814
24.5.18	ADCn_SINGLEDATA - Single Conversion Result Data (Actionable Reads) . . . . .	815
24.5.19	ADCn_SCANDATA - Scan Conversion Result Data (Actionable Reads) . . . . .	815
24.5.20	ADCn_SINGLEDATAP - Single Conversion Result Data Peek Register . . . . .	816
24.5.21	ADCn_SCANDATAP - Scan Sequence Result Data Peek Register . . . . .	816
24.5.22	ADCn_SCANDATAx - Scan Sequence Result Data + Data Source Register (Actionable Reads) . . . . .	817
24.5.23	ADCn_SCANDATAxP - Scan Sequence Result Data + Data Source Peek Register . . . . .	817
24.5.24	ADCn_APORTREQ - APORT Request Status Register . . . . .	818
24.5.25	ADCn_APORTCONFLICT - APORT Conflict Status Register . . . . .	819
24.5.26	ADCn_SINGLEFIFOCOUNT - Single FIFO Count Register . . . . .	821
24.5.27	ADCn_SCANFIFOCOUNT - Scan FIFO Count Register . . . . .	821
24.5.28	ADCn_SINGLEFIFOCLEAR - Single FIFO Clear Register . . . . .	822
24.5.29	ADCn_SCANFIFOCLEAR - Scan FIFO Clear Register . . . . .	822
24.5.30	ADCn_APORTMASTERDIS - APORT Bus Master Disable Register . . . . .	823
<b>25.</b>	<b>IDAC - Current Digital to Analog Converter. . . . .</b>	<b>826</b>
25.1	Introduction . . . . .	826
25.2	Features . . . . .	826
25.3	Functional Description . . . . .	827
25.3.1	Current Programming . . . . .	827
25.3.2	IDAC Enable and Warm-up . . . . .	827
25.3.3	Output Control . . . . .	828
25.3.4	Output Modes . . . . .	828
25.3.5	APORT Configuration . . . . .	829
25.3.6	Interrupts . . . . .	830
25.3.7	Minimizing Output Transition . . . . .	830
25.3.8	Duty Cycle Configuration . . . . .	830
25.3.9	Calibration . . . . .	830
25.3.10	PRS Input. . . . .	830
25.3.11	PRS Triggered Charge Injection . . . . .	831

25.5	Register Description . . . . .	832
25.5.1	IDAC_CTRL - Control Register . . . . .	832
25.5.2	IDAC_CURPROG - Current Programming Register . . . . .	835
25.5.3	IDAC_DUTYCONFIG - Duty Cycle Configuration Register . . . . .	836
25.5.4	IDAC_STATUS - Status Register . . . . .	836
25.5.5	IDAC_IF - Interrupt Flag Register . . . . .	837
25.5.6	IDAC_IFS - Interrupt Flag Set Register . . . . .	837
25.5.7	IDAC_IFC - Interrupt Flag Clear Register . . . . .	838
25.5.8	IDAC_IEN - Interrupt Enable Register . . . . .	838
25.5.9	IDAC_APORTREQ - APORT Request Status Register . . . . .	839
25.5.10	IDAC_APORTCONFLICT - APORT Request Status Register . . . . .	839
<b>26.</b>	<b>GPCRC - General Purpose Cyclic Redundancy Check . . . . .</b>	<b>840</b>

26.1 Introduction . . . . .	840
26.2 Features . . . . .	840
26.3 Functional Description . . . . .	841
26.3.1 Polynomial Specification . . . . .	842
26.3.2 Input and Output Specification . . . . .	842
26.3.3 Automatic Initialization . . . . .	842
26.3.4 DMA Usage . . . . .	842
26.3.5 Byte-Level Bit Reversal and Byte Reordering . . . . .	843
26.4 Register Map. . . . .	845
26.5 Register Description . . . . .	846
26.5.1 GPCRC_CTRL - Control Register . . . . .	846
26.5.2 GPCRC_CMD - Command Register . . . . .	848
26.5.3 GPCRC_INIT - CRC Init Value . . . . .	848
26.5.4 GPCRC_POLY - CRC Polynomial Value . . . . .	849
26.5.5 GPCRC_INPUTDATA - Input 32-bit Data Register . . . . .	849
26.5.6 GPCRC_INPUTDATAHWORD - Input 16-bit Data Register . . . . .	850
26.5.7 GPCRC_INPUTDATABYTE - Input 8-bit Data Register . . . . .	850
26.5.8 GPCRC_DATA - CRC Data Register . . . . .	851
26.5.9 GPCRC_DATAREV - CRC Data Reverse Register . . . . .	851
26.5.10 GPCRC_DATABYTEREV - CRC Data Byte Reverse Register . . . . .	852
<b>27. CRYPTO - Crypto Accelerator. . . . .</b>	<b>853</b>
27.1 Introduction . . . . .	853
27.2 Features . . . . .	854
27.3 Usage and Programming Interface . . . . .	854
27.4 Functional Description . . . . .	855
27.4.1 Data and Key Registers . . . . .	856
27.4.1.1 DATA0 Zero . . . . .	857
27.4.1.2 DDATA0 and DDATA1 Quick Observation . . . . .	858
27.4.1.3 Result Width . . . . .	858
27.4.2 Instructions and Execution . . . . .	858
27.4.2.1 Sequences . . . . .	858
27.4.2.2 Available Instructions. . . . .	859
27.4.2.3 MULx details . . . . .	861
27.4.2.4 DATA1INC and DATA1INCCLR instructions . . . . .	861
27.4.2.5 BBSWAP128 instruction. . . . .	862
27.4.2.6 Carry . . . . .	862
27.4.3 Repeated Sequence . . . . .	862
27.4.4 AES . . . . .	863
27.4.5 SHA . . . . .	865
27.4.6 ECC . . . . .	865
27.4.7 GCM and GMAC. . . . .	866
27.4.8 DMA . . . . .	866
27.4.8.1 DMA Initial Bytes Skip . . . . .	867
27.4.8.2 DMA Unaligned Read/Write . . . . .	867
27.4.9 BUFC Data Transfer . . . . .	868
27.4.10 Debugging . . . . .	869
27.4.11 Example: Cipher Block Chaining (CBC). . . . .	869

27.4.11.1 CBC Encryption . . . . .	870
27.4.11.2 CBC Decryption . . . . .	871
27.5 Register Map. . . . .	872
27.6 Register Description . . . . .	874
27.6.1 CRYPTO_CTRL - Control Register . . . . .	874
27.6.2 CRYPTO_WAC - Wide Arithmetic Configuration . . . . .	877
27.6.3 CRYPTO_CMD - Command Register . . . . .	880
27.6.4 CRYPTO_STATUS - Status Register . . . . .	886
27.6.5 CRYPTO_DSTATUS - Data Status Register . . . . .	887
27.6.6 CRYPTO_CSTATUS - Control Status Register . . . . .	888
27.6.7 CRYPTO_KEY - KEY Register Access (No Bit Access) (Actionable Reads) . . . . .	890
27.6.8 CRYPTO_KEYBUF - KEY Buffer Register Access (No Bit Access) (Actionable Reads) . . . . .	890
27.6.9 CRYPTO_SEQCTRL - Sequence Control . . . . .	891
27.6.10 CRYPTO_SEQCTRLB - Sequence Control B . . . . .	892
27.6.11 CRYPTO_IF - AES Interrupt Flags . . . . .	892
27.6.12 CRYPTO_IFS - Interrupt Flag Set Register . . . . .	893
27.6.13 CRYPTO_IFC - Interrupt Flag Clear Register . . . . .	894
27.6.14 CRYPTO_IEN - Interrupt Enable Register . . . . .	895
27.6.15 CRYPTO_SEQ0 - Sequence register 0 . . . . .	895
27.6.16 CRYPTO_SEQ1 - Sequence Register 1 . . . . .	896
27.6.17 CRYPTO_SEQ2 - Sequence Register 2 . . . . .	896
27.6.18 CRYPTO_SEQ3 - Sequence Register 3 . . . . .	897
27.6.19 CRYPTO_SEQ4 - Sequence Register 4 . . . . .	897
27.6.20 CRYPTO_DATA0 - DATA0 Register Access (No Bit Access) (Actionable Reads) . . . . .	898
27.6.21 CRYPTO_DATA1 - DATA1 Register Access (No Bit Access) (Actionable Reads) . . . . .	898
27.6.22 CRYPTO_DATA2 - DATA2 Register Access (No Bit Access) (Actionable Reads) . . . . .	899
27.6.23 CRYPTO_DATA3 - DATA3 Register Access (No Bit Access) (Actionable Reads) . . . . .	899
27.6.24 CRYPTO_DATA0XOR - DATA0XOR Register Access (No Bit Access) (Actionable Reads) . . . . .	900
27.6.25 CRYPTO_DATA0BYTE - DATA0 Register Byte Access (No Bit Access) (Actionable Reads) . . . . .	900
27.6.26 CRYPTO_DATA1BYTE - DATA1 Register Byte Access (No Bit Access) (Actionable Reads) . . . . .	901
27.6.27 CRYPTO_DATA0XORBYTE - DATA0 Register Byte XOR Access (No Bit Access) (Actionable Reads) . . . . .	901
27.6.28 CRYPTO_DATA0BYTE12 - DATA0 Register Byte 12 Access (No Bit Access) . . . . .	902
27.6.29 CRYPTO_DATA0BYTE13 - DATA0 Register Byte 13 Access (No Bit Access) . . . . .	902
27.6.30 CRYPTO_DATA0BYTE14 - DATA0 Register Byte 14 Access (No Bit Access) . . . . .	903
27.6.31 CRYPTO_DATA0BYTE15 - DATA0 Register Byte 15 Access (No Bit Access) . . . . .	903
27.6.32 CRYPTO_DDATA0 - DDATA0 Register Access (No Bit Access) (Actionable Reads) . . . . .	904
27.6.33 CRYPTO_DDATA1 - DDATA1 Register Access (No Bit Access) (Actionable Reads) . . . . .	904
27.6.34 CRYPTO_DDATA2 - DDATA2 Register Access (No Bit Access) (Actionable Reads) . . . . .	905
27.6.35 CRYPTO_DDATA3 - DDATA3 Register Access (No Bit Access) (Actionable Reads) . . . . .	905
27.6.36 CRYPTO_DDATA4 - DDATA4 Register Access (No Bit Access) (Actionable Reads) . . . . .	906
27.6.37 CRYPTO_DDATA0BIG - DDATA0 Register Big Endian Access (No Bit Access) (Actionable Reads) . . . . .	906
27.6.38 CRYPTO_DDATA0BYTE - DDATA0 Register Byte Access (No Bit Access) (Actionable Reads) . . . . .	907
27.6.39 CRYPTO_DDATA1BYTE - DDATA1 Register Byte Access (No Bit Access) (Actionable Reads) . . . . .	907
27.6.40 CRYPTO_DDATA0BYTE32 - DDATA0 Register Byte 32 access. (No Bit Access) . . . . .	908
27.6.41 CRYPTO_QDATA0 - QDATA0 Register Access (No Bit Access) (Actionable Reads) . . . . .	908

27.6.42	CRYPTO_QDATA1 - QDATA1 Register Access (No Bit Access) (Actionable Reads)	909
27.6.43	CRYPTO_QDATA1BIG - QDATA1 Register Big Endian Access (No Bit Access) (Actionable Reads)	909
27.6.44	CRYPTO_QDATA0BYTE - QDATA0 Register Byte Access (No Bit Access) (Actionable Reads)	910
27.6.45	CRYPTO_QDATA1BYTE - QDATA1 Register Byte Access (No Bit Access) (Actionable Reads)	910
<b>28.</b>	<b>GPIO - General Purpose Input/Output.</b>	<b>911</b>

28.5	Register Description	923
28.5.1	GPIO_Px_CTRL - Port Control Register	923
28.5.2	GPIO_Px_MODEL - Port Pin Mode Low Register	925
28.5.3	GPIO_Px_MODEH - Port Pin Mode High Register	931
28.5.4	GPIO_Px_DOUT - Port Data Out Register	936
28.5.5	GPIO_Px_DOUTTGL - Port Data Out Toggle Register	937
28.5.6	GPIO_Px_DIN - Port Data In Register	937
28.5.7	GPIO_Px_PINLOCKN - Port Unlocked Pins Register	938
28.5.8	GPIO_Px_OVTDIS - Over Voltage Disable for all modes	938
28.5.9	GPIO_EXTIPSELL - External Interrupt Port Select Low Register	939
28.5.10	GPIO_EXTIPSELH - External Interrupt Port Select High Register	942
28.5.11	GPIO_EXTIPINSELL - External Interrupt Pin Select Low Register	945
28.5.12	GPIO_EXTIPINSELH - External Interrupt Pin Select High Register	948
28.5.13	GPIO_EXTIRISE - External Interrupt Rising Edge Trigger Register	951
28.5.14	GPIO_EXTIFALL - External Interrupt Falling Edge Trigger Register	951
28.5.15	GPIO_EXTILEVEL - External Interrupt Level Register	952
28.5.16	GPIO_IF - Interrupt Flag Register	953
28.5.17	GPIO_IFS - Interrupt Flag Set Register	953
28.5.18	GPIO_IFC - Interrupt Flag Clear Register	954

28.5.19	GPIO_IEN - Interrupt Enable Register . . . . .	954
28.5.20	GPIO_EM4WUEN - EM4 wake up Enable Register . . . . .	955
28.5.21	GPIO_ROUTEPEN - I/O Routing Pin Enable Register . . . . .	956
28.5.22	GPIO_ROUTELOC0 - I/O Routing Location Register . . . . .	957
28.5.23	GPIO_INSENSE - Input Sense Register . . . . .	957
28.5.24	GPIO_LOCK - Configuration Lock Register . . . . .	958
<b>29.</b>	<b>APOINT - Analog Port . . . . .</b>	<b>959</b>
29.1	Introduction . . . . .	959
29.2	Features . . . . .	959
29.3	Functional Description . . . . .	960
29.3.1	APOINT ABUS Naming . . . . .	961
29.3.2	Managing ABUSes . . . . .	963
<b>Appendix 1.</b>	<b>Abbreviations . . . . .</b>	<b>965</b>
<b>Table of Contents . . . . .</b>		<b>968</b>

## Simplicity Studio

One-click access to MCU and wireless tools, documentation, software, source code libraries & more. Available for Windows, Mac and Linux!

### Disclaimer

Silicon Laboratories intends to provide customers with the latest, accurate, and in-depth documentation of all peripherals and modules available for system and software implementers using or intending to use the Silicon Laboratories products. Characterization data, available modules and peripherals, memory sizes and memory addresses refer to each specific device, and "Typical" parameters provided can and do vary in different applications. Application examples described herein are for illustrative purposes only. Silicon Laboratories reserves the right to make changes without further notice and limitation to product information, specifications, and descriptions herein, and does not give warranties as to the accuracy or completeness of the included information. Silicon Laboratories shall have no liability for the consequences of use of the information supplied herein. This document does not imply or express copyright licenses granted hereunder to design or fabricate any integrated circuits. The products must not be used within any Life Support System without the specific written consent of Silicon Laboratories. A "Life Support System" is any product or system intended to support or sustain life and/or health, which, if it fails, can be reasonably expected to result in significant personal injury or death. Silicon Laboratories products are generally not intended for military applications. Silicon Laboratories products shall under no circumstances be used in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such weapons.

### Trademark Information

Silicon Laboratories Inc., Silicon Laboratories, Silicon Labs, SiLabs and the Silicon Labs logo, CMEMS®, EFM, EFM32, EFR, Energy Micro, Energy Micro logo and combinations thereof, "the world's most energy friendly microcontrollers", Ember®, EZLink®, EZMac®, EZRadio®, EZRadioPRO®, DSPLL®, ISOmodem®, Precision32®, ProSLIC®, SiPHY®, USBXpress® and others are trademarks or registered trademarks of Silicon Laboratories Inc.
