Reference manual

STM32U575/585 Arm®-based 32-bit MCUs

Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32U575/585 microcontrollers memory and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

For information on the Arm® Cortex®-Mx cores, refer to the corresponding Arm® Technical Reference Manuals available on http://infocenter.arm.com.

STM32U575/585 microcontrollers include ST state-of-the-art patented technology.

1.1 General information

The STM32U575/585 devices have an Arm®(a) Cortex®-M33 core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.

1.4 Availability of peripherals

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.

2 Memory and bus architecture

2.1 System architecture

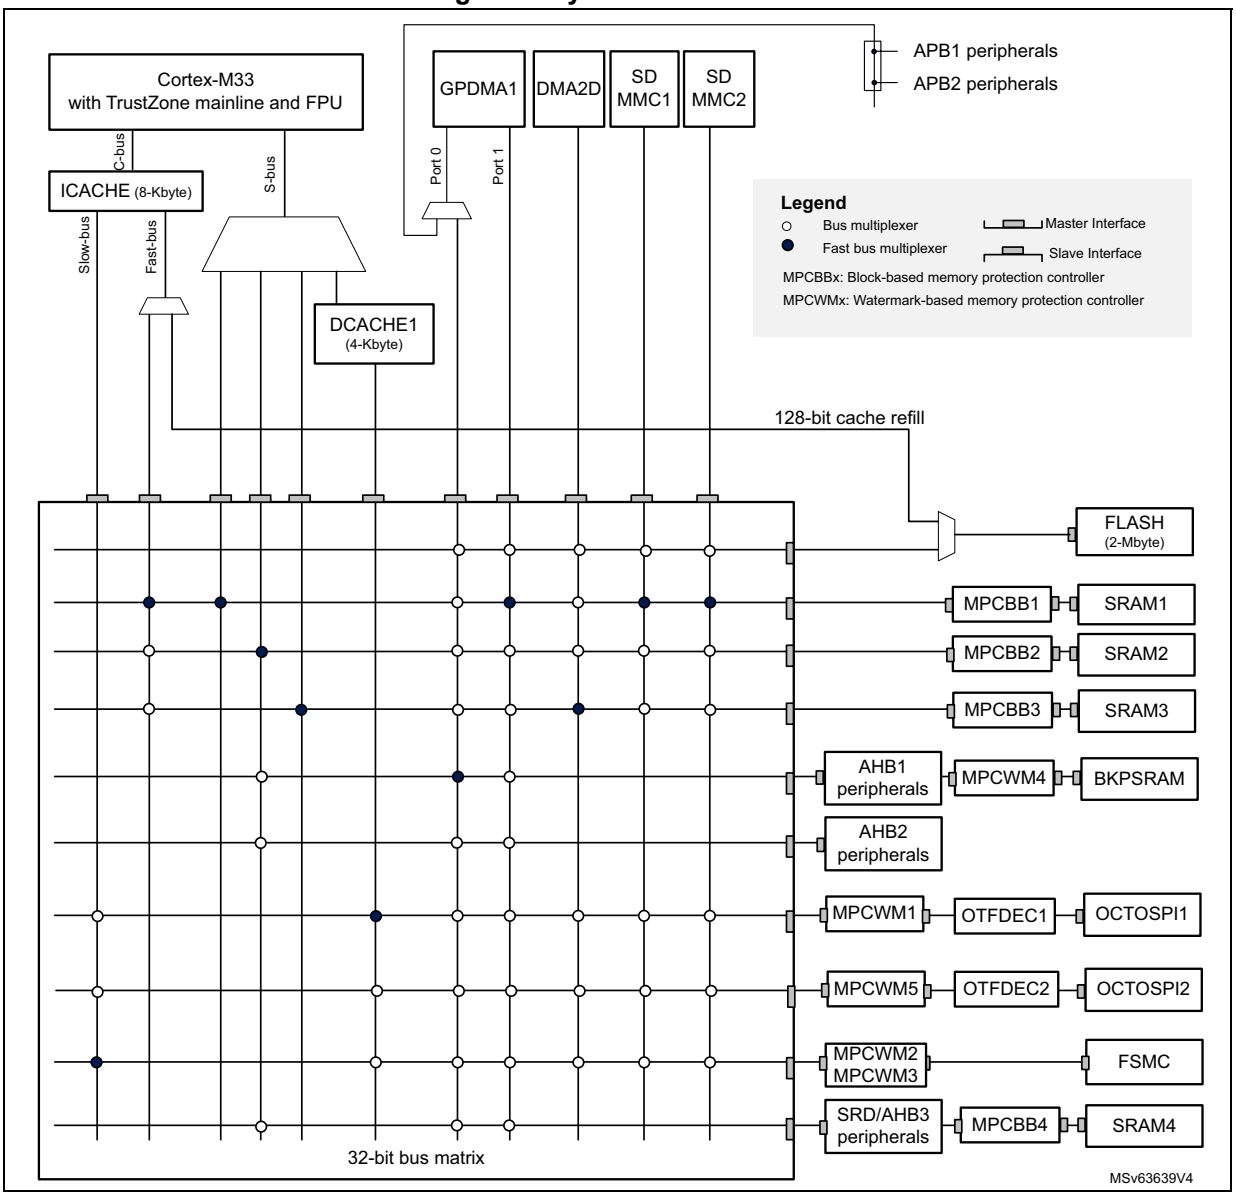
The STM32U575/585 architecture relies on a Arm Cortex-M33 core optimized for execution thanks to an instruction cache having a direct access to the embedded Flash memory.

This architecture also features a 32-bit multilayer AHB bus matrix that interconnects:

- up to 11 masters:
  - Fast C-bus, connecting Cortex-M33 with Arm TrustZone® mainline and FPU core C-bus to the internal SRAMs through the instruction cache
  - Slow C-bus, connecting Cortex-M33 with Arm TrustZone mainline and FPU core C-bus to the external memories through the instruction cache
  - Cortex-M33 with Arm TrustZone mainline and FPU core S-bus (three masters connected to three internal SRAMs without latency)
  - Cortex-M33 with Arm TrustZone mainline and FPU core S-bus connected to the external memories through the data cache
  - GPDMA1 (general purpose DMA featuring two master ports)
  - DMA2D
  - SDMMC1
  - SDMMC2
- up to 10 slaves:
  - internal Flash memory (2 Mbytes)
  - internal SRAM1 (192 Kbytes)
  - internal SRAM2 (64 Kbytes)
  - internal SRAM3 (512 Kbytes)
  - AHB1 peripherals and backup RAM (2-Kbyte BKPSRAM) including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - FSMC (flexible static memory controller)
  - OCTOSPI1
  - OCTOSPI2
  - SmartRun domain (SRD) AHB3 peripherals and SRAM4 (16 Kbytes), including AHB to APB bridge and APB peripherals (connected to APB3)

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

Figure 1. System architecture



2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the internal Flash memory and to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in code region. This bus targets the internal Flash memory and the internal SRAMs (SRAM1, SRAM2 and SRAM3).

SRAM1, SRAM2 and SRAM3 are accessible on this bus with a continuous mapping.

2.1.2 Slow C-bus

This bus connects the C-bus of the Cortex-M33 core to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in code region. This bus targets the external memories (FSMC and OCTOSPIs).

2.1.3 S-bus

This bus connects the system bus of the Cortex-M33 core to the bus matrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4 and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the SRD peripherals.

SRAM1, SRAM2 and SRAM3 are accessible on this bus with a continuous mapping.

Note: The bus matrix has a zero latency when accessing SRAM1, SRAM2 and SRAM3.

2.1.4 DCache S-bus

This bus connects the system bus of the Cortex-M33 core to the bus matrix via the data cache. This bus is used for instruction fetch and data access to the external memories mapped in data region. This bus targets the external memories (FSMC and OCTOSPIs).

Note: Fetching instructions through this bus is less efficient than fetching instructions through the slow C-bus.

2.1.5 GPDMA-bus

These buses connect the two AHB master interfaces of the GPDMA to the bus matrix. These buses target the internal Flash memory, the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4 and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals, the SRD peripherals and the external memories through FSMC or OCTOSPIs.

2.1.6 SDMMC1 and SDMMC2 controllers DMA buses

These buses connect the SDMMC1 and SDMMC2 DMA master interfaces to the bus matrix. These buses are used only by the SDMMC1 and SDMMC2 DMA to load/store data from/to the memory. These buses target the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2 and SRAM3) and external memories through FSMC or OCTOSPIs.

2.1.7 Bus matrix

The bus matrix manages the access arbitration between masters. The arbitration uses a Round-Robin algorithm. This bus matrix features a fast bus multiplexer used to connect each master to a given slave without latency (see *Figure 1*). For the same master, other slaves undergo a latency of at least one cycle at each new access.

2.1.8 AHB/APB bridges

The three AHB/APB bridges provide full synchronous connections between the AHB and the APB buses, allowing flexible selection of the peripheral frequency.

Refer to *Section 2.3.2: Memory map and register boundary addresses* for the address mapping of the peripherals connected to these bridges.

After each device reset, all peripheral clocks are disabled (except for the internal SRAMs and Flash memory interfaces). Before using a peripheral, its clock must be enabled in the RCC_AHBxENR and RCC_APBxENR registers.

Note: When a 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.1.9 SmartRun domain (SRD)

The SRD architecture relies on a DMA allowing autonomous operation during low-power modes down to Stop 2.

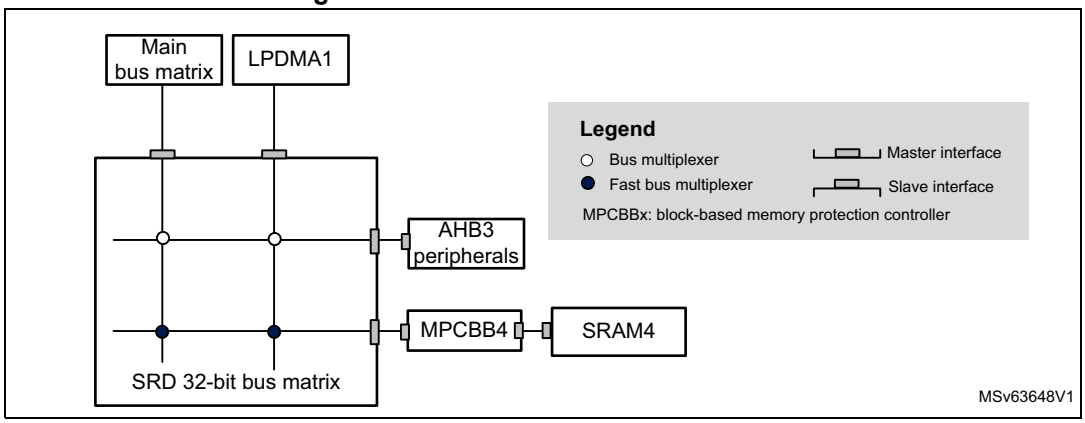
This architecture also features a 32-bit AHB bus matrix that interconnects:

- two masters:
  - the main AHB bus matrix
  - LPDMA1 (low-power DMA featuring one master port)
- two slaves:
  - AHB3 peripherals including AHB to APB bridge connected to APB3
  - internal SRAM4

Note: The SRAM4 is the only SRAM that can be accessed by the LPDMA1.

This architecture is shown in the figure below.

Figure 2. SmartRun domain architecture



2.2 Arm TrustZone security architecture

The security architecture is based on Arm TrustZone with the Armv8-M mainline extension.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

When the TrustZone is enabled, the SAU (security-attribution unit) and IDAU (implementation-defined-attribution unit) defines the access permissions based on secure and non-secure states.

- SAU: Up to eight SAU configurable regions are available for security attribution.
- IDAU: provides a first memory partition as non-secure or non-secure callable attributes. The IDAU memory map partition is not configurable and fixed by hardware implementation (refer to *Figure 3: Memory map based on IDAU mapping*). It is then

combined with the results from the SAU security attribution and the higher security state is selected.

Based on IDAU security attribution, the Flash memory, system SRAMs and peripherals memory space are aliased twice for secure and non-secure states. However, the external memories space is not aliased.

The table below shows an example of typical eight SAU regions mapping based on IDAU regions. The user can split and choose the secure, non-secure or NSC regions for external memories as needed.

Table 1. Example of memory map security attribution versus SAU configuration regions

Region description	Address range	IDAU security attribution	SAU security attribution typical configuration	Final security attribution
Code - external memories	0x0000_0000 0x07FF_FFFF	Non-secure	Secure, non-secure or NSC(1)	Secure, non-secure or NSC
Code - Flash memory and SRAM	0x0800_0000 0x0BFF_FFFF	Non-secure	Non-secure	Non-secure
	0x0C00_0000 0x0FFF_FFFF	NSC	Secure or NSC	Secure or NSC
Code - external memories	0x1000_0000 0x17FF_FFFF	Non-secure	Non-secure	
	0x1800_0000 0x1FFF_FFFF			
SRAM	0x2000_0000 0x2FFF_FFFFF	Non-secure		
	0x3000_0000 0x3FFF_FFFFF	NSC	Secure or NSC	Secure or NSC
Peripherals	0x4000_0000 0x4FFF_FFFFF	Non-secure	Non-secure	Non-secure
	0x5000_0000 0x5FFF_FFFFF	NSC	Secure or NSC	Secure or NSC
External memories	0x6000_0000 0xDFFF_FFFF	Non-secure	Secure, non-secure or NSC	Secure, non-secure or NSC

1. NSC = non-secure callable

2.2.1 Default Arm TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is detailed below:

- CPU:
  - Cortex-M33 is in secure state after reset. The boot address must be at a secure address.
- Memory map:
  - SAU is fully secure after reset. Consequently, all memory map is fully secure. Up to height SAU configurable regions are available for security attribution.
- Flash memory:
  - The Flash memory security area is defined by watermark user options.
  - Flash block-based security attributions are non-secure after reset.
- SRAMs:

  - All SRAMs are secure after reset. MPCBBx (block-based memory protection controller) are secure.
- External memories:
  - FSMC and OCTOSPIs banks are secure after reset. MPCWMx (watermark-based memory protection controller) are secure.
- Peripherals (see *Table 2* and *Table 3* for a list of securable and TrustZone-aware peripherals)
  - Securable peripherals are non-secure after reset.
  - TrustZone-aware peripherals are non-secure after reset. Their secure configuration registers are secure.
- All GPIO are secure after reset.
- Interrupts:
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and non-secure state.
  - TZIC: All illegal access interrupts are disabled after reset (see *GTZC TrustZone system architecture*).

2.2.2 Arm TrustZone peripheral classification

When the TrustZone security is active, a peripheral can be either securable or TrustZone-aware type as follows:

- Securable: peripheral protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties
- TrustZone-aware: peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure.

Refer to *GTZC TrustZone system architecture* for more details.

The tables below list the securable and TrustZone-aware peripherals within the system.

Table 2. Securable peripherals by TZSC

Bus	Peripheral
AHB3	ADF1

1. Always secure when TZEN = 1.

2.3 Memory organization

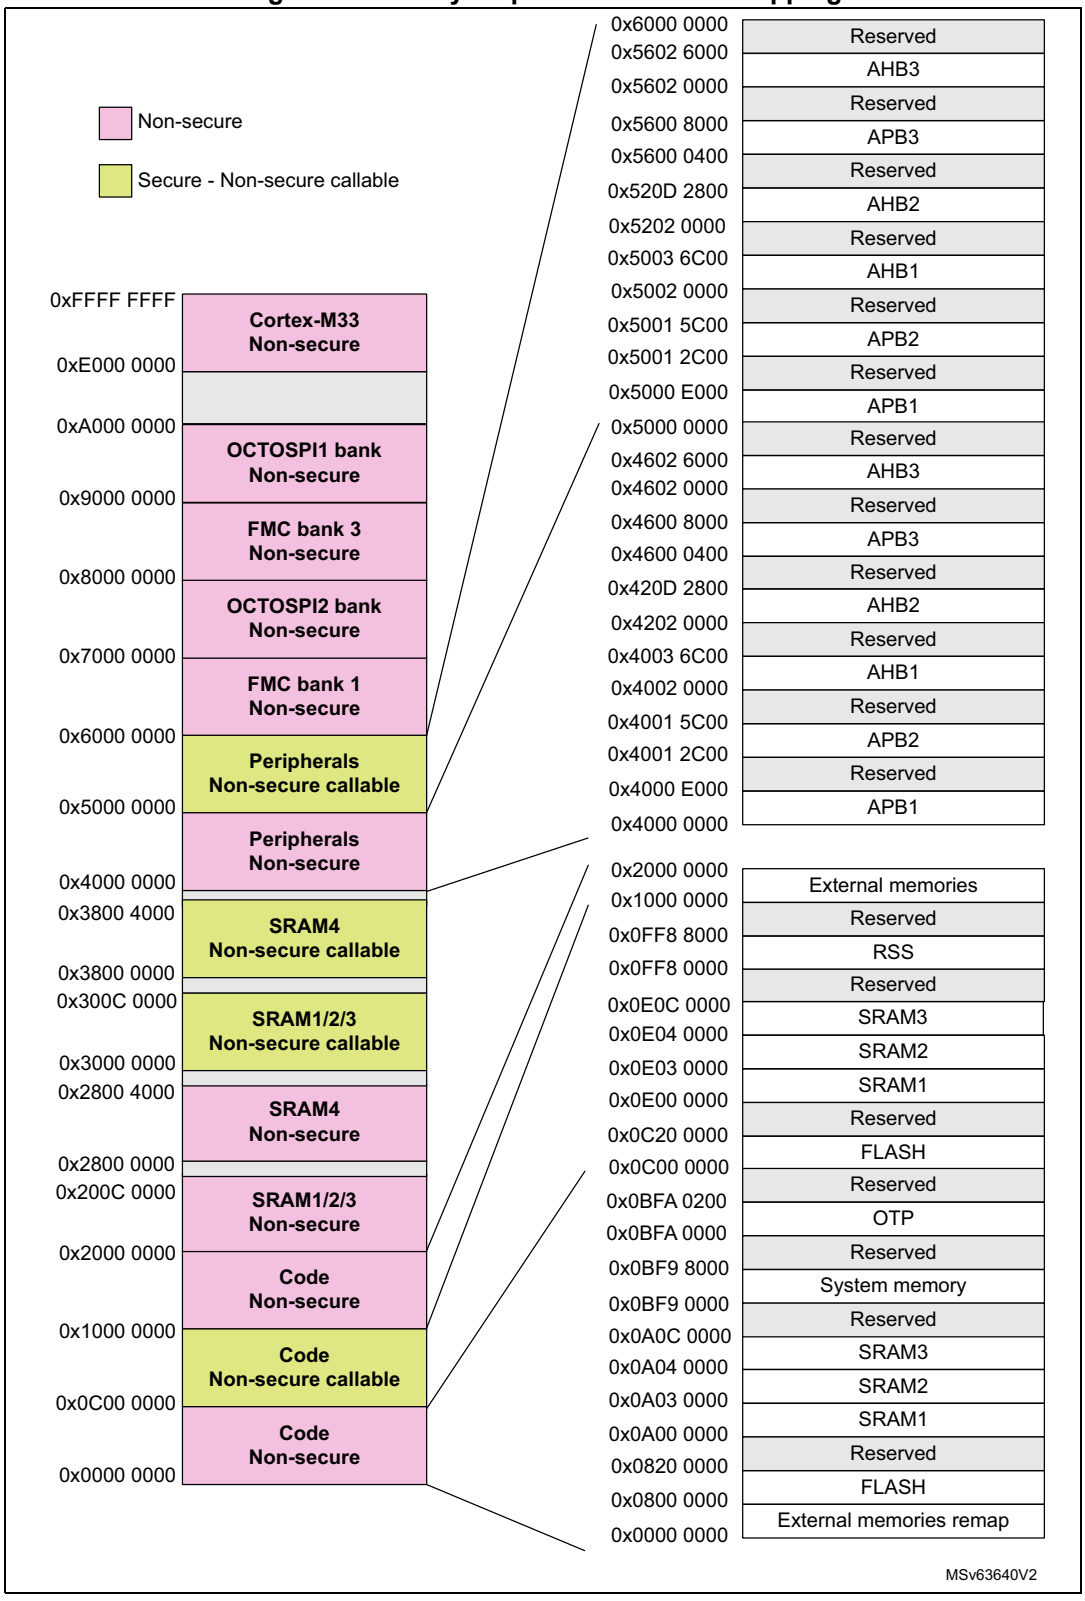
2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Figure 3. Memory map based on IDAU mapping



All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. The following table gives the boundary addresses of the peripherals available in the devices.

Table 4. Memory map and peripheral register boundary addresses

Bus	Secure boundary address	Non-secure boundary address	Size (bytes)	Peripheral	Peripheral register map
AHB3	0x5602 6000 - 0x5FFF FFFF	0x4602 6000 - 0x4FFF FFFF	164 M	Reserved	-

2.3.3 Embedded SRAM

The devices feature up to 786-Kbyte SRAMs:

- 192-Kbyte SRAM1
- 64-Kbyte SRAM2
- 512-Kbyte SRAM3
- 16-Kbyte SRAM4
- 2-Kbyte BKPSRAM

These SRAMs can be accessed as bytes, half-words (16 bits) or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1, SRAM2 and SRAM3 through the system bus or through the C-bus depending on the selected address. The CPU can access the SRAM4 and BKPSRAM through the system bus only.

When the TrustZone security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as non-secure with a block granularity. For more details, refer to *Section 5: Global TrustZone controller (GTZC)*.

SRAM features are detailed in *Section 6.3.1: Internal SRAMs features*.

2.3.4 Flash memory overview

The Flash memory is composed of two distinct physical areas:

- The main Flash memory block, that contains the application program and user data.
- The information block, that is composed of the following parts:
  - option bytes for hardware and memory protection user configuration
  - system memory that contains ST proprietary code
  - OTP (one-time programmable) area

The Flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the Flash memory operations (program/erase) controlled through the Flash registers plus security access control features. Refer to *Section 7: Embedded Flash memory (FLASH)* for more details.

3 System security

The STM32U575/585 are designed with a comprehensive set of security features, some of which being based on the standard Arm TrustZone technology.

These security features simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEM and third-party developers, by facilitating the re-use, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on the STM32U575/585 devices.

3.1 Key security features

- Resource isolation using privilege mode and Armv8-M mainline security extension of Cortex-M33, extended to securable I/Os, memories and peripherals
- Secure firmware installation (SFI) with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the download of image through USART, USB, I^2C, SPI, FDCAN and JTAG
- Secure boot thanks to the unique boot entry feature and hide-protect area (HDP) mechanism
- Secure storage, featuring:
  - Non-volatile on-chip secure storage, protected with secure and HDP areas
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID and JTAG 32-bit device-specific ID
  - On-chip enhance storage technology, using hardware secret non-volatile derived hardware unique keys (DHUK), and application-defined volatile boot hardware key (BHK), both loadable by hardware to the DPA-resistant SAES engine
- General purpose cryptographic acceleration
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM and CCM chaining modes
  - Secure AES 256-bit security co-processor, supporting ECB and CBC chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting MD5/SHA-1 checksums and SHA-2 secure hash
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified
- On-the-fly decryption of encrypted image stored on external Flash memory connected through the OCTOSPI
  - Almost-zero latency with standard NOR Flash memories
  - Can be used to encrypt the image using device-unique secret keys
  - Automatic key erase in case of tamper

- Flexible life-cycle scheme with readout protection (RDP), including support for product decommissioning (auto-erase)
  - Debug protection, depending on the RDP level
  - Optional password-based RDP level regressions, including for RDP Level 2
- Protected firmware distribution scheme, using TrustZone, on-the-fly decryption and RDP Level 0.5
- Active tamper and protection against temperature, voltage and frequency attacks
  - Eight active inputs, eight active output tamper pins, available in all power modes

3.2 Secure install

The secure firmware install (SFI) is an STMicroelectronics secure service authenticated and decrypted by the immutable RSS code stored in the device. The SFI allows secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The confidentiality of the installed images written either in the internal Flash memory or encrypted in an external Flash memory, is also protected, using the AES.

The SFI native service leverages the following hardware security features:

- secure boot (see *Section 3.3*)
- resource isolation using TrustZone (see *Section 3.5*)
- temporal isolation using hide protection (see *Section 3.6.1*)
- secure execution (see *Section 3.7*)
- secure storage, with associated cryptographic engines (see *Section 3.8* and *Section 3.9*)

Further information can be found in the application note *Overview secure firmware install (SFI)* (AN4992).

3.3 Secure boot

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The actual functions of the secure boot depend on the availability of TrustZone features, and on the firmware stored in the device. However, the secure boot typically initializes the secure storage, and installs on-the-fly decryption keys in the OTFDEC, to be able to use encrypted firmware stored in an external Flash memory.

The device Trusted Firmware-M (TFM) application, supported by the STM32 ecosystem, provides a root of trust solution including secure boot functions.For more information, refer to the user manual *Getting started with STM32CubeU5 TFM application* (UM2851).

In the devices, the secure boot takes benefit of hardware security features such as:

- resource isolation using TrustZone (see *Section 3.5*)
- temporal isolation using hide protection (see *Section 3.6.1*)

- secure execution (see *Section 3.7*)
- secure install and update (see *Section 3.2* and *Section 3.4*)
- secure storage, with associated cryptographic engines if available (see *Section 3.8* and *Section 3.9*)

This section describes the features specifically designed for secure boot.

3.3.1 Unique boot entry and BOOT_LOCK

When TrustZone is activated (TZEN = 1) and BOOT_LOCK secure option bit is cleared, the application selects a boot entry point located either in the system Flash memory (see the next section), or in the secure user Flash memory, at the address defined by SECBOOTADD0 option bytes.

When TrustZone is activated (TZEN = 1) and BOOT_LOCK secure option bit is set, the device unique boot entry is the unmodifiable secure address defined by SECBOOTADD0 option bytes. All these option bytes cannot be modified by the application anymore when BOOT_LOCK is set.

Note: As long as it is cleared, the BOOT_LOCK option bit can be set without any constraint. But once set, the BOOT_LOCK option bit cannot be cleared when RDP level > 0.

For more information on the boot mechanisms, refer to *Section 4: Boot modes*.

3.3.2 Immutable root of trust in system Flash memory

The immutable root-of-trust code stored in the system Flash memory is first used to initiate SFI, allowing secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when a secure application sets the SYSCGFG_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when the BOOT_LOCK secure option bit is set, and the secure address defined by SECBOOTADD0 is set on the secure user flash memory.

3.4 Secure update

The secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on the availability of the TrustZone features, and on the firmware stored in the device.

The device Trusted Firmware-M (TFM) application, supported by the STM32 ecosystem, allows the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.

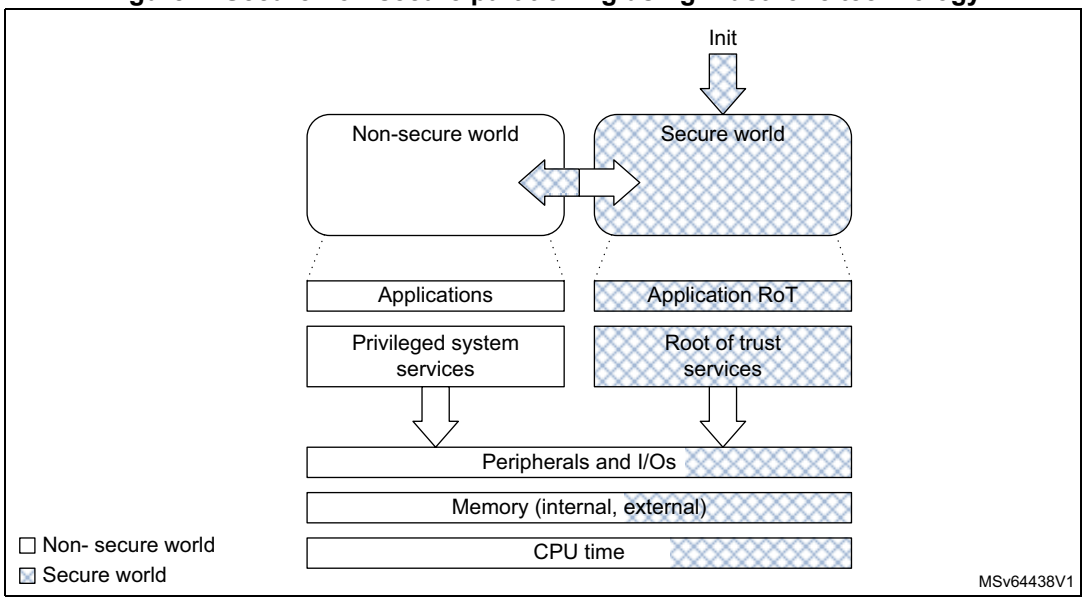
A firmware update can be done either on a single firmware image including both secure and non-secure parts, or on the secure (respectively non-secure) part of the firmware image, independently.

In the devices, the secure update application leverages the same hardware security as the firmware install described in *Section 3.2*. For more information, refer to the user manual *Getting started with STM32CubeU5 TFM application* (UM2851).

3.5 Resource isolation using TrustZone

In the STM32U575/585 devices, the hardware and software resources can be partitioned so that they exist either in the secure world or in the non-secure world, as shown in the figure below.

Figure 4. Secure/non-secure partitioning using TrustZone technology



Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after reset of the device.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the non-secure world.

Note: The secure code is typically small and rarely modified, while non-secure code is more exposed, and prone to firmware updates.

3.5.1 TrustZone security architecture

The Armv8-M TrustZone technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. The device TrustZone hardware features include:

- the Armv8-M mainline security extension of Cortex-M33, enabling a new processor secure state, with its associated secure interrupts
- the dynamic allocation of memory and peripherals to TrustZone using eight security attribution unit (SAU) regions of Cortex-M33
- a global TrustZone framework (GTZC), extending the TrustZone protection against transactions coming from other masters in the system than the Cortex-M33
- TrustZone-aware embedded Flash memory and peripherals

Note: The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

3.5.2 Armv8-M security extension of Cortex-M33

The Arm security extension of the Cortex-M33 is an evolution, not a revolution. It uses the programmer model from earlier Cortex-M subfamilies like Cortex-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU. Armv8-M also uses the nested vectored interrupt controller (NVIC).

The Armv8-M TrustZone implementation in STM32U575/585 devices is composed of the following features:

- a new processor state, with almost no additional code/cycle overhead, as opposed to Armv8-A TrustZone, that uses a dedicated exception routine for triggering a secure/non-secure world change
- two memory map views of a shared 4-Gbyte address space
- a low interrupt latency for both secure and non-secure domains, and a new interrupt configuration for security grouping and priority setting
- separated exception vector tables for the secure and non-secure exceptions
- micro-coded context preservation
- banking of specific registers across secure/non-secure states, including stack pointers with stack-limit checkers
- banking of following Cortex-M33 programmable components (two separate units for secure and non-secure):
  - SysTick timer
  - MPU configuration registers (eight MPU regions in secure, eight in non-secure)
  - some of the system control block (SCB) registers
- new system exception (SecureFault) for handling of security violations
- configurable debug support, as defined in *Section 3.11*

For more information, refer to Cortex-M33 programming manual (PM0264).

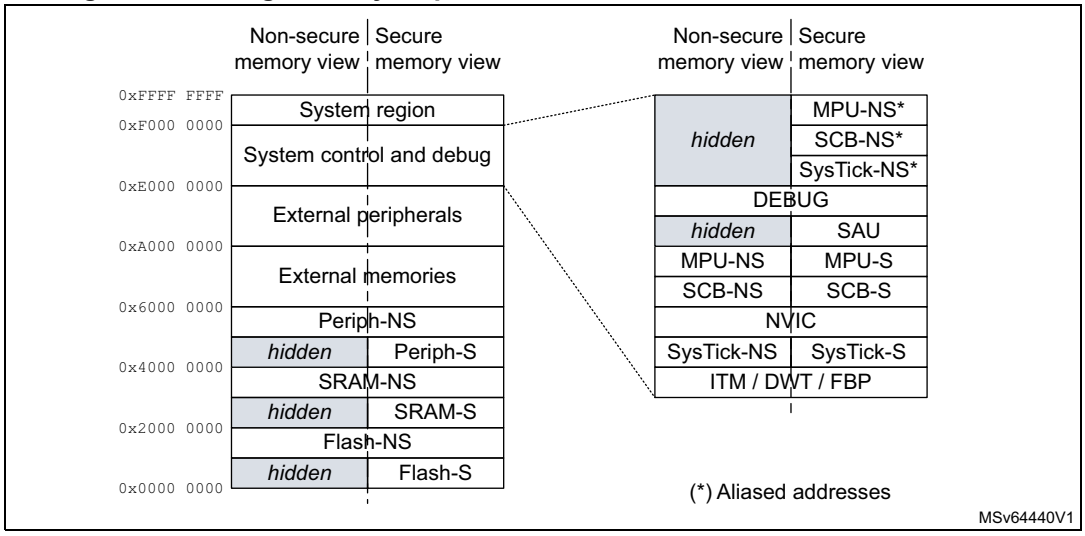
3.5.3 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated on *Figure 5*, the Armv8-M non-secure memory view is similar to Armv7-M (that can be found in Cortex-M4), with the difference that the secure memory is hidden. The secure memory view shows the Flash memory, SRAM and peripherals that are only accessible while the Cortex processor executes in Secure state.

The figure below shows the 32-bit address space viewed after the SAU configuration by the secure code.

Figure 5. Sharing memory map between CPU in secure and non-secure state

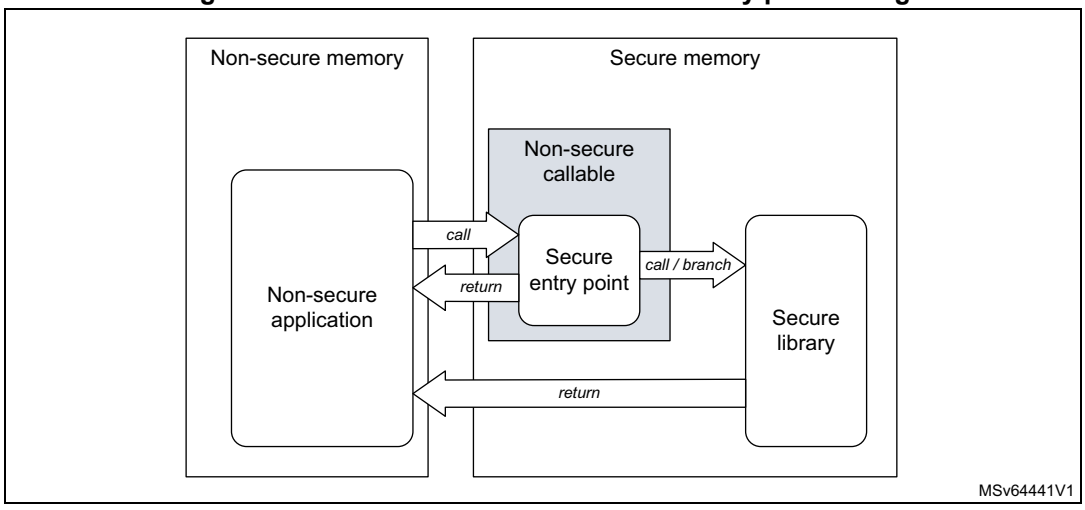


The Cortex processor state (and associated rights) depends on the security attribute assigned to the memory region where it is executed:

- A processor in a non-secure state only executes from non-secure (NS) program memory, while a processor in a secure state only executes from secure (S) program memory.
- While running in secure state, the processor can access data from both S and NS memories. Running in non-secure state, the CPU is limited to non-secure memories.

In order to manage transitions to the secure world, developers must create non-secure callable (NSC) regions that contain valid entry points to the secure libraries. The first instruction in these entry points must be the new `secure gate` (SG) instruction, used by the non-secure code to call a secure function (see the figure below).

Figure 6. Secure world transition and memory partitioning



Programming security attributes

In Cortex-M33, the static implementation defined attribution unit (IDAU) works in conjunction with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS or NSC) to a specific address, as shown in the table below.

Table 5. Configuring security attributes with IDAU and SAU

IDAU security attribution	SAU security attribution(1)	Final security attribution
Non-secure	Secure	Secure
	Secure-NSC	Secure-NSC
	Non-secure	Non-secure
Secure-NSC	Secure	Secure
	Non-secure	Secure-NSC

1. Defined regions are aligned to 32-byte boundaries.

The SAU can only be configured by the Cortex-M33 in the secure-privilege state. When the TrustZone is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program the SAU to create NSC or NS regions, as shown in the previous table.

Note: The SAU/IDAU settings are applicable only to the Cortex-M33*. The other masters like DMA are not affected by these policies.*

A memory space not covered by an SAU region is fixed as secure.

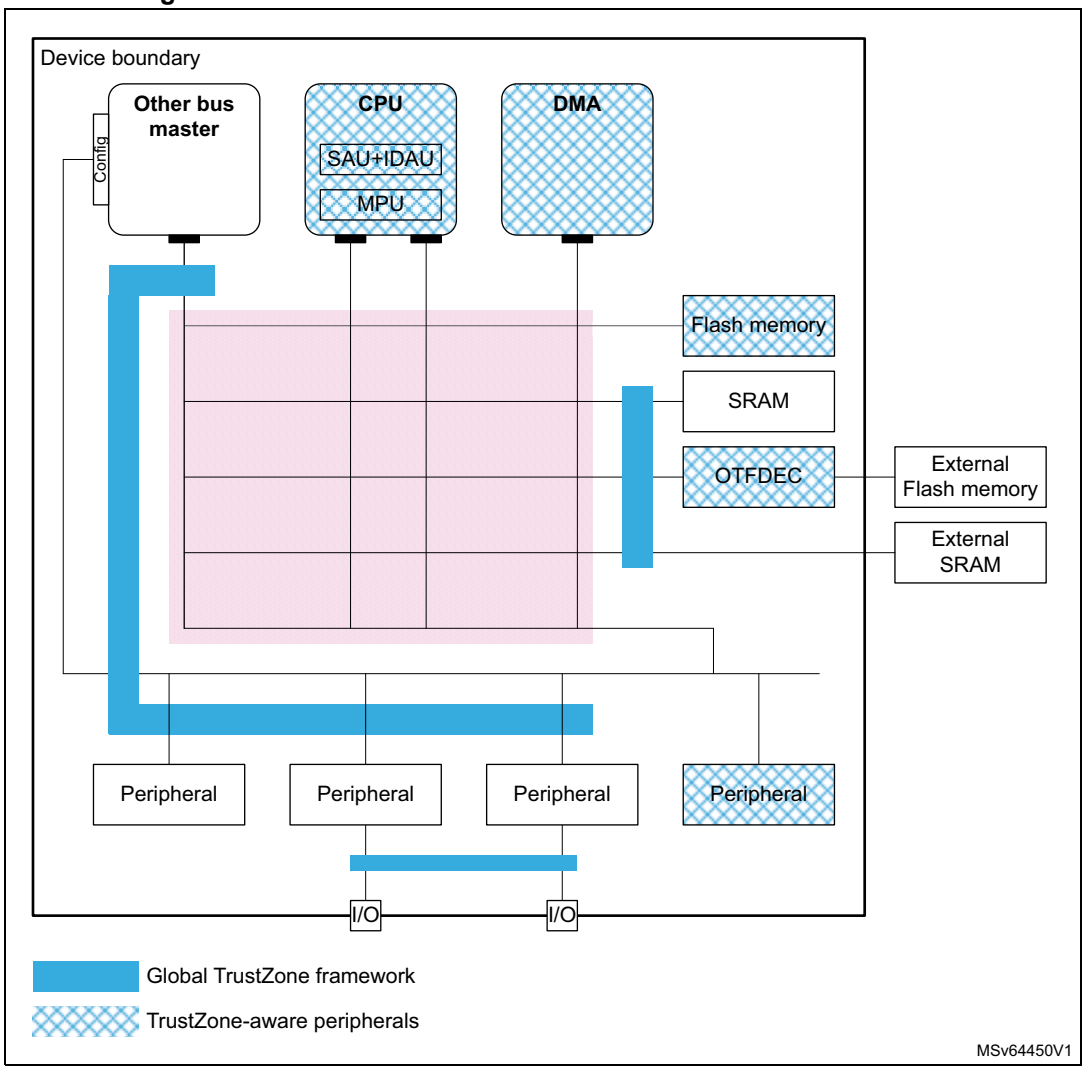
For more information on memory security attribution using IDAU/SAU, refer to the application note *TrustZone features on STM32L5 and STM32U5 Series* (AN5347).

3.5.4 Memory and peripheral allocation using GTZC

Global TrustZone framework architecture

On top of the Armv8-M TrustZone security extension in Cortex-M33, the devices embed complementary security features that reinforce, in a flexible way, the isolation between the secure and the non-secure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy memories and peripherals against non-secure transactions coming from other masters than the Cortex-M33.

Figure 7. Global TrustZone framework and TrustZone awareness



Securing peripherals with TZSC

When the TrustZone security is active, a peripheral is either securable through the TZSC in GTZC, or is natively TrustZone-aware, as shown in the previous figure:

- A securable peripheral or memory is protected by an AHB/APB firewall gate, that is controlled by the TrustZone security controller (TZSC).
- A TrustZone-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific TrustZone behavior, such as a subset of secure registers or a secure memory area.

When a securable peripheral is made secure-only with the GTZC, if this peripheral is master on the interconnect (SDMMC), it automatically issues secure transactions. The SDMMC is an example of securable master. TrustZone-aware AHB masters like Cortex-M33 or DMAs, drive a secure signal in the AHB interconnect, according to their security mode, independently to the GTZC.

Note: Like with TrustZone, a peripheral can be made privileged-only with TZSC (see Section 3.6.2). In this case, if this peripheral is master on the interconnect, it automatically issues privileged transactions.

Securing memories with TZSC and MPCBB

The TZSC block in GTZC provides the capability to manage the security and privilege for all securable external memories, programming the MPCWM resources as defined in the table below.

Table 6. MPCWMx resources

Memory	MPC resource	Type of filtering	Number of regions	Default security	On-the-fly decryption(1)
OCTOSPI1	MPCWM1	Non-secure privileged or unprivileged region (watermarks)	2	Secure privileged(2)	Yes
FMC_NOR bank	MPCWM2		2		No
FMC_NAND bank	MPCWM3		1		
Backup SRAM (BKPSRAM)	MPCWM4		1		
OCTOSPI2	MPCWM5		2		Yes

1. Using the OTFDEC.
2. Assuming TrustZone is activated on the device, non-secure unprivileged otherwise.

The MPCBB resources in GTZC provide the capability to configure the security and privilege of embedded SRAM blocks, as defined in the table below.

Table 7. MPCBBx resources

Memory	MPC resource	Type of filtering	Memory size (Kbytes)	Block size (Bytes)	Number of super-blocks	Default security
SRAM1	GTZC1_MPCBB1	Block based, managing security and privilege	192	512(1)	12	Secure privileged(2)
SRAM2	GTZC1_MPCBB2		64		4	
SRAM3	GTZC1_MPCBB3		512		32	
SRAM4	GTZC2_MPCBB4		16		1	

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, non-secure unprivileged otherwise.

Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:

- statically programmed during the secure boot, locked and not changed afterwards
- dynamically re-programmed using a specific application code or real-time kernel

When the dynamic option is selected and the configuration is not locked:

- MPCBB secure blocks or MPCWM non-secure region size can be changed by a secure software. This software must be privileged for MPCWM, can be unprivileged if the particular block is not privileged-only.

- The secure (respectively privilege) state of each peripheral can be changed writing to GTZC_TZSC_SECCFRGx (respectively GTZC_TZSC_PRIVCFGRx) registers.

Securing peripherals with TZSC

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals. The list of these peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

Note: When the TrustZone is deactivated, the resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only (see Section 3.6.2).

When the TrustZone is activated, peripherals are set as non-secure and unprivileged after reset.

TrustZone-aware peripherals

The devices include the following TrustZone-aware peripherals:

- GPIOA to GPIOI, configured in LPGPIO alternate function or not
- GTZCx_MPCBB, GTZCx_TZIC and GTZCx_TZSC (GTZC blocks)
- OTFDEC1/2, writable only in secure if TZEN = 1
- EXTI
- Flash memory
- RCC and PWR
- GPDMA and LPDMA
- SYSCFG registers
- RTC and TAMP
- MCU debug unit DBGMCU

The way illegal accesses to those peripherals are monitored through the TZIC registers is described in *Section 5: Global TrustZone controller (GTZC)*.

For more details, refer to *Section 3.5.5*.

TrustZone illegal access controller (TZIC)

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone-aware peripherals, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone enabled (TZEN = 1). All accesses to TZIC registers must be secured and privileged.

For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

Note: By default, all events are masked.

3.5.5 Managing security in TrustZone-aware peripherals

This section gives more details on how the security is implemented in the TrustZone-aware peripherals listed in the previous section.

Embedded Flash memory

When the TrustZone security is enabled through option bytes (TZEN = 1), the whole Flash memory is secure after reset and the following protections, shown in the figure below, are available to the application:

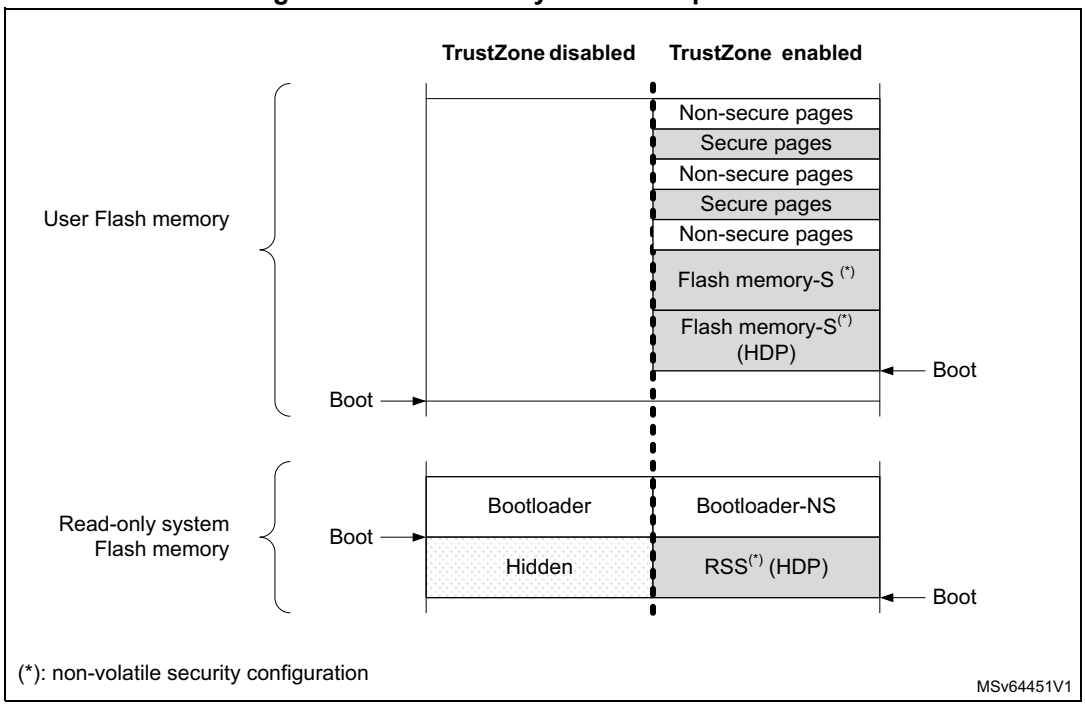
- non-volatile user secure areas, defined with non-volatile secure user option bytes
  - watermark-based secure only area (x2)
  - secure hide protection (HDP) area, stickily hidden after boot (x2)
- volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as non-secure (example: outside watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers.

Note: All areas are aligned on the Flash memory page granularity.

The Flash memory area can be configured as secure while it is tagged as non-secure in Cortex-M33 IDAU/SAU. In this case, non-secure accesses by the CPU to the Flash memory are denied.

Erase or program operations can be available to secure (resp. non-secure) code only for secure (resp. non-secure) pages or memory. A Flash memory is considered secure if at least one page is secure.

Figure 8. Flash memory TrustZone protections



As shown above, when TrustZone is activated (TZEN = 1), the application code can use the HDP area that is part of the Flash watermark-based secure area. Indeed, when the application sets the HDPx_ACCDIS bit, data read, write and instruction fetch on this HDP area are denied until next system reset.

For example, the software code in the secure Flash HDP area can be executed only once, with any further access to this area denied until the next system reset. Additionally, any Flash memory page belonging to an active HDP area cannot be erased anymore.

When the TrustZone is deactivated (TZEN = 0), the volatile/non-volatile secure area features are deactivated and all secure registers are RAZ/WI.

See *Section 7: Embedded Flash memory (FLASH)* for more details.

On-the-fly encryption/decryption (OTFDEC)

When the TrustZone security is activated (TZEN = 1), the OTFDEC can only be initialized by secure applications. Each of the four encrypted regions, once the configuration is confirmed, can be write-locked until next power-on-reset.

Note: Any application (secure or non-secure) can verify the initialization context of each OTFDEC region (including CRC of the keys), by reading the peripheral registers.

Key registers in each OTFDEC are write-only.

See *Section 3.9.3* for more details on this cryptographic engine.

Direct memory access controllers (LPDMA and GPDMA)

When a DMA channel x is defined as secure (SECx = 1 in LP/GPDMA_SECCFGR), the source and destination transfers can be independently set as secure or non-secure by a secure application using SSEC and DSEC bits in LP/GPDMA_CxTR1. The table below summarizes these security options available in each DMA channel.

Table 8. DMA channel use (security)(1)

Destination type	Secure DMA channel x (SECx = 1)		Non-secure DMA channel y (SECy = 0)	
	Secure source	Non-secure source	Secure source	Non-secure source
Secure destination	OK	OK(2)	Transfer blocked	
Non-secure destination	OK(3)	OK(4)	Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros. Also an illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.
2. If the source is a memory, the transfer is only possible if SSEC = 0, otherwise the transfer is blocked.
3. If the destination is a memory, the transfer is only possible if DSEC = 0, otherwise the transfer is blocked.
4. If the transfer is memory-to-memory, the transfer is only possible if SSEC = 0 and DSEC = 0, otherwise the transfer is blocked.

When a channel is configured as secure:

- Registers allocated to this channel (excluding LP/GPDMA_SECCFGR, LP/GPDMA_PRIVCFGR and LP/GPDMA_RCFGLOCKR) are read as zero. Write are ignored for non-secure accesses. A secure illegal access event may also be triggered toward the TZIC peripheral.

  - Writes to LP/GPDMA_SECCFGR and LP/GPDMA_RCFGLOCKR must be secure. For each bits in LP/GPDMA_PRIVCFGR, write must be secure if corresponding bit in LP/GPDMA_SECCFGR is set.
- In linked-list mode, the loading of the next linked-list data structure from memory is performed with secure transfers.
- When switching to a non-secure state, the secure application must abort the channel or wait until the secure channel is completed before doing the switch.

Note: DMA secure channels are not available when TrustZone is deactivated.

When a channel is configured as non-secure, in linked-list mode, the loading of the next linked-list data structure from memory is performed with non-secure transfers.

See *Section 18: Low-power direct memory access controller (LPDMA)* and *Section 17: General purpose direct memory access controller (GPDMA)* for more details.

Power control (PWR)

When the TrustZone security is activated (TZEN = 1), the selected PWR registers can be secured through PWR_SECCFGR, protecting the following PWR features:

- low-power mode setup
- wakeup (WKUP) pins definition
- voltage detection and monitoring
- Backup domain control

Other PWR configuration bits become secure:

- when the system clock selection is secure in the RCC: the voltage scaling (VOS) and the regulator booster (BOOSTEN) configurations become secure.
- when a GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.
- when the USB Type-C/USB power delivery interface (UCPD) is configured as secure in TZSC: PWR_UCPDR register becomes secure.

See *Section 10: Power control (PWR)* for details.

Secure clock and reset (RCC)

When the TrustZone security is activated (TZEN = 1) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets become TrustZone-aware:

- If the peripheral is securable and programmed as secure in the TZSC, the peripheral clock and reset bits become secure.
- If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure as soon as at least one function is configured as secure inside the peripheral.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

The SHSI configuration and status bits are secured when the SAES is configured as secure.

Additionally, the following configurations can be made secure-only using RCC_SECCFGR:

- external clock (such as HSE or LSE), internal oscillator (such as HSI, MSI, or LSI)
- main PLL and AHB prescaler
- system clock source selection
- reset flag clearing

- automatic internal oscillator waking up configuration

See *Section 11: Reset and clock control (RCC)* for details.

Real time clock (RTC)

Like all TrustZone-aware peripherals, a non-secure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC.

After a Backup domain power-on reset, all RTC registers can be read or written in both secure and non-secure modes. The secure boot code can then change this security setup, making registers Alarm A, alarm B, wakeup timer and timestamp secure or not, using RTC_SECCFGR.

When the SEC bit is set in secure-only RTC_SECCFGR:

- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR is always possible in secure and non-secure modes. All the other RTC registers can be read only in secure mode.

When SEC is cleared in secure-only RTC_SECCFGR, it is still possible to restrict access in secure mode to some RTC registers by setting dedicated control bits: INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC and ALRBSEC.

Note: The RTC security configuration is not affected by a system reset.

See *Section 54: Real-time clock (RTC)* for more details.

Tamper and backup registers (TAMP)

Like all TrustZone-aware peripherals, a non-secure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC.

After a Backup domain power-on reset, all TAMP registers can be read or written in both secure and non-secure modes. The secure boot code can change this security setup, making some registers secure or not as needed, using TAMP_SECCFGR register.

When TAMPSEC is set in TAMP_SECCFGR:

- Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
- Reading the TAMP registers (with the exception of TAMP_SECCFGR, TAMP_PRIVCFGR and TAMP_MISR) returns zero if the access is non-secure. Backup registers have their own read protection (see below).

The application can also:

- make TAMP_COUNTR register read and write secure-only by setting the CNT1SEC bit in TAMP_SECCFGR secure register
- in backup registers increase security for two of the three protection zones configured using BKPRWSEC[7:0] and BKPWSEC[7:0] bitfields in TAMP_SECCFGR:
  - protection zone 1 is read non-secure, write non-secure
  - protection zone 2 is read non-secure, write secure
  - protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See *Section 55: Tamper and backup registers (TAMP)* for more details.

General-purpose I/Os (GPIO)

When the TrustZone security is activated (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR registers. Only a secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin of GPIO is set as secure.

When an I/O pin is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE), and I/O data are RAZ/WI in case of non-secure access.

When digital alternate function is used (input/output mode), in order to protect the data transiting from/to the I/O managed by a secure peripheral, the devices add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- If the peripheral is secure, the I/O pin must also be secure to allow input/output of data.
- If the peripheral is not secure, the connection is allowed regardless of the I/O pin state.

The TrustZone-aware logic around GPIO ports, used as alternate function, is summarized in the table below.

Table 9. Secure alternate function between peripherals and allocated I/Os

Security configuration		Alternate function logic		Comment
Peripheral	**Allocated I/O pin**	**Input**	**Output**	
Secure	Secure	I/O data	Peripheral data	-
Non-secure				Out of reset configuration
Secure	Non-secure	Zero	Zero	-
Non-secure		I/O data	Peripheral data	

When an analog function with an analog switch is used, the connection to the peripherals listed in the table below, is blocked by hardware when the peripheral is non-secure and the I/O is secure.

Table 10. Non-secure peripheral functions that are not connected to secure I/Os

Peripheral	Analog function(1)	Input	Output	How to set a peripheral or function as secure
ADC1	ADC1_INy (y = 1 to 17)	X	-	Set ADC12SEC in GTZC1_TZSC_ SECCFGR3
ADC4	ADC4_INy (y = 1 to 19)			Set ADC4SEC in GTZC2_TZSC_ SECCFGR1
OPAMPx (x = 1, 2)	OPAMPx_VINy (x = 1, 2; y = 1, 2)			Set OPAMPSEC in GTZC2_TZSC_ SECCFGR1
COMPx (x = 1, 2)	COMPx_INy (x = 1; y = 1 to 3) COMPx_INy (x = 2; y = 1, 2)			Set COMPSEC in GTZC2_TZSC_ SECCFGR1

1. Used to find the I/O corresponding to the signal/function on the package (refer to the product datasheet).

Finally, regarding GPIO and security, the table below summarizes the list of peripheral functions that do not have any hardware protection linked to TrustZone. The listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral function is non secure.

For example, when a secure application sets PA4 as secure to be used as LPTIM2_OUT, if the DAC is non-secure, it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is non-secure, it can be programmed to capture the USART input traffic through the TAMP_IN function.

It is important that, for each case described in the table below, the secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential), then the secure application must configure the TAMP as secure even if it is not used by the secure application.

Note: How to make a peripheral secure is summarized in the right column of the table below.

Table 11. Non-secure peripheral functions that can be connected to secure I/Os

Peripheral	Signal[1]	Input	Output	How to set the peripheral or function as secure
DAC	DAC1_OUTx (x = 1, 2)	-	X	Set DAC1SEC in GTZC2_TZSC_SECCFGR1.
USB	OTG_FS_VBUS	X	X	Set OTGSEC in GTZC1_TZSC_ SECCFGR3.
UCPD	UCPD1_CCx (x = 1, 2)	X	X	Set UCPD1SEC in GTZC1_TZSC_ SECCFGR1.
	UCPD1_DBx (x = 1, 2)	X	-	
TAMP	TAMP_INx (x = 1 to 8)	X	-	Set TAMPSEC in TAMP_SECCFGR
	TAMP_OUTx (x = 1 to 8)	-	X	
RTC	RTC_OUTx (x = 1, 2)	-	X	Set SEC in RTC_SECCFGR.
	RTC_TS	X	-	Set TSSEC in RTC_SECCFGR.
PWR	WKUPx (x = 1 to 8)	X	-	Set WUPxSEC in PWR_SECCFGR.
RCC	LSCO	-	X	Set LSESEC in RCC_SECCFGR.
EXTI	EXTIx (x= 0 to 22)	X	-	Set SECx bit in EXTI_SECCFGR.

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to *Section 13: General-purpose I/Os (GPIO)* for more details.

Extended interrupts and event controller (EXTI)

When the TrustZone security is activated (TZEN = 1), the EXTI is able to protect event register bits from being modified by non-secure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGR1. When an input event is configured as secure, only a secure application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

The security configuration in EXTI_SECCFGR1 can be globally locked after reset in EXTI_LOCKR.

See *Section 21: Extended interrupts and event controller (EXTI)* for more details.

System configuration controller (SYSCFG)

Like all TrustZone-aware peripherals, when the TrustZone security is activated (TZEN = 1), a non-secure read/write access to a secured SYSCFG register is RAZ/WI. Such access also generates an illegal access event that triggers a secure illegal access interrupt if the SYSCFG illegal access event is not masked in the TZIC.

See *Section 15: System configuration controller (SYSCFG)* for more details.

Microcontroller debug unit (DBGMCU)

The MCU debug component (DBGMCU) helps the debugger, providing support for:

- low-power mode behavior during debug
- peripheral freeze during debug, applicable to I2Cs, IWDG, WWDG, timers, low-power timers, and LP/GPDMA channels

The DBGCMU is a TrustZone-aware peripheral, managing accesses to its control registers as described in the table below.

Table 12. TrustZone-aware DBGMCU access management

Debug profile	Peripheral status(1)	DBG_xx_STOP control bits	
		Write access	Read access
Non-secure invasive (SPIDEN = 0)	NS	Yes (S(2) or NS)	Yes (S or NS)
	S	None (S or NS)	
Secure invasive (SPIDEN = 1)	NS	Yes (S or NS)	
	S	Yes (S only)	

1. As reported by the GTZC, the TrustZone-aware peripheral or the DMA channel.
2. Secure access from debugger is converted to non-secure access in the device.

Refer to *Section 65.12: Microcontroller debug unit (DBGMCU)* for more details.

3.5.6 Activating TrustZone security

The TrustZone is deactivated by default in all STM32U575/585 devices. It can be activated by setting the TZEN user option bit in FLASH_OPTR when in RDP Level 0. Once TZEN has changed from 0 to 1, the default security state, after reset, is always the following:

- CPU subsystem
  - Cortex-M33 exits reset in secure state, hence the boot address must point toward a secure memory area.
  - All interrupt sources are secure (in NVIC).
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure.
- Embedded Flash memory
  - Flash memory non-volatile secure areas (with their HDP zone), are defined with non-volatile registers FLASH_SECWMxR (x = 1, 2). Default secure option bytes setup is all user Flash secure, without HDP area defined.
  - Volatile block-based security attributions of the Flash memory are non-secure. The secure boot code can change this setup, making blocks secure.

- Embedded SRAM memories
  - All SRAMs are secure, as defined in GTZC/MPCBB (see *Section 3.5.4*). The secure boot code can change this security setup, making blocks secure or not.
- External memories
  - All memory devices connected to the FSMC and OCTOSPIs are secure, as defined in GTZC/MPCWM (see *Section 3.5.4*). The secure-boot code can change this security setup, making components secure or not.
- All GPIOs are secure.
- All LP/GPDMA channels are non-secure.
- Backup registers are non-secure.
- Peripherals and GTZC:
  - Securable peripherals are non-secure and unprivileged.
  - TrustZone-aware peripherals are non-secure, with their secure configuration registers being secure.
  - All illegal access interrupts in GTZC/TZIC are disabled.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

3.5.7 Deactivating TrustZone security

Once TrustZone is activated, it can only be deactivated during a RDP regression to Level 0.

Note: Such RDP regression triggers the erase of embedded memories (SRAM2, Flash memory), and the reset of all peripherals, including the OTFDEC and all crypto engines.

After the TrustZone deactivation, most of the features mentioned in *Section 3.5* are no longer available:

- The non-volatile secure area of the embedded Flash memory is deactivated, including the HDP area.
- The NVIC only manages non-secure interrupts.
- All secure registers in TrustZone-aware peripherals are RAZ/WI.

Note: When the TrustZone is deactivated, the resource isolation using privilege stays available (see Section 3.6.2 for details).

For more information, refer to the application note *Arm® TrustZone® features for STM32L5 and STM32U5 Series* (AN5347).

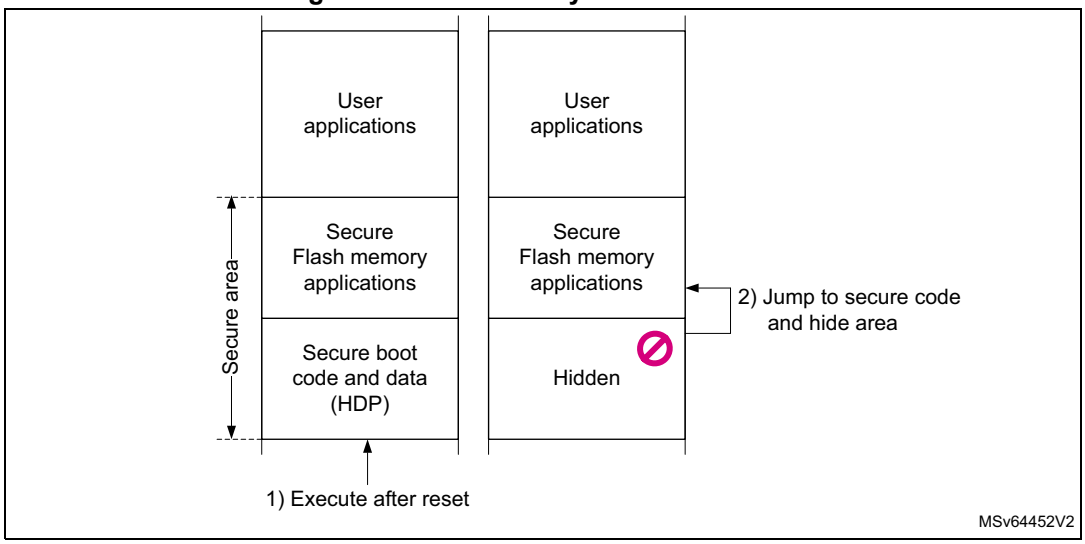
3.6 Other resource isolations

These are hardware mechanisms offering an additional level of isolation on top of the TrustZone technology.

3.6.1 Temporal isolation using secure hide protection (HDP)

When the TrustZone security is enabled (TZEN = 1), the embedded Flash memory allows an HDP area per watermarked-secure area of each bank (8-Kbyte page granularity) to be defined. The code executed in this HDP area, with its related data and keys, can be hidden after boot until the next system reset. The hide protection principle is pictured on the figure below.

Figure 9. Flash memory secure HDP area



When the HDPxEN and HDPx_ACCDIS bits (x = 1, 2) are set, data read, write and instruction fetch on the area defined by SECWMx_PSTRT and HDPx_PEND option bytes, are denied until the next device reset.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

The HDP area can be resized by a secure application if the area is not hidden and if RDP Level ≠ 2.

3.6.2 Resource isolation using Cortex privileged mode

In parallel to the TrustZone isolation described in *Section 3.5*, the hardware and software resources of STM32U575/585 devices can be partitioned so that they are restricted to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, available even if TrustZone is deactivated (TZEN = 0), critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

Memory and peripheral privileged allocation using MPU

The Cortex-M33 MPU divides the unified memory into eight regions, each aligned to a multiple of 32 bytes. Each memory regions can be programmed to generate faults when accessed inappropriately by unprivileged software.

Memory and peripheral privileged allocation using GTZC

For the Cortex-M33 master, to complement the coarse isolation provided by the MPU, the GTZC reinforces, in a flexible way, the isolation between privileged and unprivileged tasks, for peripherals and selected memories.

For masters other than the Cortex-M33, the GTZC can assign them as unprivileged initiators, automatically protecting resources defined as privileged against this master.

- Securing peripherals with TZSC (privileged-only)

  In the devices, a peripheral is either securable privileged-only through GTZC, or is natively privileged-aware:

  – A securable privileged-only peripheral or memory is protected by an AHB/APB firewall gate that is controlled by the TZSC.

  – A privileged-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific behavior such as a subset of registers or a memory area is privilege-only.

    When such peripheral is made privileged-only with GTZC, if it is master on the interconnect (SDMMC), it automatically issues privileged transactions. Privilege-aware masters like GPDMA or LPDMA, drive privileged signal in the AHB interconnect according to their internal privileged mode, independently to the GTZC.

    The list of securable peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

- Securing memories with TZSC and MPCBB (privileged-only)

  The TZSC logic in GTZC provides the capability to manage the privilege level for all securable external memories, programming the MPCWM resources defined in *Section 3.5.4*.

  Similarly, the GTZC provides the capability to configure the privilege level of embedded SRAM blocks, programming the MPCBB resources defined in *Section 3.5.4*.

- Error management (privileged-only)

  – Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal unprivileged read and write accesses.

  – The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write.

  – When an illegal unprivileged access occurs, no bus error is generated, except when this access is an instruction fetch, accessing a privileged memory or a peripheral register.

Managing security in privileged-aware peripherals

TrustZone-aware peripherals also implement privileged-only access mode. The privileged protection is valid even if TZEN = 0:

- *Embedded Flash memory*

  By default all embedded Flash registers can be read or programmed in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in FLASH_PRIVCFGR, reading and writing the Flash secure registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is deactivated (TZEN = 0).

  When non-secure privileged bit NSPRIV is set in FLASH_PRIVCFGR, reading and writing the Flash non-secure registers are possible only in privileged mode.

  Regarding privileged protection of the embedded Flash memory, the devices offer the following features:

  – The system Flash memory can be accessed both in privileged and unprivileged modes.

  – Each watermark-based secure area, including its secure HDP area, is accessible in secure-privileged and secure-unprivileged mode, if applicable.

  – Each 8-Kbyte page of the embedded Flash memory can be programmed on-the-fly as privileged only, using the block-based privileged configuration registers FLASH_PRIV1BBRx and FLASH_PRIV2BBRx. An unprivileged page is accessible by a privileged or unprivileged access.

Note: Switching a page from privileged to unprivileged does not erase the content of the page.

When applicable, an erase or program operation is always available to privileged code, and is available to unprivileged code only for unprivileged pages or unprivileged memory.

- *On-the-fly encryption/decryption (OTFDEC)*

  When privileged bit PRIV is set in OTFDEC_PRIVCFGR, the OTFDEC can only be initialized by a privileged application.

Note: OTFDEC_PRIVCFGR can be read by both privileged and unprivileged code.

- *Direct memory access controllers (LPDMA and GPDMA)*

  When a DMA channel x is defined as privileged (PRIVx = 1 in LP/GPDMA_PRIVCFGR), special rules apply when accessing privileged/unprivileged source or destination. Those rules are summarized on the table below.

Table 13. DMA channel use (privilege)

Destination	Privileged DMA channel x (PRIVx = 1)		Unprivileged DMA channel y (PRIVy = 0)	
	Privileged source	Unprivileged source	Privileged source	Unprivileged source
Privileged	OK		Transfer blocked(1)	
Unprivileged			Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros.

See *Section 18: Low-power direct memory access controller (LPDMA)* and *Section 17: General purpose direct memory access controller (GPDMA)* for more details.

- *Power control (PWR)*

  By default, after a power-on or a system reset, all PWR registers but PWR_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in PWR_PRIVCFGR, reading and writing the PWR securable registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

  When non-secure privileged bit NSPRIV is set in PWR_PRIVCFGR, reading and writing the PWR non-secure registers are possible only in privileged mode.

  See *Section 10: Power control (PWR)* for details.

- *Secure clock and reset (RCC)*

  By default, after a power-on or a system reset, all RCC registers but RCC_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in RCC_PRIVCFGR, reading and writing the RCC securable bits are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

  When non-secure privileged bit NSPRIV is set in RCC_PRIVCFGR, reading and writing the RCC non-secure bits are possible only in privileged mode.

  See *Section 11: Reset and clock control (RCC)* for details.

- *Real time clock (RTC)*

  By default after a Backup domain reset, all RTC registers but RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When PRIV bit is set in privileged-only RTC_PRIVCFGR:

  – Writing the RTC registers is possible only in privileged mode.

  – Reading the RTC_SECCFGR, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privileged and unprivileged modes.

  All the other RTC registers can be read only in privileged mode.

  When PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode to some RTC registers by setting dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRV or ALRBPRIV.

  See *Section 54: Real-time clock (RTC)* chapter for details.

- *Tamper and backup registers (TAMP)*

  By default after any Backup domain reset, all TAMP registers but TAMP_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When PRIV bit is set in privileged-only TAMP_PRIVCFGR:

  – Writing the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters that have their own protection setting.

  – Reading the TAMP_SECCFGR or TAMP_PRIVCFGR is always possible in privilege and unprivilege modes. All the other TAMP registers can be read only in privilege mode, except for the backup registers and the monotonic counters that have their own protection setting.

The application can also:

– make TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR

– increase security for two of the three protection zones in backup registers, using BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:

– Make protection zone 1 read privileged, write privileged.

– Make protection zone 2 read privileged or unprivileged, write privileged.

– Protection zone 3 is always read and write privileged or unprivileged.

- *General-purpose I/Os (GPIO)*

  All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

- *Extended interrupts and event controller (EXTI)*

  The EXTI peripheral is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in the privileged-only EXTI_PRIVCFGR1 register. When an input event is configured as privileged, only a privileged application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

  The security configuration in EXTI_PRIVCFGR1 can be globally locked after reset in EXTI_LOCKR.

  See *Section 21: Extended interrupts and event controller (EXTI)* for more details.

- *System configuration controller (SYSCFG)*

  All SYSCFG registers can be read and written in both privileged and unprivileged modes, except:

  – FPUSEC bit in SYSCFG_SECCFGR registers (privileged only)

  – SYSCFG registers for CPU configuration: SYSCFG_CSLOCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR

  See *Section 15: System configuration controller (SYSCFG)* for more details.

3.7 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

3.7.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters

- Cortex-M33 operating mode (privileged, unprivileged)
- data/instruction fetch

The memory map and the programming of the non-secure and secure MPUs split memory into regions (up to eight per MPU). Secure MPU is only available when TrustZone is activated.

3.7.2 Embedded Flash memory write protection

The embedded Flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded Flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes, writing the start and end addresses: two write-protected areas can be defined in each bank, with the granularity of a 8-Kbyte page.

WRP areas can be modified through option byte changes unless corresponding FLASH_WRPxA/BR has its UNLOCK option bit cleared (meaning ROM emulation). UNLOCK can be set only when regressing from RDP Level 1 to Level 0.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.7.3 Tamper detection and response

Principle

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: V_{BAT}, V_{DDA}), temperature and clocking (LSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered automatically with V_{DD} or V_{BAT}

See *Section 55: Tamper and backup registers (TAMP)* for more details.

Tamper detection sources

The devices support eight active input/output pins, allowing four independent active-tamper meshes, or up to seven meshes if the same output pin is shared by several input pins (for a total of eight active-tamper I/Os). The active-tamper balls are mapped in the center of packages that can be used in POS market (such as WLCSP90).

The active pins are clocked by the LSE, and are functional in all system operating modes (Run, Sleep, Stop, Standby or Shutdown), and in V_{BAT} mode.

Detection time is programmable, and a digital filtering is available (tamper triggered after two false comparison in four consecutive comparison samples).

Note: Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in the table below.

Table 14. Internal tampers in TAMP

Tamper input	NOER bit number in TAMP_CR3	Tamper source
itamp1	0	Backup domain voltage continuous monitoring, functional in V_{BAT} mode
itamp2	1	Temperature monitoring, functional in V_{BAT} mode
itamp3	2	LSE monitoring(1), functional in V_{BAT} mode
itamp4	-	Not used
itamp5	4	RTC calendar overflow (rtc_calovf)
itamp6	5	JTAG/SWD access when RDP > 0
itamp7, 12, 13	6, 11, 12	Voltage monitoring (V_{CORE}, V_{REF+}), through ADC analog watchdog, functional down to Stop 2 mode
itamp8	7	Monotonic counter overflow (generated internally)
itamp9	8	Fault generation for cryptographic peripherals (SAES, PKA, AES, RNG)
itamp11	10	IWDG timeout and potential tamper (IWDG reset when at least one enabled tamper flag is set)

1. LSE missing or over frequency detection (> 2MHz), Glitch filter (> 2 MHz).

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxNOER bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in SAES, AES, HASH and OTFDEC (encrypted Flash memory regions are read as zero)
  - asymmetric keys stored in PKA SRAM, erased when V_{DD} is present
  - other secrets stored in SRAM2 and CPU instruction cache memory (SRAM2 erased when V_{DD} is present)
  - non-volatile information used to derive the DHUK in SAES is zeroed until complete SRAM2 erase
  - 2-Kbyte backup SRAM (depending on configuration bit), erased when V_{DD} is present
  - ICACHE and DCACHE erased when V_{DD} is present

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If V_{DD} is not present, the secrets that are erased when V_{DD} is present, are only erased at the next V_{DD} power on.

Note: Device secret erase is also triggered by setting the BKERASE bit in TAMP_CR2, or by performing a RDP regression as defined in Section 3.10.1.

Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxNOER bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such situation, when the tamper flag is raised, access to below secrets is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, backup SRAM, SRAM2: read-as-zero, write-ignored
- AES, SAES and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to such a tamper flag, an IWDG reset triggers automatically the erase of secrets.

Tamper detection and low-power modes

The effect of low-power modes on a tamper detection are summarized on the table below.

Table 15. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI Tamper events cause the device to exit the Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI Tamper events cause the device to exit the Standby mode.
Shutdown	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE Tamper events cause the device to exit the Shutdown mode.

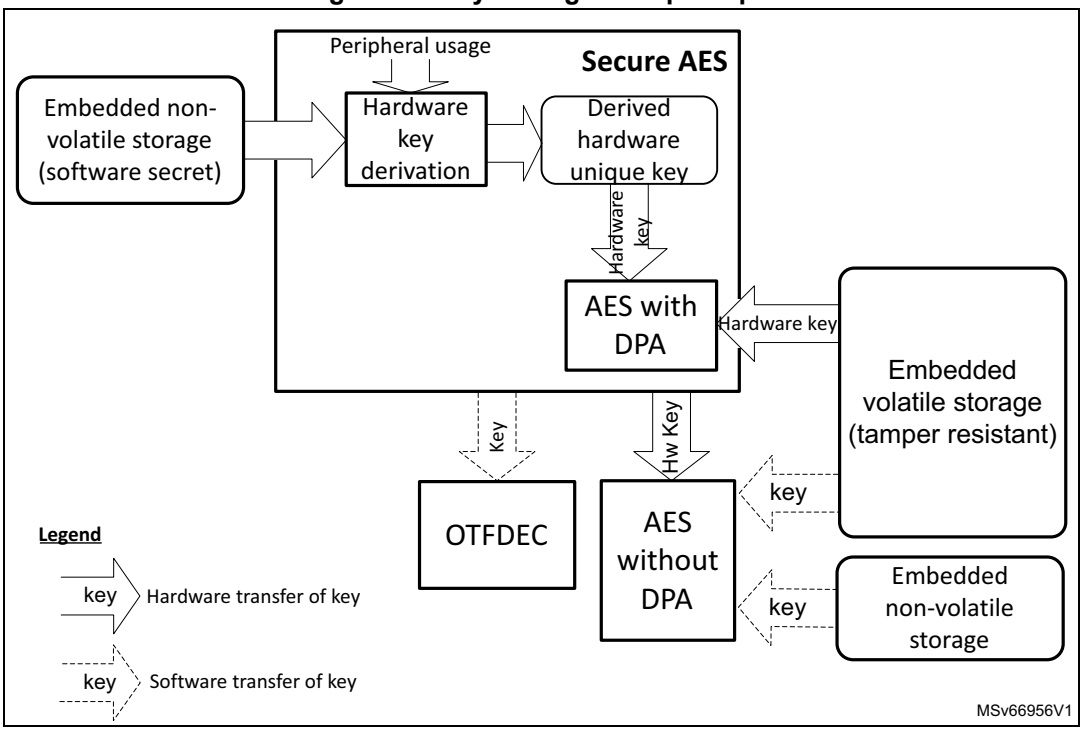
3.8 Secure storage

A critical feature of any security system is how long term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

Figure 10 shows how key management service application can use the AES engine for example to compute external image decryption keys. A non-volatile key can be stored in the embedded secure HDP area (see *Section 3.6.1*), while volatile key storage consists in the battery-powered, tamper-protected SRAM or registers in TrustZone-aware TAMP.

Figure 10 also shows keys that are manipulated by software (like OTFDEC keys), or keys that are managed only by hardware (like DHUK). More information on those hardware keys can be found in *Section 3.8.1*.

Figure 10. Key management principle



Details on tamper protection is found in *Section 3.7.3*, while TAMP TrustZone features are briefly described in *Section 3.5.5*.

3.8.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys, using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in case of tamper.

There are three different sources of hardware secret keys:

- DHUK: derived keys based on 256-bit non-volatile device unique secret in Flash memory. The generation of this key takes into account the TrustZone state and key use state (KMOD).

Note: DHUK is the same for all devices when RDP = 0 (debug/development mode).

- BHK: 256-bit application key stored in tamper-resistant volatile storage in TAMP
  This key is written at boot time, then read/write locked to application until next reset.
- XORK: result of a XOR of BHK and DHUK

These keys can be used:

- as normal key, loading in write-only key registers (software key mode)
- as encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as encryption/decryption key for another key, to be used in a faster AES engine (shared key mode)

3.8.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see *Section 66.1: Unique device ID register (96 bits)*).

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (see *Section 3.8.1*).

3.9 Crypto engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the U.S.A, BSI for Germany or ANSSI for France. Those algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The crypto engines embedded in STM32 reduces weaknesses on the implementation of critical cryptographic functions, preventing for example the use of weak cryptographic algorithms and key sizes. They also enable lower processing times and lower power consumption when performing cryptographic operations, offloading those computations from Cortex-M33. This is especially true for asymmetric cryptography.

For product certification purpose, ST can provide certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to their respective sections in the reference manual.

3.9.1 Crypto engines features

Table 16 lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available (both can be reserved to secure application only).

Note: Additional operations can be added using firmware.

The PKA can accelerate asymmetric crypto operations (like key pair generation, ECC scalar multiplication, point on curve check). See Section 45: Public key accelerator (PKA) for more details.

Table 16. Accelerated cryptographic operations

Operations	Algo-rithm	Specification	Key lengths (in bit)	Modes
Get entropy	RNG	NIST SP800-90B(1)	N/A	Software and hardware(2) modes running in parallel
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR(3)
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D	128, 256	GCM, CCM
Cipher-based message authentication code		NIST SP800-38D	128, 256	GMAC
Checksum	MD5	IETF RFC 1321	N/A	Digest 128-bit
	SHA-1	FIPS PUB 180-4		Digest 160-bit
Cryptographic hash	SHA-2			SHA-224, SHA-256
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long (>64 bytes)	-
Encryption/decryption key-pair generation(4)	RSA	IETF RFC 8017 NIST SP800-56B	Up to 4160	RSAES-OAEP
Signature(4) with hashing Signature verification	RSA	IETF RFC 8017 FIPS PUB 186-4	Up to 4160	PKCS1-v1_5, PSS
	ECDSA	ANSI X9.62 IETF RFC 7027 FIPS PUB 186-4	Up to 640	Refer to the table 'Family of supported curves for ECC operations' in PKA section for details
Key agreement	ECDH	ANSI X9.42		

1. Certifiable using STMicroelectronics reviewed documents.
2. Random numbers distribution to SAES and PKA using a dedicated hardware bus.
3. ECB and CBC chaining modes protected against side-channel and timing attacks in SAES (see *Section 3.9.2*).
4. Private key cryptography protected against side-channel and timing attacks.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

3.9.2 Secure AES co-processor (SAES)

The devices provide an additional on-chip hardware AES encryption and decryption engine, that implements counter-measures and mitigations against power and electromagnetic side-channel attacks.

Clocked by a dedicated 48 MHz SHSI clock, SAES is also slower than the AES, in order to provide best-in-class side-channel protections. The SAES engine supports 128-bit or 256-bit key in electronic code book (ECB) or cipher block chaining (CBC) mode.

As shown in *Section 3.8*, the SAES can be used for extra-secure on-chip storage for sensitive information. It can also be made secure-only.

For more information, refer to *Section 42: Secure AES coprocessor (SAES)*.

3.9.3 On-the-fly decryption engine (OTFDEC)

The OTFDEC TrustZone-aware peripheral proposes on-the-fly decryption of encrypted images stored on external Flash memory, connected through the OCTOSPI. This decryption process introduces almost no additional cycle overhead when the standard NOR Flash memory is used. The OTFDEC can also be used to encrypt Flash memory images on the device (for example to encrypt with a device unique secret key).

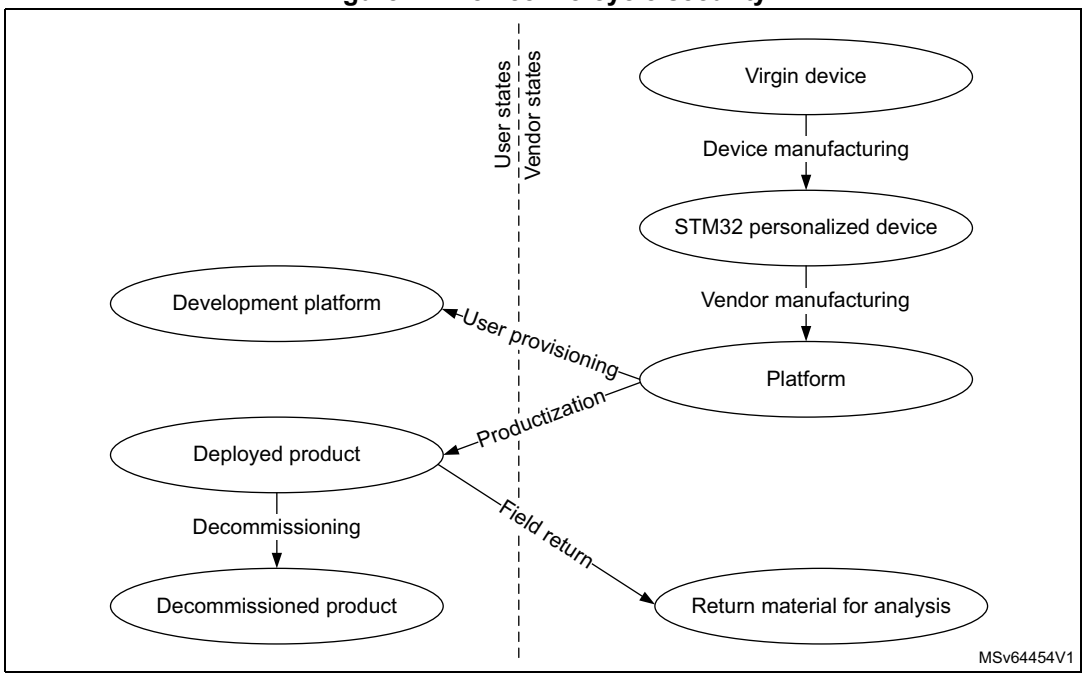
When a tamper event is confirmed in TAMP, all OTFDEC keys are erased and encrypted regions are read as zero until the OTFDEC is properly initialized again.

An OTFDEC typical use is detailed in *Section 3.12.2*. For more details on the peripheral programming, refer to *Section 44: On-the-fly decryption engine (OTFDEC)*.

3.10 Product life-cycle

A typical IoT device life-cycle is summarized in the figure below. For each step, the devices propose secure life-cycle management mechanisms embedded in the hardware.

Figure 11. Device life-cycle security



More details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in *Table 17*.

Table 17. Main product life-cycle transitions

Transitions	Description
Device manufacturing	STMicroelectronics creates new STM32 devices, always checking for manufacturing defects. During this process STM32 is provisioned with ROM firmware, secure firmware install (SFI) unique key pair, and a public ID.
Vendor manufacturing	One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“productization” transition) or he/she can use the platform for software development (“user provisioning” transition).
Productization	The end user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.
User provisioning	Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.
Field return or decommissioning	Those are one-way transitions, with devices kept in user premises or returned to the manufacturer. In both cases, all data including user data are destroyed, therefore the devices loose the ability to operate securely (like connecting to a managed IoT network).

The features described hereafter contribute to secure the device life-cycle.

3.10.1 Life-cycle management with readout protection (RDP)

The readout protection mechanism (full hardware feature) controls the access to the devices debug, test and provisioned secrets, as summarized in the table below.

Table 18. Typical product life-cycle phases

RDP protection level		Debug	Comments
Level 0	Device open	Secure(1) and non-secure	Boot address must target a secure area when TrustZone is enabled (secure SRAM, secure Flash memory, RSS in system Flash memory). Both OEM1 and OEM2 unlocking keys can be provisioned in the Flash user options. The DHUK in SAES peripheral is the same for all devices.
Level 0.5(2)	Device partially closed (closed-secure)	Non-secure only	Boot address must target a secure area when TrustZone is enabled (secure user or system Flash memory). Boot on SRAM is not permitted. Access to non-secure Flash memory is allowed when debug is connected. Both OEM1 and OEM2 unlocking keys can be provisioned in the Flash user options. The DHUK is different for every device.
Level 1	Device memories protected	Non-secure only (conditioned)	Boot address must target the secure user Flash memory. Accesses to non-secure Flash memory, encrypted Flash memory(3), SRAM2 and backup registers are **not allowed** when debug is connected. Both OEM1 and OEM2 unlocking keys can be provisioned in the Flash user options. The DHUK is different for every device.
Level 2	Device closed	None (JTAG fuse)	Boot address must target the user Flash memory (secure if TZEN = 1). Option bytes are read-only, hence RDP level 2 cannot be changed, unless OEM2 unlocking key is activated (see *Table 19*). The DHUK is different for every device.

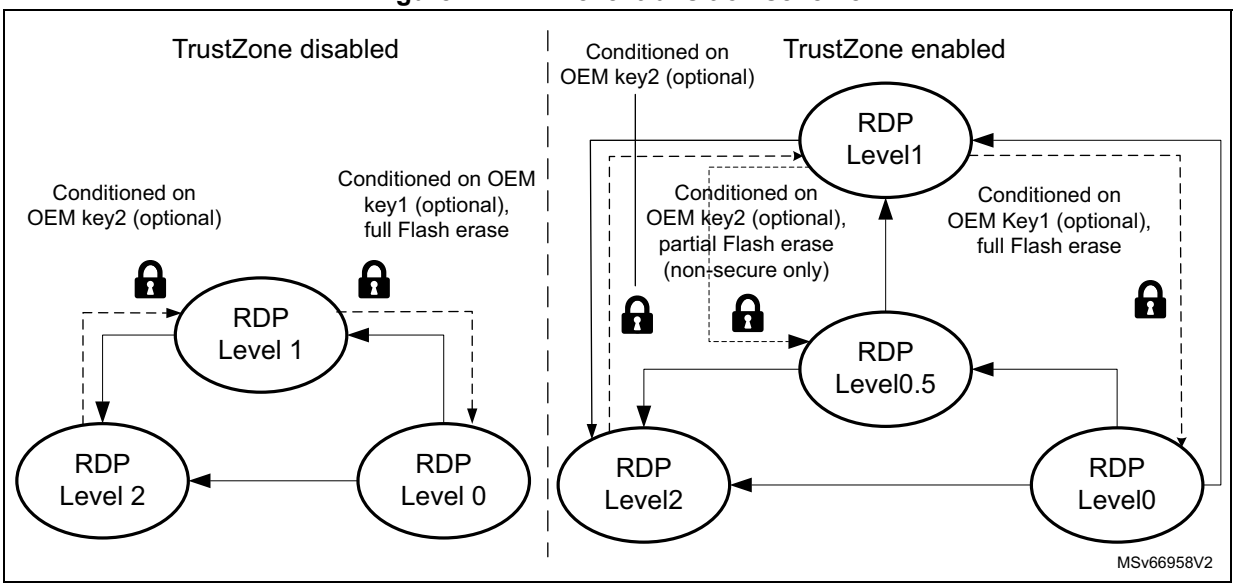
1. Debug is not available when executing RSS code.
2. Only applicable when TrustZone security is activated in the product.

3. External Flash memory area decrypted on-the-fly with the OTFDEC.

Note: OEM1KEY option byte can be modified when OEM1LOCK = 0 (RDP = 0.5 or 1 only).
OEM2KEY option byte can be modified when OEM2LOCK = 0 (RDP = 1 only).

The supported transitions, summarized in the figure below, can be requested (when available) through the debug interface or via the system bootloader.

Figure 12. RDP level transition scheme



As shown in the previous figure, the user Flash memory is automatically erased, either partially or in totality, during a RDP regression from RDP1. Those regressions can be conditioned to dedicated 64-bit password keys, if provisioned by the OEM (see next subsection). During the regression from RDP Level1 to RDP Level 0.5, only non-secure embedded Flash memory is erased, keeping functional, for example, the secure boot and the secure firmware update. In all regressions from Level 1, the OTP area in the Flash memory is kept, all SRAMS and targeted device secrets are erased. These secrets, also erased as response to tamper, are defined in *Section 3.7.3*.

Note: Enabling TrustZone using option byte TZEN is only possible when RDP level is 0.

For more details on RDP, refer to *Section 7: Embedded Flash memory (FLASH)*.

RDP unlocking sequences

The use of the two OEM password keys described in the last figure, is further described hereafter.

Note: The devices support both permanent RDP Level 2 (legacy mode) or password-based RDP Level 2 regression to Level 1. This Level 2 regression does not erase the application code, and it does not change the RDP Level 1 protections in place.

Details on the password-based regression can be found in *Table 19*.

Table 19. OEM1/2 RDP unlocking methods

OEM1 password options			OEM2 password options		
OEM1 LOCK	**Initial RDP level**	**RDP regression**	**OEM2 LOCK**	**Initial RDP level**	**RDP regression**
1	1	Regression to Level 0 possible only through OEM1 unlock sequence (see below)	1	1	Regression to Level 0.5 possible only through OEM2.1 unlock sequence (see below)
				2	Automatic regression to Level 1 triggered upon successful OEM2.2 unlock sequence (see below)
0		Regression to Level 0 always granted	0	1	Regression to Level 0.5 always granted
				2	Regression to Level 1 never granted RDP remains a permanent state.

- OEM1 unlock sequence, starting at RDP Level 1:
  - Shift password key through JTAG/SWD (see the note below).
  - If this key matches the OEM1KEY provisioned in the device, the application can trigger a regression sequence to Level 0. After the regression is completed, the whole embedded Flash memory and device secrets are erased. The OTP area is not erased.
  - In case of mismatch value, the RDP regression is blocked and RDP Level 1 protections are enforced until next power-on reset.
- OEM2.1 unlock sequence, starting at RDP Level 1:
  - Shift password key through JTAG/SWD under reset (see the note below).
  - If this key matches the OEM2KEY provisioned in the device, the application can trigger a regression sequence to Level 0.5. After the regression is completed, the non-secure embedded Flash memory and device secrets are erased. The OTP area is not erased.
  - In case of mismatch value, the RDP regression is blocked and RDP Level 1 protections are enforced until next power-on reset.
- OEM2.2 unlock sequence, starting at RDP Level 2:
  - Shift password key through JTAG/SWD under reset (see the note below).
  - If this key matches the OEM2KEY provisioned in the device, the device automatically triggers a regression sequence to Level 1. After the regression is completed, a power-on reset has to be performed by the user.
  - In case of mismatch value, the RDP regression is blocked and RDP Level 2 protections are enforced until next power-on reset.

Note: Unlocking the device with a password is possible only once per power cycle.

Shifting the password key through JTAG/SWD corresponds to writing two 32-bit key words, AUTH_KEY[31:0], then AUTH_KEY[63:32], in DBGMCU_DBG_AUTH_HOST register.

JTAG 32-bit device specific ID

Unless the JTAG port is de-activated (OEM2LOCK = 0 and RDP Level = 2), a 32-bit device specific quantity can always be read though the JTAG port. This information is stored in DBGMCU_DBG_AUTH_DEVICE.

The OEM can use this 32-bit information to derive the expected OEM password keys to unlock this specific device.

3.10.2 Recommended option byte settings

Most of the time, the user threat model focuses mainly on software attacks. In this case, it may be sufficient to keep the RDP Level 1 as device protection.

For a more aggressive threat model, where the user fears physical attacks on the STM32 device, it is recommended to optimize the level of security by setting the RDP Level 2.

The recommended settings are detailed below:

- If TrustZone is disabled (TZEN = 0)
  - RDP Level 2
  - non-secure boot address option bytes set in user Flash memory
- If TrustZone is enabled (TZEN = 1)
  - RDP Level 2
  - BOOT_LOCK = 1
  - secure boot address option bytes set in user secure Flash memory

As described in the previous section, the customer can decide to allow any RDP Level 2 part to regress to RDP Level 1, provided the OEM Key2 has been successfully provisioned, and OEM2LOCK option bit is set.

3.11 Access controlled debug

The device restricts access to embedded debug features, in order to guarantee the confidentiality of customer assets against unauthorized usage of debug and trace features.

3.11.1 Debug protection with readout protection (RDP)

As described in *Section 3.10.1,* the hardware RDP mechanism automatically controls the accesses to the device debug and test. The protection of these debug features are defined in the table below. Possible password-based regressions are described in *Section 3.10.1*.

Table 20. Debug protection with RDP

RDP protection level		Debug features protection
Level 0	Device open	Any debug(1)
Level 0.5(2)	Device partially closed	Secure debug is no longer available.
Level 1	Device memories protected	Non-secure debug can no longer debug code and data stored in the embedded Flash memory, the encrypted external Flash memory(3), SRAM2 and backup registers.
Level 2	Device closed	JTAG is physically deactivated, unless it is kept operational only for password key injection (OEM2LOCK = 1). See *Section 3.10.1* for details.

1. Including ST engineering test modes, used for field returns.
2. Only applicable when TrustZone security is activated in the product.
3. External Flash memory area decrypted on-the-fly with the OTFDEC.

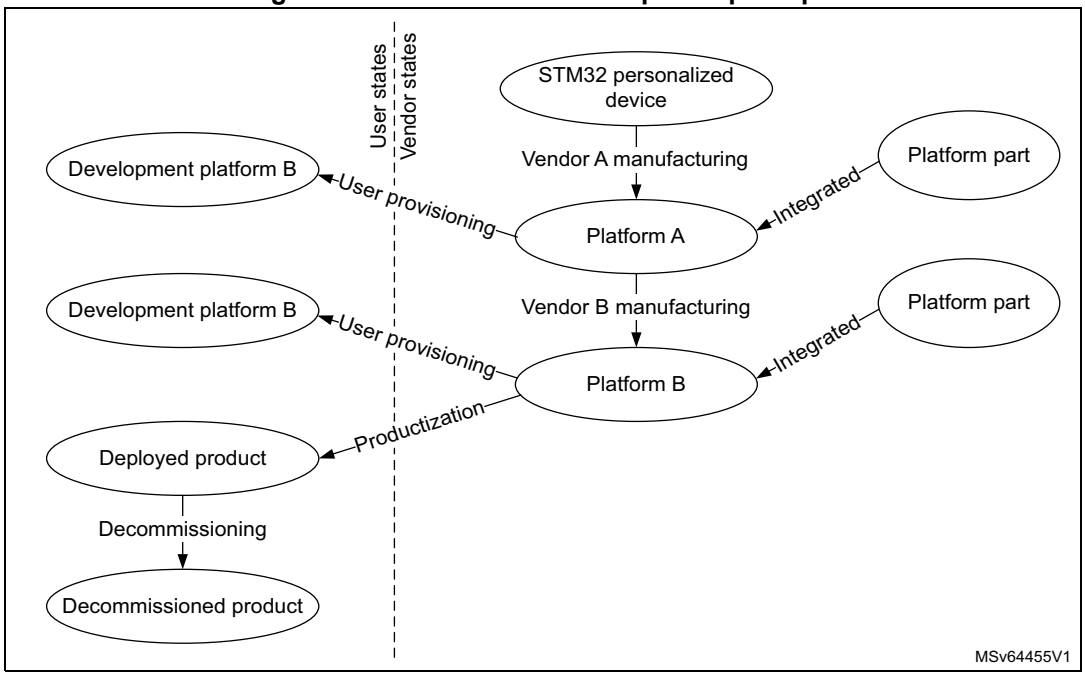
3.12 Software intellectual property protection and collaborative development

Thanks to software intellectual property protection and collaborative model, the devices allow the design of solutions integrating innovative third-party libraries.

Collaborative development is summarized on the figure below. Starting from a personalized device sold by STMicroelectronics, a vendor A can integrate a portion of hardware and software on a platform A, that can then be used by a vendor B, who does the same before deploying a final product to the end users.

Note: Each platform vendor can provision individual platforms for development not to be connected to a production cloud network ("Development Platform X").

Figure 13. Collaborative development principle



The features described hereafter contribute to securing the software intellectual property within such a collaborative development.

3.12.1 Software intellectual property protection with RDP

As described in *Section 3.10.1,* the hardware RDP mechanism automatically controls the accesses to secrets provisioned in the device.

The protection of these secrets are defined in the table below.

Table 21. Software intellectual property protection with RDP

RDP protection level		Secrets protection
Level 0	Device open	No special protections.
Level 0.5(1)	Device partially closed	All peripherals and memories mapped as secure during secure boot cannot be dumped, debugged or traced
Level 1	Device memories protected	Data and code stored in embedded Flash memory, encrypted external Flash memory(2), SRAM2 and backup registers are no more accessible via debugger.
Level 2	Device closed	All data and code stored in the device or encrypted in external Flash memory cannot be dumped clear-text, debugged or traced.

1. Only applicable when TrustZone security is activated in the product.
2. External Flash memory area decrypted on-the-fly with OTFDEC peripheral.

3.12.2 Software intellectual property protection with OTFDEC

As described in *Section 3.9.3,* the OTFDEC associated with the OCTOSPI is able to decrypt on the fly, the encrypted images stored in external SPI Flash memories.

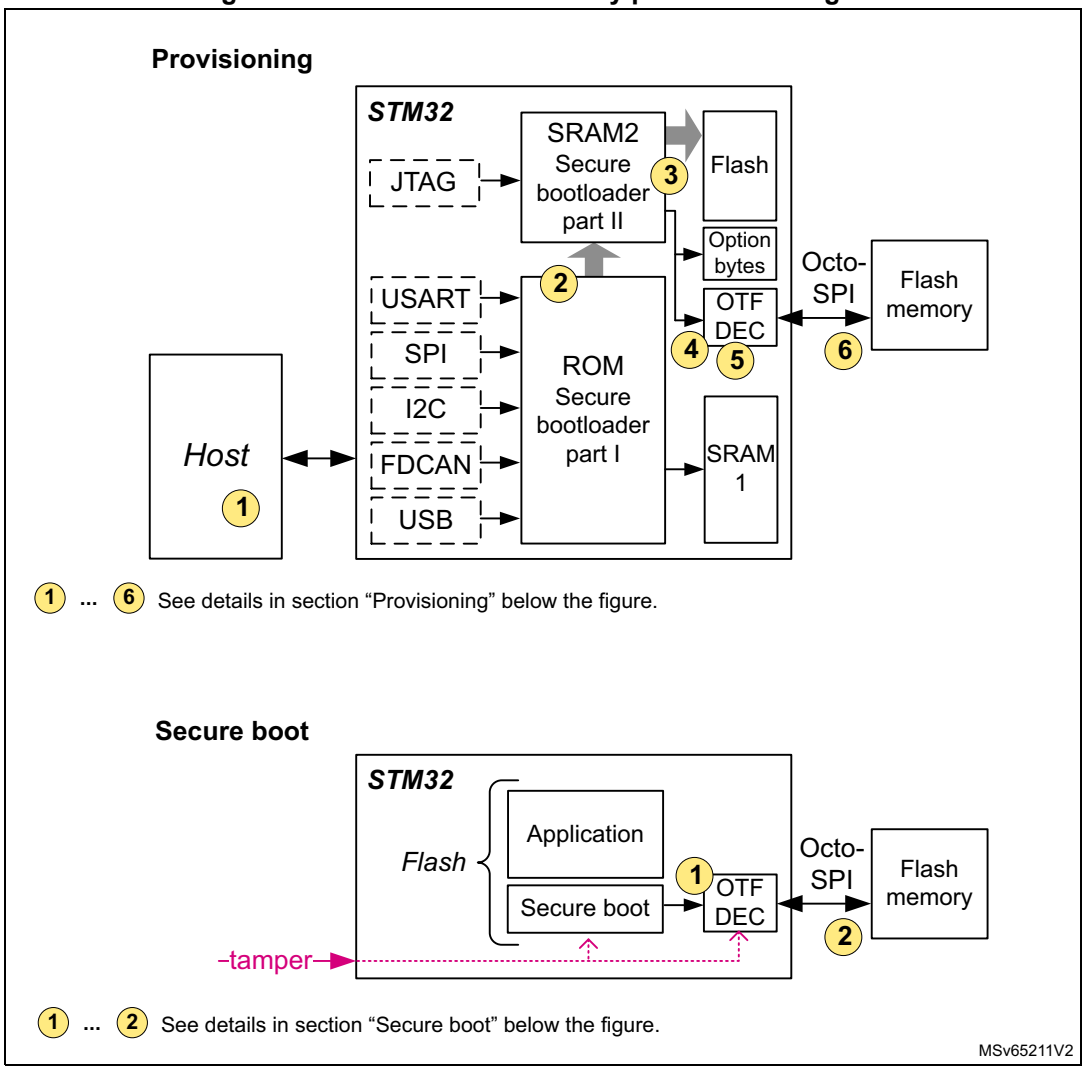
Thanks to this feature, the devices allow the installation of intellectual properties, in one of the following ways:

- over the air, with the image already encrypted with a key provisioned in the device
- through a provisioning host located in a trusted or a non-trusted environment/facility

Figure 14 illustrates this last case, with the provisioning, in a non-trusted environment, of software intellectual properties both in the embedded Flash memory and in an external SPI Flash memory (encrypted).

Note: Since the OTFDEC uses the AES in counter mode (CTR) to achieve the lowest possible latency, each time the content of one encrypted region is changed, the corresponding cryptographic context (key or initialization vector) must be changed. This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR Flash memory.

Figure 14. External Flash memory protection using SFI



Provisioning

Assuming the device is virgin, the first step is to provision both Flash memories, as detailed below:

1. The user creates a SFI image, composed of:
   - encrypted internal firmware and data (including external Flash memory drivers)
   - encrypted external firmware and data AES key (up to 4)
   - encrypted external firmware and data image
2. The secure bootloader stored in the system memory, loads the second part of the secure bootloader in SRAM, through the supported communication ports (USART, SPI, I2C, FDCAN, USB and JTAG). This second part runs in the secure SRAM and is responsible for executing the SFI process, applying the SFI protocol thanks to the commands received through the above mentioned supported communication ports.

3. The internal Flash memory is programmed with decrypted option bytes, internal firmware and data, and external firmware and data AES keys. Alternatively, device unique external firmware AES keys can be used instead of such global keys.
4. The OTFDEC is properly initialized with encrypted region information, including the corresponding external firmware and data AES key.
5. Running the SFI process, chunks of encrypted external firmware and data image are decrypted in the device, then re-encrypted in the OTFDEC.
6. After a chunk OTFDEC re-encryption, the user external Flash memory programmer is responsible for programming the last encrypted chunks to the external SPI Flash memories through the OCTOSPI.

Alternatively, external firmware and data AES keys for OTFDEC can be generated on the device, if they are not generated by the signing tool.

Secure boot

After provisioning, each time the device initializes on a trusted firmware, the following actions are required:

1. Secure-boot firmware executes, programming the external firmware and data AES keys to the OTFDEC write-only key registers, along with the other needed information.
2. The application reads or executes the encrypted external firmware and data through the Octo-SPI in Memory mapped mode, unless a tamper event is detected. In this case, all OTFDEC keys are erased and encrypted regions are read as zero until the OTFDEC is properly initialized again.

For more information on SFI solutions for the devices, refer to the application note *Overview secure firmware install (SFI) (*AN4992).

3.12.3 Other software intellectual property protections

The device additional protections to software intellectual property are:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds.
- Non-invasive attacks, such as side channel attacks, are countered by not leaking secret information via side channels such as timing, power and EM emissions.

4 Boot modes

At startup, a BOOT0 pin, NBOOT0 and NSBOOTADDx[24:0]/SECBOOTADD0[24:0] option bytes are used to select the boot memory address that includes:

- Boot from any address in user Flash memory.
- Boot from system memory (bootloader).
- Boot from any address in embedded SRAM.
- Boot from root security service (RSS).

The BOOT0 value may come from the PH3-BOOT0 pin or from an option bit depending on the value of a user option bit to free the GPIO pad if needed.

The bootloader, located in the system memory, is used to reprogram the Flash memory by using USART, I2C, SPI, FDCAN or USB_FS in device mode through the DFU (device firmware upgrade).

Table 22 and *Table 23* detail the boot modes when TrustZone is disabled or enabled.

Table 22. Boot modes when TrustZone is disabled (TZEN = 0)

NBOOT0 FLASH_ OPTR[27]	BOOT0 pin PH3	NSWBOOT0 FLASH_ OPTR[26]	Boot address option-byte selection	Boot area	ST programmed default value
-	0	1	NSBOOTADD0[24:0]	Boot address defined by user option bytes NSBOOTADD0[24:0]	Flash: 0x0800 0000
-	1	1	NSBOOTADD1[24:0]	Boot address defined by user option bytes NSBOOTADD1[24:0]	Bootloader: 0x0BF9 0000
1	-	0	NSBOOTADD0[24:0]	Boot address defined by user option bytes NSBOOTADD0[24:0]	Flash: 0x0800 0000
0	-	0	NSBOOTADD1[24:0]	Boot address defined by user option bytes NSBOOTADD1[24:0]	Bootloader: 0x0BF9 0000

When TrustZone is enabled by setting the TZEN option bit, the boot space must be in secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address.

A unique boot entry option can be selected by setting the BOOT_LOCK option bit. All other boot options are ignored.

Table 23. Boot modes when TrustZone is enabled (TZEN = 1)

BOOT_LOCK	NBOOT0 FLASH_OPTR[27]	BOOT0 pin PH3	NSWBOOT0 FLASH_OPTR[26]	RSS com-mand	Boot address option-byte selection	Boot area	ST programmed default value
0	-	0	1	0	SECBOOTADD0 [24:0]	Secure boot address defined by user option bytes SECBOOTADD0[24:0]	Flash: 0x0C00 0000
	-	1	1	0	N/A	RSS	RSS: 0x0FF8 0000
	1	-	0	0	SECBOOTADD0 [24:0]	Secure boot address defined by user option bytes SECBOOTADD0[24:0]	Flash: 0x0C00 0000
	0	-	0	0	N/A	RSS	RSS: 0x0FF8 0000
	-	-	-	≠ 0	N/A	RSS	RSS: 0x0FF8 0000
1	-	-	-	-	SECBOOTADD0 [24:0]	Secure boot address defined by user option bytes SECBOOTADD0[24:0]	Flash: 0x0C00 0000

The boot address option bytes are used to program any boot memory address. However, the allowed address space depends on Flash read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced either in the secure Flash memory or the non-secure Flash memory depending on TrustZone security option as described in the table below.

Table 24. Boot space versus RDP protection

RDP	TZEN = 1	TZEN = 0
0	Any boot address	Any boot address
0.5	Boot address only in RSS: 0x0FF80000 or in secure Flash memory – 0x0C00 0000-0x0C1F FFFF Otherwise the boot address is forced to 0x0FF8 0000.	N/A
1		Any boot address
2		Boot address only in Flash memory – 0x0800 0000-0x081F FFFF Otherwise boot address forced is 0x0800 0000.

The BOOT0 value (either coming from the pin or the option bit) is latched upon reset release. It is up to the user to set NBOOT0 or BOOT0 values to select the required boot mode.

The BOOT0 pin or user option bit (depending on nSWBOOT0 in FLASH_OPTR) is also resampled when exiting Standby mode. Consequently, the BOOT0 pin or user option bit must be kept in the required boot mode configuration in Standby mode. After startup delay, the selection of the boot area is done before releasing the processor reset.

PH3/BOOT0 GPIO is configured as follows:

- in input mode during the complete reset phase if the option bit NSWBOOT0 is set in FLASH_OPTR, and then switches automatically in analog mode after reset is released (BOOT0 pin)
- in input mode from the reset phase to the completion of the option byte loading if the bit NSWBOOT0 is cleared into FLASH_OPTR (BOOT0 value coming from the option bit), and then switches automatically to the analog mode even if the reset phase is not complete

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. Refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

Embedded root security services (RSS)

The embedded RSS are located in the secure information block, programmed by ST during production. Refer to the application note *Overview secure firmware install (SFI)* (AN4992).

5 Global TrustZone controller (GTZC)

5.1 Introduction

This section describes the global TrustZone controller (GTZC) block that contains the following sub-blocks:

- **TZSC**: TrustZone security controller

  This sub-block defines the secure/privileged state of slave peripherals. It also controls the sub-region area size and properties for the watermark memory peripheral controller (MPCWM). The TZSC informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.
- **MPCBB**: memory protection controller - block based

  This sub-block configures the internal RAM in a TrustZone-system product having segmented SRAM (pages of 512 bytes) with programmable-security and privileged attributes.
- **TZIC**: TrustZone illegal access controller

  This sub-block gathers all illegal access events in the system and generates a secure interrupt towards NVIC.

These sub-blocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes such as:

- on-chip RAM with programmable secure and/or privileged blocks (pages)
- AHB and APB peripherals with programmable security and/or privileged access
- off-chip memories with secure and/or privileged areas

5.2 GTZC main features

The GTZC main features are listed below:

- 3 independent 32-bit AHB interface for TZSC, TZIC and MPCBB
- TZIC accessible only with secure transactions
- Secure and non-secure access supported for privileged and unprivileged part of TZSC and MPCBB
- Set of registers to define product security settings:
  - Secure/privileged blocks for internal SRAMs
  - Secure/privileged regions for external memories and internal backup SRAM
  - Secure/privileged access mode for securable peripherals
  - Secure/privileged access mode for securable masters

GTZC TrustZone system architecture

The Armv8-M supports security per TrustZone-M model with isolation between:

- a secure world, where usually security sensitive applications are run and critical resources are located
- a non-secure or public world (such as usual non secure operating system and user space)

The TrustZone architecture is extended beyond AHB and Armv8-M with:

- AHB/APB bridge used as secure gate to block or propagate secure/non-secure and privileged/unprivileged transaction towards APB agents
- PPC (peripheral protection controller) used as secure gate to block or propagate secure/non-secure and privileged/unprivileged transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards internal SRAMs
- TrustZone watermark MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards external memories

AHB and APB Peripherals can be categorized as:

- **privileged**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (such as TZIC)
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **non-secure and unprivileged:** peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA)

AHB securable masters can be configured in the TZSC to be secure/non-secure and/or privileged/unprivileged.

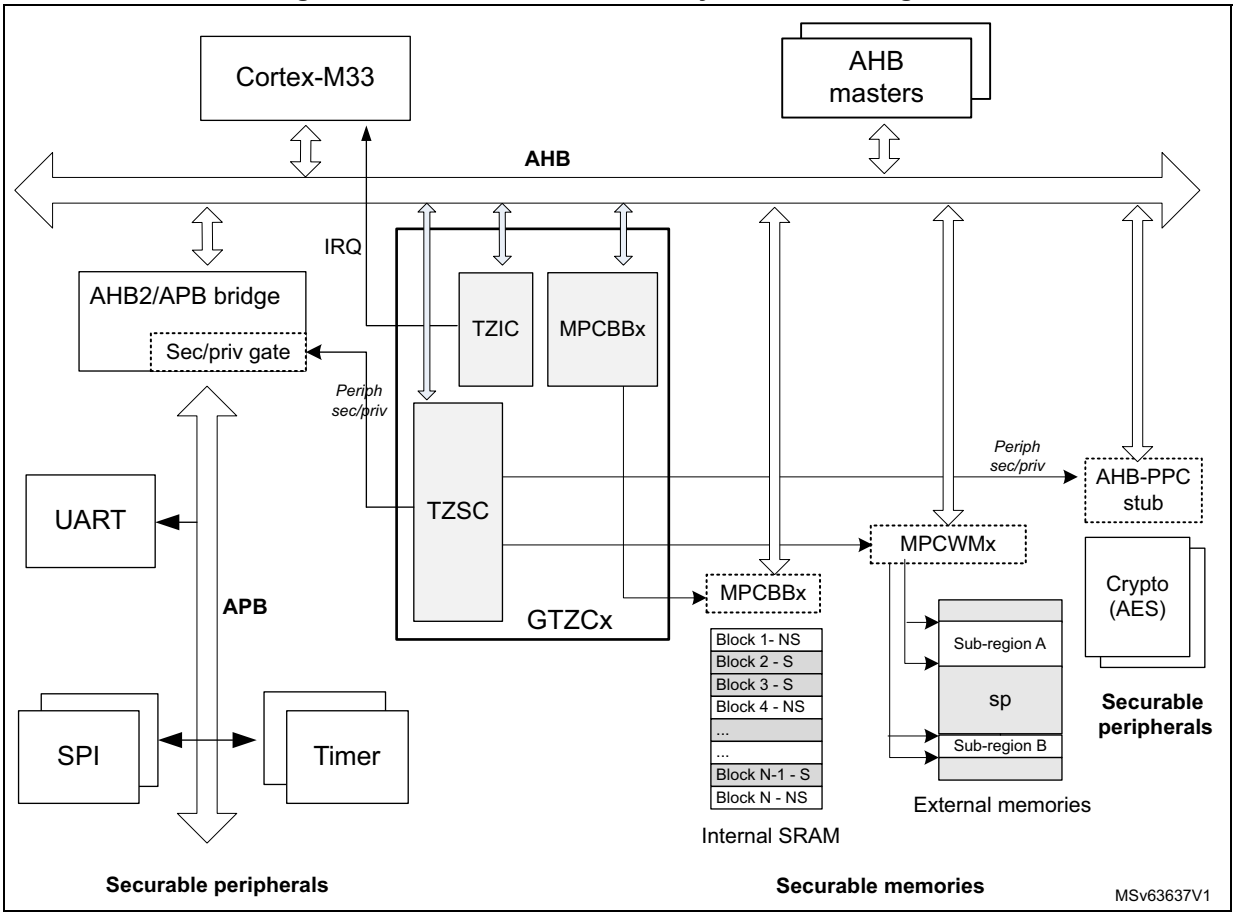
Application information

The TZSC, MPCBB and TZIC can be used in one of the following ways:

- programmed during secure boot only, locked and not changed afterwards
- dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH region or secure SRAM. Same remark applies to the GTZC_TZSC_SECCFGRx/PRIVCFGRx registers that define secure/privileged state of each peripheral.

The Armv8-M security architecture with secure, securable and TrustZone-aware peripherals is shown in the figure below.

Figure 15. GTZC in Armv8-M subsystem block diagram



5.3 GTZC implementation

The STM32U575/585 devices embed two instances of GTZC.

Table 25. GTZC features

GTZC sub-blocks	GTZC1	GTZC2
TZSC	X	X
TZIC	X	X
MPCBB sub-block (number of MPCBB)	X (3)	X (1)

The tables below shows the address offset of GTZC sub-blocks versus GTZC base address (refer to *Section 2.3* for GTZC1 and GTZC2 base addresses).

Table 26. GTZC1 sub-blocks address offset

GTZC1 sub-block	Address offset
GTZC1_TZSC	0x0
GTZC1_TZIC	0x400
GTZC1_MPCBB1	0x800
GTZC1_MPCBB2	0xC00
GTZC1_MPCBB3	0x1000

Table 27. GTZC2 sub-blocks address offset

GTZC2 sub-blocks	Address offset
GTZC2_TZSC	0x0
GTZC2_TZIC	0x400
GTZC2_MPCBB4	0x800

The table below describes the characteristics of the available MPCWM.

Table 28. MPCWM resource assignment

GTZC	MPC	Target memory interface	Number of sec/non-sec and priv/unpriv regions	Watermark granularity (bytes)
GTZC1	MPCWM1	OCTOSPI1	2	128 K
	MPCWM2	FSMC_NOR bank	2	128 K
	MPCWM3	FSMC_NAND bank	1	128 K
	MPCWM4	BKPSRAM	1	32
	MPCWM5	OCTOSPI2	2	128 K

The table below describes the characteristics of the available MPCBB.

Table 29. MPCBB resource assignment

GTZC	MPC	Resource	Memory size (Kbytes)	Block size (bytes)	Number of blocks	Number of super-blocks
GTZC1	MPCBB1	SRAM1	192	512	384	12
	MPCBB2	SRAM2	64		128	4
	MPCBB3	SRAM3	512		1024	32
GTZC2	MPCBB4	SRAM4	16		32	1

5.4 GTZC functional description

5.4.1 GTZC block diagram

The figure below describes the combined feature of TZSC, MPCBB and TZIC. Each sub-block is controlled by its own AHB configuration port.

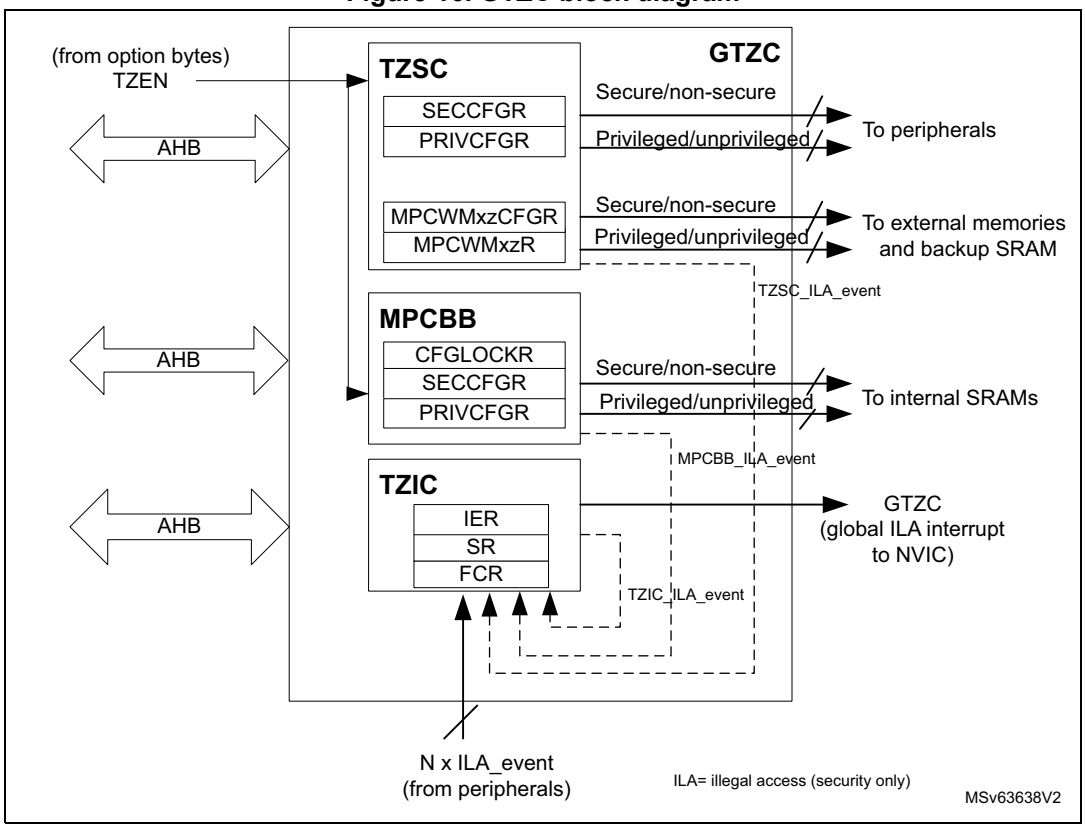
The TZSC defines which peripheral is secure and/or privileged.The privileged configuration bit of a peripheral can be modified by a secure privileged transaction when the peripheral is configured as secure. Otherwise, a privileged transaction (non-secure) is sufficient.

On the opposite, the secure configuration bit of a peripheral can be modified only with a secure privileged transaction if the peripheral is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The secure configuration bit of a given ram block can be modified only with a secure privileged transaction if the same RAM block is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The TZIC gathers illegal events generated within the system when an illegal access is detected. TZIC can then generate a secure interrupt towards the CPU if needed.

Figure 16. GTZC block diagram



5.4.2 Illegal access definition

Three different types of illegal access exist:

- Illegal non-secure access

  Any non-secure transaction trying to write a secure resource is considered as illegal and thus the addressed resource generates an illegal access interrupt for illegal write access and a bus error for illegal fetch access. However some exceptions exist on secure and privileged configuration registers: these later ones authorize non secure read access to secure registers (see GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx).

- Illegal secure access

  Any secure transaction trying to access non-secure block in internal block-based SRAM or watermarked memory is considered as illegal.

  Correct TZIC settings allows the capture of the associated event and then generates the GTZC_IRQn interrupt to the NVIC. This applies for read, write and execute access.

  Concerning the MPCBB controller, there is an option to ignore secure data read/write access on non-secure SRAM blocks, by setting the SRWILADIS bit in the GTZC_MPCBBz_CR register. Secure read and write data transactions are then allowed on non-secure SRAM blocks, while secure execution access remains not allowed.

  Any secure execute transaction trying to access a non-secure peripheral register is considered as illegal and generate a bus error.

- Illegal unprivileged access

  Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal read and write access. The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write. No bus error is generated. A bus error is generated when any unprivileged execute transaction tries to access a privileged memory.

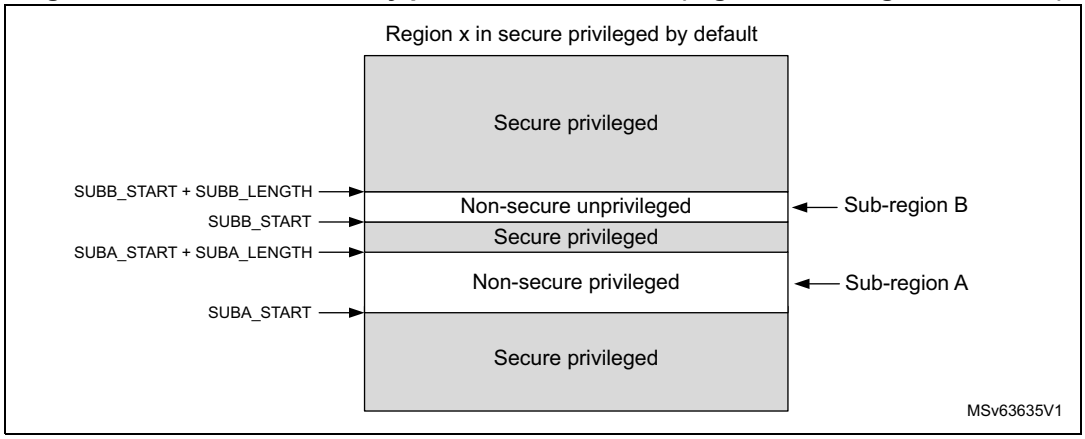
5.4.3 TrustZone security controller (TZSC)

The TZSC is composed of a configurable set of registers, providing the following features:

- Control of secure and privileged state for all peripherals, done through:
  - GTZC_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals
  - GTZC_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals
- For watermark memory protection controller (external memories and backup SRAM), two independent regions can be defined and the following fields are used to program:
  - the start of the first protected sub-region on external memory/backup SRAM: SUBA_START[10:0]
  - the length of the first protected sub-region on external memory/backup SRAM: SUBA_LENGTH[11:0]
  - the start of the second protected sub-region on external memory/backup SRAM: SUBB_START[10:0]
  - the length of the second protected sub-region on external memory/backup SRAM: SUBB_LENGTH[11:0]

A control register for each sub-region can be used to enable/disable the watermark memory protection controller as well as defining the right attributes of each sub-region.

Figure 17. Watermark memory protection controller (region x/sub-regions A and B)



In the figure above, region x represents the external memory or backup SRAM region (such as FSMC bank, OCTOSPI1, OCTOSPI2 or BKPSRAM). Secure and privileged attributes of sub-regions A and B are independently configurable. When no sub-regions are defined or enabled on the region x, then the default attribute of the region x is set as “secure-privileged”.

The tables below describe the secure/privileged properties of the common area of sub-region A and B when an overlap exists.

Table 30. Secure properties of sub-regions A and B

Sub-region A	Sub-region B	Properties of overlapped region A and B
Non-secure	Non-secure	Non-secure
Non-secure	Secure	Non-secure
Secure	Non-secure	Non-secure
Secure	Secure	Secure

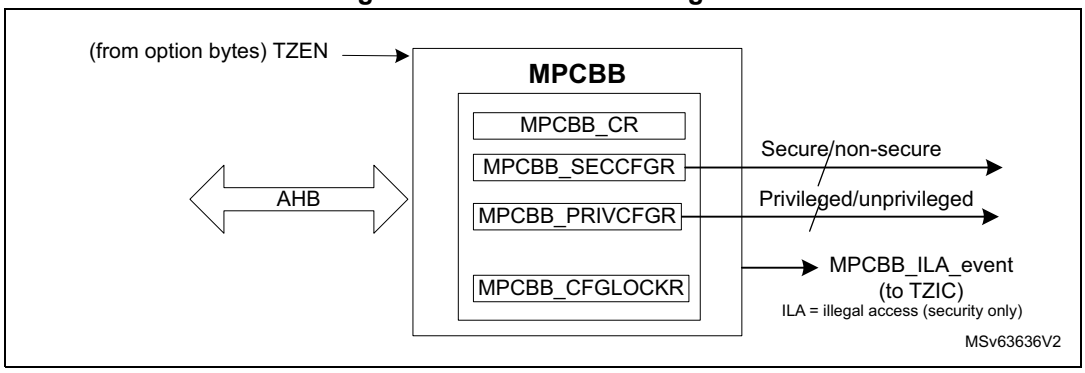
Table 31. Privileged properties of sub-regions A and B

Sub-region A	Sub-region B	Properties of overlapped region A and B
Unprivileged	Unprivileged	Unprivileged
Unprivileged	Privileged	Unprivileged
Privileged	Unprivileged	Unprivileged
Privileged	Privileged	Privileged

5.4.4 Memory protection controller - block based (MPCBB)

The MPCBB is composed of a configurable set of registers allowing to define security and privileged policy for internal SRAM memories. The security and privileged policy can be individually configured per each 512-byte block of SRAM.

Figure 18. MPCBB block diagram



In order to setup the MPCBB, the following actions are needed (for example at boot time):

- Secure firmware must define which memory blocks are secure by setting the correct bits in GTZC_MPCBBz_SECCFGRx.
- Privileged firmware must define which memory blocks are privileged by setting the correct bits in GTZC_MPCBBz_PRIVCFGRx.

A MPCBB super-block is made of 32 consecutive blocks. For each super-block, secure application can lock all related security/privileged bits using the correct bits in GTZC_MPCBBz_CFGLOCKR1. This lock remains active until the next system reset.

*Note: The block size is 512 bytes.The super-block size is 512 * 32 = 16 Kbytes.*

5.4.5 TrustZone illegal access controller (TZIC)

The TZIC concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 1).

TZIC allows the trace (flag) of which event trigged the secure illegal access interrupt. Register masks (GTZC_TZIC_IERx) are available to filter unwanted event. On unmasked illegal event, TZIC generates the GTZC_IRQn interrupt to the NVIC.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC_TZIC_SRx and GTZC_TZIC_FCRx). The reset value of mask registers (GTZC_TZIC_IERx) is such that all events are masked.

5.4.6 Power-on/reset state

The power-on and reset state of the TZSC clear to 0 all bits of GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx, meaning that all securable peripherals are respectively set to non-secure and unprivileged.

For internal SRAMx (x = 1 to 4), all GTZC_MPCBBz_SECCFGRx and GTZC_MPCBBz_PRIVCFGRx are set:

- to 0xFFFF FFFF, making these internal memories block secure and privileged by default when TrustZone security is enabled at system level (TZEN = 1).
- to 0x0000 0000, making these internal memories block non-secure and unprivileged by default when TrustZone security is disabled at system level (TZEN = 0)

For external memories and backup SRAM, all GTZC_TZSC_MPCWMxzR registers are set:

- to 0x0000 0000, making these memories secure and privileged by default when TrustZone security is enabled a system level (TZEN = 1).
- to 0x0800 0000, making these memories non-secure and non-privilege by default when TrustZone security is disabled at system level (TZEN = 0)

Secure boot code can then program the security settings, making components secure or not as needed.

5.5 GTZC interrupts

TZIC is a secure peripheral, thus it systematically generates an illegal access event when accessed by a non-secure access. The MPCBB and TZSC are TrustZone-aware peripherals, meaning that secure and non-secure registers co-exist within the peripheral.

Table 32. GTZC interrupt request

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
GTZC	Illegal access	All flags in GTZC_TZIC_SRx	All bits in GTZC_TZIC_IERx	Write 1 in the bit GTZC_TZIC_FCRx	Yes	Yes	No

5.6 GTZC1 TZSC registers

All registers are accessed only by words (32-bit).

5.6.1 GTZC1 TZSC control register (GTZC1_TZSC_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LCK**: lock the configuration of GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx registers until next reset

This bit is cleared by default and once set, it can not be reset until system reset.

0: configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx registers not locked

1: configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx registers locked

5.6.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1)

Address offset: 0x010

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC1_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.3 GTZC1 TZSC secure configuration register 2 (GTZC1_TZSC_SECCFGR2)

Address offset: 0x014

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC1_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.4 GTZC1 TZSC secure configuration register 3 (GTZC1_TZSC_SECCFGR3)

Address offset: 0x018

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC1_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.5 GTZC1 TZSC privilege configuration register 1 (GTZC1_TZSC_PRIVCFGR1)

Address offset: 0x020

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when corresponding GTZC1_TZSC_SECCFGR register signal is set to1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.6 GTZC1 TZSC privilege configuration register 2 (GTZC1_TZSC_PRIVCFGR2)

Address offset: 0x024

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when corresponding GTZC1_TZSC_SECCFGR register signal is set to1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.8 GTZC1 TZSC memory x sub-region z watermark configuration register (GTZC1_TZSC_MPCWMxzCFGR) (z = A to B)

Address offset: Block A: 0x40 + 0x10 *(x - 1) (x = 1 to 5)
Address offset: Block B: 0x48 + 0x10 *(x - 1) (x = 1, 2, 5)
Reset value: 0x0000 0000

Secure privilege access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	PRIV	SEC	Res.	Res.	Res.	Res.	Res.	Res.	SRLOCK	SREN
						rw	rw							rs	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **PRIV**: Privileged sub-region z of base region x
This bit is taken into account only if SREN is set.
0: Privileged and unprivileged accesses are granted in sub-region z.
1: Only privileged accesses are granted in sub-region z of region x.

Bit 8 **SEC**: Secure sub-region z of base region x
This bit is taken into account only if SREN is set.
0: Only non-secure data accesses are granted to sub-region z of region x.
1: Only secure data accesses are granted to sub-region z of region x.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **SRLOCK**: Sub-region z lock

This bit, once set, can be cleared only by a system reset.
0: GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR can be written.
1: Writes to GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR are ignored.

Bit 0 **SREN**: Sub-region z enable

0: Sub-region z is disabled. Access control of base region x applies to any access between this sub-region start- and end-addresses.
1: Sub-region z of region x is enabled. Access control defined in GTZC1_TZSC_MPCWMx_CFGR applies to any access between this sub-region start- and end-addresses, both defined in GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR .

Note: External memories that are watermark controlled start fully non-secure/unprivileged at reset when TZEN = 0. When TZEN = 1, external memories start fully secure/fully privileged (inverted reset-value).

5.6.9 GTZC1 TZSC memory x sub-region A watermark register (GTZC1_TZSC_MPCWMxAR)

Address offset: 0x44 + 0x10 *(x - 1) (x = 1 to 5)
Reset value: 0x0000 0000
The given reset value is valid when TZEN = 1. The reset value is 0x0800 0000 when TZEN = 0.
Secure privilege access only.

When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.
When an overlap of sub-region A and B exists, secure/privileged attributes of both sub-regions apply on the common section (see *Section 5.4.3: TrustZone security controller (TZSC)*)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	SUBA_START[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBA_LENGTH[11:0]**: Length of sub-region A in region x

This field defines the length of the sub-region A, to be multiplied by the granularity defined in *Table 28*.

When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.

If SUBA_LENGTH = 0, the sub-region A is disabled.(SREN bit in GTZC1_TZSC_MPCMWxACFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBA_START[10:0]**: Start of sub-region A in region x

This field defines the address offset of the sub-region A, to be multiplied by the granularity defined in *Table 28*, versus the start of the region x.

External memories that are watermark controlled, start fully non-secure at reset when TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).

5.6.10 GTZC1 TZSC memory x sub-region B watermark register (GTZC1_TZSC_MPCWMxBR)

Address offset: 0x4C + 0x10 *(x - 1) (x = 1, 2, 5)
Reset value: 0x0000 0000
The given reset value is valid when TZEN = 1. The reset value is 0x0800 0000 when TZEN = 0.
Secure privilege access only.
When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.
When an overlap of sub-region A and B exists, secure/privileged attributes of both sub-regions apply on the common section (see *Section 5.4.3: TrustZone security controller (TZSC)*)

Res.	Res.	Res.	Res.	Res.	SUBB_START[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBB_LENGTH[11:0]**: Length of sub-region B in region x
This field defines the length of the sub-region B, to be multiplied by the granularity defined in *Table 28*.
When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.
If SUBB_LENGTH = 0, the sub-region B is disabled.(SREN bit in GTZC1_TZSC_MPCMWxBCFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBB_START[10:0]**: Start of sub-region B in region x
This field defines the address offset of the sub-region B, to be multiplied by the granularity defined in *Table 28*, versus the start of the region x.
External memories that are watermark controlled, start fully non-secure at reset when TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).

Refer to *Table 26: GTZC1 sub-blocks address offset*.

5.7 GTZC1 TZIC registers

All registers are accessed only by words (32-bit).

5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **UCPD1IE**: illegal access interrupt enable for UCPD1
0: interrupt disabled
1: interrupt enabled

Bit 18 **FDCAN1IE**: illegal access interrupt enable for FDCAN1
0: interrupt disabled
1: interrupt enabled

Bit 17 **LPTIM2IE**: illegal access interrupt enable for LPTIM2
0: interrupt disabled
1: interrupt enabled

Bit 16 **I2C4IE**: illegal access interrupt enable for I2C4
0: interrupt disabled
1: interrupt enabled

Bit 15 **CRSIE**: illegal access interrupt enable for CRS
0: interrupt disabled
1: interrupt enabled

Bit 14 **I2C2IE**: illegal access interrupt enable for I2C2
0: interrupt disabled
1: interrupt enabled

Bit 13 **I2C1IE**: illegal access interrupt enable for I2C1
0: interrupt disabled
1: interrupt enabled

Bit 12 **UART5IE**: illegal access interrupt enable for UART5
0: interrupt disabled
1: interrupt enabled

Bit 11 **UART4IE**: illegal access interrupt enable for UART4
0: interrupt disabled
1: interrupt enabled

Bit 10 **USART3IE**: illegal access interrupt enable for USART3
0: interrupt disabled
1: interrupt enabled

Bit 9 **USART2IE**: illegal access interrupt enable for USART2
0: interrupt disabled
1: interrupt enabled

Bit 8 **SPI2IE**: illegal access interrupt enable for SPI2
0: interrupt disabled
1: interrupt enabled

Bit 7 **IWDGIE**: illegal access interrupt enable for IWDG
0: interrupt disabled
1: interrupt enabled

Bit 6 **WWDGIE**: illegal access interrupt enable for WWDG
0: interrupt disabled
1: interrupt enabled

Bit 5 **TIM7IE**: illegal access interrupt enable for TIM7
0: interrupt disabled
1: interrupt enabled

Bit 4 **TIM6IE**: illegal access interrupt enable for TIM6
0: interrupt disabled
1: interrupt enabled

Bit 3 **TIM5IE**: illegal access interrupt enable for TIM5
0: interrupt disabled

0: interrupt disabled
1: interrupt enabled

Bit 1 **TIM3IE**: illegal access interrupt enable for TIM3
0: interrupt disabled
1: interrupt enabled

Bit 0 **TIM2IE**: illegal access interrupt enable for TIM2
0: interrupt disabled
1: interrupt enabled

5.7.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2)

Address offset: 0x004

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1: interrupt enabled

Bit 12 **HASHIE**: illegal access interrupt enable for HASH
0: interrupt disabled
1: interrupt enabled

Bit 11 **AESIE**: illegal access interrupt enable for AES
0: interrupt disabled
1: interrupt enabled

Bit 10 **OTGIE**: illegal access interrupt enable for OTG_FS
0: interrupt disabled
1: interrupt enabled

Bit 9 **DCMIIE**: illegal access interrupt enable for DCMI and PSSI
0: interrupt disabled
1: interrupt enabled

Bit 8 **ADC12IE**: illegal access interrupt enable for ADC1
0: interrupt disabled
1: interrupt enabled

Bit 7 **DCACHE1_REGIE**: illegal access interrupt enable for DCACHE1 registers
0: interrupt disabled
1: interrupt enabled

Bit 6 **ICACHE_REGIE**: illegal access interrupt enable for ICACHE registers
0: interrupt disabled
1: interrupt enabled

Bit 5 **DMA2DIE**: illegal access interrupt enable for register of DMA2D
0: interrupt disabled
1: interrupt enabled

Bit 4 **TSCIE**: illegal access interrupt enable for TSC
0: interrupt disabled
1: interrupt enabled

Bit 3 **CRCIE**: illegal access interrupt enable for CRC
0: interrupt disabled
1: interrupt enabled

Bit 2 **FMACIE**: illegal access interrupt enable for FMAC
0: interrupt disabled
1: interrupt enabled

Bit 1 **CORDICIE**: illegal access interrupt enable for CORDIC
0: interrupt disabled
1: interrupt enabled

Bit 0 **MDF1IE**: illegal access interrupt enable for MDF1
0: interrupt disabled
1: interrupt enabled

5.7.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4)

Address offset: 0x00C

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Table 26: GTZC1 sub-blocks address offset*.

5.8 GTZC1 MPCBBz registers (z = 1 to 3)

All registers are accessed only by words (32-bit).

5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1 to 3)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRWILADIS	INVSECSTATE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
															rs

Bit 31 **SRWILADIS**: secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction access a non-secure blocks of the block-based SRAM (secure fetch on non-secure block is always considered illegal).

0: enabled, secure read/write access not allowed on non-secure SRAM block

1: disabled, secure read/write access allowed on non-secure SRAM block

Bit 30 **INVSECSTATE**: SRAMx clocks security state

This bit is used to define the internal SRAMs clocks control in RCC as secure or not.

0: SRAMs clocks are secure if a secure area exists in the MPCBB. It is non secure if there is no secure area.

1: SRAMs clocks are non-secure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: lock the control register of the MPCBB until next reset

This bit is cleared by default and once set, it can not be reset until system reset.

0: control register not locked

1: control register locked

5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1 (GTZC1_MPCBBz_CFGLOCKR1) (z = 1 to 3)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SPLCKy**: Security/privilege configuration lock for super-block (y = 31 to 0)
This bit is set by software and can be cleared only by system reset.
0: GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy can be written.
1: Writes to GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy are ignored

5.8.3 GTZC1 SRAMz MPCBB security configuration for super-block x register (GTZC1_MPCBBz_SECCFGRx) (z = 1 to 3)

Address offset: 0x100 + 0x04 * x, (x = 0 to 31)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is secure only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECy**: Security configuration for block y (y = 31 to 0)
0: Non-secure access only to block y, belonging to super-block x. Secure access is also allowed if the SRWILADIS bit is set in GTZC1_MPCBBz_CR.
1: Secure access only to block y, belonging to super-block x.
Unprivileged write to this bit is ignored if PRIVy bit is set in GTZC1_MPCBBz_PRIVCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCKR1.

5.8.4 GTZC1 SRAMz MPCBB privileged configuration for super-block x register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1 to 3)

Address offset: 0x200 + 0x04 * x, (x = 0 to 31)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is privileged only. Any read is allowed.

Bits 31:0 **PRIVy**: Privileged configuration for block y, belonging to super-block x (y = 31 to 0).
0: Privileged and unprivileged access to block y, belonging to super-block x
1: Only privileged access to block y, belonging to super-block x
Non-secure write to this bit is ignored if SECy bit is set in GTZC1_MPCBBz_SECCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCKR1.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LCK**: lock the configuration of GTZC2_TZSC_SECCFGRx and GTZC2_TZSC_PRIVCFGRx registers until next reset

This bit is cleared by default and once set, it can not be reset until system reset.

0: configuration of all GTZC2_TZSC_SECCCFGRx and all GTZC2_TZSC_PRIVCFGRx registers not locked

1: configuration of all GTZC2_TZSC_SECCCFGRx and all GTZC2_TZSC_PRIVCFGRx registers locked

5.9.2 GTZC2 TZSC secure configuration register 1 (GTZC2_TZSC_SECCFGR1)

Address offset: 0x010

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC2_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.9.3 GTZC2 TZSC privilege configuration register 1 (GTZC2_TZSC_PRIVCFGR1)

Address offset: 0x020

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privilege transaction when corresponding GTZC2_TZSC_SECCFGR register signal is set to1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privilege or not.

Refer to *Table 27: GTZC2 sub-blocks address offset*.

5.11 GTZC2 MPCBB4 registers

All registers are accessed only by words (32-bit).

5.11.1 GTZC2 SRAM4 MPCBB control register (GTZC2_MPCBB4_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRWILADIS	INVSECSTATE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GLOCK
															rs

Bit 31 **SRWILADIS**: secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction access a non-secure blocks of the block-based SRAM (secure fetch on non-secure block is always considered illegal).

0: enabled, secure read/write access not allowed on non-secure SRAM block

1: disabled, secure read/write access allowed on non-secure SRAM block

Bit 30 **INVSECSTATE**: SRAMx clocks security state
This bit is used to define the internal SRAMs clocks control in RCC as secure or not.
0: SRAMs clocks are secure if a secure area exists in the MPCBB. It is non secure if there is no secure area.
1: SRAMs clocks are non-secure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: lock the control register of the MPCBB until next reset
This bit is cleared by default and once set, it can not be reset until system reset.
0: control register not locked
1: control register locked

5.11.2 GTZC2 SRAM4 MPCBB configuration lock register 1 (GTZC2_MPCBB4_CFGLOCKR1)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SPLCK0
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SPLCK0**: Security/privilege configuration lock for super-block 0
This bit is set by software and can be cleared only by system reset.
0: GTZC2_MPCBB4_SECCFGR0 and GTZC2_MPCBB4_PRIVCFGR0 can be written.
1: Writes to GTZC2_MPCBB4_SECCFGR0 and GTZC1_MPCBB4_PRIVCFGR0 are ignored.

5.11.3 GTZC2 SRAM4 MPCBB security configuration for super-block 0 register (GTZC2_MPCBB4_SECCFGR0)

Address offset: 0x100

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is secure only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SEC31	SEC30	SEC29	SEC28	SEC27	SEC26	SEC25	SEC24	SEC23	SEC22	SEC21	SEC20	SEC19	SEC18	SEC17	SEC16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECy**: Security configuration for block y, belonging to super-block 0 (y = 31 to 0)
0: Non-secure access only to block y, belonging to super-block 0. Secure access is also allowed if the SRWILADIS bit is set in GTZC2_MPCBB4_CR.
1: Secure access only to block y, belonging to super-block 0.
Unprivileged write to this bit is ignored if PRIVy bit is set in GTZC2_MPCBB4_PRIVCFGR0.
Write are ignored if SPLCK0 bit is set in GTZC2_MPCBB4_CFGLOCKR1.

5.11.4 GTZC2 SRAM4 MPCBB privileged configuration for super-block 0 register (GTZC2_MPCBB4_PRIVCFGR0)

Address offset: 0x200

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is privileged only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRIV31	PRIV30	PRIV29	PRIV28	PRIV27	PRIV26	PRIV25	PRIV24	PRIV23	PRIV22	PRIV21	PRIV20	PRIV19	PRIV18	PRIV17	PRIV16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRIV15	PRIV14	PRIV13	PRIV12	PRIV11	PRIV10	PRIV9	PRIV8	PRIV7	PRIV6	PRIV5	PRIV4	PRIV3	PRIV2	PRIV1	PRIV0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVy**: Privileged configuration for block y, belonging to super-block 0 (y = 31 to 0).
0: Privileged and unprivileged access to block y, belonging to super block 0
1: privileged access only to block y, belonging to super-block 0
Non-secure write to this bit is ignored if SECy bit is set in GTZC2_MPBCC4_SECCFGR0.
Write are ignored if SPLCK0 bit is set in GTZC2_MPCBB4_CFGLOCKR1.

Refer to *Table 27: GTZC2 sub-blocks address offset*.

6 RAMs configuration controller (RAMCFG)

6.1 Introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4, and BKPSRAM).

6.2 RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:

- Error code correction (ECC):
  - Single error detection and correction with interrupt generation
  - Double error detection with interrupt or NMI generation
  - Status with failing address
- Write protection (1-Kbyte granularity)
- Programmable wait states for voltage scaling range 4
- SRAM software erase

6.3 RAMCFG functional description

6.3.1 Internal SRAMs features

Five SRAMs are embedded in the devices, each with specific features:

- SRAM1, SRAM2, SRAM3 are the main SRAMs. SRAM4 is in the SRAM used for peripherals low-power background autonomous mode (LPBAM) in Stop 2 mode.

  These SRAMs are made of several blocks that can be powered down in Stop mode to reduce consumption:
  - SRAM1: three 64-Kbyte blocks (total 192 Kbytes)
  - SRAM2: 8-Kbyte + 56-Kbyte blocks (total 64 Kbytes). In addition SRAM2 blocks can be retained in Standby mode.
  - SRAM3: eight 64-Kbyte blocks (total 512 Kbytes)
  - SRAM4: 16-Kbyte

  The backup SRAM (BKPSRAM) can be retained in all low-power modes and when V_{DD} is off in V_{BAT} mode.

  Refer to *Section 10: Power control (PWR)* for more details.
- All internal SRAMs are erased by hardware in case of Readout protection (RDP) level regression to Level 0.5 or Level 0. Refer to *Section 7: Embedded Flash memory (FLASH)* for more details.
- SRAM2 is erased when a system reset occurs if the SRAM2_RST option bit is selected in the Flash memory user option bytes. SRAM1, SRAM3 and SRAM4 are erased when a system reset occurs if the SRAM134_RST option bit is selected in the Flash memory

user option bytes. Refer to *Section 7: Embedded Flash memory (FLASH)* for more details.

- SRAM2 and optionally backup SRAM are protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. They are also erased by hardware in case of a Backup domain reset. Refer to *Section 55: Tamper and backup registers (TAMP)* for more details.
- The RAMCFG embeds the registers related to the internal SRAMs ECC, write protection, wait state configuration and software erase.

The table below summarizes the features supported by each internal SRAM

Table 39. Internal SRAMs features

SRAM feature	SRAM1 (192 Kbytes)	SRAM2 (64 Kbytes)	SRAM3 (512 Kbytes)	SRAM4 (16 Kbytes)	BKPSRAM (2 Kbytes)
LPBAM in Stop 0/1 modes	X	X	X	X	X
LPBAM in Stop 2 mode	-	-	-	X	-
Optional retention in Standby mode	-	X	-	-	X
Optional retention in V_{BAT} mode	-	-	-	-	X
Erased with RDP regression	X	X	X	X	X
Erased or blocked by tamper detection, and erased with Backup domain reset	-	X	-	-	X(1)
Optionally erased with system reset	X	X	X	X	-
Software erase	X	X	X	X	X
ECC	-	X	X	-	X
Write protection	-	X	-	-	-
Wait states	X	X	X	X	X

1. Optional: BKPSRAM can be configured to be erased or not on tamper detection.

6.3.2 Error code correction (SRAM2, SRAM3, BKPSRAM)

The ECC is supported by SRAM2, SRAM3 and BKPSRAM when enabled with the SRAM2_ECC, SRAM3_ECC and BKPRAM_ECC user option bits. Refer to *Section 7: Embedded Flash memory (FLASH)* for more details.

Seven ECC bits are added per 32 bits of SRAM, allowing two bits error detection and one bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is WSC[2:0] + 2 AHB clock cycles (refer to *Section 6.3.4: Read access latency*).

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when SRAM is no more accessed).

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDC/CSEDC bits are set in the *RAMCFG memory interrupt status register (RAMCFG_MxISR)* and *RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)* respectively. An interrupt is generated if enabled by the SEIE bit in the *RAMCFG memory x interrupt enable register (RAMCFG_MxIER)*. The failing address is stored in the *RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)* if the ALE bit is set in the *RAMCFG memory x control register (RAMCFG_MxCR)*.

Caution: Single errors cannot be detected when the SEDC bit is set.

When a double error is detected, the DED and CDED bits are set in the *RAMCFG memory interrupt status register (RAMCFG_MxISR)* and *RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)* respectively. An interrupt or NMI is generated if enabled by the DEIE or ECCNMI bit in the *RAMCFG memory x interrupt enable register (RAMCFG_MxIER)*. The failing address is stored in the *RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR)* if the ALE bit is set in the *RAMCFG memory x control register (RAMCFG_MxCR)*.

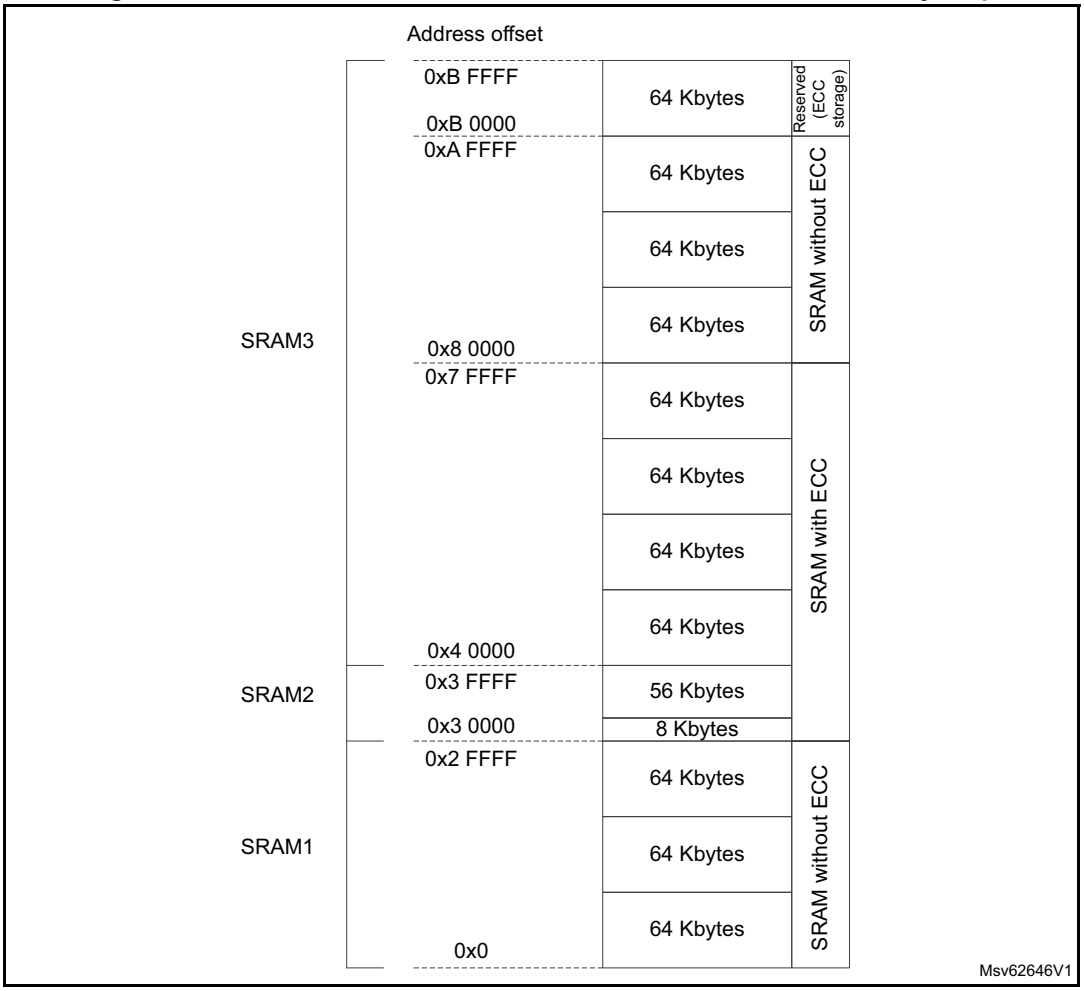
Caution: Double errors cannot be detected when the DED bit is set.

SRAM3 ECC specific management

When the ECC is enabled for SRAM3, only the first 256 Kbytes of SRAM3 are with ECC. The next 192 Kbytes are without ECC, and the last block is used to store the ECC, so cannot be used for application.

The figure below shows the SRAM areas, when SRAM2 and SRAM3 ECC are enabled.

Figure 19. SRAM1, SRAM2 with ECC and SRAM3 with ECC memory map



When ECC is enabled by user option bits, the ECCE bit is automatically set after system reset in the related *RAMCFG memory x control register (RAMCFG_MxCR)*.

The ECC can be deactivated by executing the following software sequence:

1. Write 0xAE in the *RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR)*.
2. Write 0x75 in the *RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR)*.
3. Write 0 in the ECCE bit of the *RAMCFG memory x control register (RAMCFG_MxCR)*.

In case ECC is deactivated (ECCE = 0), the SRAM3 ECC storage area (from offset 0xB0000 to offset 0xBFFFF) can be read and written as other SRAM3 areas. In order to test the ECC mechanism, only the first 256 Kbytes of SRAM3 can be modified, 1 or 2 bits by word (for single or double error test respectively).

The procedure to check ECC is the following:

1. On an erased memory, write data with ECC ON.
2. Disable ECC.
3. Write same data with 1- or 2-bit modification (for single or double error test respectively).
4. Enable ECC.
5. Read data. Enabled interrupt is generated because of single or double error.

Warning: The ECC fault injection test triggers a system break events in TIM1/TIM8/TIM15/TIM16/TIM17, if the SPL bit is set in SYSCFG_CFGR2.
This implies that the test must be performed while the PWM outputs of the timers are in idle state.

6.3.3 Write protection (SRAM2)

The SRAM2 is made of 64 1-Kbyte pages. Each 1-Kbyte page can be write-protected by setting its corresponding PxWP (x = 0 to 63) bit in the *RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1)* and *RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2)*.

6.3.4 Read access latency

To correctly read data from SRAMs, the number of wait states must be correctly programmed in the WSC[2:0] field of the *RAMCFG memory x control register (RAMCFG_MxCR)*, depending on AHB clock frequency (HCLK) and voltage scaling range, as shown in the table below.

Table 40. Number of wait states versus HCLK frequency and voltage range scaling

Wait states (WS) (Latency)	HCLK (MHz)			
	V_{CORE} range 1	V_{CORE} range 2	V_{CORE} range 3	V_{CORE} range 4 LPBAM(1)
0 WS (1 AHB cycle)	≤ 160	≤ 110	≤ 55	≤ 16
1 WS (2 AHB cycle)	-	-	-	≤ 25

1. LPBAM: low-power background autonomous mode. The system clock can be requested in Stop mode to perform DMA transfers.

6.3.5 Software erase

SRAM erase can be requested by executing this software sequence:

1. Write 0xCA in the *RAMCFG memory x erase key register (RAMCFG_MxERKEYR)*.
2. Write 0x53 in the *RAMCFG memory x erase key register (RAMCFG_MxERKEYR)*.
3. Write 1 in the SRAMER bit of the *RAMCFG memory x control register (RAMCFG_MxCR)*.

SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is on going.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is read or written while an erase is on going, wait states are inserted on the AHB bus until the end of the erase operation.

6.4 RAMCFG low-power modes

Table 41. Effect of low-power modes on RAMCFG

Mode	Description
Sleep	No effect. RAMCFG interrupts cause the device to exit the Sleep mode.
Stop	The content of RAMCFG registers is kept. The ECC is functional and ECC error interrupt or NMI causes the device to exit from Stop 0 and Stop 1 modes.
Standby	The RAMCFG peripheral is powered down and must be reinitialized after exiting Standby.

6.5 RAMCFG interrupts

The table below gives the list of RAMCFG interrupt requests.

Table 42. RAMCFG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit the Sleep mode	Exit the Stop mode	Exit the Standby modes
RAMCFG	ECC single error detection and correction	SEDC	SEIE	Write 1 in CSEDC	Yes	Yes(1)	No
	ECC double error detection	DED	DEIE = 1 and ECCNMI = 0	Write 1 in CDED	Yes	Yes(1)	No
NMI	ECC double error detection	DED	ECCNMI	Write 1 in CDED	Yes	Yes(1)	No

1. Stop 0 and Stop 1 modes only

6.6 RAMCFG registers

In the registers described below, x refers to:

- SRAM1/2/3/4 when x = 1/2/3/4 respectively

- BKPSRAM when x = 5

6.6.1 RAMCFG memory x control register (RAMCFG_MxCR)

Address offset: 0x040 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 000X

ECCE reset value depends on ECC enable user option bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WSC[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	ALE	Res.	Res.	Res.	ECCE
							rs				rw				rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WSC[2:0]**: Wait state configuration

This field is used to program the number of wait states inserted on the AHB when reading the SRAM, depending on its access time.

000: 0 wait state

001: 1 wait state

...

111: 7 wait states (not needed)

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY field of the RAMCFG_MxERKEYR register. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation on going

1: Erase operation on going

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable

0: Failing address not stored in the SRAMx ECC single/double error address registers

1: Failing address stored in the SRAMx ECC single/double error address registers

Note: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 control registers.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ECCE**: ECC enable.

This bit reset value is defined by the user option bit configuration. When set, it can be cleared by software only after writing the unlock sequence in the RAMCFG_MxECCKEYR register.

0: ECC disabled

1: ECC enabled

Note: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 control registers.

6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER)

Address offset: 0x004 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCNMI	Res.	DEIE	SEIE
												rs		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCNMI**: Double error NMI

This bit is set by software and cleared only by a global RAMCFG reset.

0: NMI not generated in case of ECC double error

1: NMI generated in case of ECC double error

Note: if ECCNMI is set, the RAMCFG maskable interrupt is not generated whatever DEIE bit value.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DEIE**: ECC double error interrupt enable

0: Double error interrupt disabled

1: Double error interrupt enabled

Bit 0 **SEIE**: ECC single error interrupt enable

0: Single error interrupt disabled

1: Single error interrupt enabled

6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR)

Address offset: 0x008 + 0x040 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMBUSY	Res.	Res.	Res.	Res.	Res.	Res.	DED	SEDC
							r							r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation

0: No erase operation on going

1: Erase operation on going

Note: Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option bit is enabled, tamper detection or readout protection regression. Refer to Table 39: Internal SRAMs features.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DED**: ECC double error detected

0: No double error

1: Double error detected

Note: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 interrupt status registers.

Bit 0 **SEDC**: ECC single error detected and corrected

0: No single error

1: Single error detected and corrected

Note: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 interrupt status registers.

6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)

Address offset: 0x00C + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ESEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ESEA[31:0]**: ECC single error address

When the ALE bit is set in the RAMCFG_MxCR register, this field is updated with the address corresponding to the ECC single error.

6.6.5 RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR)

Address offset: 0x010 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EDEA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EDEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **EDEA[31:0]**: ECC double error address

When the ALE bit is set in the RAMCFG_MxCR register, this field is updated with the address corresponding to the ECC double error.

6.6.6 RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)

Address offset: 0x014 + 0x040 * (x - 1), (x = 2, 3, 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CDED	CSEDC
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **CDED**: Clear ECC double error detected

Writing 1 to this flag clears the DED bit in the RAMCFG_MxISR register. Reading this flag returns the DED value.

Bit 0 **CSEDC**: Clear ECC single error detected and corrected

Writing 1 to this flag clears the SEDC bit in the RAMCFG_MxISR register. Reading this flag returns the SEDC value.

6.6.7 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ECCKEY[7:0]**: ECC write protection key

The following steps are required to unlock the write protection of the ECCE bit in the RAMCFG_MxCR register.

1) Write 0xAE into ECCKEY[7:0].

2) Write 0x75 into ECCKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.10 RAMCFG memory x erase key register (RAMCFG_MxERKEYR)

Address offset: 0x028 + 0x040 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of the SRAMER bit in the RAMCFG_MxCR register.

1) Write 0xCA into ERASEKEY[7:0].

2) Write 0x53 into ERASEKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.11 RAMCFG register map

Refer to *Section 2.3* for the register boundary addresses.

7 Embedded Flash memory (FLASH)

7.1 Introduction

The Flash memory interface manages accesses to the Flash memory, maximizing throughput to the CPU, instruction cache and DMAs. It implements the Flash memory erase and program operations as well as the read and write protection mechanisms. It also implements the security and privilege access control features. It is optimized in terms of power consumption with dedicated modes when the MCU is in low-power modes.

7.2 FLASH main features

- Up to 2 Mbytes of Flash memory supporting read-while-write capability (RWW).
- Memory organization
  - Dual bank architecture (bank 1 and bank 2)
  - Main memory: up to 1 Mbyte per bank
  - Information block: 64.5 Kbytes in bank 1
- 128-bit wide data read with prefetch
- Standard and burst programming modes
- Read, program and erase operations in all voltage ranges
- 10 kcycles endurance on all Flash memory. 100 kcycles on 256 Kbytes per bank
- Page erase, bank erase and mass erase (both banks)
- Bank swapping: the user Flash memory address mapping of each bank can be swapped.
- Product security activated by TrustZone option bit (TZEN)
- Device life cycle managed by readout protection option byte (RDP)
- Four write protection areas (two per bank)
- TrustZone support:
  - Two secure areas (1 per bank)
  - Two secure HDP (hide protection) areas part of the secure areas (one per bank)
- Configurable protection against unprivileged accesses with Flash page granularity
- Error code correction: 9 bits ECC per 128-bit quad-word allowing two bits error detection and one bit error correction
- Option-byte loader
- Advanced low-power modes (low-power read mode, bank power-down mode)

7.3 FLASH functional description

7.3.1 Flash memory organization

The Flash memory has the following main features:

- Capacity up to 2 Mbytes
- Dual-bank mode:
  - 1 Mbyte per bank for main memory
  - 8 Kbytes page size
  - 137 bits wide data read and write (128 effective bits plus 9 ECC bits)
  - Page, bank and mass erase

The Flash memory is organized as follows:

- Main memory block organized as two banks of 1 Mbyte each containing 128 pages of 8 Kbytes
- An information block containing:
  - 32 Kbytes for system memory. This area is immutable and reserved for use by STMicroelectronics. It contains the bootloader that is used to reprogram the Flash memory through one of the user communication interfaces such as USB (DFU). The system memory is programmed by STMicroelectronics when the device is manufactured. For further details, refer to the application note *STM32 microcontroller system memory boot mode (*AN2606).
  - 32 Kbytes immutable secure area containing the root security services (RSS and RSS library) developed by STMicroelectronics
  - 512 bytes OTP (one-time programmable) bytes for user data (32 quad-words). The OTP data cannot be erased and can be written only once.
  - option bytes for user configuration. Unlike user Flash memory and system memory, it is not mapped to any memory address and can be accessed only through the Flash register interface.

The memory organization is based on a main area and an information block as shown in the table below.

Table 44. Flash module 2-Mbyte dual bank organization

Flash area		Flash memory address	Size	Name
Main memory	Bank 1	0x0800 0000 - 0x0800 1FFF	8 Kbytes	Page 0
		0x0800 2000 - 0x0800 3FFF	8 Kbytes	Page 1
		...	...	...
		0x080F E000 - 0x080F FFFF	8 Kbytes	Page 127
	Bank 2	0x0810 0000 - 0x0810 1FFF	8 Kbytes	Page 0
		0x0810 2000 - 0x0810 3FFF	8 Kbytes	Page 1
		...	...	...
		0x081F E000 - 0x081F FFFF	8 Kbytes	Page 127
Non-secure information block		0x0BF9 0000 - 0x0BF9 7FFF	32 Kbytes	System memory
		0x0BFA 0000 - 0x0BFA 01FF	512 bytes	OTP area

Table 44. Flash module 2-Mbyte dual bank organization (continued)

Flash area	Flash memory address	Size	Name
Secure information block	0x0FF8 0000 - 0x0FF8 5FFF	24 Kbytes	RSS
	0x0FF8 6000 - 0x0FF8 7FFF	8 Kbytes	RSS library

Note: The secure information block is only accessible when TrustZone is active.

7.3.2 Error code correction (ECC)

Data in Flash memory are 137-bit words: Nine bits are added per quad-word (128 bits). The ECC mechanism supports:

- one error detection and correction
- two errors detection

When one error is detected and corrected, the ECCC flag (ECC correction) is set in the *FLASH ECC register (FLASH_ECCR)*. If the ECCCIE bit is set, an interrupt is generated.

When two errors are detected, the ECCD flag (ECC detection) is set in the *FLASH ECC register (FLASH_ECCR)*. In this case, a NMI is generated.

When an ECC error is detected, the address of the failing quad-word and its associated bank are saved in ADDR_ECC[19:0] and BK_ECC in the *FLASH ECC register (FLASH_ECCR)*. ADDR_ECC[3:0] are always cleared.

When ECCC or ECCD is set, ADDR_ECC and BK_ECC are not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

Caution: When the ECCC flag is set, a further two-errors detection is not able to generate the NMI or break signal to timers. It is therefore recommended to clear the ECCC flag as soon as a correction is operated, to preserve the ECC error detection capability. In case of a double ECC error detection (ECCD flag set and NMI triggered), the software must clean the cache in the NMI handler. Refer to *STM32U5 Series safety manual* (UM2875) for the full description of the implications on safety standards compliance.

Caution: For an erased Flash line, one error is detected and corrected but two errors detection is not supported.
When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

The following addresses in the system Flash memory are used to store words including ECC errors to allow run-time tests by software on ECC correction detection capability:

- 0x0BFA1F00 (embeds a word with 1-bit error)
- 0x0BFA1F80 (embeds a word with 2-bit error)

In case the second address is read, for instance by the debugger memory viewer, a NMI is generated.

7.3.3 Read access latency

To correctly read data from Flash memory, the number of wait states (latency) must be correctly programmed in the *FLASH access control register (FLASH_ACR)* according to the frequency of the CPU clock (HCLK) and the internal voltage range of the device V_{CORE}. Refer to *Section 10.5.4: Dynamic voltage scaling management*.

The table below shows the correspondence between wait states and CPU clock frequency.

Table 45. Number of wait states according to CPU clock (HCLK) frequency (LPM = 0)

Wait states (WS) (latency)	HCLK (MHz)			
	V_{CORE} range 1	V_{CORE} range 2	V_{CORE} range 3	V_{CORE} range 4
0 WS (1 CPU cycle)	≤ 32	≤ 30	≤ 24	≤ 12
1 WS (2 CPU cycles)	≤ 64	≤ 60	≤ 48	≤ 25
2 WS (3 CPU cycles)	≤ 96	≤ 90	≤ 55	-
3 WS (4 CPU cycles)	≤ 128	≤ 110	-	-
4 WS (5 CPU cycles)	≤ 160	-	-	-

The Flash memory supports a low-power read mode when setting the LPM bit in the *FLASH access control register (FLASH_ACR)*. The table below shows the correspondence between wait states and CPU clock frequency when LPM bit is set.

Table 46. Number of wait states according to CPU clock (HCLK) frequency (LPM = 1)

Wait states (WS) (Latency)	HCLK (MHz)	
	V_{CORE} range 1/2/3	V_{CORE} range 4
0 WS (1 CPU cycle)	WS ≥ HCLK (MHz) / 10 -1 Maximum HCLK frequency is given by *Table 45*	≤ 8
1 WS (2 CPU cycles)		≤ 16
2 WS (3 CPU cycles)		≤ 25
3 WS (4 CPU cycles)		-
...		-
15 WS (16 CPU cycles)		-

After reset, the CPU clock frequency is 4 MHz, 0 wait state (WS) is configured in the *FLASH access control register (FLASH_ACR)* and the normal read mode is selected (LPM = 0).

Instruction prefetch

The Cortex-M33 fetches instructions and literal pools (constants/data) over the C-Bus and through the instruction cache if it is enabled. The prefetch block aims at increasing the efficiency of C-Bus accesses in case the instruction cache is enabled by reducing the cache refill latency. Prefetch is efficient in case of sequential code; prefetch in the Flash memory allows the next sequential instruction line to be read from the Flash memory while the current instruction line is being filled in instruction cache and executed by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the *FLASH access control register (FLASH_ACR)*. PRFTEN must be set only if at least one wait state is needed to access the Flash memory.

Note: Prefetch tends to increase the code execution performance at the cost extra Flash memory accesses. It must be used carefully in low-power applications.

When changing the CPU frequency, the software sequences detailed below must be applied in order to tune the number of wait states needed to access the Flash memory.

Increase the CPU frequency

1. Program the new number of wait states to the LATENCY bits in the *FLASH access control register (FLASH_ACR)*.
2. Check that the new number of wait states is taken into account to access the Flash memory by reading back the *FLASH access control register (FLASH_ACR)*.
3. Modify the CPU clock source by writing the SW bits in the RCC_CFGR1 register.
4. Modify the CPU clock prescaler, if needed, by writing the HPRE bits in RCC_CFGR2.
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR1 and RCC_CFGR2 registers.

Decrease the CPU frequency

1. Modify the CPU clock source by writing the SW bits in the RCC_CFGR1 register.
2. Modify the CPU clock prescaler, if needed, by writing the HPRE bits in RCC_CFGR2.
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR1 and RCC_CFGR2 registers.
4. Program the new number of wait states to the LATENCY bits in the *FLASH access control register (FLASH_ACR)*.
5. Check that the new number of wait states is used to access the Flash memory by reading back the *FLASH access control register (FLASH_ACR)*.

The software sequences detailed below must be applied in order to modify the read mode.

From normal read mode to low-power read mode

1. Set the LPM bit in the *FLASH access control register (FLASH_ACR)*.
2. Check that the low-power read mode is activated by reading the *FLASH access control register (FLASH_ACR)*.

From low-power read mode to normal read mode

1. Reset the LPM bit in the *FLASH access control register (FLASH_ACR)*.
2. Check that the normal read mode is activated by reading the *FLASH access control register (FLASH_ACR)*.

7.3.4 Bank power-down mode

After reset, both banks are in normal mode. In order to reduce power consumption, each bank can be independently put in power-down mode by setting the PDREQx bit in the *FLASH access control register (FLASH_ACR)*.

Request entry in power-down mode for bank x

- Check that bank x is not in power-down mode and no request to put it in power-down mode is pending (PDx bit in *FLASH non-secure status register (FLASH_NSSR)* and PDREQx bit in *FLASH access control register (FLASH_ACR)* must be reset).
- Unlock PDKEYxR with correct keys. Refer to *FLASH bank 1 power-down key register (FLASH_PDKEY1R)* or *FLASH bank 2 power-down key register (FLASH_PDKEY2R)*
- Set the PDREQx bit in the *FLASH access control register (FLASH_ACR)*.
- Check that the PDx bit in the *FLASH non-secure status register (FLASH_NSSR)* is set. The PDREQx bit in the *FLASH access control register (FLASH_ACR)* is automatically reset and the PDKEYxR is locked.

Note: If bank x is currently being accessed, the power-down request is delayed until the access is completed.

Requesting power-down entry for a bank already in power-down mode has no effect. The PDREQx bit in the *FLASH access control register (FLASH_ACR)* is automatically reset and the PDKEYxR is locked.

Return to normal mode

Any access to a bank in power-down mode automatically wakes up the bank. A penalty of 5 µs minimum is taken to wake up the bank.

Wake up bank 1 (respectively bank 2) is done in one of the following cases:

- upon a valid read access to bank 1 (resp. bank 2)
- upon a valid write access to bank 1(resp. bank 2)
- upon a valid bank erase on bank 1 (resp. bank 2)

Waking up both bank 1 and bank 2 is done in one of the following cases:

- upon a valid mass erase
- upon an option byte modification
- upon an option byte loading
- upon system reset

Note: The software can reduce the Flash bank wake-up time by enabling HSI16 before waking up the bank.

7.3.5 Flash memory program and erase operations

The embedded Flash memory can be programmed using in-circuit programming or in-application programming.

The **in-circuit programming (ICP)** method is used to update the entire contents of the Flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, **in-application programming (IAP)** can use any communication interface supported by the microcontroller (such as I/Os, USB, CAN, UART, I2C or SPI) to download programming data into the memory. IAP allows the user to re-program the Flash memory while the application is running. Nevertheless, part of the application must have been previously programmed in the Flash memory using ICP.

An ongoing Flash memory operation does not block the CPU as long as the CPU does not access the same Flash memory bank. Code or data fetches are possible on one bank while

a write/erase operation is performed to the other bank (refer to *Section 7.3.10: Read-while-write (RWW)*).

On the contrary, during a program/erase operation to the Flash memory, any attempt to read the same Flash memory bank stalls the bus. The read operation proceeds correctly once the program/erase operation has been completed.

The MCU supports TrustZone that defines secure and non-secure areas in the Flash memory. All program and erase operations can be performed in secure mode through the secure registers or in non-secure mode through the non-secure registers. For more information, refer to *Section 7.5: FLASH TrustZone security and privilege protections*.

Unlock the secure/non-secure Flash control registers

After reset, write is not allowed in the Flash control registers (*FLASH secure control register (FLASH_SECCR)* and *FLASH non-secure control register (FLASH_NSCR)*) in order to protect the Flash memory against possible unwanted operations due, for example, to electric disturbances.

The following sequence is used to unlock these registers:

1. Write KEY1 = 0x45670123 in the *FLASH secure key register (FLASH_SECKEYR)* or *FLASH non-secure key register (FLASH_NSKEYR)*.
2. Write KEY2 = 0xCDEF89AB in the *FLASH secure key register (FLASH_SECKEYR)* or *FLASH non-secure key register (FLASH_NSKEYR)*.

Any wrong sequence locks up the *FLASH secure control register (FLASH_SECCR)* or *FLASH non-secure control register (FLASH_NSCR)* register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a hard fault interrupt is generated.

The FLASH_NSCR (resp. FLASH_SECCR) register can be locked again by software by setting the LOCK bit in the FLASH_NSCR (resp. FLASH_SECCR) register.

*Note: The FLASH_*NSCR and FLASH_SECCR *registers cannot be written when the BSY bits are set. Any attempt to write them with the BSY bits set, causes the AHB bus to stall until the BSY bits are cleared.*

Wait for data-to-write flags (WDW)

The WDW flags in the *FLASH non-secure status register (FLASH_NSSR)* and *FLASH secure status register (FLASH_SECSR)* are both set when a secure or non-secure write access has been done in the write buffer. They are cleared when the BSY flags are set (meaning that the write buffer is freed and the programming operation actually starts in the Flash memory) or in case of error.

It is the software responsibility to ensure that the four words in the same quad-word are all written.

Flash secure and non-secure busy flags

The BSY flags in the *FLASH non-secure status register (FLASH_NSSR)* and *FLASH secure status register (FLASH_SECSR)* are both set when a secure or non-secure Flash operation is started:

- Erase operation: setting the STRT bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*
- Write operation: setting the PG bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)* and writing a quad-word in the Flash memory
- Option-byte programming: setting the OPTSTRT in the *FLASH non-secure control register (FLASH_NSCR)*

7.3.6 Flash main memory erase sequences

The Flash memory erase operation can be performed at page level, bank level or on the whole Flash memory (mass erase). Mass erase does not affect the information block (system Flash, OTP and option bytes). The erase operation is either secure or non-secure.

Page erase

To erase a page, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PER bit and select the page to erase (PNB) with the associated bank (BKER) in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.
4. Set the STRT bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.
5. Wait for the BSY bit to be cleared in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.

Bank 1 or bank 2 mass erase

To perform a bank mass erase, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 or MER2 bit (depending on the bank) in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*. Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set the STRT bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.

5. Wait for the BSY bit to be cleared in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
6. The MER1 or MER2 bits can be cleared if no more bank erase is requested.

Mass erase

To perform a mass erase, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
2. Check and clear all non-secure error programming flags due to a previous programming. If not, the PGSERR bit is set.
3. Set the MER1 bit and MER2 bits in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.
4. Set the STRT bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.
5. Wait for the BSY bit to be cleared in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
6. The MER1 and MER2 bit can be cleared if no more mass erase is requested.

Note: The internal oscillator HSI16 (16 MHz) is enabled automatically when the STRT bit is set, and disabled automatically when the STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

To erase a page, a bank or to perform a mass erase, the software must have sufficient privilege (see Table 64 and Table 65).

7.3.7 Flash main memory programming sequences

The Flash memory is programmed 137 bits at a time (128-bit data + 9 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets the PROGERR flag in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.

It is only possible to program quad-word (4 x 32-bit data).

- Any attempt to write byte or half-word sets the SIZERR flag in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
- Any attempt to write a quad-word that is not aligned with a quad-word address sets the PGAERR flag in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.

Flash programming

The Flash memory programming sequence is as follows:

1. Check that no Flash main memory operation is ongoing by checking the BSY bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
2. Check that the write buffer is empty by checking the WDW bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.

4. Set the PG bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.
5. Perform the data write operation at the desired Flash memory address, or in the OTP area. Only a quad-word can be programmed and OTP can be only programmed in non-secure access:
   – Write a first word in an address aligned on a quad-word address. The WDW bits in the *FLASH non-secure status register (FLASH_NSSR)* and *FLASH secure status register (FLASH_SECSR)* are set to indicate that more data can be written in the write buffer.
   – Write the second, third and fourth word in the same quad-word.
6. The BSY bit gets set. WDW is reset automatically.
7. Wait until the BSY bit is cleared in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*. The software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.
8. If the EOP flag is set in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)* (meaning that the programming operation has succeeded and the EOPIE bit is set), it must be cleared by software.
9. Clear the PG bit in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)* if there is no more programming request.

Note: When the Flash memory interface received a good sequence (a quad-word), programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

No option bytes modification nor erase request is allowed when the WDW bit is set.

Programming is possible only if the privileged and security attributes are respected. Refer to Section 7.7: Summary of Flash memory and Flash memory registers access control.

If the user needs to program only one word, the quad-word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the quad-word to program.

Flash burst programming (8 quad-words)

The Flash memory burst programming sequence is as follows:

1. Check that no Flash main memory operation is ongoing by checking the BSY bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
2. Check that the write buffer is empty by checking the WDW bit in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*.
3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
4. Set the BWR and PG bits in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)*.
5. Perform the data write operation at the desired Flash memory address, or in the OTP area. Only 8 quad-words can be programmed:
   – Write a first 32-bit word in an address aligned on a 8*quad-word address (multiple of 0x80). The WDW bits in the *FLASH non-secure status register (FLASH_NSSR)*

and *FLASH secure status register (FLASH_SECSR)* are set to indicate that more data can be written in the write buffer.

– Write the 31 other 32-bit words consecutively.

6. The BSY bit gets set. WDW is reset automatically.
7. Wait until the BSY bit is cleared in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)*. The software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared
8. If the EOP flag is set in the *FLASH non-secure status register (FLASH_NSSR)* or *FLASH secure status register (FLASH_SECSR)* (meaning that the programming operation has succeeded and the EOPIE bit is set), it has to be cleared by software.
9. Clear the BWR and PG bits in the *FLASH non-secure control register (FLASH_NSCR)* or *FLASH secure control register (FLASH_SECCR)* if there is no more programming request.

Note: When the Flash memory interface received a good sequence, programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

No option bytes modification nor erase request is allowed when the WDW bit is set.

Programming is possible only if the privileged and security attributes are respected. Refer to Section 7.7: Summary of Flash memory and Flash memory registers access control.

7.3.8 Flash memory endurance

Each Flash memory page can be written and erased 10 000 times. In addition, up to 256 Kbytes (32 pages) per bank feature an increased endurance of 100 kcycles, that can be used for data storage that usually needs more intensive cycling capability than code storage. Any Flash page can be chosen to be cycled more than 10 000 times (up to 100 000 times). It is the application responsibility to limit the size of the Flash area cycled more than 10 000 times to 256 Kbytes per bank.

7.3.9 Flash memory errors flags

Flash programming errors

Several kind of errors can be detected during secure and non-secure operations. In case of error, the Flash memory operation (programming or erasing) is aborted.

The secure errors flags are only set during a secure operation and non-secure flags are only set during a non-secure operation.

- **PROGERR**: secure/non-secure programming error

  It is set when the word to program is pointing to an address:

  – not previously erased
  – already fully programmed to 0
  – already partially programmed (contains 0 and 1) and the new value to program is not full zero
  – for OTP programming, when the address is already partially programmed (contains 0 and 1)

- **SIZERR**: secure/non-secure size programming error

  Only 32-bit data can be written. SIZERR flag is set if a byte or a half-word is written.
- **PGAERR**: secure/non-secure alignment programming error

  It is set when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address.

  For burst programming, it is set when the first word to be programmed is not aligned on a 8 *quad-word address or if the following word writes are not done at consecutive 32-bit addresses.
- **PGSERR**: programming sequence error

  PGSERR is set if one of the following conditions occurs during a erase or program operation:
  - A data is written when PG is cleared.
  - A program operation is requested during erase: PG is set while MER1 or MER2 or PER is set.
  - In the erase sequence, PG is set while STRT is already set.
  - In the erase sequence, if STRT is set while MER1 and MER2 and PER are cleared.
  - If page and mass erase are requested at the same time, STRT and PER are set while MER1 or MER2 is set.
  - If an operation is started while the write buffer is waiting for the next data, STRT or OPTSTRT is set while WDW is already set.
  - If STRT and OPTSTRT are set at the same time.
  - A non-secure PGSERR is set if the non secure STRT bit is set by a secure access.
  - A secure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPERR or PGSERR is already set due to a previous programming error.
  - A non-secure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPERR, PGSERR or OPTWERR is already set due to a previous programming error.
- **WRPERR**: write protection error
  - Refer to *Table 59* to *Table 62* for all the conditions of WRPERR flag setting.
- **OPTWERR**: option bytes write error

  OPTWERR is set if when user option bytes are modified with an invalid configuration. It is set when attempting:
  - to program an invalid secure watermark-based area. Refer to *Table 50*
  - to set or clear the TZEN option bit when RDP is not at correct level (refer to *Rules for modifying specific option bytes*)
  - to clear the BOOT_LOCK option bit when RDP is not at correct level (refer to *Rules for modifying specific option bytes*)
  - to modify SWAP_BANK option bit while BOOT_LOCK and TZEN are set
  - to modify SECBOOTADD0 option bit while BOOT_LOCK is set
  - to modify DUALBANK option bit while BOOT_LOCK and TZEN are set
  - to modify SECWM1Rx (resp. SECWM2Rx) while HDP1_ACCDIS (resp. HDP2_ACCDIS) is set
  - to modify the option bytes, except the SWAP_BANK option bit, when RDP is set to two

- to regress from RDP level 0.5 to RDP level 0
- to modify OEM1KEYRx while RDP level is 0.5 or 1 and OEM1LOCK bit is set
- to modify OEM2KEYRx while RDP level is 1 and OEM2LOCK bit is set
- to regress from RDP level 1 to RDP level 0 while OEM1LOCK bit is set and a wrong OEM1KEY is shifted through JTAG or SWD
- to regress from RDP level 1 to RDP level 0.5 while OEM2LOCK bit is set and a wrong OEM2KEY is shifted through JTAG or SWD
- to modify WRPxyR while its UNLOCK bit is cleared
- to set the UNLOCK bit in the WRPxyR when RDP is not at correct level (refer to *Rules for modifying specific option bytes*)

If an error occurs during a secure or non-secure program or erase operation, one of the following programming error flags is set:

- non-secure programming error flags: PROGERR, SIZERR, PGAERR, PGSERR, OPTWRERR or WRPERR is set in the *FLASH non-secure status register (FLASH_NSSR)*.

  If the non-secure error interrupt enable bit ERRIE is set in the *FLASH non-secure control register (FLASH_NSCR)*, an interrupt is generated and the operation error flag OPERR is set in the FLASH_NSSR register.
- Secure programming error flags: PROGERR, SIZERR, PGAERR, PGSERR or WRPERR is set in the *FLASH secure status register (FLASH_SECSR)*.

  If the secure error interrupt enable bit ERRIE is set in the *FLASH secure control register (FLASH_SECCR)*, an interrupt is generated and the operation error flag OPERR is set in the FLASH_SECSR register.

Note: If several successive errors are detected (for example, in case of DMA transfer to the Flash memory), the error flags cannot be cleared until the end of the successive write requests.

Any programming error flushes the write buffer.

7.3.10 Read-while-write (RWW)

The Flash memory is divided into two banks allowing read-while-write operations. This feature allows a read operation to be performed from one bank while erase or program operation is performed to the other bank.

Note: Write-while-write operations are not allowed. As an example, It is not possible to perform an erase operation on one bank while programming the other one.

Read from bank 1 while page erasing in bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa).

Read from bank 1 while mass erasing bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa).

Read from bank 1 while programming bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a program operation on the bank 2 (and vice versa).

Note: Due to the Cortex-M33 unified C-Bus, user software must ensure to not stall C-Bus with multiple consecutive writes. It is recommended to wait for the BSY flag to be cleared before programming the next quad-word.

7.3.11 Power-down during Flash programming or erase operation

The contents of the Flash memory currently being accessed are not guaranteed if a power-down occurs during a Flash memory program or erase operation.

7.3.12 Reset during Flash programming or erase operation

The contents of the Flash memory currently being accessed are not guaranteed if a reset occurs during a Flash memory program or erase operation. The status of the Flash memory can be recovered from the *FLASH operation status register (FLASH_OPSR)* when a system reset occurs during a Flash memory program or erase operation.

It is the software responsibility to check the status of the Flash memory and to take corrective actions. This must be done after each system reset before any other programming or erase operation is performed.

The table below describes the corrective action to be taken according to the status provided in the CODE_OP field of the *FLASH operation status register (FLASH_OPSR)*.

Table 47. Flash operation interrupted by a system reset

CODE_OP	Operation interrupted	Address	Bank	System Flash	Corrective action
0x0	No operation	Reserved			None
0x1	Single write	ADDR_OP	BK_OP	SYSF_OP	Page erase and single write at same location
0x2	Burst write	ADDR_OP	BK_OP	SYSF_OP	Page erase and burst write at same location
0x3	Page erase	ADDR_OP	BK_OP	Reserved	Erase same page
0x4	Bank erase	Reserved	BK_OP	Reserved	Erase same bank
0x5	Mass erase	Reserved			Mass erase
0x6	Option change	Reserved			Option change
0x7	Reserved				

Note: For single and burst write, it is mandatory to perform a page erase because the current Flash memory locations may no longer be writable. Consequently, the remaining page content must be saved before page erase and restored afterwards.

For OTP write, it is not possible to perform a page erase. The OTP quad-word is lost.

For burst write, ADDR_OP gives the first address of burst. User must restart the same burst operation.

For page erase, ADDR_OP gives the first address of erased page.

7.4 FLASH option bytes

7.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog may be selected in hardware or software mode (refer to *Section 7.4.2: Option-byte programming*). The user option bytes are accessible through the Flash memory registers interface.

The table below describes the organization of all user option bytes available in the Flash memory interface registers.

Table 48. User option-byte organization mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Register map

7.4.2 Option-byte programming

After reset, the options related to the operation bits OPTSTRT and OBL_LAUNCH in the FLASH_NSCR register, are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the *FLASH non-secure control register (FLASH_NSCR)* must be cleared.

The following sequence is used to unlock this register:

1. Unlock the FLASH_NSCR register with the LOCK clearing sequence (refer to *Unlock the secure/non-secure Flash control registers*).
2. Write OPTKEY1 = 0x08192A3B in the FLASH_OPTKEYR register.
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If the LOCK bit in FLASH_NSCR *is set by software, OPTLOCK is automatically set too.*

Option bytes modification sequence

To modify the user options value, follow the procedure below:

1. Check that no Flash memory operation is on going by checking the BSY bit in the FLASH_NSSR register.
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers.
4. Set the options start bit OPTSTRT in the FLASH_NSCR register.
5. Wait for the BSY bit to be cleared.
6. Set the OBL_LAUNCH option bit to start option bytes loading.

Note: If the OPTWERR or PGSERR error bit is set, the old option byte values are kept.

Option byte loading

After the BSY bit is cleared, all new options are updated into the Flash memory but they are not applied to the system. They affect the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

- when OBL_LAUNCH bit is set in the *FLASH non-secure control register (FLASH_NSCR)*
- after a power reset (BOR reset or exit from Standby/Shutdown modes)

On system reset rising, internal option registers are copied into option registers. These registers are also used to modify the option bytes. If these registers are not modified by user, they reflect the options state of the system.

Rules for modifying specific option bytes

Some of the option byte field must respect specific rules before being updated with new values. These option bytes, as well as the associated constraints, are described below:

- TZEN option bit
  - TZEN can only be set on RDP level 0.
  - Deactivation of TZEN is only possible when RDP is changing from level 1 to level 0.

- BOOT_LOCK option bit
  - BOOT_LOCK has only effect when TZEN is set.
  - BOOT_LOCK can be set without any constraint.
  - Deactivation of BOOT_LOCK is only possible when RDP is level 0.
- SWAP_BANK option bit
  - It cannot be modified when BOOT_LOCK and TZEN option bits are set.
- SECBOOTADD0 option bytes
  - It cannot be modified when BOOT_LOCK option bit is set.
- DUALBANK option bit
  - It cannot be modified when BOOT_LOCK and TZEN option bits are set.
- SECWMxRy option bits
  - It is not possible to modify secure (SECWMx_PSTRT[6:0] and SECWMx_PEND[6:0] option bits), and HDP (HDPx_PEND[6:0] and HDPxEN option bits) area in bank x when the HDPx_ACCDIS bit is set.
- RDP option bits
  - Refer to *Device life cycle managed by readout protection (RDP) transitions*.
- WRPxyR option bits
  - These bits cannot be modified when their UNLOCK bit is cleared.
- UNLOCK option bits
  - These bits can be set only when regressing from RDP level 1 to level 0.

If the user options modification tries to set or modify one of the listed option bytes without following their associated rules, the option bytes modification is discarded and the OPTWERR error flag is set.

7.5 FLASH TrustZone security and privilege protections

7.5.1 TrustZone security protection

The global TrustZone system security is activated by setting the TZEN option bit in the FLASH_OPTR register.

When TrustZone is active (TZEN = 1), the following additional security features are available:

- Secure watermark-based user options bytes defining secure and HDP areas
- Secure or non-secure block-based areas can be configured on-the-fly after reset. This is a volatile secure area.
- An additional RDP protection: RDP level 0.5
- Erase or program operation can be performed in secure or non-secure mode with associated configuration bit.

When the TrustZone is disabled (TZEN = 0), the above features are deactivated and all secure registers are RAZ/WI.

Activate TrustZone security

When the TrustZone is activated (TZEN is modified from 0 to 1), the secure watermark-based user options bytes are set to default secure state: all Flash memory is secure, and no HDP area, as shown in the table below.

Table 49. Default secure option bytes after TZEN activation

Secure watermark option bytes values after OBL when TZEN is activated (from 0 to 1)	Security attribute
SECWMx_PSTRT = 0 and SECWMx_PEND = 0x7F	All Flash memory secure
HDPxEN = 0 and HDPx_PEND = 0	No secure HDP area

Illegal access generation

A non-secure access to a secure Flash memory area is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in the TZIC_IER2 register.

A non-secure access to a secure Flash register generates an illegal access event. An illegal access interrupt is generated if the FLASH_REGIE illegal access interrupt is enabled in the TZIC_IER2 register.

Deactivate TrustZone security

Deactivation of TZEN (from 1 to 0) is only possible when the RDP is changing from level 1 to level 0.

When the TrustZone is deactivated (TZEN is modified from 1 to 0) after option bytes loading, the following security features are deactivated:

- Watermark-based secure area (refer to *Section 7.5.2*)
- Block-based secure area (refer to *Section 7.5.4*)
- RDP level 0.5 (refer to *Section 7.6.2: Readout protection (RDP)*)
- Secure interrupts (refer to *Section 7.8: FLASH interrupts*)
- All secure registers are RAZ/WI

7.5.2 Watermark-based secure Flash memory area protection

When TrustZone security is active (TZEN = 1), a part of the Flash memory can be protected against non-secure read and write accesses. Up to two different non-volatile secure areas can be defined by option bytes and can be read or written by a secure access only: one area per bank can be selected with a page granularity.

The secure areas are defined by a start-page offset and end-page offset using the SECWMx_PSTRT and SECWMx_PEND (x=1,2 for area 1 and area 2) option bytes. These offsets are defined in the secure watermark registers address registers *FLASH secure watermark1 register 1 (FLASH_SECWM1R1)* and *FLASH secure watermark2 register 1 (FLASH_SECWM2R1)*.

The SECWMx_PSTRT and SECWMx_PEND option bytes can only be modified by secure firmware when the HDPx_ACCDIS bit is reset. If the HDPx_ACCDIS bit is set, the SECWMx_PSTRT and SECWMx_PEND cannot be modified until next system reset.

Table 50. Secure watermark-based area

Secure watermark option bytes values (x = 1,2)	Secure watermark protection area
SECWMx_PSTRT > SECWMx_PEND	No secure area
SECWMx_PSTRT = SECWMx_PEND	One page defined by SECWMx_PSTRT is secure watermark-based protected
SECWMx_PSTRT < SECWMx_PEND	The area between SECWMx_PSTRT and SECWMx_PEND is secure watermark-based protected.

Caution: Switching a Flash memory area from secure to no-secure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to non-secure attribute whenever is needed. It is also recommended to flush the instruction cache.

7.5.3 Secure hide protection (HDP)

The secure HDP area is part of the Flash memory watermark-based secure area. Access to the hide protection area can be denied by setting the HDPx_ACCDIS bit in the *FLASH secure HDP control register (FLASH_SECHDPCR)*.

When the HDPx_ACCDIS bit is set, instruction fetch, data read, write and erase operations on this hide protection area are denied. For example, software code in the secure Flash hide protected area can be executed only once and deny any further access to this area until next system reset. The HDPx_ACCDIS bit can be only cleared by a system reset.

Note: It is the software responsibility to take any appropriate action to protect the HDP code before resetting the HDPxEN bit such as erasing the HDP area and flushing the instruction cache.

One non-volatile secure hide protection (HDP) area per bank can be defined with a page granularity.

The secure HDP area is enabled by the HDPxEN (x = 1,2 for area 1 and area 2). When the HDPxEN bit is reset, there is no HDP area. The HDPxEN bit can be set or reset on the fly by the secure firmware if the HDPx_ACCDIS bit is reset. If the HDPx_ACCDIS bit is set, the HDPxEN bit and secure watermark configuration cannot be modified until next system reset.

The secure HDP area size is defined by the end-page offset using the HDPx_PEND option bytes while the start-page offset is already defined by SECWMx_PSTRT option bytes.These offsets are defined in the secure watermark registers address registers: *FLASH secure watermark1 register 1 (FLASH_SECWM1R1)*, *FLASH secure watermark1 register 2 (FLASH_SECWM1R2)*, *FLASH secure watermark2 register 1 (FLASH_SECWM2R1)* and *FLASH secure watermark2 register 2 (FLASH_SECWM2R2)*.

For example, to protect by HDP from the address 0x0C00 4000 (included) to the address 0x0C00 5FFF (included):

- If the banks are not swapped, the option bytes registers must be programmed with:
  - SECWM1_PSTRT = 0x2
  - HDP1_PEND = 0x3
- If the two banks are swapped, the protection must apply to bank 2 and the option bytes registers must be programmed with:
  - SECWM2_PSTRT = 0x2
  - HDP2_PEND = 0x3

Note: For more details on the bank swapping mechanism, refer to Section 7.5.8.

If an invalid secure HDP area is defined as described in the table below, the OPTWERR flag error is set and option bytes modification is discarded.

Table 51. Secure hide protection

HDPx watermark option bytes values (x = 1,2)		Hide protection area
HDPxEN = 0	-	No secure HDP area
HDPxEN = 1	SECWMx_PSTRT ≤ HDPx_PEND ≤ SECWMx_PEND	The area between SECWMx_PSTRT and HDPx_PEND is secure HDP protected.
	Others	Invalid secure area. Hide protection area is defined outside the secure area.

The table below summarizes the possible secure and HPD protection area configurations.

Table 52. Secure and HDP protections

Secure and HDP watermark option byte values		Protections area
HDPxEN	Option bytes	
x	SECWMx_PSTRT > SECWMx_PEND	No secure area
0	SECWMx_PSTRT ≤ SECWMx_PEND	No secure HDP area Secure between SECWMx_PSTRT and SECWMx_PEND – If SECWMx_PSTRT = SECWMx_PEND, one page defined by SECWMx_PSTRT is secure protected.
1	SECWMx_PSTRT ≤ HDPx_PEND ≤ SECWMx_PEND	The area between SECWMx_PSTRT and HDPx_PEND is secure HDP protected. – If SECWMx_PSTRT = HDPx_PEND, one page defined by HDPx_PEND is secure HDP protected.
	Others	Invalid secure area HDP area is defined outside the secure area.

7.5.4 Block-based secure Flash memory area protection

Any page can be programmed on the fly as secure or non-secure using the block-based configuration registers. FLASH_SECBB1Rx (resp. FLASH_SECBB2Rx) registers are used to configure the security attribute for pages in bank 1 (resp. bank 2).

When the page security attribute, bit i in SECyBBRx, is set, the security attribute is the same as the secure watermark-based area. The secure page is only accessible by a secure access.

If the SECyBBi bit is set or reset for a page already included in a secure watermark-based area, the page keeps the watermark-based protection security attributes.

To modify a block-based page security attribution, the following actions are recommended:

- Check that no Flash memory operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in SECyBBRx.

Caution: Switching a page or memory block from secure to non-secure does not erase the content of the associated block. User secure software must perform the following needed operations before switching a block to non-secure attribute:

- Erase page content,
- Invalidate the instruction cache.

Note: For SECyBBRx bit i access control, refer to Table 66: SECyBBRx registers access when TrustZone is active (TZEN = 1).

7.5.5 Flash security attribute state

The Flash memory is secure when at least one secure area is defined either by watermark-based option bytes or block-based security registers.

It is possible to override the Flash security state using the INV bit in the FLASH_SECCR register.

The FLASHEN and FLASHSMEN bits security attributes in RCC follow the Flash memory security attribute. It is possible to override the Flash memory security attribute in RCC using the INV bit in the FLASH_SECCR register. A secure firmware setting this INV bit allows a non-secure firmware to disable the Flash memory clock when the Flash memory is in power down or when the MCU enters low-power modes.

Table 53. Flash security state

Secure area	INV bit	Flash security state
None	0	Non-secure
	1	Secure
Yes	0	Secure
	1	Non-secure

7.5.6 Block-based privileged Flash memory area protection

Any page can be programmed on the fly as privileged or unprivileged using the block-based configuration registers. FLASH_PRIVBB1Rx (resp. FLASH_PRIVBB2Rx) registers are used to configure the privilege attribute for pages in bank 1 (resp. bank 2).

When the page privilege attribute, bit i in PRIVyBBRx, is set, the page is only accessible by a privileged access. An unprivileged page is accessible by a privileged or unprivileged access.

To modify a block-based privilege attribution, the following actions are recommended:

- Check that no Flash operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in PRIVyBBRx.

Caution: Switching a page or memory block from privileged to unprivileged does not erase the content of the associated block.

Note: For PRIVyBBRx bit i access control, refer to Table 67: PRIVyBBRx registers access when TrustZone is active (TZEN = 1) and Table 68: PRIVyBBRx registers access when TrustZone is disabled (TZEN = 0).

7.5.7 Flash memory registers privileged and unprivileged modes

The Flash memory registers can be read and written by privileged and unprivileged accesses depending on the SPRIV and NSPRIV bits in *FLASH privilege configuration register (FLASH_PRIVCFGR)*, with the following rules:

- When the SPRIV (resp. NSPRIV) bit is reset, all secure (resp. non-secure) Flash memory registers can be read and written by both privileged or unprivileged access.
- When the SPRIV (resp. NSPRIV) bit is set, all secure (resp. non-secure) Flash memory registers can be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

Table 63: Flash registers access summarizes the Flash memory registers access control.

7.5.8 Flash memory bank attributes in case of bank swap

The SWAP_BANK option bit modifies the address of each bank in the memory map. When SWAP_BANK is reset, the Flash memory bank 1 is at the lower address range. When SWAP_BANK is set, the Flash memory bank 1 is at the higher address range.

Flash memory bank attributes follow their bank so there is no need to modify the following registers when swapping banks:

- FLASH secure watermark y register x FLASH_SECWMyRx
- FLASH write protection x area y FLASH_WRPxyR (refer to *Section 7.6.1*)
- FLASH secure block based bank y register x FLASH_SECyBBRx
- FLASH privilege block based bank y register x FLASH_PRIVyBBRx
- PDREQx bits in the *FLASH access control register (FLASH_ACR)*
- PDx bits in the *FLASH non-secure status register (FLASH_NSSR)*

Note: The BK_ECC bit in the FLASH ECC register (FLASH_ECCR) always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.

The BK_OP bit in the FLASH operation status register (FLASH_OPSR) always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.

The figures below show how security attributes and protections behave in case of bank swap.

Figure 20. Flash memory security attributes and protections in case of no bank swap (SWAP_BANK = 0)

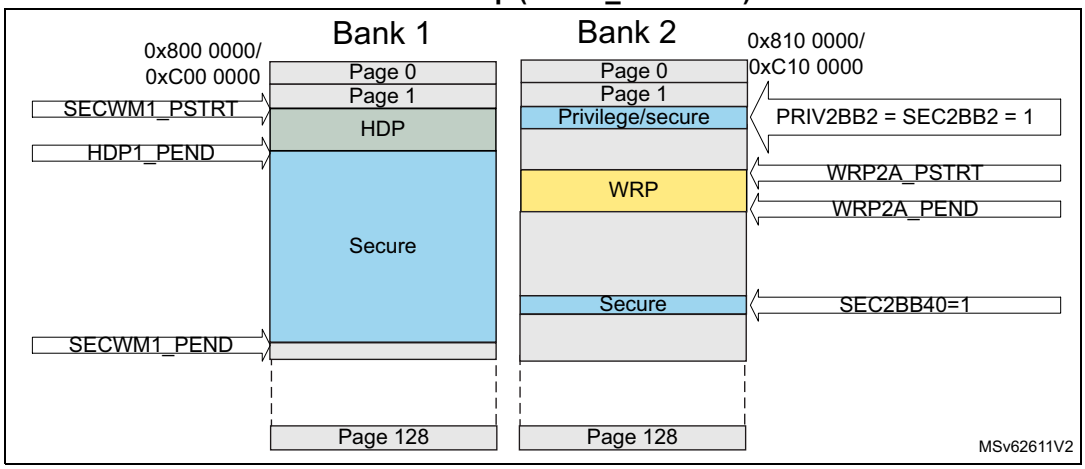

Figure 21. Flash memory security attributes and protections in case of bank swap (SWAP_BANK = 1)

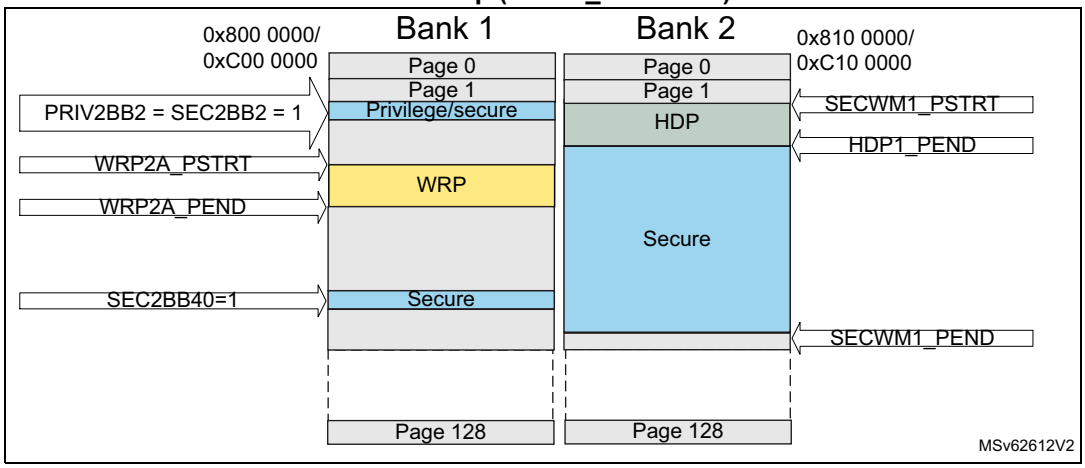

7.6 FLASH memory protection

The Flash memory interface implements the following protection mechanisms:

- write protection (WRP)
- readout protection (RDP)
- additional secure protections when TrustZone is active (refer to *Section 7.5*)
  - up to two secure watermark-based non-volatile areas
  - up to two secure hide protection areas
  - secure block-based volatile areas with page granularity
- privileged block-based volatile areas with page granularity (refer to *Section 7.5.6*)

7.6.1 Write protection (WRP)

The user area in Flash memory can be protected against unwanted write operations. Two write-protected (WRP) areas can be defined in each bank, with page granularity.

Each area is defined by a start page offset and an end page offset related to the physical Flash bank base address. These offsets are defined in the WRP address registers: *FLASH WRP1 area A address register (FLASH_WRP1AR)*, *FLASH WRP1 area B address register (FLASH_WRP1BR)*, *FLASH WPR2 area A address register (FLASH_WRP2AR)* and *FLASH WPR2 area B address register (FLASH_WRP2BR)*.

The bank “x” WRP “y” area (x = 1,2 and y = A,B) is defined as follows:

- from the address: bank “x” base address + [WRPxy_PSTRT x 0x2000] (included)
- to the address: bank “x” base address + [(WRPxy_PEND+1) x 0x2000] (excluded)

For example, to protect by WRP from the address 0x0806 2000 (included) to the address 0x0807 3FFF (included):

- If the banks are not swapped, FLASH_WRP1AR register must be programmed with:
  - WRP1A_PSTRT = 0x31
  - WRP1A_PEND = 0x39

  WRP1B_PSTRT and WRP1B_PEND in FLASH_WRP1BR can be used instead (area “B” in bank 1).
- If the two banks are swapped, the protection must apply to bank 2, and FLASH_WRP2AR register must be programmed with:
  - WRP2A_PSTRT = 0x31
  - WRP2A_PEND = 0x39

  WRP2B_PSTRT and WRP2B_PEND in FLASH_WRP2BR can be used instead (area “B in bank 2).

Note: For more details on the bank swapping mechanism, refer to Section 7.5.8: Flash memory bank attributes in case of bank swap.

When WRP is active, protected Flash memory pages cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the Flash memory is attempted, the secure or non-secure write protection error flag (WRPERR) is set in the FLASH_NSSR or FLASH_SECSR register. This flag is also set for any write access to the following:

- system Flash memory
- OTP area

Note: When the memory readout protection level 1 is selected (RDP level = 1), it is not possible to program or erase the Flash memory (secure or non-secure) if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or system Flash memory, even if WRP is not activated.

When the memory readout protection level 0.5 is selected (RDP level = 0.5), it is not possible to program or erase the Flash secure memory if the CPU debug features are connected (JTAG or single wire), even if WRP is not activated.

Note: To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in the Flash control register.

Table 54. WRP protection

WRP registers values (x = 1/2 y = A/B)	WRP area
WRPxy_PSTRT = WRPxy_PEND	Page WRPxy is protected.
WRPxy_PSTRT > WRPxy_PEND	No WRP area
WRPxy_PSTRT < WRPxy_PEND	The pages from WRPxy_PSTRT to WRPxy_PEND are protected.

Write protection lock

Each WRP area can be independently locked by writing 0 to the UNLOCK bit in the *FLASH WRP1 area A address register (FLASH_WRP1AR)*, *FLASH WRP1 area B address register (FLASH_WRP1BR)*, *FLASH WPR2 area A address register (FLASH_WRP2AR)* or *FLASH WPR2 area B address register (FLASH_WRP2BR)*. Once a WRP area is locked, it is not possible to modify its settings. In order to unlock a WRP area, a regression to RDP level 0 must be launched.

In order to make the WRP area immutable and act as a ROM, the following actions are needed:

- If RDP level is 0, 0.5 or 1, provision a OEM1KEY in order to prevent a regression to RDP level 0 for users not knowing the key.
- If RDP level is 2, either provision a OEM1KEY (refer to first bullet) or do not provision a OEM2KEY (preventing regression from level 2 to level 1).

For more information on RDP regressions, refer to *Device life cycle managed by readout protection (RDP) transitions*.

7.6.2 Readout protection (RDP)

The readout protection protects the Flash main memory, the option bytes, the backup registers, the backup RAM and the SRAMs. In order to reach the best protection level, it is recommended to activate TrustZone and to set the RDP Level 2 with password authentication regression enabled (refer to *Readout protection levels when TrustZone is enabled*).

Readout protection levels when TrustZone is disabled

There are three levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2).

The Flash memory is protected according to the RDP option byte value shown in the table below.

Table 55. Flash memory Readout protection status (TZEN=0)

RDP byte value	Readout protection level
0xAA	Level 0
Any value except 0xAA or 0xCC	Level 1
0xCC	Level 2

- Level 0: no protection

  Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.
- Level 1: readout protection

  When the readout protection level 1 is set:
  - **User mode:** code executing in user mode (**boot Flash**) can access the Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
  - **Debug, boot RAM and bootloader modes**: in debug mode or when the microcontroller boots from RAM or system memory, the Flash main memory, the backup registers, the backup RAM and the SRAM2 are totally inaccessible; any read or write access to the Flash main memory generates a bus error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.
- Level 2: no debug

  When the readout protection level 2 is set:
  - The protection level 1 is guaranteed.
  - All debug features are disabled:

    . if OEM2 key has not been provided, JTAG and SWD are definitively disabled.

    . if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST and DBGMCU_DBG_AUTH_DEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.
  - The boot from SRAM (boot RAM mode) and the boot from system memory (bootloader mode) are no longer available.
  - Only boot from main Flash memory is possible; all operations are allowed on the Flash main memory. Read, erase and program accesses to the Flash memory and SRAMs from user code are allowed.
  - Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to *OEM2 RDP lock mechanism*).

Note: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).

Table 56. Access status versus protection level and execution modes when TZEN = 0

Area	RDP level	User execution (boot from Flash)			Debug/boot from RAM/ bootloader(1)		
		Read	Write	Erase	Read	Write	Erase
Flash main memory	1	Yes	Yes	Yes	No	No	No(4)
	2	Yes	Yes	Yes	N/A	N/A	N/A
System memory (2)	1	Yes	No	No	Yes	No	No
	2	Yes	No	No	N/A	N/A	N/A
Option bytes(3)	1	Yes	Yes(4)	N/A	Yes	Yes(4)	N/A
	2	Yes	No(5)	N/A	N/A	N/A	N/A
OTP	1	Yes	Yes(6)	N/A	Yes	Yes(6)	N/A
	2	Yes	Yes(6)	N/A	N/A	N/A	N/A
Backup registers	1	Yes	Yes	N/A	No	No	N/A(7)
	2	Yes	Yes	N/A	N/A	N/A	N/A
SRAM2/backup RAM	1	Yes	Yes	N/A	No	No	N/A(8)
	2	Yes	Yes	N/A	N/A	N/A	N/A
OTFDEC regions (OCTOSPI)	1	Yes	Yes	Yes	No	Yes	Yes(9)
	2	Yes	Yes	Yes	N/A	N/A	N/A

1. When the protection level 2 is active, the debug port, the boot from RAM and the boot from system memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. Option bytes are only accessible through the Flash registers interface and OPTSTRT bit.
4. The Flash main memory is erased when the RDP option byte changes from level 1 to level 0.
5. SWAP_BANK option bit can be modified.
6. OTP can only be written once.
7. The backup registers are erased when RDP changes from level 1 to level 0.
8. All SRAMs are erased when RDP changes from level 1 to level 0.
9. The OTFDEC keys are erased when the RDP option byte changes from level 1 to level 0.

Readout protection levels when TrustZone is enabled

There are four levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2). The Flash memory is protected according to the RDP option byte value shown in the table below.

Table 57. Flash memory readout protection status (TZEN = 1)

RDP byte value	Readout protection level
0xAA	Level 0
0x55	Level 0.5

Table 57. Flash memory readout protection status (TZEN = 1) (continued)

RDP byte value	Readout protection level
Any value except 0xAA or 0x55 or 0xCC	Level 1
0xCC	Level 2

- Level 0: no protection

  Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.

  – **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.

- Level 0.5: non-secure debug only

  All read and write operations (if no write protection is set) from/to the non-secure Flash memory are possible. The debug access to secure area is prohibited. Debug access to non-secure area remains possible.

  – **User mode:** code executing in user mode (**boot Flash**) can access the Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).

  – **Non-secure debug mode**: non-secure debug is possible when the CPU is in non-secure state. The secure Flash memory, the secure backup registers and SRAMs area are inaccessible; the non-secure Flash memory, the non-secure backup registers and the non-secure SRAMs area remain accessible for debug purpose.

  – **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.

  – **Boot RAM mode**: boot from SRAM is not possible.

- Level 1: readout protection

  When the readout protection level 1 is set:

  – **User mode:** code executing in user mode (**boot Flash**) can access the Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).

  – **Non-secure debug mode**: non-secure debug is possible when the CPU is in non-secure state. However, an intrusion is detected in case of debug access: the Flash main memory, the backup registers, the backup RAM and the SRAM2 are totally inaccessible; any read or write access to the Flash main memory generates a bus error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.

  – **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.

  – **Boot RAM mode**: boot from SRAM is not possible.

- Level 2: no debug

  When the readout protection level 2 is set:

  – The protection level 1 is guaranteed.

  – All debug features are disabled

  . if OEM2 key has not been provided, JTAG and SWD are definitively disabled.

  . if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST and DBGMCU_DBG_AUTH_DEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.

  – The boot from SRAM (boot RAM mode) and the boot from system memory (boot loader mode) are no longer available.

  – Boot from RSS is possible.

  – When booting from main Flash or RSS, all operations are allowed on the Flash main memory. Read, erase and program accesses to Flash memory and SRAMs from user code are allowed.

  – Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to *OEM2 RDP lock mechanism*).

Note: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).

Table 58. Access status versus protection level and execution modes when TZEN = 1

Area	RDP level	User execution (boot from Flash)			Debug/bootloader(1)		
		Read	Write	Erase	Read	Write	Erase
Flash main memory	0.5	Yes	Yes	Yes	Yes(2)	Yes(2)	Yes(2)
	1	Yes	Yes	Yes	No	No	No(5)
	2	Yes	Yes	Yes	N/A	N/A	N/A
System memory (3)	0.5	Yes	No	No	Yes	No	No
	1	Yes	No	No	Yes	No	No
	2	Yes	No	No	N/A	N/A	N/A
Option bytes(4)	0.5	Yes	Yes (5)	N/A	Yes	Yes (5)	N/A
	1	Yes	Yes(5)	N/A	Yes	Yes(5)	N/A
	2	Yes	No(6)	N/A	N/A	N/A	N/A
OTP	0.5	Yes	Yes(7)	N/A	Yes	Yes(7)	N/A
	1	Yes	Yes(7)	N/A	Yes	Yes(7)	N/A
	2	Yes	Yes(7)	N/A	N/A	N/A	N/A

Table 58. Access status versus protection level and execution modes when TZEN = 1 (continued)

Area	RDP level	User execution (boot from Flash)			Debug/bootloader(1)		
		Read	Write	Erase	Read	Write	Erase
Backup registers	0.5	Yes	Yes	N/A	Yes(2)	Yes(2)	N/A(8)
	1	Yes	Yes	N/A	No	No	N/A(8)
	2	Yes	Yes	N/A	N/A	N/A	N/A
SRAM2/ backup RAM	0.5	Yes	Yes	N/A	Yes(2)	Yes(2)	N/A(9)
	1	Yes	Yes	N/A	No	No	N/A(9)
	2	Yes	Yes	N/A	N/A	N/A	N/A
OTFDEC regions (OCTOSPI)	0.5	Yes	Yes	Yes	No	Yes	Yes(10)
	1	Yes	Yes	Yes	No	Yes	Yes(10)
	2	Yes	Yes	Yes	N/A	N/A	N/A

1. When the protection level 2 is active, the debug port and the bootloader mode are disabled.
2. Depends on TrustZone security access rights.
3. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
4. Option bytes are only accessible through the Flash registers interface and OPTSTRT bit.
5. The Flash main memory is erased when the RDP option byte regresses from level 1 to level 0.
6. SWAP_BANK option bit can be modified.
7. OTP can only be written once.
8. The backup registers are erased when RDP changes from level 1 to level 0 and when RDP changes from level 1 to level 0.5.
9. All SRAMs are erased when RDP changes from level 1 to level 0 and when RDP changes from level 1 to level 0.5.
10. The OTFDEC keys are erased when the RDP option byte changes from level 1 to level 0 and when RDP changes from level 1 to level 0.5.

Device life cycle managed by readout protection (RDP) transitions

It is easy to move from level 0 or level 0.5 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 0.5 or from level 1. Once in level 2, it is no longer possible to modify the readout protection level unless an OEM2 key is provisioned (refer to *OEM2 RDP lock mechanism*).

When the RDP is reprogrammed to the value 0xAA to move from level 1 to level 0, a mass erase of the Flash main memory and all SRAMs is performed. The backup registers, the OTFDEC keys, ICACHE, DCACHE, and PKA SRAM are also erased. The OTP area is not erased.

At RDP level 0.5, it is not possible to request RDP level 0. Instead, a RDP increase to level 1 followed by a RDP regression to level 0 is required.

When the RDP is programmed to the value 0x55 to move from level 1 to level 0.5, a partial mass erase of the Flash main memory is performed. Only non-secure watermark-based areas are erased (even if it is defined as secure by block-based). The backup registers, the OTFDEC keys, ICACHE, DCACHE, PKA SRAM, and all SRAMs are mass erased. The

OTP area is not erased. The RDP level 0.5 and partial non-secure erase are only available when TrustZone is active.

Note: Full mass erase is performed only when level 1 is active and level 0 requested. When the protection level is increased (0 to 0.5, 0 to 1, 0.5 to 1, 1 to 2, 0 to 2 or 0.5 to 2), there is no mass erase.

To validate the readout protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in FLASH non-secure control register (FLASH_NSCR).

Before launching a RDP regression, the software must invalidate the ICACHE and wait for the BUSYF bit to get cleared.

Figure 22. RDP level transition scheme when TrustZone is disabled (TZEN = 0)

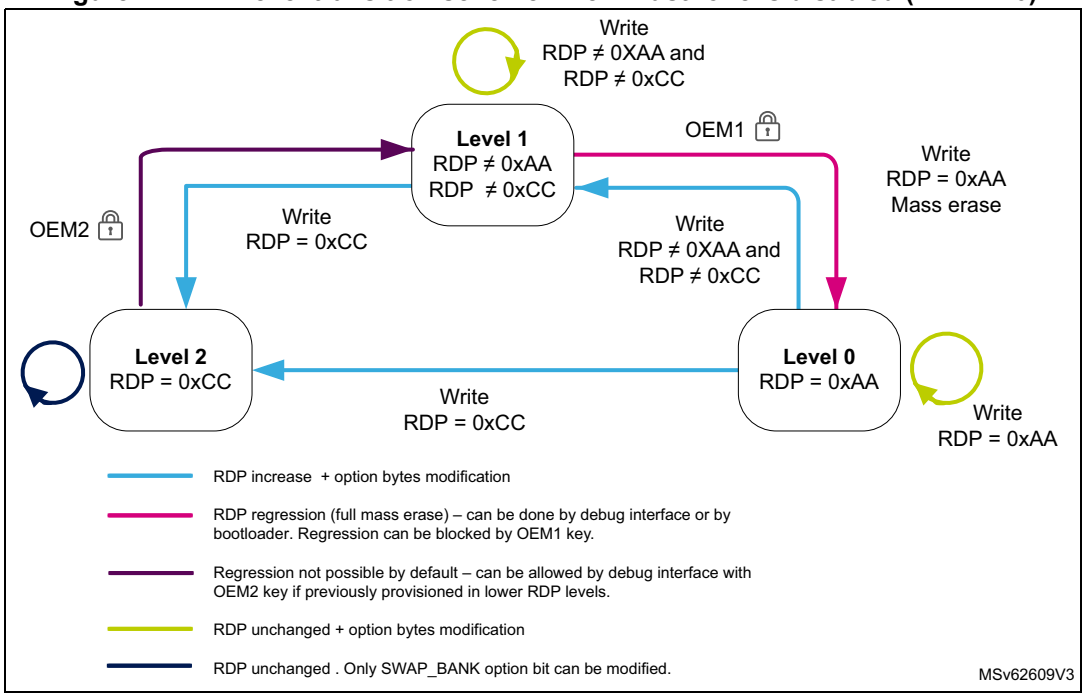

Figure 23. RDP level transition scheme when TrustZone is enabled (TZEN = 1)

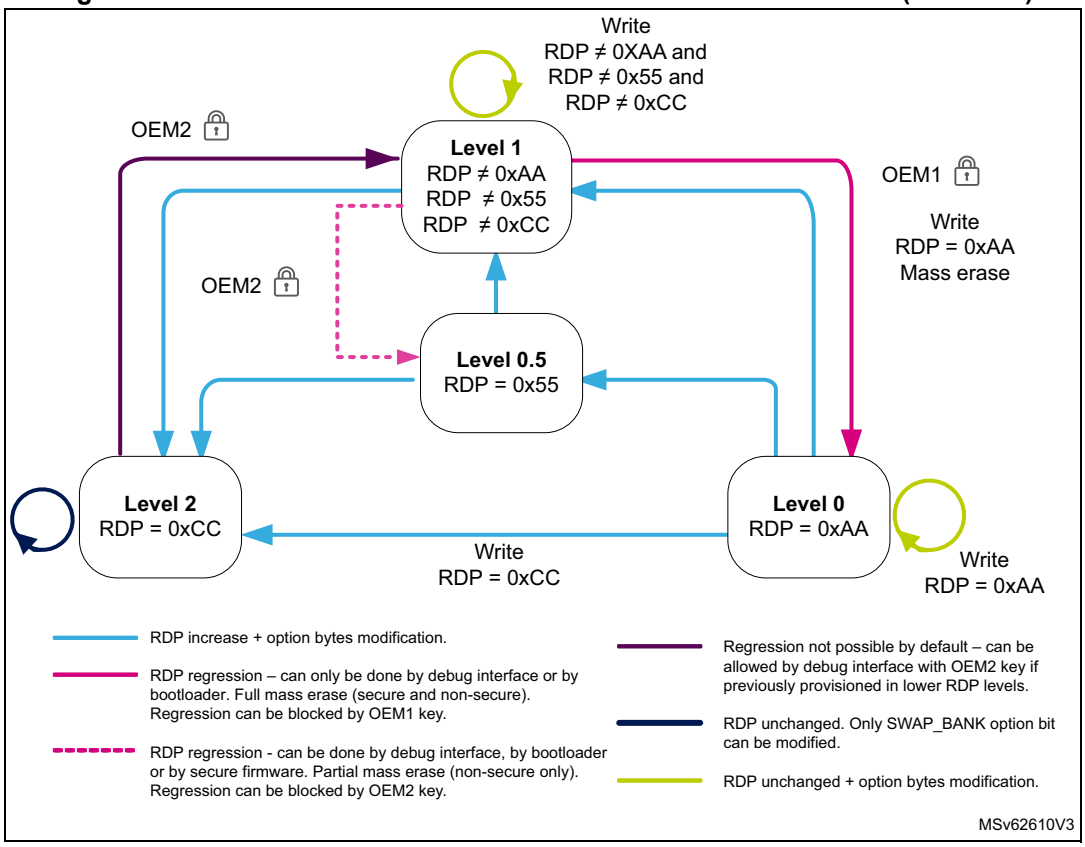

OEM1/OEM2 lock activation

Two 64-bit keys (OEM1KEY and OEM2KEY) can be defined in order to lock the RDP regression. Each 64-bit key is coded on two registers *FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)* (resp. *FLASH OEM2 key register 1 (FLASH_OEM2KEYR1)*) and *FLASH OEM1 key register 2 (FLASH_OEM1KEYR2)* resp. *FLASH OEM2 key register 2 (FLASH_OEM2KEYR2)*. OEM1KEY and OEM2KEY cannot be read through these registers. They are read as zero.

OEM1KEYcan be modified:

- in readout protection level 0
- in readout protection level 0.5 or 1 if OEM1LOCK = 0 in *FLASH non-secure status register (FLASH_NSSR)*

OEM2KEYcan be modified:

- in readout protection level 0 or 0.5
- in readout protection level 1 if OEM2LOCK = 0 in *FLASH non-secure status register (FLASH_NSSR)*

When attempting to modify the *FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)*, *FLASH OEM1 key register 2 (FLASH_OEM1KEYR2)* or *FLASH OEM2 key register 1 (FLASH_OEM2KEYR1)*, *FLASH OEM2 key register 2 (FLASH_OEM2KEYR2)* without following these rules, the user option modification is not done and the OPTWERR bit is set.

In order to activate OEM1 lock mechanism, the following steps are needed:

- Check that the OEM1LOCK bit is not set or that the readout protection is at level 0.
- Write a 64-bit key in *FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)* and *FLASH OEM1 key register 2 (FLASH_OEM1KEYR2)*.
- Launch option modification by setting the OPTSTRT bit in the *FLASH non-secure control register (FLASH_NSCR)*.
- Wait for the BSY bit to be cleared and check that OPTWERR is not set.
- Set the OBL_LAUNCH option bit to start option bytes loading or perform a power-on reset.
- Check that OEM1LOCK is set.

In order to activate OEM2 lock mechanism, the following steps are needed:

- Check that the OEM2LOCK bit is not set or that the readout protection is at level 0 or 0.5.
- Write a 64-bit key in *FLASH OEM2 key register 1 (FLASH_OEM2KEYR1)* and *FLASH OEM2 key register 2 (FLASH_OEM2KEYR2)*.
- Launch option modification by setting the OPTSTRT bit in the *FLASH non-secure control register (FLASH_NSCR)*.
- Wait for the BSY bit to be cleared and check that OPTWERR is not set.
- Set the OBL_LAUNCH option bit to start option bytes loading or perform a power-on reset.
- Check that OEM2LOCK is set.

Note: The OEM1KEY and OEM2KEY must not contain only 1 or only 0.

OEM1 RDP lock mechanism

The OEM1 RDP lock mechanism is active when the OEM1LOCK bit is set. It blocks the RDP level 1 to RDP level 0 regression.

In order to regress from RDP level 1 to RDP level 0, the following unlock sequence must be applied:

- Shift OEM1KEY[31:0] then OEM1KEY[63:32] through JTAG or SWD in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM1KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
- If the key does not match the OEM1KEY value, the RDP regression and any access to the Flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 1 to RDP level 0 without following this sequence sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM1LOCK =0), the regression from RDP level 1 to RDP level 0 is always granted.

OEM2 RDP lock mechanism

The OEM2 RDP lock mechanism is active when the OEM2LOCK bit is set. It allows the following actions:

- Block RDP level 1 to RDP level 0.5 regression.
- Authorize RDP level 2 to RDP level 1 regression.

In order to regress from RDP level 1 to RDP level 0.5, the following unlock sequence must be applied:

- Shift OEM2KEY[31:0] then OEM2KEY[63:32] through JTAG or SWD under reset in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM2KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
- If the key does not match the OEM2KEY value, the RDP regression and any access to the Flash memory are blocked until a next power-on reset.

In order to regress from RDP level 2 to RDP level 1, the following unlock sequence must be applied:

- Shift OEM2KEY[31:0] then OEM2KEY[63:32] through JTAG or SWD under reset in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM2KEY value:
  - the RDP regression is launched by hardware (it is not possible to execute instructions when the key is matching).
  - apply a power-on reset (cycle V_{DD} power supply OFF and ON).
- if the key does not match the OEM2KEY value, the RDP regression and any access to the Flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 2 to RDP level 1 without following these sequences, leaves option bytes unchanged.

Attempting to regress from RDP level 1 to RDP level 0.5 without following these sequences, sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM2LOCK =0), the following happens:

- The regression from RDP level 1 to RDP level 0.5 is always granted.
- The regression from RDP level 2 to RDP level 1 is never granted. When attempting to modify the options bytes, the protection error flag OPTWERR is set in the FLASH_NSSR register and an interrupt can be generated.

7.7 Summary of Flash memory and Flash memory registers access control

The tables below summarize all the Flash memory and registers accesses status versus RDP level, WRP and HDP protections.

Table 59. Flash memory access versus RDP level when TrustZone is active (TZEN = 1)

<table>
<tr><th colspan="2" rowspan="3">Access type</th><th colspan="3">RDP Level 0, RDP Level 0.5, RDP Level 1 no intrusion(1) or RDP Level 2</th><th>RDP Level 1 with intrusion(2)</th></tr>
<tr><th rowspan="2">Non-secure page</th><th colspan="2">Secure page</th><th rowspan="2">Non-secure or secure page</th></tr>
<tr><th>HDP area (HDPxEN=1 and ACCDIS = 1)</th><th>Others(3)</th></tr>
<tr><td rowspan="4">Secure</td><td>Fetch</td><td>Bus error</td><td rowspan="2">RAZ</td><td rowspan="2">OK</td><td rowspan="3">Bus error</td></tr>
<tr><td>Read</td><td>RAZ, Flash illegal access event</td></tr>
<tr><td>Write</td><td rowspan="2">WI, secure WRPERR flag set, Flash illegal access event</td><td rowspan="2">WI, secure WRPERR flag set</td><td rowspan="2">No WRP: OK
WRP pages: WI and secure WRPERR flag set</td></tr>
<tr><td>Page erase</td><td>WI, secure WRPERR flag set</td></tr>
<tr><td rowspan="4">Non-Secure</td><td>Fetch</td><td rowspan="2">OK</td><td colspan="2">Bus error</td><td rowspan="2">Bus error</td></tr>
<tr><td>Read</td><td colspan="2">RAZ, Flash illegal access event</td></tr>
<tr><td>Write</td><td>No WRP: OK
WRP pages: WI and non secure WRPERR flag set</td><td colspan="2" rowspan="2">WI, non secure WRPERR flag set,
Flash illegal access event</td><td rowspan="2">WI, non secure WRPERR flag set</td></tr>
<tr><td>Page erase</td></tr>
</table>

1. RDP level 1 no intrusion = when booting from user Flash memory and no debug access.
2. RDP level 1 with intrusion = when debug access detected.
3. Others refers to the other Flash memory secure configurations than the one described for HDP protections. Example: Flash memory secure and HDP area enabled but ACCDIS = 0.

Table 60. Flash memory access versus RDP level when TrustZone is disabled (TZEN = 0)

<table>
<tr><th>Access type</th><th>RDP level 0, RDP leve -1 no intrusion(1) or RDP level 2</th><th>RDP level 1 with intrusion(2)</th></tr>
<tr><td>Fetch</td><td rowspan="2">OK</td><td rowspan="2">Bus error</td></tr>
<tr><td>Read</td></tr>
<tr><td>Write</td><td rowspan="2">No WRP: OK
WRP pages: WI and non secure WRPERR flag set</td><td rowspan="2">WI and non secure WRPERR flag set</td></tr>
<tr><td>Erase</td></tr>
</table>

1. RDP Level 1 no intrusion = when booting from user Flash memory and no debug access.
2. RDP Level 1 with intrusion = when booting from RAM or system memory or debug access detected.

Table 61. Flash memory mass erase versus RDP level when TrustZone is active (TZEN = 1)

Access type		RDP level 0, RDP level 0.5, RDP level 1 no intrusion(1) or RDP level 2				RDP level 1 with intrusion(2)
		Non-secure Flash	Secure Flash		Mix non-secure and secure Flash memory	Non-secure or secure Flash memory
			HDP area (HDPxEN=1 and ACCDIS = 1)	Others(3)		
Secure	Bank or mass erase	WI, secure WRPERR flag set, Flash memory illegal access event	WI, secure WRPERR flag set	No WRP: OK WRP pages: WI and secure WRPERR flag set	WI, secure WRPERR flag set, Flash memory illegal access event	WI, secure WRPERR flag set
Non-secure	Bank or mass erase	No WRP: OK WRP pages: WI and non-secure WRPERR flag set	WI, non-secure WRPERR flag set, Flash memory illegal access event			WI, non secure WRPERR flag set

1. RDP Level 1 no intrusion = when booting from user Flash memory and no debug access.
2. RDP Level 1 with intrusion = when debug access detected.
3. Others refers to the other Flash memory secure configurations than the one described for HDP protections. Example: Flash memory secure and HDP area enabled but ACCDIS = 0.

Table 62. Flash system memory, OTP and RSS accesses(1)

Access type		System memory (bootloader)	OTP	RSS
Secure (TZEN = 1)	Fetch	Bus error		RAZ
	Read	RAZ, Flash memory register illegal access event	OK	
	Write	WI, secure WRPERR flag set, Flash memory illegal access event		WI, secure WRPERR flag set
Non-secure (TZEN = 0 or TZEN = 1)	Fetch	OK	Bus error	Bus error
	Read		OK	RAZ(2)
	Write	WI and non secure WRPERR flag set	OK if not virgin: WI, non secure PROGERR flag set	WI, non secure WRPERR flag set

1. Valid for all RDP levels.
2. Flash memory illegal access event is generated when TZEN = 1.

Table 63. Flash registers access(1)

Access type			Non-secure register		Secure register	
			NSPRIV = 1	NSPRIV = 0	SPRIV = 1	SPRIV = 0
Fetch	Secure/ non-secure	Privileged/ unprivileged	Bus error			
Read/ Write	Secure(2)	Privileged	OK			
		Unprivileged	RAZ/WI	OK	RAZ/WI	OK
	Non-secure(3)	Privileged	OK		RAZ/WI and a Flash memory register illegal access event(4)	
		Unprivileged	RAZ/WI	OK		

1. Except SECyBBRx, PRIVyBBRx and PRIVCFGR registers.
2. Secure access is only valid when TrustZone is active (TZEN = 1).
3. Non-secure access are valid when TrustZone is active or disabled.
4. Flash register illegal access event is only generated when TZEN = 1.

Table 64. Flash page access versus privilege mode(1)

Access type		Unprivileged page	Privileged page
Fetch, Read/Write, Page erase	Privileged	OK	
Fetch, Read	Unprivileged	OK	RAZ
Write, Page erase	Unprivileged		WI, secure or non secure WRPERR flag set

1. When TZEN = 1, access must be granted by security firewall before privilege is considered.

Table 65. Flash mass erase versus privilege mode(1)

Access type		Unprivileged Flash memory	Privileged Flash memory	Mix unprivileged and privileged Flash memory
Mass erase	Privileged	OK		
Mass erase	Unprivileged	OK	WI, secure or non-secure WRPERR flag set	

1. When TZEN = 1, access must be granted by security firewall before privilege is considered.

Table 66. SECyBBRx registers access when TrustZone is active (TZEN = 1)

Access type			Bit i in PRIVyBBRx	Bit i in SECyBBRx
Fetch	Secure/non-secure	Privileged/unprivileged	-	Bus error
Read	Secure/non-secure	Privileged/unprivileged	-	OK

Table 66. SECyBBRx registers access when TrustZone is active (TZEN = 1) (continued)

Access type			Bit i in PRIVyBBRx	Bit i in SECyBBRx
Write	Secure	Privileged	-	OK
		Unprivileged	0	OK for bit i
		Unprivileged	1	WI for bit i
	Non-secure	Privileged/unprivileged	-	WI and a Flash memory register illegal access event

Table 67. PRIVyBBRx registers access when TrustZone is active (TZEN = 1)

Access type			Page secure state (watermark or blocked based)	Bit i in PRIVyBBRx
Fetch	Privileged/unprivileged	Secure/non-secure	-	Bus error
Read	Privileged/unprivileged	Secure/non-secure	-	OK for all bits
Write	Privileged	Secured	-	OK for all bits
		Non-secure	Non-secure	OK for bit i
		Non-secure	Secure	WI for bit i
	Unprivileged	Secured/non-secure	-	WI for all bits

Table 68. PRIVyBBRx registers access when TrustZone is disabled (TZEN = 0)

Access type		PRIVyBBRx
Fetch	Privileged/unprivileged	Bus error
Read	Privileged/unprivileged	OK
Write	Privileged	OK
	Unprivileged	WI

7.8 FLASH interrupts

Table 69. Flash interrupt requests

Interrupt vector	Interrupt event	Event flag	Event flag/interrupt clearing method	Interrupt enable control bit	Exit Sleep mode	Exit Stop and Standby modes
FLASH_S	Secure end of operation	Secure EOP(1)	Write secure EOP = 1	Secure EOPIE	Yes	No
	Secure operation error	Secure OPERR(2)	Write secure OPERR = 1	Secure ERRIE	Yes	No

Table 69. Flash interrupt requests (continued)

Interrupt vector	Interrupt event	Event flag	Event flag/interrupt clearing method	Interrupt enable control bit	Exit Sleep mode	Exit Stop and Standby modes
FLASH	Non-secure end of operation	Non-secure EOP(1)	Write non-secure EOP = 1	Non-secure EOPIE	Yes	No
	Non-secure operation error	Non-secure OPERR(2)	Write non-secure OPERR = 1	Non-secure ERRIE	Yes	No
	ECC correction	ECCC	Write ECCC=1	ECCCIE	Yes	No

1. Secure EOP (resp. non-secure EOP) is set only if secure EOPIE (resp. non-secure EOPIE) is set.
2. Secure OPERR (resp. non-secure OPERR) is set only if secure ERRIE (resp. non-secure ERRIE) is set.

7.9 FLASH registers

7.9.1 FLASH access control register (FLASH_ACR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait state when no Flash memory read is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SLEEP_PD	PDREQ2	PDREQ1	LPM	Res.	Res.	PRFTEN	Res.	Res.	Res.	Res.	LATENCY[3:0]			
	rw	rs	rs	rw			rw					rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **SLEEP_PD**: Flash memory power-down mode during Sleep mode

This bit determines whether the Flash memory is in power-down mode or Idle mode when the device is in Sleep mode.

0: Flash in Idle mode during Sleep mode

1: Flash in power-down mode during Sleep mode

Caution: The Flash must not be put in power-down while a program or an erase operation is ongoing.

Bit 13 **PDREQ2**: Bank 2 power-down mode request
This bit is write-protected with FLASH_PDKEY2R. This bit requests bank 2 to enter power-down mode. When bank 2 enters power-down mode, this bit is cleared by hardware and the PDKEY2R is locked.
0: No request for bank 2 to enter power-down mode
1: Bank 2 requested to enter power-down mode

Bit 12 **PDREQ1**: Bank 1 power-down mode request
This bit is write-protected with FLASH_PDKEY1R. This bit requests bank 1 to enter power-down mode. When bank 1 enters power-down mode, this bit is cleared by hardware and the PDKEY1R is locked.
0: No request for bank 1 to enter power-down mode
1: Bank 1 requested to enter power-down mode

Bit 11 **LPM**: Low-power read mode
This bit puts the Flash memory in low-power read mode.
0: Flash not in low-power read mode
1: Flash in low-power read mode

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **PRFTEN**: Prefetch enable
This bit enables the prefetch buffer in the embedded Flash memory.
0: Prefetch disabled
1: Prefetch enabled

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **LATENCY[3:0]**: Latency
These bits represent the ratio between the HCLK (AHB clock) period and the Flash memory access time.
0000: Zero wait state
0001: One wait state
0010: Two wait states
...
1111: Fifteen wait states

7.9.2 FLASH non-secure key register (FLASH_NSKEYR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV =1 in the FLASH_PRIVCFGR register.

Address offset: 0x08

Reset value: 0x0000 0000

Access: one wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NSKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NSKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **NSKEY[31:0]**: Flash memory non-secure key

The following values must be written consecutively to unlock the FLASH_NSCR register, allowing the Flash memory non-secure programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

7.9.3 FLASH secure key register (FLASH_SECKEYR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x0C

Reset value: 0x0000 0000

Access: one wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SECKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SECKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **SECKEY[31:0]**: Flash memory secure key

The following values must be written consecutively to unlock the FLASH_SECCR register, allowing the Flash memory secure programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

7.9.4 FLASH option key register (FLASH_OPTKEYR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x10

Reset value: 0x0000 0000

Access: one wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPTKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OPTKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OPTKEY[31:0]**: Option byte key

The following values must be written consecutively to unlock the FLASH_OPTR register allowing option byte programming/erasing operations:
KEY1: 0x0819 2A3B
KEY2: 0x4C5D 6E7F

7.9.5 FLASH bank 1 power-down key register (FLASH_PDKEY1R)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x18

Reset value: 0x0000 0000

Access: no wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PDKEY1[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PDKEY1[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **PDKEY1[31:0]**: Bank 1 power-down key

The following values must be written consecutively to unlock the PDREQ1 bit in FLASH_ACR:
PDKEY1_1: 0x0415 2637
PDKEY1_2: 0xFAFB FCFD

7.9.6 FLASH bank 2 power-down key register (FLASH_PDKEY2R)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x1C

Reset value: 0x0000 0000

Access: no wait state; word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PDKEY2[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PDKEY2[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **PDKEY2[31:0]**: Bank 2 power-down key

The following values must be written consecutively to unlock the PDREQ2 bit in FLASH_ACR:
PDKEY2_1: 0x4051 6273
PDKEY2_2: 0xAFBF CFDF

7.9.7 FLASH non-secure status register (FLASH_NSSR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x20

Reset value: 0x000X 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PD2	PD1	OEM2LOCK	OEM1LOCK	WDW	BSY
										r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	OPTWERR	Res.	Res.	Res.	Res.	Res.	PGSERR	SIZERR	PGAERR	WRPERR	PROGERR	Res.	OPERR	EOP
		rc_w1						rc_w1	rc_w1	rc_w1	rc_w1	rc_w1		rc_w1	rc_w1

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **PD2**: Bank 2 in power-down mode

This bit indicates that the Flash memory bank 2 is in power-down state. It is reset when bank 2 is in normal mode or being awaken.

Bit 20 **PD1**: Bank 1 in power-down mode

This bit indicates that the Flash memory bank 1 is in power-down state. It is reset when bank 1 is in normal mode or being awaken.

Bit 19 **OEM2LOCK**: OEM2 lock

This bit indicates that the OEM2 RDP key read during the OBL is not virgin. When set, the OEM2 RDP lock mechanism is active.

Bit 18 **OEM1LOCK**: OEM1 lock

This bit indicates that the OEM1 RDP key read during the OBL is not virgin. When set, the OEM1 RDP lock mechanism is active.

Bit 17 **WDW**: Non-secure wait data to write

This bit indicates that the Flash memory write buffer has been written by a secure or non-secure operation. It is set when the first data is stored in the buffer and cleared when the write is performed in the Flash memory.

Bit 16 **BSY**: Non-secure busy

This indicates that a Flash memory secure or non-secure operation is in progress. This bit is set at the beginning of a Flash operation and reset when the operation finishes or when an error occurs.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OPTWERR**: Option write error

This bit is set by hardware when the options bytes are written with an invalid configuration. It is cleared by writing 1.

Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **PGSERR**: Non-secure programming sequence error

This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1.

Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.

Bit 6 **SIZERR**: Non-secure size error

This bit is set by hardware when the size of the access is a byte or half-word during a non-secure program sequence. Only quad-word programming is allowed by means of successive word accesses. This bit is cleared by writing 1.

Bit 5 **PGAERR**: Non-secure programming alignment error

This bit is set by hardware when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address. This bit is cleared by writing 1.

Bit 4 **WRPERR**: Non-secure write protection error

This bit is set by hardware when a non-secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the Flash memory. This bit is cleared by writing 1.

Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.

Bit 3 **PROGERR**: Non-secure programming error

This bit is set by hardware when a non-secure quad-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Non-secure operation error

This bit is set by hardware when a Flash memory non-secure operation (program/erase) completes unsuccessfully. This bit is set only if non-secure error interrupts are enabled (NSERRIE = 1). This bit is cleared by writing 1.

Bit 0 **EOP**: Non-secure end of operation

This bit is set by hardware when one or more Flash memory non-secure operation (program/erase) has been completed successfully. This bit is set only if the non-secure end of operation interrupts are enabled (EOPIE = 1 in FLASH_NSCR). This bit is cleared by writing 1.

7.9.8 FLASH secure status register (FLASH_SECSR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x24

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WDW	BSY
														r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PGSERR	SIZERR	PGAERR	WRPERR	PROGERR	Res.	OPERR	EOP
								rc_w1	rc_w1	rc_w1	rc_w1	rc_w1		rc_w1	rc_w1

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **WDW**: Secure wait data to write

This bit indicates that the Flash memory write buffer has been written by a secure or non-secure operation. It is set when the first data is stored in the buffer and cleared when the write is performed in the Flash memory.

Bit 16 **BSY**: Secure busy

This bit indicates that a Flash memory secure or non-secure operation is in progress. This is set on the beginning of a Flash operation and reset when the operation finishes or when an error occurs.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **PGSERR**: Secure programming sequence error

This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1.

Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.

Bit 6 **SIZERR**: Secure size error

This bit is set by hardware when the size of the access is a byte or half-word during a secure program sequence. Only quad-word programming is allowed by means of successive word accesses.This bit is cleared by writing 1.

Bit 5 **PGAERR**: Secure programming alignment error

This bit is set by hardware when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address.This bit is cleared by writing 1.

Bit 4 **WRPERR**: Secure write protection error

This bit is set by hardware when a secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the Flash memory.This bit is cleared by writing 1.

Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.

Bit 3 **PROGERR**: Secure programming error

This bit is set by hardware when a secure quad-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Secure operation error

This bit is set by hardware when a Flash memory secure operation (program/erase) completes unsuccessfully. This bit is set only if secure error interrupts are enabled (SECERRIE = 1). This bit is cleared by writing 1.

Bit 0 **EOP**: Secure end of operation

This bit is set by hardware when one or more Flash memory secure operation (program/erase) has been completed successfully. This bit is set only if the secure end of operation interrupts are enabled (EOPIE = 1 in FLASH_SECCR). This bit is cleared by writing 1.

7.9.9 FLASH non-secure control register (FLASH_NSCR)

This register can only be written when the BSY or OBL_LAUNCH are reset. Otherwise, the write access is stalled until the BSY bits are reset.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x28

Reset value: 0xC000 0000

Access: no wait state when no Flash memory operation is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK:** Non-secure lock

This bit is set only. When set, the FLASH_NSCR register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_NSKEYR register.

In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30 **OPTLOCK:** Option lock

This bit is set only. When set, all bits concerning user options in FLASH_NSCR register are locked. This bit is cleared by hardware after detecting the unlock sequence. The LOCK bit in the FLASH_NSCR must be cleared before doing the unlock sequence for OPTLOCK bit.

In case of an unsuccessful unlock operation, this bit remains set until the next reset.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **OBL_LAUNCH**: Force the option byte loading
When set to 1, this bit forces the option byte reloading. This bit is cleared only when the option byte loading is complete. It cannot be written if OPTLOCK is set.
0: Option byte loading complete
1: Option byte loading requested

Bit 26 Reserved, must be kept at reset value.

Bit 25 **ERRIE**: Non-secure error interrupt enable
This bit enables the interrupt generation when the OPERR bit in the FLASH_NSSR is set to 1.
0: Non-secure OPERR error interrupt disabled
1: Non-secure OPERR error interrupt enabled

Bit 24 **EOPIE**: Non-secure end of operation interrupt enable
This bit enables the interrupt generation when the EOP bit in the FLASH_NSSR is set to 1.
0: Non-secure EOP Interrupt disabled
1: Non-secure EOP Interrupt enabled

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **OPTSTRT**: Options modification start
This bit triggers an options operation when set. It can not be written if OPTLOCK bit is set. This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_NSSR.

Bit 16 **STRT**: Non-secure start
This bit triggers a non-secure erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, the PGSERR bit in FLASH_NSSR is set (this condition is forbidden).
This bit is set only by software and is cleared when the BSY bit is cleared in FLASH_NSSR.

Bit 15 **MER2**: Non-secure bank 2 mass erase
This bit triggers the bank 2 non-secure mass erase (all bank 2 user pages) when set.

Bit 14 **BWR**: Non-secure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Non-secure bank selection for page erase
0: Bank 1 selected for non-secure page erase
1: Bank 2 selected for non-secure page erase

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Non-secure page number selection
These bits select the page to erase.
0000000: page 0
0000000: page 1
...
1111111: page 127

Bit 2 **MER1**: Non-secure bank 1 mass erase
This bit triggers the bank 1 non-secure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Non-secure page erase
0: Non-secure page erase disabled
1: Non-secure page erase enabled

Bit 0 **PG**: Non-secure programming
0: Non-secure Flash programming disabled
1: Non-secure Flash programming enabled

7.9.10 FLASH secure control register (FLASH_SECCR)

This register can only be written when the BSY or OBL_LAUNCH are reset. Otherwise, the write access stalls until the BSY bits are reset.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x2C

Reset value: 0x8000 0000

Access: no wait state when no Flash memory operation is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK:** Secure lock
This bit is set only. When set, the FLASH_SECCR register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_SECKEYR register.
In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **INV:** Flash memory security state invert
This bit inverts the Flash memory security state.

Bits 28:26 Reserved, must be kept at reset value.

Bit 25 **ERRIE**: Secure error interrupt enable
This bit enables the interrupt generation when the OPERR bit in the FLASH_SECSR is set to 1.
0: Secure OPERR error interrupt disabled
1: Secure OPERR error interrupt enabled

Bit 24 **EOPIE**: Secure End of operation interrupt enable
This bit enables the interrupt generation when the EOP bit in the FLASH_SECSR is set to 1.
0: Secure EOP Interrupt disabled
1: Secure EOP Interrupt enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **STRT**: Secure start
This bit triggers a secure erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, the PGSERR in the FLASH_SECSR is set (this condition is forbidden).
This bit is set only by software and is cleared when the BSY bit is cleared in FLASH_SECSR.

Bit 15 **MER2**: Secure bank 2 mass erase
This bit triggers the bank 2 secure mass erase (all bank 2 user pages) when set.

Bit 14 **BWR**: Secure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Secure bank selection for page erase
0: Bank 1 selected for secure page erase
1: Bank 2 selected for secure page erase

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Secure page number selection
These bits select the page to erase:
00000000: page 0
00000001: page 1
...
11111111: page 127

Bit 2 **MER1**: Secure bank 1 mass erase
This bit triggers the bank 1 secure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Secure page erase
0: Secure page erase disabled
1: Secure page erase enabled

Bit 0 **PG**: Secure programming
0: Secure Flash programming disabled
1: Secure Flash programming enabled

7.9.11 FLASH ECC register (FLASH_ECCR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x30

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECCD	ECCC	Res.	Res.	Res.	Res.	Res.	ECCIE	Res.	SYSF_ECC	BK_ECC	Res.	ADDR_ECC[19:16]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ECCD**: ECC detection

This bit is set by hardware when two ECC errors have been detected (only if ECCC and ECCD were previously cleared). When this bit is set, a NMI is generated. This bit is cleared by writing 1.

Bit 30 **ECCC**: ECC correction

This bit is set by hardware when one ECC error has been detected and corrected (only if ECCC and ECCD were previously cleared). An interrupt is generated if ECCIE is set. This bit is cleared by writing 1.

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **ECCIE**: ECC correction interrupt enable

This bit enables the interrupt generation when the ECCC bit in the FLASH_ECCR register is set.

0: ECCC interrupt disabled

1: ECCC interrupt enabled.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SYSF_ECC**: System Flash memory ECC fail

This bit indicates that the ECC error correction or double ECC error detection is located in the system Flash memory.

Bit 21 **BK_ECC**: ECC fail bank

This bit indicates which bank is concerned by the ECC error correction or by the double ECC error detection.

0: Bank 1

1: Bank 2

Bit 20 Reserved, must be kept at reset value.

Bits 19:0 **ADDR_ECC[19:0]**: ECC fail address

This field indicates which address is concerned by the ECC error correction or by the double ECC error detection. The address is given by bank from address 0x0 0000 to 0xF FFF0.

7.9.12 FLASH operation status register (FLASH_OPSR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x34

Reset value: 0xX0XX XXXX

(0xX0XX XXXX after system reset and 0x0000 0000 after power-on reset)

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADDR_OP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 **CODE_OP[2:0]**: Flash memory operation code

This field indicates which Flash memory operation has been interrupted by a system reset:
000: No Flash operation interrupted by previous reset
001: Single write operation interrupted
010: Burst write operation interrupted
011: Page erase operation interrupted
100: Bank erase operation interrupted
101: Mass erase operation interrupted
110: Option change operation interrupted
111: Reserved

Bits 28:23 Reserved, must be kept at reset value.

Bit 22 **SYSF_OP**: Operation in system Flash memory interrupted

This bit indicates that the reset occurred during an operation in the system Flash memory.

Bit 21 **BK_OP**: Interrupted operation bank

This bit indicates which Flash memory bank was accessed when reset occurred
0: Bank 1
1: Bank 2

Bit 20 Reserved, must be kept at reset value.

Bits 19:0 **ADDR_OP[19:0]**: Interrupted operation address

This field indicates which address in the Flash memory was accessed when reset occurred. The address is given by bank from address 0x0 0000 to 0xF FFF0.

7.9.13 FLASH option register (FLASH_OPTR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x40

Reset value: 0xXXXX XXXX (register bits 0 to 31 are loaded with values from the Flash memory at OBL)

ST production value: 0x1FEF F8AA

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **TZEN:** Global TrustZone security enable
0: Global TrustZone security disabled
1: Global TrustZone security enabled

Bit 30 **IO_VDDIO2_HSLV:** High-speed IO at low V_{DDIO2} voltage configuration bit
This bit can be set only with V_{DDIO2} below 2.5 V.
0: High-speed IO at low V_{DDIO2} voltage feature disabled (V_{DDIO2} can exceed 2.5 V)
1: High-speed IO at low V_{DDIO2} voltage feature enabled (V_{DDIO2} remains below 2.5 V)

Bit 29 **IO_VDD_HSLV:** High-speed IO at low V_{DD} voltage configuration bit
This bit can be set only with V_{DD} below 2.5V
0: High-speed IO at low V_{DD} voltage feature disabled (V_{DD} can exceed 2.5 V)
1: High-speed IO at low V_{DD} voltage feature enabled (V_{DD} remains below 2.5 V)

Bit 28 **PA15_PUPEN:** PA15 pull-up enable
0: USB power delivery dead-battery enabled/TDI pull-up deactivated
1: USB power delivery dead-battery disabled/TDI pull-up activated

Bit 27 **NBOOT0:** NBOOT0 option bit
0: NBOOT0 = 0
1: NBOOT0 = 1

Bit 26 **NSWBOOT0:** Software BOOT0
0: BOOT0 taken from the option bit NBOOT0
1: BOOT0 taken from PH3/BOOT0 pin

Bit 25 **SRAM2_RST:** SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs

Bit 24 **SRAM2_ECC:** SRAM2 ECC detection and correction enable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bit 23 **SRAM3_ECC:** SRAM3 ECC detection and correction enable
0: SRAM3 ECC check enabled
1: SRAM3 ECC check disabled

Bit 22 **BKPRAM_ECC:** Backup RAM ECC detection and correction enable
0: Backup RAM ECC check enabled
1: Backup RAM ECC check disabled

Bit 21 **DUALBANK:** Dual-bank on 1-Mbyte Flash memory devices
0: Single bank Flash with contiguous address in bank 1
1: Dual-bank Flash with contiguous addresses

Bit 20 **SWAP_BANK:** Swap banks
0: Bank 1 and bank 2 addresses not swapped
1: Bank 1 and bank 2 addresses swapped

Bit 19 **WWDG_SW:** Window watchdog selection
0: Hardware window watchdog selected
1: Software window watchdog selected

Bit 18 **IWDG_STDBY:** Independent watchdog counter freeze in Standby mode
0: Independent watchdog counter frozen in Standby mode
1: Independent watchdog counter running in Standby mode

Bit 17 **IWDG_STOP:** Independent watchdog counter freeze in Stop mode
0: Independent watchdog counter frozen in Stop mode
1: Independent watchdog counter running in Stop mode

Bit 16 **IWDG_SW:** Independent watchdog selection
0: Hardware independent watchdog selected
1: Software independent watchdog selected

Bit 15 **SRAM1345_RST:** SRAM1, SRAM3 and SRAM4 erase upon system reset
0: SRAM1, SRAM3 and SRAM4 erased when a system reset occurs
1: SRAM1, SRAM3 and SRAM4 not erased when a system reset occurs

Bit 14 **NRST_SHDW:** Reset generation in Shutdown mode
0: Reset generated when entering the Shutdown mode
1: No reset generated when entering the Shutdown mode

Bit 13 **NRST_STDBY:** Reset generation in Standby mode
0: Reset generated when entering the Standby mode
1: No reset generate when entering the Standby mode

Bit 12 **NRST_STOP:** Reset generation in Stop mode
0: Reset generated when entering the Stop mode
1: No reset generated when entering the Stop mode

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **BOR_LEV[2:0]:** BOR reset level

These bits contain the V_{DD} supply level threshold that activates/releases the reset.
000: BOR level 0 (reset level threshold around 1.7 V)
001: BOR level 1 (reset level threshold around 2.0 V)
010: BOR level 2 (reset level threshold around 2.2 V)
011: BOR level 3 (reset level threshold around 2.5 V)
100: BOR level 4 (reset level threshold around 2.8 V)

Bits 7:0 **RDP[7:0]:** Readout protection level

0xAA: Level 0 (readout protection not active)
0x55: Level 0.5 (readout protection not active, only non-secure debug access is possible). Only available when TrustZone is active (TZEN=1)
0xCC: Level 2 (chip readout protection active)
Others: Level 1 (memories readout protection active)

Note: Refer to Section 7.6.2: Readout protection (RDP) for more details.

7.9.14 FLASH non-secure boot address 0 register (FLASH_NSBOOTADD0R)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x44

Reset value: 0xXXXX XXXX (option bytes are loaded with values from the Flash memory at reset release)

ST production value: 0x0800 007F

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NSBOOTADD0[24:9]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NSBOOTADD0[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw							

Bits 31:7 **NSBOOTADD0[24:0]**: Non-secure boot base address 0

The non-secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. The NSBOOTADD0 option bytes are selected following the BOOT0 pin or NSWBOOT0 state.
Examples:
NSBOOTADD0[24:0] = 0x0100000: Boot from non-secure Flash memory (0x0800 0000)
NSBOOTADD0[24:0] = 0x017F200: Boot from system memory bootloader (0x0BF9 0000)
NSBOOTADD0[24:0] = 0x0400000: Boot from non-secure SRAM1 on S-Bus (0x2000 0000)

Bits 6:0 Reserved, must be kept at reset value.

7.9.15 FLASH non-secure boot address 1 register (FLASH_NSBOOTADD1R)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x48

Reset value: 0xXXXX XXXX (option bytes are loaded with values from the Flash memory at reset release)

ST production value: 0x0BF9 007F

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NSBOOTADD1[24:9]

NSBOOTADD1[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw							

Bits 31:7 **NSBOOTADD1[24:0]**: Non-secure boot address 1

The non-secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. The NSBOOTADD0 option bytes are selected following the BOOT0 pin or NSWBOOT0 state.

Examples:

NSBOOTADD1[24:0] = 0x0100000: Boot from non-secure Flash memory (0x0800 0000)

NSBOOTADD1[24:0] = 0x017F200: Boot from system memory bootloader (0x0BF9 0000)

NSBOOTADD1[24:0] = 0x0400000: Boot from non-secure SRAM1 on S-Bus (0x2000 0000)

Bits 6:0 Reserved, must be kept at reset value.

7.9.16 FLASH secure boot address 0 register (FLASH_SECBOOTADD0R)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x4C

Reset value: 0xXXXX XXXX (option bytes are loaded with values from the Flash memory at reset release)

ST production value: 0x0C00 007C

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SECBOOTADD0[8:0]									Res.	Res.	Res.	Res.	Res.	Res.	BOOT_LOCK
rw	rw	rw	rw	rw	rw	rw	rw	rw							rw

Bits 31:7 **SECBOOTADD0[24:0]**: Secure boot base address 0

The secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. This bits correspond to address [31:7] The SECBOOTADD0 option bytes are selected following the BOOT0 pin or NSWBOOT0 state.

Examples:

SECBOOTADD0[24:0] = 0x018 0000: Boot from secure Flash memory (0x0C00 0000)

SECBOOTADD0[24:0] = 0x01F F000: Boot from RSS (0x0FF8 0000)

SECBOOTADD0[24:0] = 0x060 0000: Boot from secure SRAM1 on S-Bus (0x3000 0000)

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **BOOT_LOCK**: Boot lock

When set, the boot is always forced to base address value programmed in SECBOOTADD0[24:0] option bytes whatever the boot selection option. When set, this bit can only be cleared when RDP is at Level 0.

7.9.17 FLASH secure watermark1 register 1 (FLASH_SECWM1R1)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x50

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL, reserved bits are read as 1)

ST production value: 0xFFFF FF80

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **SECWM1_PEND[6:0]:** End page of first secure area
This field contains the last page of the secure area in bank 1.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **SECWM1_PSTRT[6:0]:** Start page of first secure area
This field contains the first page of the secure area in bank 1.

7.9.18 FLASH secure watermark1 register 2 (FLASH_SECWM1R2)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x54

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL)

ST production value: 0x7F80 7F80

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **HDP1EN**: Hide protection first area enable
0: No HDP area 1
1: HDP first area enabled

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **HDP1_PEND[6:0]**: End page of first hide protection area
This field contains the last page of the HDP area in bank 1.

Bits 15:0 Reserved, must be kept at reset value.

7.9.19 FLASH WRP1 area A address register (FLASH_WRP1AR)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x58

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL, reserved bits are read as 1)

ST production value: 0xFF80 FFFF

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

Bit 31 **UNLOCK**: Bank 1 WPR first area A unlock
0: WRP1A start and end pages locked
1: WRP1A start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **WRP1A_PEND[6:0]**: Bank 1 WPR first area A end page
This field contains the last page of the first WPR area in bank 1.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **WRP1A_PSTRT[6:0]**: bank 1 WPR first area A start page
This field contains the first page of the first WPR area for bank 1.

7.9.20 FLASH WRP1 area B address register (FLASH_WRP1BR)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x5C

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL)

ST production value: 0xFF80 FFFF

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **UNLOCK**: Bank 1 WPR second area B unlock
0: WRP1B start and end pages locked
1: WRP1B start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **WRP1B_PEND[6:0]**: Bank 1 WRP second area B end page
This field contains the last page of the second WRP area in bank 1.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **WRP1B_PSTRT[6:0]**: Bank 1 WRP second area B start page
This field contains the first page of the second WRP area for bank 1.

7.9.21 FLASH secure watermark2 register 1 (FLASH_SECWM2R1)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x60

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL)

ST production value: 0xFFFF FF80

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **SECWM2_PEND[6:0]**: End page of second secure area
This field contains the last page of the secure area in bank 2.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **SECWM2_PSTRT[6:0]**: Start page of second secure area
This field contains the first page of the secure area in bank 2.

7.9.22 FLASH secure watermark2 register 2 (FLASH_SECWM2R2)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x64

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL)

ST production value: 0x7F80 7F80

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

Bit 31 **HDP2EN:** Hide protection second area enable
0: No HDP area 2
1: HDP second area is enabled.

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **HDP2_PEND[6:0]**: End page of hide protection second area
HDP2_PEND contains the last page of the HDP area in bank 2.

Bits 15:0 Reserved, must be kept at reset value.

7.9.23 FLASH WPR2 area A address register (FLASH_WRP2AR)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x68

Reset value: 0xXXXX XXXX (register bits are loaded with values from the Flash memory at OBL)

ST production value: 0xFF80 FFFF

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

Bit 31 **UNLOCK**: Bank 2 WPR second area B unlock
0: WRP2B start and end pages locked
1: WRP2B start and end pages unlocked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **WRP2B_PEND[6:0]**: Bank 2 WPR second area B end page
This field contains the last page of the second WRP area in bank 2.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **WRP2B_PSTRT[6:0]**: Bank 2 WPR second area B start page
This field contains the first page of the second WRP area for bank 2.

7.9.25 FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)

This register is non-secure. It can be written by both secure and non-secure access. This register is read as zero. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x70

Reset value: 0x0000 0000

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SEC1BBi:** page secure/non-secure attribution (i = 31 to 0)

Each bit is used to set one page security attribution in bank 1.

0: Page (32 * (x - 1) + i) in bank 1 not block-based secure

1: Page (32 * (x - 1) + i) in bank 1 block-based secure

7.9.30 FLASH secure block based bank 2 register x (FLASH_SECBB2Rx)

This register is secure. It can be written only by a secure access. This register can be protected against unprivileged access (refer to *Table 66: SECyBBRx registers access when TrustZone is active (TZEN = 1)*).

Address offset: 0xA0 + 4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

Bits 31:0 **SEC2BBi:** page secure/non-secure attribution (i = 31 to 0)
Each bit is used to set one page security attribution in bank 2.
0: Page (32 * (x - 1) + i) in bank 2 not block-based secure
1: Page (32 * (x - 1) + i) in bank 2 block-based secure

7.9.31 FLASH secure HDP control register (FLASH_SECHDPCR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0xC0

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP2_ACCDIS	HDP1_ACCDIS
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HDP2_ACCDIS:** HDP2 area access disable
When set, this bit is only cleared by a system reset.
0: Access to HDP2 area granted
1: Access to HDP2 area denied (SECWM2Ry option bytes modification bocked -refer to *Rules for modifying specific option bytes*)

Bit 0 **HDP1_ACCDIS:** HDP1 area access disable
When set, this bit is only cleared by a system reset.
0: Access to HDP1 area granted
1: Access to HDP1 area denied (SECWM1Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*)

7.9.32 FLASH privilege configuration register (FLASH_PRIVCFGR)

This register can be read by both privileged and unprivileged access. NSPRIV is a non-secure bit. SPRIV is a secure bit.

Address offset: 0xC4.

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: Privileged protection for non-secure registers

This bit can be read by both privileged or unprivileged, secure and non-secure access.

0: Non-secure Flash registers can be read and written by privileged or unprivileged access.

1: Non-secure Flash registers can be read and written by privileged access only.

The NSPRIV bit can be written by a secure or non-secure privileged access. A secure or non-secure unprivileged write access on NSPRIV bit is ignored.

Bit 0 **SPRIV**: Privileged protection for secure registers

This bit can be accessed only when TrustZone is enabled (TZEN = 1). This bit can be read by both privileged or unprivileged, secure and non-secure access.

0: Secure Flash registers can be read and written by privileged or unprivileged access.

1: Secure Flash registers can be read and written by privileged access only.

The SPRIV bit can be written only by a secure privileged access. A non-secure write access on SPRIV bit is ignored. A secure unprivileged write access on SPRIV bit is ignored.

7.9.33 FLASH privilege block based bank 1 register x (FLASH_PRIVBB1Rx)

This register is privileged. It can be read written only by a privileged access. This register can be protected against non-secure access (refer to *Table 67: PRIVyBBRx registers access when TrustZone is active (TZEN = 1)*).

Address offset: 0xD0 + 4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIV1BBi:** page privileged/unprivileged attribution (i = 31 to 0)

Each bit is used to set one page privilege attribution in bank 1.

0: Page (32 * (x - 1) + i) in bank 1 accessible by unprivileged access

1: Page (32 * (x - 1) + i) in bank 1 only accessible by privileged access

7.9.34 FLASH privilege block based bank 2 register x (FLASH_PRIVBB2Rx)

This register is privilege. It can be read written only by a privileged access. This register can be protected against non-secure access (refer to *Table 67: PRIVyBBRx registers access when TrustZone is active (TZEN = 1)*).

Address offset: 0xF0 + 4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

Refer to *Section 2.3* for the register boundary addresses.

8 Instruction cache (ICACHE)

8.1 Introduction

The instruction cache (ICACHE) is introduced on C-AHB code bus of Cortex-M33 processor to improve performance when fetching instruction and data from internal and external memories.

Some specific features like dual master ports, hit-under-miss and critical-word-first refill policy, allow close to zero-wait-state performance in most use cases.

8.2 ICACHE main features

The main features of ICACHE are described below:

- Bus interface
  - one 32-bit AHB slave port, the execution port (input from Cortex-M33 C-AHB code interface)
  - two AHB master ports: master1 and master2 ports (outputs to Fast and Slow buses of main AHB bus matrix, respectively)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master access: feature used to decouple the traffic according to targeted memory. For example, ICACHE assigns fast traffic (addressing FLASH and SRAM memories) to the AHB master1 port, and slow traffic (addressing external memories sitting on OCTOSPI and FMC interfaces) to AHB master2 port, thus preventing processor stalls on lines refills from external memories. This allows ISR (interrupt service routine) fetching on internal FLASH memory to take place in parallel with a cache line refill from external memories.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, w, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Memory address remap
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the Code region, for execution from C-AHB code interface)
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls

  - Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)
- Performance counters

  ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt
- TrustZone security support
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, non interruptible

8.3 ICACHE implementation

Table 71. ICACHE features

Feature	ICACHE
Number of ways	2
Cache size	8 Kbytes
Cache line width	16 bytes
Range granularity of memory regions to be remapped	2 Mbytes
Number of regions to remap	4
Data size of AHB slave interface	32 bits
Data size of AHB fast master1 interface	128 bits
Data size of AHB slow master2 interface	32 bits

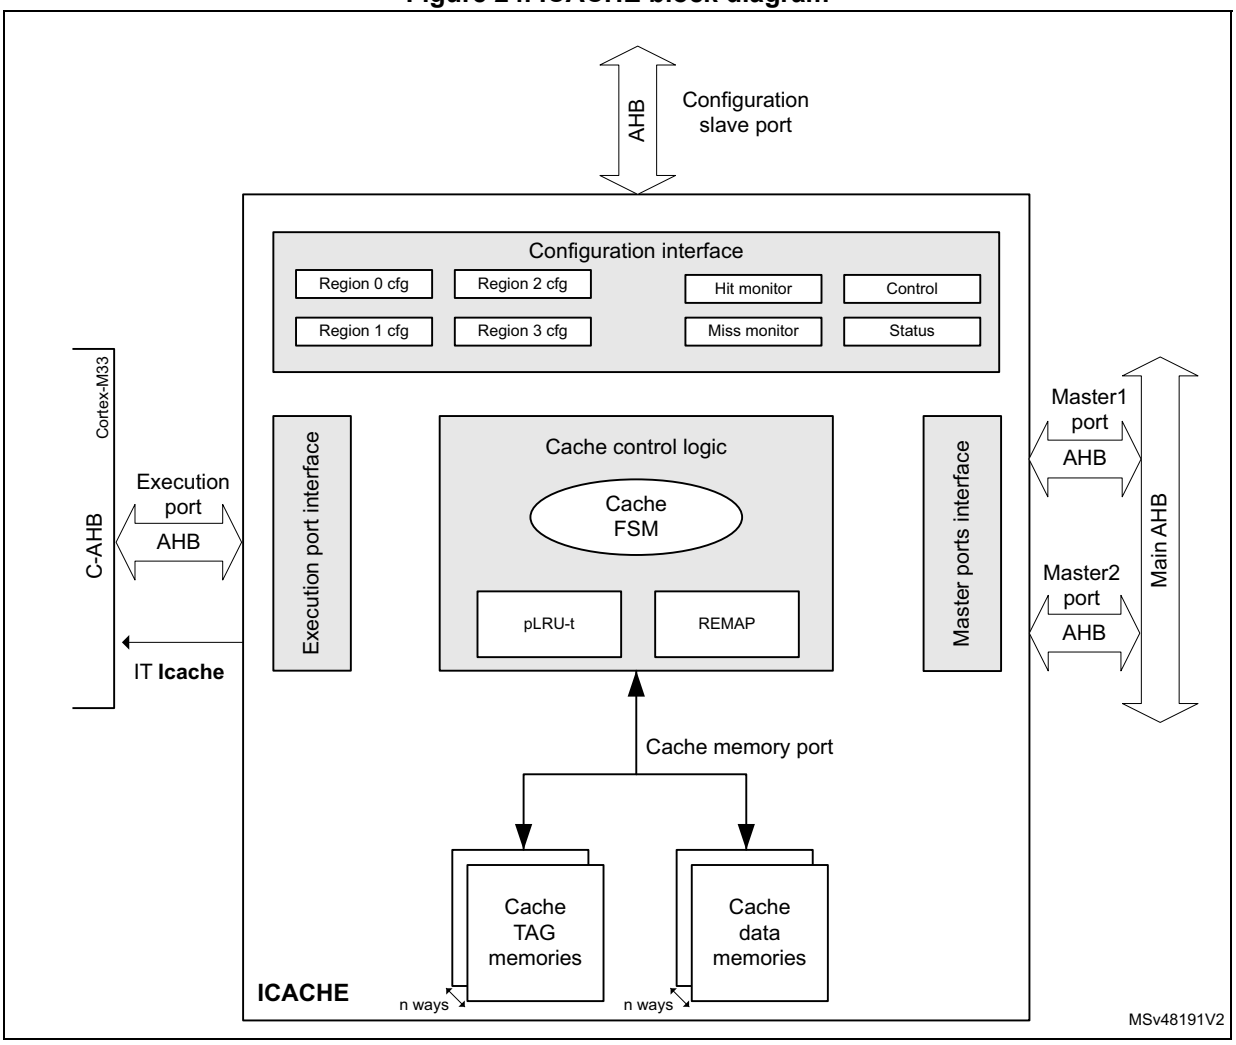
8.4 ICACHE functional description

The purpose of the instruction cache is to cache instruction fetches or instruction memories loads, coming from the processor. As such ICACHE only manages read transactions and does not manage write transactions.

For error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

8.4.1 ICACHE block diagram

Figure 24. ICACHE block diagram



8.4.2 ICACHE reset and clocks

ICACHE is clocked on Cortex-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, ICACHE is bypassed, except the remapping mechanism that is still functional: the slave input requests (remapped or not) are just forwarded to the master port(s).

8.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags, that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after ICACHE reset is released
- when cache is disabled, by setting the EN bit low in the ICACHE_CR register (by software)
- when executing ICACHE invalidate command, by setting the CACHEINV bit high in the ICACHE_CR register (by software)

When a cacheable transaction is received at input execution port, its AHB address (HADDR_in) is split into the following fields (see table below for definition of B and W):

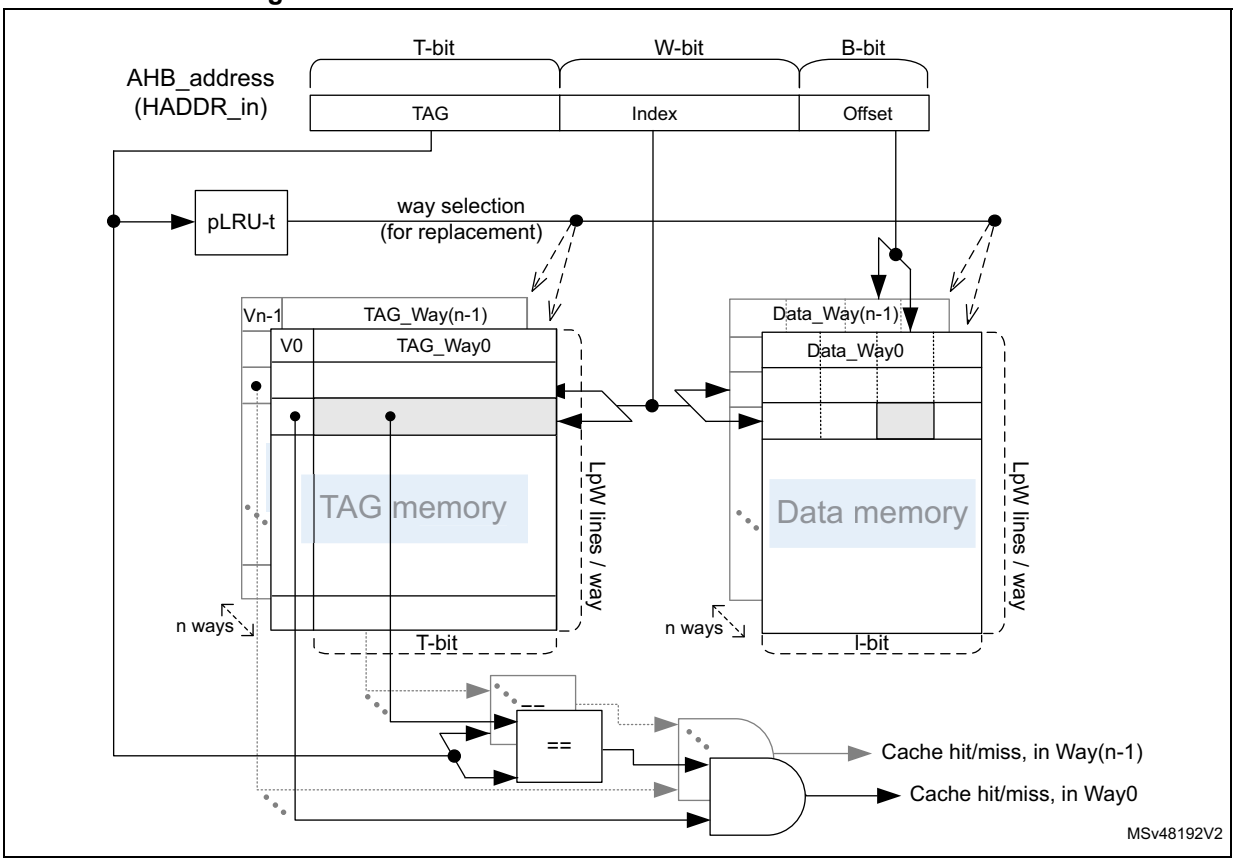
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The table below gives a summary of ICACHE main parameters for TAG memory dimensioning and *Figure 25* shows the functional view of TAG and data memories, for a n-way set associative ICACHE.

Table 72. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 25. ICACHE TAG and data memories functional view



8.4.4 Direct mapped ICACHE (1-way cache)

Default configuration (at reset) is n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure ICACHE as direct mapped by writing WAYSEL = 0 (only possible when cache is disabled, EN=0 in ICACHE_CR).

The table below gives a summary of ICACHE main parameters for TAG memory in case the direct mapped cache operating mode is selected.

Table 73. TAG memory dimensioning parameters for direct mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte=128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, remapping, invalidation) remain the same in direct mapped configuration; the only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 8.4.8*), since only one way (the unique one) is possible for any data refill.

8.4.5 ICACHE enable

In order to activate the ICACHE functioning, the EN bit must be set in the ICACHE_CR register.

When ICACHE is disabled, it is bypassed and all transactions are copied from slave port to master ports in the same clock cycle.

It is recommended to initialize or to modify the main memory content (the region to be later cached) with ICACHE disabled, and to enable ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

In order to insure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This invalidate procedure occurs when hardware reset signal is released, when ICACHE_CR.CACHEINV is set or when ICACHE_CR.EN is cleared. During the procedure, ICACHE_SR.BUSYF is set, and once finished, ICACHE_SR.BUSYF is cleared and ICACHE_SR.BSYENDF is set (raising the ICACHE interrupt if enabled on such a busy end condition).

Software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF still at 1) is treated as non cacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether ICACHE is enabled or not, if input transaction address falls into memory regions defined and enabled in ICACHE_CRRx (see *Figure 26*).

ICACHE is by default disabled at boot.

8.4.6 Cacheable and non-cacheable traffic

ICACHE is developed for Cortex-M33 core. It is placed on C-AHB bus, and thus caches the Code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

In order to make some other memory regions cacheable, ICACHE supports a memory region remapping feature. It allows the definition of up to four external memory regions, which addresses have an alias in the Code region. Addressing these external memory regions through their Code alias address allows the memory request to be routed to the C-AHB bus and to be managed by ICACHE.

Typically, any external memory space physically mapped at an address somewhere in range [0x6000 0000:0x9FFF FFFF] can be aliased with an address in range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the Code region, ICACHE implements the address remapping functionality first. If aliased, it is the remapped address which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.

The remapping functionality is available also for non-cacheable traffic and when cache is disabled.

Further details on address remapping are provided in *Section 8.4.7*.

An incoming memory request to ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 74*. This AHB attribute depends on the MPU programming for the addressed region.

Table 74. ICACHE cacheability for AHB transaction

AHB Lookup attribute	Cacheability
1	Cacheable
0	Non cacheable

In case of non cacheable access, ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port, except the transaction address which may be modified due to the address remapping feature (see *Section 8.4.7*).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In case of cacheable access, the ICACHE behaves as explained in *Section 8.4.8*.

Cacheable memory regions are defined and programmed by the user in the memory protection unit (MPU), that is responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

The table below summarizes product memories programmable configurations.

Table 75. Configurations of product memories

Product memory	Cacheable (MPU programming)	Remapped in ICACHE (ICACHE_CRRx programming)
FLASH	Yes or No	Not required
SRAM	Not recommended	Not required
External memories (OCTOSPI, FMC)	Yes	Required
	No	Required if the user wants code in external memories fetched on C-AHB bus (else on S-AHB bus)

8.4.7 Address remapping

ICACHE allows an alias address to be defined in Code region for up to four external memory regions.

The address remapping is applied on the Code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx register (x = 0 to 3, number of remapped regions). This programming can be done only when ICACHE is disabled.

The number of regions depends on the ICACHE hardware configuration embedded in a given product. Each region x can be individually enabled with the REN bit in ICACHE_CRRx. Once enabled, the remap operation occurs even if ICACHE is disabled or if the transaction is not cacheable.

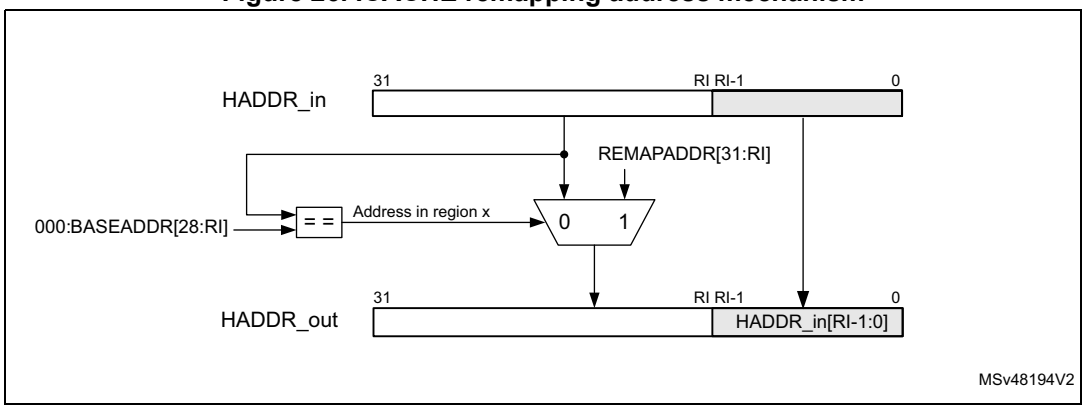
Remap regions can have different size: each region size can be programmed in the RSIZE field of its ICACHE_CRRx register. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum region size of 2 Mbytes and a maximum region size of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given Code sub-region base address, and the modification of this address into its (remapped) external physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code sub-region base address programmed in the BASEADDR field of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = log2(region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region)
- If region x is enabled, the master port output AHB address (HADDR_out) is then composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs.

The figure below describes the matching and the output address generation.

Figure 26. ICACHE remapping address mechanism



The table below summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending on RSIZE.

Table 76. ICACHE remap region size, base address and remap address

Region size (Mbytes)	Base address size (MSBs)	Remap address (MSBs)
2	8	11
4	7	10
8	6	9
16	5	8

Table 76. ICACHE remap region size, base address and remap address (continued)

Region size (Mbytes)	Base address size (MSBs)	Remap address (MSBs)
32	4	7
64	3	6
128	2	5

Care must be taken while programming BASEADDR and REMAPADDR fields in ICACHE_CRRx: if programmed value is bigger than expected (in terms of number of MSBs, see *Table 76*), the unnecessary extra LSBs are ignored.

Typical remapping example: a 128-Mbyte FMC region (NOR/SRAM) physically located in the external address range [0x6800 0000:0x6FFF FFFF], remapped in Code section range [0x1000 0000:0x17FF FFFF]:

- REMAPADDR[31:21] = 0x340
- BASEADDR[28:21] = 0x80
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], and HADDR_in/BASEADDR[26:21] are ignored for the comparison.

If the comparison matches:

- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst that is generated by ICACHE master ports on bus matrix (for cache line refill), by setting the HBURST bit in ICACHE_CRRx with:

- WRAP for remapped external memories accessed through OCTOSPI interface that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through FMC interface that does not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming SAU (secure attribution unit) and MPU (memory protection unit) attributes for both the external *regions and their aliased Code subregions.*

8.4.8 Cacheable accesses

When ICACHE receives a cacheable transaction from Cortex-M33, ICACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.

There are then three alternatives:

- Address is present inside the TAG memory, cache line is valid: **cache hit**, the data is read from cache and provided to the processor in the same cycle.
- Address is not present in the TAG memory: **cache miss**, the data is read from main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

  The burst generated on ICACHE master bus is WRAPw (w being the cache line width, in words) in case no address remap occurs. If an address remap occurs, the kind of burst depends on the HBURST bit programmed in the corresponding ICACHE_CRRx register.

  The AHB transaction attributes are also propagated to main AHB bus matrix on the master port selected for the line refill.
- Address is not present in TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache line refill, ICACHE is capable of providing the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from main memory).

In case of cache refill (due to cache miss), ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data, the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm. This algorithm points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written, is already valid, the targeted cache line must be invalidated first; this is true whatever the direct map or n-way set associative cache mode.

8.4.9 Dual master cache

ICACHE can implement a dual port AHB master on main AHB bus matrix: master1 and master2 ports. This is used to split the traffic going to different destination memories.

The non-remapped traffic goes systematically to master1 port. The re-mapped traffic to external memories must be routed on master2 port by programming the MSTSEL bit of ICACHE_CRRx (on a region basis).

Typically, code can be fetched as follows:

- internal FLASH memory and internal SRAM on master1 port (Fast bus)
- external FLASH/RAM (through OCTOSPI/FMC interfaces) memories on master2 port (Slow bus)

For systems not implementing external memories, it is possible to decouple the traffic to the internal FLASH memory from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual master feature allows the processor to have an alternative path in case of fetching from different memories.

8.4.10 ICACHE security

ICACHE implements a v8-M TrustZone as defined by Arm.

ICACHE configuration registers are protected at system level.

8.4.11 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming the CACHEINV bit in the ICACHE_CR register.

When CACHEINV is set, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, reseting each TAG valid bit to 0 (one valid bit per cache line). The CACHEINV bit of ICACHE_CR is also automatically cleared.

Once the invalidate operation is finished, ICACHE automatically clears the BUSYF flag and sets the BSYENDF flag in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the **ICACHE** interrupt is raised.

Then, the (empty) cache is available again.

8.4.12 ICACHE performance monitoring

ICACHE provides two monitors for performance analysis: a 32-bit hit monitor and a 16-bit miss monitor.

- The hit monitor counts the cacheable AHB-transactions on slave cache port that hit ICACHE content.

  The hit monitor also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see *Section 8.4.8*).
- The miss monitor counts the cacheable AHB-transactions on slave cache port that miss ICACHE content.

  The miss monitor also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through the HITMEN bit in ICACHE_CR.
- Reset the hit monitor by setting the HITMRST bit in ICACHE_CR.
- Enable/stop the miss monitor through the MISSMEN bit in ICACHE_CR.
- Reset the miss monitor by setting the MISSMRST bit in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

8.4.13 ICACHE boot

ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

Code remapping at boot is not needed for Cortex-M33 since it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.

Once boot is finished, ICACHE can be enabled (software setting the EN bit to 1 in ICACHE_CR).

8.5 ICACHE low-power modes

At product level, using ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with a lower-performance profile (in terms of hit ratio) and stringent low-power consumption constraints, may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 25*). The power consumption is then reduced by accessing, for each request, only the necessary cut of TAG and data memories. Meanwhile, the cache effect still improves fetch performance. Even if for most code execution, it is a little less efficient than with a n-way set associative cache mode.

8.6 ICACHE error management and interrupts

In case an unsupported cacheable write request is detected (functional error), ICACHE generates an error by setting the ERRF flag in ICACHE_SR. In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

Both interrupts use the same **ICACHE** interrupt vector.

Table 77. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF flag in ICACHE_SR	ERRIE bit in ICACHE_IER	Set CERRF bit to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF flag in ICACHE_SR	BSYENDIE bit in ICACHE_IER	Set CBSYENDF bit to 1 in ICACHE_FCR

ICACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master1 or master2 port back to the execution port.

8.7 ICACHE registers

8.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MISSMRST	HITMRST	MISSMEN	HITMEN
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAYSEL	CACHEINV	EN
													rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: no effect
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: no effect
1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable
0: cache miss monitor switched off. Stopping the monitor does not reset it.
1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable
0: cache hit monitor switched off. Stopping the monitor does not reset it.
1: cache hit monitor enabled

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).
0: direct mapped cache (1-way cache)
1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

8.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRF	BSYENDF	BUSYF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
- 0: no error
- 1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
- 0: cache busy
- 1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
- 0: cache not busy on a CACHEINV operation
- 1: cache executing a full invalidate CACHEINV operation

8.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	BSYENDIE	Res.
													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)
- 0: interrupt disabled on error
- 1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end
Set by software to enable an interrupt generation at the end of a cache invalidate operation.
0: interrupt disabled on busy end
1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

8.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

8.7.7 ICACHE region x configuration register (ICACHE_CRRx)

Address offset: 0x020 + 4 * x, (x = 0 to 3)

Reset value: 0x0000 0200

Define an alias address in Code region for other regions, making them cacheable.

BASEDADDR and REMAPADDR fields are write locked (read only) when EN = 1 in ICACHE_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw				rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **HBURST**: output burst type for region x
0: WRAP
1: INCR

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **MSTSEL**: AHB cache master selection for region x
0: no action (master1 selected by default)
1: master2 selected

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **REMAPADDR[31:21]**: remapped address for region x
This field replaces the alias address defined by BASEADDR field.
The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15 **REN**: enable for region x
0: disabled
1: enabled

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:9 **RSIZE[2:0]**: size for region x
000: reserved
001: 2 Mbytes
010: 4 Mbytes
011: 8 Mbytes
100: 16 Mbytes
101: 32 Mbytes
110: 64 Mbytes
111: 128 Mbytes

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **BASEADDR[28:21]**: base address for region x
This alias address is replaced by REMAPADDR field.
The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Refer to *Section 2.3* for the register boundary addresses.

9 Data cache (DCACHE)

9.1 Introduction

The data cache (DCACHE) is introduced on S-AHB system bus of Cortex-M33 processor to improve the performance of data traffic to/from external memories.

Some specific features like hit-under-miss and critical-word-first refill policy allow optimum performance on external memories data accesses.

9.2 DCACHE main features

The main features of DCACHE are described below:

- Bus interface
  - one 32-bit AHB slave port, the system port (input from Cortex-M33 S-AHB system interface)
  - one 32-bit AHB master port (output to main AHB bus matrix)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for DCACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimized cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-ways set-associative
  - Supports both write-back and write-through policies (selectable with AHB bufferable attribute)
  - Read and write-back always allocate
  - Write-through always non-allocate (write-around)
  - Supports byte, half-word and word writes
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy for read transactions, minimizing processor stalls
  - Possibility to configure burst type of all AHB memory transactions: INCRw or WRAPw (size w aligned on cache line size)
- Performance counters

  DCACHE implements four performance counters:
  - Two hit monitor counters (32-bit): number of read hits, number of write hits
  - Two miss monitor counters (16-bit): number of read misses, number of write misses

- Error management
  - Possibility to detect error for master port request initiated by DCACHE itself (a cache line written back into main memory, because of an eviction or a clean operation), to flag this error, and optionally to raise an interrupt
- TrustZone security support
- Maintenance operations
  - Cache invalidate: full cache invalidation, fast command, non interruptible
  - Cache invalidate range: invalidates cache lines (reset valid bit = 0) whose address belongs to defined range, background task, interruptible
  - Cache clean range: cleans cache lines (if dirty bit = 1, write back line, then clear dirty bit) whose address belongs to defined range, background task, interruptible
  - Cache clean and invalidate range: cleans and invalidates cache lines (if dirty bit = 1, write back line, then clear valid bit) whose address belongs to defined range, background task, interruptible

9.3 DCACHE implementation

DCACHE1 is placed on Cortex-M33 S-AHB bus and caches only the external RAM memory region (OCTOSPI and FMC), in address range [0x6000 0000:0x9FFF FFFF] of the memory map.

Indeed, by placing a bus matrix demultiplexing node in front of DCACHE1, S-AHB bus memory requests addressing SRAM region or peripherals region (respectively in ranges [0x2000 0000:0x3FFF FFFF] and [0x4000 0000:0x5FFF FFFF]) are routed directly to the main AHB bus matrix and DCACHE1 is bypassed.

Table 79. DCACHE features

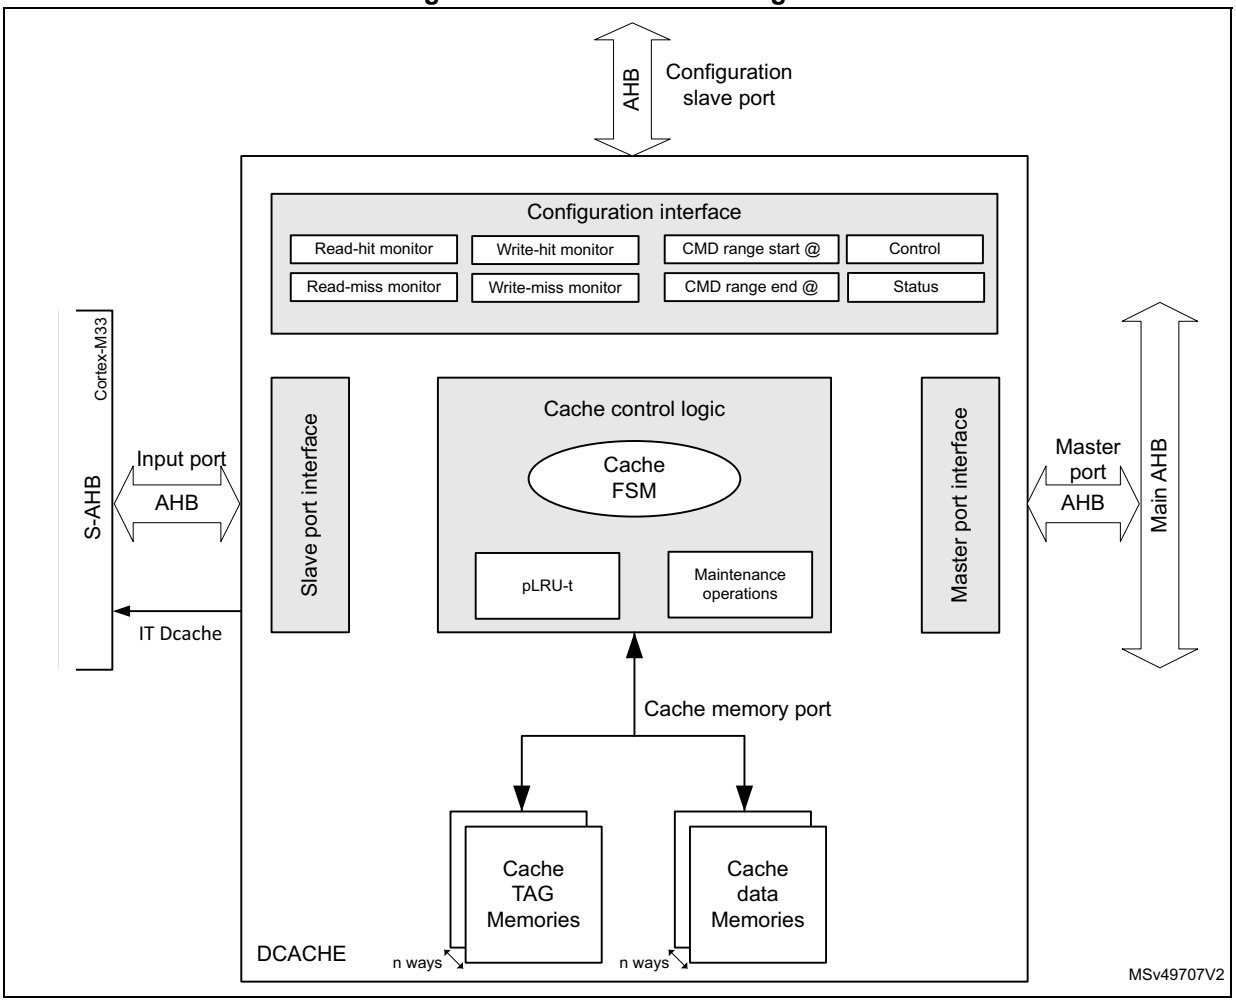
Features	DCACHE1
Number of ways	2
Cache size	4 Kbytes
Cache line width	16 bytes
Data size of AHB Master interface	32 bits

9.4 DCACHE functional description

The purpose of the data cache is to cache external memories data loads and stores coming from the processor. These accesses include the instruction fetches that may occur at an external memory address. As such DCACHE manages both read and write transactions.

9.4.1 DCACHE block diagram

Figure 27. DCACHE block diagram



9.4.2 DCACHE reset and clocks

DCACHE is clocked on the Cortex-M33 S-AHB bus clock.

When the DCACHE reset signal is released, a cache invalidate procedure is automatically launched, making DCACHE busy (DCACHE_SR = 0x0000 0001).

When this procedure is finished:

- DCACHE is invalidated: “cold cache”, with all cache line valid, dirty and privilege bits = 0 (DCACHE must be filled up)
- DCACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- DCACHE is disabled: the EN bit in DCACHE_CR holds its reset state (= 0).

Note: When disabled, DCACHE is bypassed: the slave input requests are just forwarded to the master port.

9.4.3 DCACHE TAG memory

The DCACHE TAG memory contains:

- address tags, that indicate which data are contained in the cache data memories
- validity bits
- dirty bits
- privilege bits

There is one valid bit, one dirty bit and one privilege bit per cache line (per way).

The valid bit enables/disables access to data cache line: if the line is not valid, the data access (read or write) is performed in main memory.

Valid bit is set when cache line is written (refilled by either a read miss or a write-back miss).

Valid bits are reset in any of the below cases:

- after DCACHE reset is released
- when cache is disabled, by setting the EN bit low in DCACHE_CR register (by software)
- when executing one of the DCACHE invalidate commands, setting by software the CACHEINV bit high or CACHECMD = 0b010 or 0b011 in DCACHE_CR register (see *Section 9.4.8*).

The dirty bit indicates that the cache line has up-to-date values with respect to main memory content (in other words, cache has last right value, main memory is not up to date).

Dirty bit is set when cache line is written by a slave port write transaction (only in case of an access with write-back attribute).

Dirty bits are reset in any of the below cases:

- after DCACHE reset is released
- when a line refill is performed on a read miss (on a write-back miss, the refilled cache line is modified by the written data and dirty bit = 1)
- when cache invalidation is performed
- when executing one of the DCACHE clean operations (cache line written back to the main memory), setting by software CACHECMD = 0b001 or 0b011 in DCACHE_CR register (see *Section 9.4.8*).

The privilege bit indicates if the data is managed by a privileged entity. It is assigned according to the value of AHB privileged attribute at input slave port, for the first access to this line (it is written only during the line refill, on read miss or write-back miss). The privilege bit holds same polarity as the privileged attribute: 1 for privileged access, 0 for unprivileged access.

Privilege bits are reset when cache is invalidated and after DCACHE reset is released.

When a cacheable transaction is received at input slave port, its AHB address (HADDR_in) is split into the following fields (see the table below for B and W values):

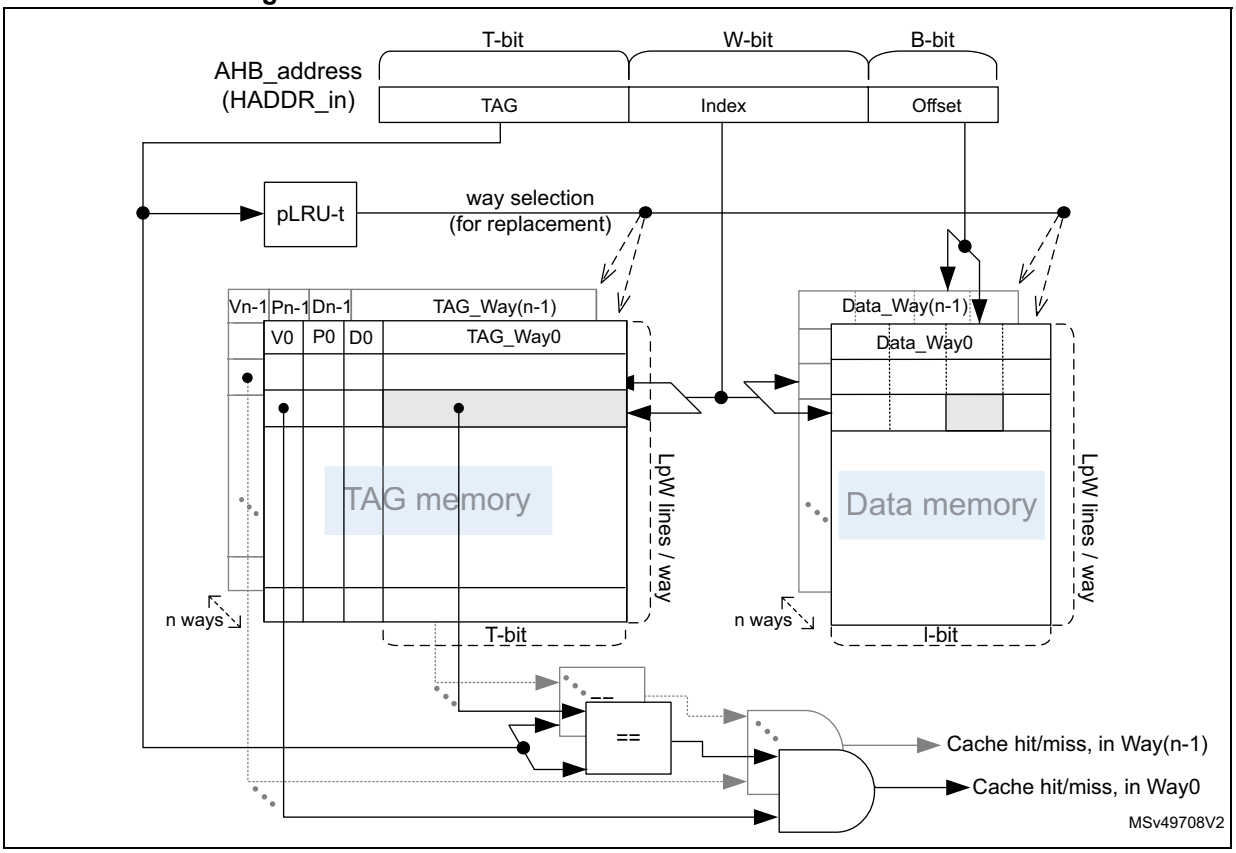
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the DCACHE.

The table below gives DCACHE main parameters for TAG memory dimensioning. *Figure 28.* shows the functional view of TAG and data memories, for a n-way set associative DCACHE.

Table 80. TAG memory dimensioning parameters

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	4 Kbytes = 4096 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines/way	128 lines/way
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	7-bit
TAG address size	T = (32 - W - B) bit	21-bit

Figure 28. DCACHE TAG and data memories functional view



9.4.4 DCACHE enable

In order to activate the DCACHE functioning, the EN bit must be set in DCACHE_CR register.

When DCACHE is disabled, it is bypassed and all transactions are copied from slave port to master port in the same clock cycle, and no comparison is performed with TAG address.

DCACHE is by default disabled at boot.

9.4.5 Cacheable and non-cacheable traffic

DCACHE is developed for Cortex-M33 core and caches the memory regions addressed by the AHB bus connected to it.

In addition, the AHB bus traffic to the memory regions can be cacheable or non-cacheable. An incoming memory request to DCACHE is defined as cacheable according to its AHB transaction memory lookup attribute.

In case of write transaction, the DCACHE write policy is defined as write-through or write-back according to its AHB transaction memory bufferable attribute (see the table below).

These AHB attributes depend on the memory protection unit (MPU) programming for the addressed region.

Table 81. DCACHE cacheability for AHB transaction

AHB lookup attribute	AHB bufferable attribute	Cacheability
0	x	Read and write: non cacheable
1	0	Read: cacheable Write: (cacheable) write-through
1	1	Read: cacheable Write: (cacheable) write-back

In case of non cacheable access, DCACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In case of cacheable access, DCACHE behaves as explained in *Section 9.4.6*.

Cacheable memory regions are defined and programmed by the user in the MPU, responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

9.4.6 Cacheable accesses

When DCACHE receives a cacheable transaction from Cortex-M33, on its slave port, DCACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.

For **read transaction**, there are then three alternatives:

- Address is present inside the TAG memory, cache line is valid: **cache read hit**, the data is read from cache and provided to the processor in the same cycle.
- Address is not present in the TAG memory: **cache read miss**, the data is read from main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first refill policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

  The kind of burst generated on DCACHE master bus depends on the HBURST bit programmed in DCACHE_CR register: either INCRw or WRAPw (w being the cache line width, in words).

  The AHB transaction attributes are also propagated from the slave input (missing) request to the master output refill request.
- Address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache read hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, DCACHE is capable of providing the requested read data as soon as the data is available at its master interface, thus avoiding a miss (with data fetch from main memory).

For **write-back transaction** (write transaction, with write-back bufferable attribute), there are three alternatives as well:

- Address is present inside the TAG memory, cache line is valid: **cache write-back hit**, the data is written in cache.
- Address is not present in the TAG memory (or cache line is not valid): **cache write-back miss**.

  First, a line allocation is performed by reading the entire cache line data from main memory. The kind of burst generated on DCACHE master bus for this line refill depends on the HBURST bit programmed in DCACHE_CR register: either INCRw or WRAPw (w being the cache line width, in words), and the AHB transaction attributes are propagated from the slave port initial request.

  Once the refilled line is written in DCACHE, the initial data provided on slave port is written in this DCACHE line (it overwrites the data part of the cache line that was refilled just before).
- Address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache write-back hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, DCACHE is capable of writing incoming data directly inside the refilled line, thus avoiding a miss (with refill from main memory).

For **write-through transaction** (write transaction, with write-through bufferable attribute), only two alternatives exist:

- Address is present inside the TAG memory, cache line is valid: **cache write-through hit**, the data is written both in cache and in main memory (through master port).
- Address is not present in the TAG memory (or cache line is not valid): **cache write-through miss**, the data incoming at slave port is written only in main memory (unlike the write-back miss, there is no line allocation and data written in cache).

In case of cache refill (due to cache miss), DCACHE selects which cache line is written with the refill data: as a 2-way set associative cache, one line among 2 can be used (the line

pointed by the address index, in each of the 2 ways). The way selection is based on a pLRU-t replacement algorithm. This algorithm points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be evicted first:

- if the dirty tag of this line equals 0 (clean data), the line is simply invalidated.
- if it equals 1 (dirty data), the line must be written back in the main memory.

  In such a case, DCACHE generates a burst write transaction on its master port, with burst type set to INCRw (w being the cache line width, in words), and with AHB memory transaction attribute signals set as below:

  – data (not instruction)
  – privileged = TAG privilege bit
  – write-back (even if it does not care)
  – normal memory
  – cacheable
  – allocate (even if it does not care)
  – non shareable

  These AHB attributes cannot be propagated from the slave port (as it is the case for all other transactions emitted by DCACHE) because the evicting transaction has no relation with the initial missing transaction. Note this AHB attributes setting is fixed, excepted the privileged bit that is copied from the TAG privilege bit of the evicted line.

9.4.7 DCACHE security

DCACHE implements a v8-M TrustZone as defined by Arm.

DCACHE configuration registers are protected at system level.

9.4.8 DCACHE maintenance

DCACHE features several maintenance operations that the software can programmed in DCACHE_CR control register:

- **Full invalidate**: invalidates the whole cache, non interruptible task.

  The software can invalidate the whole content of DCACHE by programming the CACHEINV bit in DCACHE_CR register.

  When CACHEINV is set, the DCACHE control logic sets the BUSYF flag in DCACHE_SR status register, and performs the operation of cache invalidation, reseting each TAG valid bit to 0 (one valid bit per cache line). Each dirty and privilege bits are also reset during cache invalidation to prevent unknown values at next cache line validation. The CACHEINV bit of DCACHE_CR is automatically cleared.

  Once the full invalidate operation is finished, DCACHE automatically clears the BUSYF flag and sets the BSYENDF flag in DCACHE_SR register.

  If enabled on this flag condition (BSYENDIE = 1 in DCACHE_IER), the **DCACHE** interrupt is raised. Then, the (empty) cache is available again.

  This full invalidate operation is not interruptible, meaning that cache does not treat any cacheable request while BUSYF flag is set. However, non-cacheable traffic is treated (since the request address is not compared to TAG ones), DCACHE being bypassed in the same clock cycle (same behavior as when DCACHE is disabled).

- **Invalidate range**: invalidates a certain range of addresses in the cache, back-ground task (interruptible).

  The software can invalidate a given data region in DCACHE by programming DCACHE_CR register with bits STARTCMD = 1 and CACHECMD = 0b010, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  DCACHE control logic then parses the whole TAG memory. If the read line address (TAG Address + Line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), the corresponding cache line is invalidated (line TAG bits cleared, i.e. Valid bit = Dirty bit = Privilege bit = 0).

  When STARTCMD is set, the DCACHE control logic sets the BUSYCMDF flag in DCACHE_SR and launches the invalidate range operation. The STARTCMD bit of DCACHE_CR is also automatically cleared.

  Once the operation is finished (all TAG memory parsed), DCACHE automatically clears the BUSYCMDF flag and sets the CMDENDF flag in DCACHE_SR register.

  If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the **DCACHE** interrupt is raised.

  During this invalidate range operation, DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the invalidation process. In other words, the TAG memory is accessed for invalidate range operation only if not already accessed by an external cache request. This implies that invalidate range execution is usually not performed in one go, but can be interrupted.

- **Clean range**: cleans a certain range of addresses in the cache, back-ground task (interruptible).

  Cleaning a cache line means making sure that main memory content is up-to-date with the data which might have been modified in cache. So the clean operation consists in performing the write-back in main memory of the cache lines that are tagged as “dirty” (the ones with TAG dirty bit set).

  The software can clean a given data region in DCACHE by programming DCACHE_CR register with bits STARTCMD = 1, and CACHECMD = 0b001, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  DCACHE control logic then parses the whole TAG memory. If the read line address (TAG Address + Line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR) and the corresponding line is dirty, this line is cleaned, meaning the whole cache line is written-back in memory through the DCACHE master port and its TAG dirty bit is cleared.

  When STARTCMD is set, the DCACHE control logic sets the BUSYCMDF flag in DCACHE_SR and launches the clean range operation. The STARTCMD bit of DCACHE_CR is also automatically cleared.

  Once the operation is finished (all TAG memory parsed), DCACHE automatically clears the BUSYCMDF flag and sets the CMDENDF flag in DCACHE_SR register.

  If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the **DCACHE** interrupt is raised.

  During this clean range operation, DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the cleaning process. In other words, the TAG memory is accessed for clean range operation only if not already accessed by

an external cache request. This implies that clean range execution is usually not performed in one go, but can be interrupted.

It is under the software responsibility that no bus initiator attempts to change the content of the region being cleaned until clean range is completed. For that, the software should take advantage of BUSYCMDF flag in DCACHE_SR and polls this flag to prevent any spurious access to the area being cleaned. Alternatively it can also rely on the command end flag (CMDENDF) or on the **DCACHE** interrupt to detect the end of the clean range execution.

- **Clean and invalidate range**: cleans and invalidates a certain range of addresses in the cache, back-ground task (interruptible).

  Same as clean range, with an additional reset of its TAG valid bit when a cache line is cleaned.

  The software can launch this clean and invalidate range operation, by programming DCACHE_CR register with bits STARTCMD = 1, and CACHECMD = 0b011, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  It sets and clears the same flags, and potentially the same interrupt as invalidate range or clean range operations.

9.4.9 DCACHE performance monitoring

DCACHE provides four monitors for performance analysis: two 32-bit hit monitors and two 16-bits miss monitors.

- The read-hit and the write-hit monitors count the AHB transactions at the input of DCACHE (slave port) that do not generate a transaction on DCACHE output (master port).

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see *Section 9.4.6*).

- The read-miss and the write-miss monitors count the AHB transactions at the input of DCACHE (slave port) that generate a transaction on DCACHE output (master port)

  It also takes into account all accesses whose address is not present neither in the TAG memory, nor in the refill buffer.

Upon reaching their maximum values, monitors do not wrap over.

The software can perform the following tasks:

- Enable/stop the read (write) hit monitor, through the R(W)HITMEN bit in DCACHE_CR.
- Reset the read (write) hit monitor, by setting the R(W)HITMRST bit in DCACHE_CR.
- Enable/stop the read (write) miss monitor, through the R(W)MISSMEN bit in DCACHE_CR.
- Reset the read (write) miss monitor, by setting the R(W)MISSMRST bit in DCACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

9.4.10 DCACHE boot

DCACHE is disabled (EN = 0 in DCACHE_CR) at boot.

Once boot is finished, DCACHE can be enabled (software setting the EN bit to 1 in DCACHE_CR).

9.5 DCACHE low-power modes

At product level, using DCACHE reduces the power consumption by loading/storing data from/to the internal DCACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even much higher, since the cached main memories are external.

9.6 DCACHE error management and interrupts

A transaction initiated on the DCACHE master port may return an error (a write attempt into a read-only memory, for instance). If the master port request was propagated from a slave port request, the error is propagated back to the slave port. If ever the master port request is initiated by DCACHE itself (a cache line is written back into the main memory because of an eviction or a clean operation), DCACHE receives this functional error and flags it internally by setting the ERRF flag in DCACHE_SR.

In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in DCACHE_IER).

Another case of potential interrupt generation is at the end of a full invalidate operation: when the cache busy state is finished, DCACHE sets the BSYENDF flag in DCACHE_SR.

An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in DCACHE_IER).

Last case is at the end of invalidate and/or clean range operations: when the command busy state is finished, DCACHE sets the CMDENDF flag in DCACHE_SR.

An interrupt is also generated if the corresponding interrupt enable bit is set (CMDENDIE = 1 in DCACHE_IER).

All DCACHE interrupts use the same **DCACHE** interrupt vector.

Table 82. DCACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
DCACHE	Functional error	ERRF flag in DCACHE_SR	ERRIE bit in DCACHE_IER	Set CERRF bit to 1 in DCACHE_FCR
	End of busy state (full invalidate finished)	BSYENDF flag in DCACHE_SR	BSYENDIE bit in DCACHE_IER	Set CBSYENDF bit to 1 in DCACHE_FCR
	End of cache operations (address range based)	CMDENDF flag in DCACHE_SR	CMDENDIE bit in DCACHE_IER	Set CCMDENDF bit to 1 in DCACHE_FCR

DCACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master port back to the S-AHB slave port.

9.7 DCACHE registers

9.7.1 DCACHE control register (DCACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WMISSMRST	WHITMRST	WMISSMEN	WHITMEN	RMISSMRST	RHITMRST	RMISSMEN	RHITMEN
rw								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	STARTCMD	CACHECMD[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	CACHEINV	EN
				w	rw	rw	rw							w	rw

Bit 31 **HBURST:** output burst type for cache master port read accesses
Can be set by software, only when EN = 0.
Master port write accesses are always done in INCR burst type.
0: WRAP
1: INCR

Bits 30:24 Reserved, must be kept at reset value.

Bit 23 **WMISSMRST:** write-miss monitor reset
0: no effect
1: reset cache write-miss monitor

Bit 22 **WHITMRST:** write-hit monitor reset
0: no effect
1: reset cache write-hit monitor

Bit 21 **WMISSMEN:** write-miss monitor enable
0: cache write-miss monitor switched off. Stopping the monitor does not reset it.
1: cache write-miss monitor enabled

Bit 20 **WHITMEN:** write-hit monitor enable
0: cache write-hit monitor switched off. Stopping the monitor does not reset it.
1: cache write-hit monitor enabled

Bit 19 **RMISSMRST:** read-miss monitor reset
0: no effect
1: reset cache read-miss monitor

Bit 18 **RHITMRST:** read-hit monitor reset
0: no effect
1: reset cache read-hit monitor

Bit 17 **RMISSMEN:** read-miss monitor enable
0: cache read-miss monitor switched off. Stopping the monitor does not reset it.
1: cache read-miss monitor enabled

Bit 16 **RHITMEN:** read-hit monitor enable
0: cache read-hit monitor switched off. Stopping the monitor does not reset it.
1: cache read-hit monitor enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **STARTCMD:** starts maintenance command (maintenance operation defined in CACHECMD).
Can be set by software, only when EN = 1, BUSYCMDF = 0, BUSYF = 0 and CACHECMD = 0b001, 0b010 or 0b011.
Cleared by hardware when the BUSYCMDF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: command operation (cache maintenance) finished
1: start maintenance command (cache maintenance)

Bits 10:8 **CACHECMD[2:0]:** cache command maintenance operation (cleans and/or invalidates an address range)
Can be set and cleared by software, only when no maintenance command is ongoing (BUSYCMDF = 0).
000: no operation
001: clean range
010: invalidate range
011: clean and invalidate range
others: reserved

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CACHEINV:** full cache invalidation
Can be set by software, only when EN = 1.
Cleared by hardware when the BUSYF flag is set (during full cache invalidation operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN:** enable
0: cache disabled
1: cache enabled

9.7.2 DCACHE status register (DCACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDENDF	BUSYCMDF	ERRF	BSYENDF	BUSYF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDF:** command end flag
Cleared by writing DCACHE_FCR.CCMDENDF = 1.
0: cache busy or in idle
1: CACHECMD command finished

Bit 3 **BUSYCMDF:** command busy flag
0: cache not busy on a CACHECMD command
1: cache busy on a CACHECMD command (clean and/or invalidate an address range)

Bit 2 **ERRF:** cache error flag
Cleared by writing DCACHE_FCR.CERRF = 1.
0: no error
1: an error occurred during the operation (eviction or clean operation write-back error).

Bit 1 **BSYENDF:** full invalidate busy end flag
Cleared by writing DCACHE_FCR.CBSYENDF = 1.
0: cache busy or in idle
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF:** full invalidate busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

9.7.3 DCACHE interrupt enable register (DCACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDENDIE	Res.	ERRIE	BSYENDIE	Res.
											rw		rw	rw	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDIE**: interrupt enable on command end

Set by software to enable an interrupt generation at the end of a cache command (clean and/or invalidate an address range)

0: interrupt disabled on command end

1: interrupt enabled on command end

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ERRIE:** interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (eviction or clean operation write-back error)

0: interrupt disabled on error

1: interrupt enabled on error

Bit 1 **BSYENDIE:** interrupt enable on busy end

Set by SW to enable an interrupt generation at the end of a cache full invalidate operation.

0: Interrupt disabled on busy end

1: Interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

9.7.4 DCACHE flag clear register (DCACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCMDENDF	Res.	CERRF	CBSYENDF	Res.
											w		w	w	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CCMDENDF:** clear command end flag
Set by software.
0: no effect
1: clears CMDENDF flag in DCACHE_SR

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CERRF:** clear cache error flag
Set by software.
0: no effect
1: clears ERRF flag in DCACHE_SR

Bit 1 **CBSYENDF:** clear full invalidate busy end flag
Set by software.
0: no effect
1: clears BSYENDF flag in DCACHE_SR

Bit 0 Reserved, must be kept at reset value.

9.7.5 DCACHE read-hit monitor register (DCACHE_RHMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

10 Power control (PWR)

10.1 Introduction

The power controller manages all device power supplies and power modes transitions.

10.2 PWR main features

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domain (V_{CORE})
  - V_{DD} domain
  - Backup domain
  - Analog domain (V_{DDA})
  - Supply for the SMPS power stage (available on SMPS packages)
  - V_{DDIO2} domain on port PG[15:2]
  - V_{DDUSB} for USB transceiver
- System supply voltage regulation
  - SMPS step-down converter
  - Linear voltage regulator (LDO)
- Power supply supervision
  - BOR monitor
  - PVD monitor
  - PVM monitor (V_{DDA}, V_{DDUSB}, V_{DDIO2})
  - Out of functional range temperature monitor
  - Out of functional range Backup domain voltage monitor
- Power management
  - Operating modes
  - Voltage scaling control
  - Low-power modes
- V_{BAT} battery charging
- TrustZone security and privileged protection

10.3 PWR pins and internal signals

Table 84. PWR input/output pins

Pin name	Signal type	Description
VDD	Supply	Main supply
GND	Supply	Main ground
VDDA	Supply	Analog peripherals supply
VSSA	Supply	Analog peripherals ground
VDDIO2	Supply	Independent I/O supply
VDDUSB	Supply	USB supply
VDD11 (packages with SMPS)/ VCAP (packages without SMPS)	Supply	Logic supply (V_{CORE})
VBAT	Supply	Backup domain supply
VDDSMPS	Supply	SMPS supply
VSSSMPS	Supply	SMPS ground
VLXSMPS	Supply	SMPS output
VREF+	Supply	ADC/DAC high reference voltage
VREF-	Supply	ADC/DAC low reference voltage
WKUPx (x = 1 to 8)	Input	Wakeup pins
CSLEEP	Output	MCU in Sleep mode
CDSTOP	Output	CPU domain in Stop mode
SRDSTOP	Output	SmartRun domain in Stop mode

Table 85. PWR internal input/output signals

Internal signal name	Signal type	Description
WKUPx_y (x = 1 to 8, y = 1 to 4)	Input	Wakeup event source selection

Each of the eight wakeup events, WKUPx, can be generated from four pins or internal events, selected by WUSELx[1:0] in the PWR_WUCR3 register (x = 1 to 8).

Table 86. PWR wakeup source selection

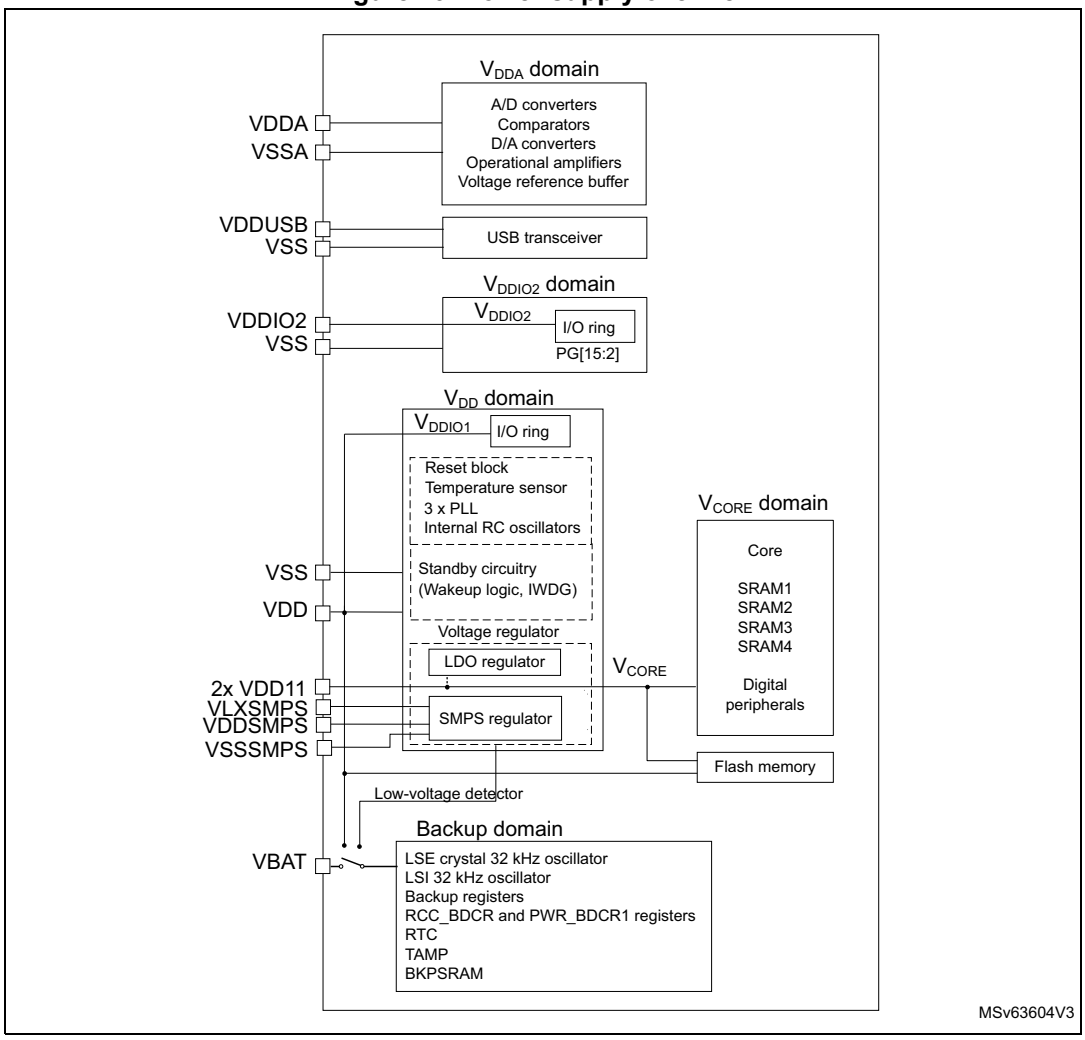
Wakeup event	Internal signal source (x = 1 to 8)			
	WKUPx_0 (WUSELx = 00)	WKUPx_1 (WUSELx = 01)	WKUPx_2 (WUSELx = 10)	WKUPx_3 (WUSELx = 11)
WKUP1	PA0	PB2	PE4	Reserved
WKUP2	PA4	PC13	PE5	Reserved
WKUP3	PE6	PA1	PB6	Reserved
WKUP4	PA2	PB1	PB7	Reserved

Table 86. PWR wakeup source selection (continued)

Wakeup event	Internal signal source (x = 1 to 8)			
	WKUPx_0 (WUSELx = 00)	WKUPx_1 (WUSELx = 01)	WKUPx_2 (WUSELx = 10)	WKUPx_3 (WUSELx = 11)
WKUP5	PC5	PA3	PB8	Reserved
WKUP6	PB5	PA5	PE7	RTC_ALRA_S or RTC_ALRB_S or RTC_WUT_S or RTC_TS_S
WKUP7	PB15	PA6	PE8	RTC_ALRA or RTC_ALRB or RTC_WUT or RTC_TS
WKUP8	PF2	PA7	PB10	TAMP or TAMP_S

10.4 PWR power supplies and supply domains

Figure 29. Power supply overview



10.4.1 External power supplies

The devices require a 1.71 V to 3.6 V V_{DD} operating voltage supply. Several independent supplies can be provided for specific peripherals. Those supplies must not be provided without a valid operating supply on the VDD pin:

- V_{DD} = 1.71 V to 3.6 V (functionality guaranteed down to V_{BOR} minimum value)

  V_{DD} is the external power supply for the I/Os, the internal regulator and the system analog such as reset, power management and internal clocks. It is provided externally through the VDD pins.
- V_{DDA} = 1.58 V (COMPs) / 1.6 V (DACs, OPAMPs) / 1.62 (ADCs) / 1.8 V (VREFBUF) to 3.6 V

  V_{DDA} is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The V_{DDA} voltage level is independent from the V_{DD} voltage and must be connected to VDD or VSS (preferably to VDD) when these peripherals are not used.
- V_{DDSMPS} = 1.71 V to 3.6 V

  V_{DDSMPS} is the external power supply for the SMPS step-down converter. It is provided externally through VDDSMPS supply pin, and must be connected to the same supply as VDD pin.
- V_{LXSMPS} is the switched SMPS step-down converter output.

Note: The SMPS power supply pins are available only on a specific package with SMPS step-down converter option.

- V_{DDUSB} = 3.0 V to 3.6 V

  V_{DDUSB} is the external independent power supply for USB transceivers. The V_{DDUSB} voltage level is independent from the V_{DD} voltage and must preferably be connected to V_{DD} when the USB is not used.
- V_{DDIO2} = 1.08 V to 3.6 V

  V_{DDIO2} is the external power supply for 14 I/Os (port G[15:2]). The V_{DDIO2} voltage level is independent from the V_{DD} voltage and must preferably be connected to V_{DD} when PG[15:2] are not used.
- V_{BAT} = 1.65 V to 3.6 V (functionality guaranteed down to V_{BOR_VBAT} minimum value, refer to the product datasheet)

  V_{BAT} is the power supply when V_{DD} is not present (through power switch) for RTC, TAMP, external and internal clocks 32 kHz oscillator, backup registers and optionally backup SRAM.
- V_{REF-}, V_{REF+}

  V_{REF+} is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

  V_{REF+} can be grounded when ADC and DAC are not active.

  The internal voltage reference buffer supports four output voltages, that are configured with VRS bit in the VREFBUF_CSR register:
  - V_{REF+} around 1.5 V. This requires $V_{DDA} \geq 1.8$ V.
  - V_{REF+} around 1.8 V. This requires $V_{DDA} \geq 2.1$ V.
  - V_{REF+} around 2.048 V. This requires $V_{DDA} \geq 2.4$ V.
  - V_{REF+} around 2.5 V. This requires $V_{DDA} \geq 2.8$ V.

VREF- and VREF+ pins are not available on all packages. When not available, they are bonded to VSSA and VDDA, respectively.

When the VREF+ is double-bonded with VDDA in a package, the internal voltage reference buffer is not available and must be kept disabled.

V_{REF-} must always be equal to V_{SSA}.

10.4.2 Internal regulators

The devices embed two regulators: one LDO and one SMPS in parallel to provide the V_{CORE} supply for digital peripherals, SRAMs (except BKPSRAM) and embedded Flash memory. The SMPS generates this voltage on VDD11 (two pins) with a total external capacitor of 4.7 µF typical and requires an external coil of 2.2 µH typical.

The LDO generates this voltage on VCAP (one or two pins depending on packages) with a total of external capacitor of 4.7 µF typical.

Both regulators can provide four different voltages (voltage scaling) and can operate in Stop mode.

It is possible to switch from SMPS to LDO and from LDO to SMPS on the fly.

10.4.3 Power-up and power-down power sequences

During power-up and power-down phases, the following power sequence requirements must be respected:

- When V_{DD} is below 1 V, other power supplies (V_{DDA}, V_{DDIO2}, V_{DDUSB}) must remain below V_{DD} + 300 mV.
- When V_{DD} is above 1 V, all power supplies are independent.

During the power-down phase, V_{DD} can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling capacitors to be discharged with different time constants during the power-down transient phase.

10.4.4 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply that can be separately filtered and shielded from noise on the PCB:

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The V_{DDA} supply voltage can be different from V_{DD}. The presence of V_{DDA} must be checked before enabling any of the analog peripherals supplied by V_{DDA} (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

After reset, the analog features supplied by V_{DDA} are logically and electrically isolated and therefore are not available. The isolation must be removed before using the analog peripherals, by setting the ASV bit in the PWR_SVMCR register, once the V_{DDA} supply is present.

The V_{DDA} supply can be monitored by the analog voltage monitors (AVM), and compared with two thresholds (1.6 V for AVM1 or 1.8 V for AVM2), refer to *Section 10.6.3: Peripheral voltage monitoring (PVM)* for more details.

When a single supply is used, V_{DDA} can be externally connected to V_{DD} through the external filtering circuit in order to ensure a noise-free V_{DDA} reference voltage.

ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+, a separate reference voltage lower than V_{DDA}. V_{REF+} is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

V_{REF+} can be provided either by an external reference of by an internal buffered voltage reference (VREFBUF). The internal voltage reference can output a configurable voltage: 1.5 V, 1.8 V, 2.048 V or 2.4 V. The internal voltage reference can also provide the voltage to external components through VREF+ pin. Refer to the device datasheet and to *Section 32: Voltage reference buffer (VREFBUF)* for further information.

10.4.5 Independent I/O supply rail

Some I/Os from port G (PG[15:2]) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the VDDIO2 pin. The V_{DDIO2} voltage level is completely independent from V_{DD} or V_{DDA}. The VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by V_{DDIO2} are logically and electrically isolated and therefore are not available. The isolation must be removed before using any I/O from PG[15:2], by setting the IO2SV bit in the PWR_SVMCR register, once the V_{DDIO2} supply is present.

The V_{DDIO2} supply is monitored by the IO2 voltage monitoring (IO2VM) and compared with the internal reference voltage (3/4 V_{REFINT}, around 0.9 V), refer to *Section 10.6.3: Peripheral voltage monitoring (PVM)* for more details.

10.4.6 Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. V_{DDUSB} range is from 3.0 V to 3.6 V and is completely independent from V_{DD} or V_{DDA}.

After reset, the USB features supplied by V_{DDUSB} are logically and electrically isolated and therefore are not available. The isolation must be removed before using the USB OTG peripheral, by setting the USV bit in the PWR_SVMCR register, once the V_{DDUSB} supply is present.

The V_{DDUSB} supply is monitored by the USB voltage monitoring (UVM) and compared with the internal reference voltage (V_{REFINT}, around 1.2 V), refer to *Section 10.6.3: Peripheral voltage monitoring (PVM)* for more details.

10.4.7 Battery Backup domain

To retain the content of the backup registers, backup SRAM, and supply the RTC and TAMP functions when V_{DD} is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The Backup domain supply is V_{SW}, which is the output of a power switch between V_{DD} and V_{BAT}. The switch between V_{DD} and V_{BAT} supplies is automatically controlled by the brownout reset circuitry.

When V_{DD} is below the lowest brownout reset threshold (V_{BOR0}), the VBAT pin powers the RTC and TAMP peripherals, the LSI and LSE oscillators. The backup SRAM is optionally powered by VBAT pin when BREN is set in PWR_BDCR1.

The following pins functions are also powered by the VBAT pin:

- PC13, PC14, and PC15 that can be configured by the RTC, the TAMP, or the LSE (see *Section 54.3: RTC functional description*)
- PE3, PE4, PE5, PE6, PC13, PA0, PA1, and PC5 when they are configured by the TAMP as tamper pins
- PB2 when configured by the RTC as RTC_OUT2 output

When V_{DD} is higher than V_{BOR0}, the VDD pin powers all previous functions.

Note: Due to the fact that the analog power switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the speed must be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (for example to drive a LED).

Warning: During $t_{RSTTEMPO}$ (temporization at V_{DD} startup) or after a PDR has been detected, the power switch between V_{BAT} and V_{DD} remains connected to V_{BAT}.
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (refer to the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into V_{BAT} through an internal diode connected between V_{DD} and the power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

If no external battery is used in the application, it is recommended to connect V_{BAT} externally to V_{DD} with a 100 nF external ceramic decoupling capacitor.

Backup domain access

After a system reset, the Backup domain (RCC Backup domain control register RCC_BDCR, RTC registers, TAMP registers, backup registers and backup SRAM) is protected against possible unwanted write accesses. To enable access to the Backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the *RCC AHB3 peripheral clock enable register (RCC_AHB3ENR)*.
2. Set the DBP bit in the *PWR disable Backup domain register (PWR_DBPR)* to enable access to the Backup domain.

V_{BAT} battery charging

When V_{DD} is present, It is possible to charge the external battery on VBAT through an internal resistance.

The V_{BAT} charging is done either through a 5 kΩ resistor or through a 1.5 kΩ resistor depending on the VBRS bit value in the PWR_BDCR2 register.

The battery charging is enabled by setting VBE bit in the PWR_BDCR2 register. It is automatically disabled in V_{BAT} mode.

10.5 PWR system supply voltage regulation

10.5.1 SMPS and LDO embedded regulators

The devices embed two internal regulators, that can be selected when the application runs, depending on the application requirements:

- a SMPS step-down converter
- a linear voltage regulator (LDO)

The SMPS allows the power consumption to be reduced but some applications can be perturbed by the noise generated by the SMPS, requiring the application to switch to LDO.

The LDO and the SMPS regulators have two modes: Main regulator mode (used when performance is needed), and Low-power regulator mode. LDO or SMPS can be used in all voltage scaling ranges, and in all Stop modes.

10.5.2 LDO and SMPS versus reset, voltage scaling, and low-power modes

After reset, the regulator is the LDO, in range 4. Switching to SMPS provides lower consumption in particular at high V_{DD} voltage. It is possible to switch from LDO to SMPS, or from SMPS to LDO in any range, by configuring the REGSEL bit.

When exiting the Stop or Standby mode, the regulator is the same than when entering low-power modes. The voltage range is the range 4.

10.5.3 LDO and SMPS step down converter fast startup

After BOR reset, the LDO and SMPS regulators starts in slow-startup mode. This slow-startup feature is selected to limit the inrush current after power-on reset. This increases the wakeup time when exiting Stop or Standby mode.

However, it is possible to configure a faster startup on the fly and it is applied for next startup either after a system reset or wakeup from low-power mode except Shutdown and V_{BAT} modes. The fast startup is selected by setting the FSTEN bit in the PWR_CR3 register.

10.5.4 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique that consists in increasing or decreasing the voltage used for the digital peripherals (V_{CORE}), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase V_{CORE} is known as overvolting. It allows the device to improve its performance.

Dynamic voltage scaling to decrease V_{CORE} is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

The regulator operates in the following ranges:

- Range 1: high performance

  It provides a typical output voltage at 1.2 V. It is used when the system clock frequency

is up to 160 MHz.

- Range 2: medium-high performance

  It provides a typical output voltage at 1.1 V. It is used when the system clock frequency is up to 110 MHz.

- Range 3: medium-low power range

  It provides a typical output voltage at 1.0 V. The system clock frequency can be up to 55 MHz.

- Range 4: low power range

  It provides a typical output voltage at 0.9 V. The system clock frequency can be up to 25 MHz.

Voltage scaling is selected through the VOS[1:0] bits in the PWR_VOSR register. The EPOD (embedded power distribution) booster must be enabled and ready before increasing the system clock frequency above 55 MHz in range 1 and range 2.

The sequence to switch the voltage scaling from range “L” (lower power) to range “P” (higher performance) with L > P is the following:

1. If target SYSCLK > 55 MHz:
   a) Configure the PLL1MBOOST[3:0] in the RCC_PLL1CFGR to generate a booster clock frequency between 4 and 16 MHz.
   b) Switch on the PLL1 oscillator clock source.
   c) Select the PLL1 clock source (PLL1SRC[1:0] in the RCC_PLL1CFGR).
2. Program the VOS[1:0] bits to range P in the PWR_VOSR register.
3. Wait until the VOSRDY flag is set in the PWR_VOSR register.
4. If target SYSCLK > 55 MHz:
   a) Set BOOSTEN in the PWR_VOSR register. This step can be done together with VOS programming.
   b) Wait until the BOOSTRDY flag is set in the PWR_VOSR register.
5. Adjust number of wait states according new frequency target in range “P” (LATENCY bits in the FLASH_ACR and WSC bits in the RAMCFG_MxCR).
6. Configure and enable the PLL if needed.
7. Configure and switch to new system frequency.

The sequence to switch the voltage scaling from range “P” (higher performance) to range “L” (lower power) with L > P is:

1. Reduce the system frequency to a value lower than range “L” maximum frequency.
2. Adjust number of wait states according new frequency target (LATENCY bits in the FLASH_ACR and WSC bits in the RAMCFG_MxCR).
3. If new SYSCLK ≤ 55 MHz, clear BOOSTEN in the PWR_VOSR register if it was set.
4. Program the VOS bits to range “L” in the PWR_VOSR register. This step can be done together with BOOSTEN clearing.

10.6 PWR power supply supervision

10.6.1 Brownout reset (BOR)

The device has an integrated Brownout reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.

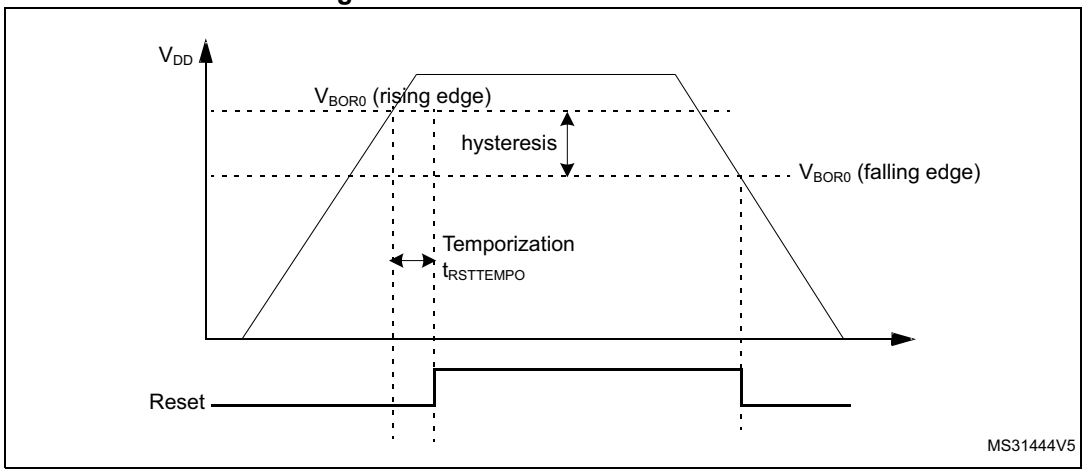
Five BOR thresholds can be selected through option bytes. BOR0 provides the always enabled power-on/power-down functionality, independent from any other higher BOR level selection.

During power-on, the BOR keeps the device under reset until the supply voltage V_{DD} reaches the specified V_{BORx} threshold. When V_{DD} drops below the selected threshold, a device reset is generated. When V_{DD} is above the V_{BORx} upper limit, the device reset is released and the system can start.

For more details on the Brownout reset thresholds, refer to the electrical characteristics section in the datasheet.

During Standby mode, it is possible to set the BOR in ultra-low-power mode to further reduce the current consumption by setting the ULPMEN bit in *PWR control register 1 (PWR_CR1)*.

Figure 30. Brownout reset waveform



1. The reset temporization $t_{RSTTEMPO}$ is present only for the BOR lowest threshold (V_{BOR0}).

10.6.2 Programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PVDLS[2:0] bits in the *PWR supply voltage monitoring control register (PWR_SVMCR)*.

The PVD is enabled by setting the PVDE bit.

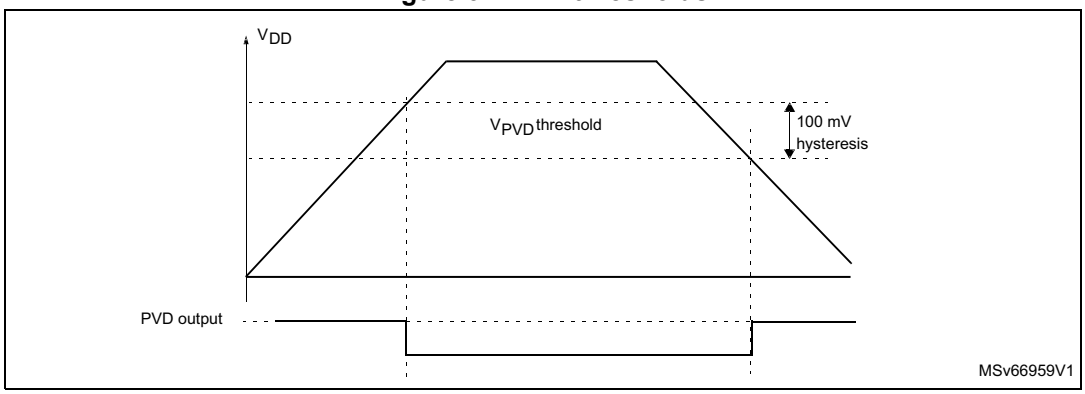
A PVDO flag is available in the *PWR supply voltage monitoring control register (PWR_SVMCR)* to indicate if V_{DD} is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers (refer to *Table 99: PWR interrupt requests*).

The rising/falling edge sensitivity of the EXTI Line must be configured according to PVD output behavior. For example, if the EXTI line is configured to rising edge sensitivity, the

interrupt is generated when V_{DD} drops below the PVD threshold. As an example, the service routine can perform emergency shutdown tasks.

The PVD can remain active in Stop 0, Stop 1, Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVD is not functional in Stop 3 mode.

Figure 31. PVD thresholds



10.6.3 Peripheral voltage monitoring (PVM)

Only V_{DD} is monitored by default, as it is the only supply required for all system-related functions. The other supplies (V_{DDA}, V_{DDIO2} and V_{DDUSB}) can be independent from V_{DD} and can be monitored with four peripheral voltage monitoring (PVM):

- The UVM monitors the USB supply V_{DDUSB}. VDDUSBRDY indicates if the V_{DDUSB} independent power supply is higher or lower than the V_{UVM} threshold.
- The IO2VM monitors the PG[15:2] supply V_{DDIO2}. VDDIO2RDY indicates if the V_{DDIO2} independent power supply is higher or lower than the V_{IO2VM} threshold.
- The AVM1 monitors the analog supply V_{DDA}. VDDA1RDY indicates if the V_{DDA} independent power supply is higher or lower than the V_{AVM1} threshold.
- The AVM2 monitors the analog supply V_{DDA}. VDDA2RDY indicates if the V_{DDA} independent power supply is higher or lower than the V_{AVM2} threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVMx output interrupt is generated when the independent power supply drops below the PVM threshold and/or when it rises above the PVM threshold, depending on EXTI line rising/falling edge configuration. Refer to *Table 99: PWR interrupt requests*.

Each PVM can remain active in Stop 0, Stop 1, Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVM is not functional in Stop 3 mode.

Table 87. PVM features

PVM	Power supply	PVM threshold
UVM	V_{DDUSB}	V_{UVM} (around 1.2 V)
IO2VM	V_{DDIO2}	V_{IO2VM} (around 0.9 V)
AVM1	V_{DDA}	V_{AVM1} (around 1.6 V)
AVM2	V_{DDA}	V_{AVM2} (around 1.8 V)

The independent supplies (V_{DDA}, V_{DDIO2} and V_{DDUSB}) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies:

- If these supplies are shorted externally to V_{DD}, the application assumes they are available without enabling any peripheral voltage monitoring.
- If these supplies are independent from V_{DD}, the peripheral voltage monitoring (PVM) can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB OTG peripheral:

1. If V_{DDUSB} is independent from V_{DD}:
   a) Enable the UVM by setting UVMEN bit in the *PWR supply voltage monitoring control register (PWR_SVMCR)*.
   b) Wait for the UVM wakeup time.
   c) Wait until VDDUSBRDY bit is set in the *PWR supply voltage monitoring status register (PWR_SVMSR)*.
   d) Disable the UVM for consumption saving (optional).
2. Set the USV bit in the *PWR supply voltage monitoring control register (PWR_SVMCR)* to remove the V_{DDUSB} power isolation.

The following sequence must be done before using any I/O from PG[15:2]:

1. If V_{DDIO2} is independent from V_{DD}:
   a) Enable the IO2VM by setting IO2VM bit in the *PWR supply voltage monitoring control register (PWR_SVMCR)*.
   b) Wait for the IO2CVM wakeup time.
   c) Wait until VDDIO2RDY bit is set in the *PWR supply voltage monitoring status register (PWR_SVMSR)*.
   d) Disable the IO2VM for consumption saving (optional).
2. Set the IO2SV bit in the *PWR supply voltage monitoring control register (PWR_SVMCR)* to remove the V_{DDIO2} power isolation.

The following sequence must be done before using any of these analog peripherals: analog to digital converters, digital to analog converters, comparators, operational amplifiers, voltage reference buffer:

1. If V_{DDA} is independent from V_{DD}:
   a) Enable the AVM1 or AVM2 by setting AVM1EN or AVM2EN bit in the *PWR supply voltage monitoring control register (PWR_SVMCR)*.
   b) Wait for the AVM wakeup time.
   c) Wait until VDDA1RDY or VDDA2RDY bit is set in the *PWR supply voltage monitoring status register (PWR_SVMSR)*.
   d) Disable the AVM for consumption saving (optional).
2. Set the ASV bit in the *PWR supply voltage monitoring control register (PWR_SVMCR)* to remove the V_{DDA} power isolation.

10.6.4 Backup domain voltage and temperature monitoring

When the Backup domain voltage and temperature monitoring is enabled (MONEN = 1 in the PWR_DBPR register), the Backup domain voltage and the temperature are monitored.

If the Backup domain voltage monitoring internal tamper is enabled in the TAMP peripheral (ITAMP1E = 1 in the TAMP_CR1 register), a tamper event is generated when the Backup domain voltage is above the functional range. In case the Backup domain voltage is below the functional range, a Brownout reset is generated, erasing all device including Backup domain.

Note: The Backup domain voltage is V_{DD} when present, V_{BAT} otherwise.

If the temperature monitoring internal tamper is enabled in the TAMP peripheral (ITAMP2E = 1 in the TAMP_CR1 register), a tamper event is generated when the temperature is above or below the functional range.

10.7 PWR power management

10.7.1 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The device features these low-power modes:

- Sleep mode:

  CPU clock off, all peripherals including Cortex-M33 core such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs. Refer to *Section 10.7.5: Sleep mode*.

- Stop 0, Stop 1, Stop 2, Stop 3 modes:

  Stop mode achieves the lowest power consumption while retaining the content of SRAM and registers. All clocks in the core domain are stopped. The PLL, the MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are disabled. The LSE or LSI is still running.

  The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

  Some peripherals are autonomous and can operate in Stop mode by requesting their kernel clock and their bus (APB or AHB) when needed, in order to transfer data with DMA (GPDMA1 or LPDMA1 depending on peripherals and power mode).

  In Stop 2 and Stop 3 modes, most of the core domain is put in a lower leakage mode. Stop 0 and Stop 1 offers the largest number of active peripherals and wakeup sources, a smaller wakeup time but a higher consumption than Stop 2.

  In Stop 0 mode, the regulator remains in main regulator mode, allowing a very fast wakeup time but with much higher consumption.

  Stop 3 is the lowest power mode with full retention, but the functional peripherals and sources of wakeup are reduced to the same ones than in Standby mode.

  The system clock when exiting from Stop mode can be either MSIS up to 24 MHz or HSI16, depending on software configuration.

  Refer to *Section 10.7.6: Stop 0 mode*, *Section 10.7.7: Stop 1 mode*, *Section 10.7.8: Stop 2 mode* and *Section 10.7.9: Stop 3 mode*.

- Standby mode:

  The Standby mode is used to achieve the lowest power consumption with BOR. The

internal regulator is switched off so that the core domain is powered off. The PLL, the MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are also switched off.

The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

The Brownout reset (BOR) always remains active in Standby mode.

The state of each I/O during Standby mode can be selected by software: I/O with internal pull-up, internal pull-down or floating.

After entering Standby mode, SRAMs and register contents are lost except for registers and backup SRAM in the Backup domain and Standby circuitry. Optionally, the full SRAM2 or 8 Kbytes or 56 Kbytes can be retained in Standby mode, supplied by the low-power regulator (standby with RAM2 retention mode).

The BORL (Brownout reset detector low) can be configured in ultra-low-power mode to further reduce power consumption during standby mode.

The device exits Standby mode when an external reset (NRST pin), an IWDG reset, WKUP pin event (configurable rising or falling edge), a RTC event occurs (alarm, periodic wakeup, timestamp), or a tamper detection. The tamper detection can be raised either due to external pins or due to an internal failure detection.

The system clock after wakeup is MSIS up to 4 MHz.

Refer to *Section 10.7.10: Standby mode*.

- Shutdown mode:

  The Shutdown mode allows the lowest power consumption. The internal regulator is switched off so that the core domain is powered off. The PLL, the HSI16, the MSI (MSIS and MSIK), the LSI and the HSE oscillators are also switched off.

  The RTC can remain active (Shutdown mode with RTC, Shutdown mode without RTC). The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

  SRAMs and register contents are lost except for registers in the Backup domain.

  The device exits Shutdown mode when an external reset (NRST pin), a WKUP pin event (configurable rising or falling edge), or a RTC event occurs (alarm, periodic wakeup, timestamp), or a tamper detection.

  The system clock after wakeup is MSIS at 4 MHz.

  Refer to *Section 10.7.11: Shutdown mode*.

The table below shows the power modes overview.

Table 88. Low-power mode summary

Mode name	Entry	Wakeup source(1)	Wakeup system clock	Effect on clocks	Voltage regulators
Sleep (Sleep-now or Sleep-on-exit)	WFI or Return from ISR	Any interrupt except OTG_FS and UCPD in range 4	Same as before entering Sleep mode	CPU clock OFF No effect on other clocks or analog clock sources	Range 1, 2, 3, 4
	WFE	Wakeup event			

Table 88. Low-power mode summary (continued)

Mode name	Entry	Wakeup source[1]	Wakeup system clock	Effect on clocks	Voltage regulators
Stop 0	LPMS = 000 + SLEEPDEEP bit + WFI or Return from ISR or WFE	Any EXTI line (configured in the EXTI registers) Specific peripherals events	HSI16 when STOPWUCK = 1 in RCC_CFGR1 MSIS with the frequency before entering the Stop mode, limited to 24 MHz, when STOPWUCK = 0	All clocks OFF except LSI and LSE MSIK or HSI16 can be enabled temporarily when requested by a peripheral during LPBAM.	Range 1, 2, 3, 4
Stop 1	LPMS = 001 + SLEEPDEEP bit + WFI or Return from ISR or WFE				Low-power regulator (SMPS or LDO)
Stop 2	LPMS = 010 + SLEEPDEEP bit + WFI or Return from ISR or WFE				
Stop 3	LPMS = 011 + SLEEPDEEP bit + WFI or Return from ISR or WFE	WKUP pin edge, RTC event, external reset in NRST pin, IWDG reset		All clocks OFF except LSI and LSE	
Standby with SRAM2_ 8 Kbytes	LPMS = 10x+ RRS1 = 1 + SLEEPDEEP bit + WFI or Return from ISR or WFE		MSIS from 1 MHz up to 4 MHz		
Standby with SRAM2_Full	LPMS = 10x+ RRS1 = RRS2 = 1+ SLEEPDEEP bit + WFI or Return from ISR or WFE				
Standby	LPMS = 10x + RRS1 = RRS2 = 0 + SLEEPDEEP bit + WFI or Return from ISR or WFE				OFF
Shutdown	LPMS = 11x + SLEEPDEEP bit + WFI or Return from ISR or WFE	WKUP pin edge, RTC event, external reset in NRST pin	MSIS 4 MHz	All clocks OFF except LSE	OFF

1. Refer to the next table.

Table 89. Functionalities depending on the working mode(1)

Peripheral	Run	Sleep	Stop 0/1		Stop 2		Stop 3		Standby		Shutdown		VBAT
			-	Wakeup capability	-	Wakeup capability	-	Wakeup capability	-	Wakeup capability	-	Wakeup capability

GPIOs	O	O	O	O	O	O	(18)	24 pins	(18)	24 pins	(19)	24 pins	-

1. Y = yes (enable). O = optional (disable by default, can be enabled by software). - = not available.
   Gray cells highlight the wakeup capability in each mode.
2. The Flash memory can be configured in power-down mode. By default, it is not in power-down mode.
3. The SRAMs can be powered on or off independently.
4. The SRAM clock can be gated on or off independently.

5. ECC error interrupt or NMI wakes up from Stop mode.
6. 8 Kbytes, 56 Kbytes or full SRAM2 content can be preserved.
7. Sub-blocks or full SRAM1 and SRAM3, full SRAM2 and SRAM4 can be powered-off to save power consumption. SRAM1, SRAM2, SRAM3 and SRAM4 can be accessed by GPDMA in Stop 0 and Stop 1 modes. SRAM4 can be accessed by LPDMA in Stop 0, Stop 1 and Stop 2 modes.
8. GPDMA transfers are functional and autonomous in Stop mode, and generates a wakeup interrupt on transfer events.
9. LPDMA transfers are functional and autonomous in Stop mode, and generates a wakeup interrupt on transfer events.
10. Some peripherals with autonomous mode and wakeup from Stop capability can request HSI16, MSIS or MSIK to be enabled. In this case, the oscillator is woken up by the peripheral, and is automatically put off when no peripheral needs it.
11. OTG_FS is functional in voltage scaling range 1, 2 and 3.
12. USART and LPUART reception and transmission is functional and autonomous in Stop mode, in asynchronous and in SPI master modes, and generates a wakeup interrupt on transfer events.
13. I2C reception and transmission is functional and autonomous in Stop mode, and generates a wakeup interrupt on transfer events.
14. SPI reception and transmission is functional and autonomous in Stop mode, and generates a wakeup interrupt on transfer events.
15. ADC conversion is functional and autonomous in Stop mode, and generates a wakeup interrupt on conversion events.
16. LPTIM is functional and autonomous in Stop mode, and generates a wakeup interrupt on events.
17. MDF and ADF is functional and autonomous in Stop mode, and generates a wakeup interrupt on events.
18. I/Os can be configured with internal pull-up, pull-down or floating in Standby mode.
19. I/Os can be configured with internal pull-up, pull-down or floating in Shutdown mode but the configuration is lost when exiting the Shutdown mode.

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks and configuring voltage scaling to lower-power ranges.
- Gating the clocks to the APB and AHB peripherals when they are unused.
- Powering off unused RAMs

When a SRAM has been powered off, it can be powered on again by following the procedure:

1. Reset SRAMxPD in PWR_CR1.
2. Wait for 1.6 µs.
3. Set SRAMxEN in RCC_AHBxENR.

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop 1, Stop 2, Stop 3, Standby or Shutdown mode while the debug features are used. This is due to the fact that the Cortex-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Section 65.2.5: Debug and low-power modes*.

10.7.2 Low-power background autonomous mode (LPBAM)

The devices support a low-power background autonomous mode (LPBAM), that allows peripherals to be functional and autonomous in Stop 0, Stop 1 and Stop 2 modes (without any software running).

Stop 0 and Stop 1 modes

In Stop 0 and Stop 1 modes, the autonomous peripherals are ADC4, DAC1, LPTIMx (x = 1 to 4), USARTx (x = 1 to 5), LPUART1, SPIx (x = 1 to 3), I2Cx (x = 1 to 4), MDF1, ADF1, GPDMA1 and LPDMA1:

- ADC4, DAC1, LPTIM1, LPTIM3, LPUART1, SPI3, I2C3 and ADF1 are autonomous only with LPDMA1 and SRAM4.
- LPTIM2, USARTx (x = 1 to 5), SPI1, SPI2, I2C1, I2C2, I2C4 and MDF1 are autonomous only with GPDMA1 and SRAM1 to SRAM4.

Stop 2 mode

In Stop 2 mode, the autonomous peripherals are ADC4, DAC1, LPTIM1, LPTIM3, LPUART1, SPI3, I2C3, ADF1 and LPDMA1. In this mode, the SRAM4 can be accessed by the LPDMA1.

LPBAM features

Those autonomous peripherals support the following features:

- Functionality in Stop mode thanks to its own independent clock (named kernel clock) request capability: the peripheral kernel clock is automatically switched on when requested by a peripheral, and automatically switched off when no peripheral requests it.
- DMA transfers supported in Stop mode thanks to the system clock request capability: the system clock (MSIS or HSI16) automatically switched on when requested by a peripheral, and automatically switched off when no peripheral requests it. When the system clock is requested by an autonomous peripheral, the system clock is woken up and distributed to all peripherals enabled in the RCC. This allows the DMA to access the enabled SRAM, and any enabled peripheral register (for instance GPIO or LPGPIO registers).
- Automatic start of the peripheral thanks to the hardware synchronous or asynchronous triggers (such as I/Os edge detection and low-power timer event)
- Wakeup from Stop mode with peripheral interrupt

The GPDMA1 and LPDMA1 are fully functional and the linked-list is updated in Stop mode, allowing the different DMA transfers to be linked without any CPU wakeup. This can be used to chain different peripherals transfers, or to write peripherals registers in order to change their configuration while remaining in Stop mode.

The DMA transfers from memory to memory can be started by hardware synchronous or asynchronous triggers, and the DMA transfers between peripherals and memories can also be gated by those triggers.

Here below some use-cases that can be done while remaining in Stop mode:

- ADC or DAC conversion triggered by a low-power timer (or any other trigger)
  - Wakeup from Stop mode on analog watchdog if the ADC conversion result is out of the programmed thresholds
  - Wakeup from Stop mode on DMA buffer event
- Audio digital filter data transfer into SRAM
  - Wakeup from Stop on sound activity detection
- I2C slave reception or transmission, SPI reception, UART/LPUART reception
  - Wakeup at the end of peripheral transfer or on DMA buffer event
- I2C master transfer, SPI transmission, UART/LPUART transmission, triggered by a low-power timer (or any other trigger)
  - Example: Sensor periodic read
  - Wakeup at the end of peripheral transfer or on DMA buffer event
- Bridges between peripherals
  - Example: ADC converted data transferred by communication peripherals
- Data transfer from/to GPIO/LPGPIO to/from SRAM for:
  - Controlling external components
  - Implementing data transmission and reception protocols
- Data transfer from a SRAM to another one

10.7.3 Run mode

Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to *Section 11: Reset and clock control (RCC)*.

Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers. This bit must be set for the peripherals requesting clocks in Stop mode for LPBAM.

Disabling the peripherals autonomous clock in Stop 2 mode can be performed automatically by resetting the corresponding bit in the RCC_AHB3AMENR and RCC_APB3AMENR registers.

10.7.4 Low-power modes

Entering into a low-power mode

The MCU enters in low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex-M33 system control register is set on *Return from ISR*.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Caution: The peripherals with autonomous mode feature are able to generate an AHB or APB clock request, depending on their internal events. If a clock request is present when WFI or WFE is executed, the low-power mode entry is delayed until the clock request is released.

Exiting a low-power mode

The way the MCU exits the Sleep or Stop mode depends on the way the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - an NVIC IRQ interrupt:

    - When SEVONPEND = 0 in the Cortex-M33 system control register

    By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. Only NVIC interrupts with high enough priority wake up and interrupt the MCU.

    - When SEVONPEND = 1 in the Cortex-M33 system control register

    By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. All NVIC interrupts wake up the MCU, even the disabled ones. Only enabled NVIC interrupts with high enough priority wake up and interrupt the MCU.
  - an event:

    Configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits Stop 3, Standby or Shutdown mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC/TAMP event (see *Figure 622: RTC block diagram*).

After waking up from Standby or Shutdown mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).

Caution: When the device is in Stop mode, a peripheral interrupt powers on an internal oscillator. The corresponding NVIC interrupt channel must be enabled to allow the interrupt to exit the device from Stop mode. It is not allowed to disable a peripheral interrupt by disabling only the NVIC channel while keeping the peripheral interrupt enable, as the device could remain in Stop mode with clock ON.
The peripherals with autonomous mode feature are able to generate an AHB or APB clock request when the device is in Stop mode, depending on their internal events. The software must ensure that either DMA transfer or interrupt is served, by configuring properly and in a consistent way the RCC, the autonomous peripherals, the DMA channels and NVIC. Note that when an autonomous peripheral requests the bus clock in Stop mode, the AHB and APB clocks are distributed to all enabled peripherals (limited to SmartRun domain peripherals in Stop 2 mode). Consequently, enabled peripherals, even without autonomous mode capability, are temporarily clocked and can also generate an interrupt during this time. These peripherals interrupts wake up the device from Stop mode.

10.7.5 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering Sleep mode

The MCU enters the Sleep mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is clear (see the table below for details on how to enter the Sleep mode).

Exiting Sleep mode

The MCU exits the Sleep mode as described in *Exiting a low-power mode* (see the table below for details on how to exit the Sleep mode).

Table 90. Sleep mode

Sleep mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP = 0 – No interrupt (for WFI) or event (for WFE) pending Refer to the Cortex-M33 system control register.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 – No interrupt pending Refer to the Cortex-M33 system control register.

Table 90. Sleep mode (continued)

Sleep mode	Description
Mode exit	If WFI or Return from ISR was used for entry Interrupt (see *Table 153: STM32U575/585 vector table*) If WFE was used for entry and SEVONPEND = 0: Wakeup event (see *Section 17.3: EXTI functional description*) If WFE was used for entry and SEVONPEND = 1: Interrupt even when disabled in NVIC (see *Table 153: STM32U575/585 vector table*) or Wakeup event (see *Section 17.3: EXTI functional description*)
Wakeup latency	None

10.7.6 Stop 0 mode

The Stop 0 mode is based on the Cortex-M33 Deepsleep mod combined with the peripheral clock gating. The voltage regulator is configured in main regulator mode. In Stop 0 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled.

Some peripherals with the LPBAM capability can switch on HSI16 or MSIS or MSIK for transferring data (see *Section 10.7.2* for details).

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 0 mode.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering Stop 0 mode

The MCU enters the Stop 0 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 91* for details on how to enter the Stop 0 mode).

If the Flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming the individual control bits:

- The Independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 52.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in the *RCC Backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BCDR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BCDR.

Several peripherals can be autonomous in Stop 0 mode and can add consumption if they are enabled (see *Section 10.7.2* for more details).

The OPAMPs, the COMPs, the PVM and the PVD can be used in Stop 0 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 4), the DAC1 (two channels), the temperature sensor and the VREFBUF can consume power during the Stop 0 mode, unless they are disabled before entering this mode.

Exiting Stop 0 mode

The MCU exits the Stop 0 mode as described in *Exiting a low-power mode* (see *Table 91* for details on how to exit Stop 0 mode).

When exiting Stop 0 mode by issuing an interrupt or a wakeup event, HSI16 is selected as system clock if the bit STOPWUCK is set in *RCC clock configuration register 1 (RCC_CFGR1)*. The MSIS oscillator is selected as system clock if STOPWUCK is cleared. The MSIS selection allows a wakeup at higher frequency (up to 24 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wakeup from Stop capability. All peripheral clocks must be enabled to allow a wakeup from Stop interrupt (see *Peripheral clock gating*).

When exiting the Stop 0 mode, the MCU is in Run mode, range 4.

Table 91. Stop 0 mode

Stop 0 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 000 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 000 in PWR_CR1
	Note: To enter Stop 0 mode, all EXTI line pending bits (in the EXTI rising edge pending register (EXTI_RPR2)), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop 0 mode entry procedure is ignored and the program execution continues.

Table 91. Stop 0 mode (continued)

Stop 0 mode	Description
Mode exit	If WFI or Return from ISR was used for entry: - any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see *Table 153: STM32U575/585 vector table*). - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: - any EXTI line configured in event mode (see *Section 17.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: - any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see *Table 153: STM32U575/585 vector table*). - any EXTI line configured in event mode (see *Section 17.3: EXTI functional description*) - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request
	Note: All peripheral clocks must be enabled to allow this peripheral to generate a wakeup from Stop interrupt ([PERIPH]EN, [PERIPH]SMEN and [PERIPH]AMEN bits must be set in the RCC, and a functional independent clock must be selected).
Wakeup latency	Longest wakeup time between: MSIS or HSI16 wakeup time and Flash wakeup time from Stop 0 mode.

10.7.7 Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the regulator is in low-power mode (see the table below for details on how to enter and exit Stop 1 mode).

Table 92. Stop 1 mode

Stop 1 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 001 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 001 in PWR_CR1
	Note: To enter Stop 1 mode, all EXTI line pending bits (in EXTI rising edge pending register (EXTI_RPR1)), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop 1 mode entry procedure is ignored and the program execution continues.

Table 92. Stop 1 mode (continued)

Stop 1 mode	Description
Mode exit	If WFI or Return from ISR was used for entry - any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see *Table 153: STM32U575/585 vector table*). - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: - any EXTI line configured in event mode (see *Section 17.3: EXTI functional description*) If WFE was used for entry and SEVONPEND = 1: - any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see *Table 153: STM32U575/585 vector table*). - any EXTI line configured in event mode (see *Section 17.3: EXTI functional description*) - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request
	Note: All peripheral clocks must be enabled to allow this peripheral to generate a wakeup from Stop interrupt ([PERIPH]EN, [PERIPH]SMEN and [PERIPH]AMEN bits must be set in the RCC, and a functional independent clock must be selected).
Wakeup latency	Longest wakeup time between: MSIS or HSI16 wakeup time and regulator wakeup time from low-power mode + Flash wakeup time from Stop 1 mode.

10.7.8 Stop 2 mode

The Stop 2 mode is based on the Cortex-M33 Deepsleep mode combined with peripheral clock gating. In Stop 2 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled.

Some peripherals with the LPBAM capability can switch on HSI16 or MSIS or MSIK for transferring data (see *Section 10.7.2* for more details).

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 2 mode.

I/O states in Stop 2 mode

In the Stop 2 mode, all I/O pins keep the same state as in the Run mode.

Entering Stop 2 mode

The MCU enters the Stop 2 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 93* for details on how to enter the Stop 2 mode).

If the Flash memory programming is ongoing, the Stop 2 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 2 mode entry is delayed until the APB access is finished.

In Stop 2 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 52.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in the *RCC Backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

Several peripherals can be autonomous in Stop 2 mode and can add consumption if they are enabled (see *Section 10.7.2* for more details).

The OPAMPs, the COMPs, the PVM and the PVD can be used in Stop 2 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 4), the DAC1 (two channels), the temperature sensor and the VREFBUF can consume power during the Stop 2 mode, unless they are disabled before entering this mode.

Caution: All the peripherals that cannot be enabled in Stop 2 mode must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring the RCC registers.

Exiting Stop 2 mode

The MCU exits the Stop 2 mode as defined in *Exiting a low-power mode* (see *Table 93* for details on how to exit Stop 2 mode).

When exiting Stop 2 mode by issuing an interrupt or a wakeup event, HSI16 is selected as system clock if the bit STOPWUCK is set in *RCC clock configuration register 1 (RCC_CFGR1)*. MSIS is selected as system clock if STOPWUCK is cleared. The MSI selection allows a wakeup at higher frequency (up to 24 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wakeup from Stop capability. All peripheral clocks must be enabled to allow a wakeup from Stop interrupt (see *Peripheral clock gating*).

When exiting the Stop 2 mode, the MCU is in Run mode, range 4.

Table 93. Stop 2 mode

Stop 2 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 010 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 010 in PWR_CR1
	Note: To enter Stop 2 mode, all EXTI line pending bits (in EXTI rising edge pending register (EXTI_RPR2)), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop mode entry procedure is ignored and the program execution continues.
Mode exit	If WFI or Return from ISR was used for entry: - any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see *Table 153: STM32U575/585 vector table*). - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC) If WFE was used for entry and SEVONPEND = 0: - any EXTI line configured in event mode (see *Section 17.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: - any EXTI line configured in interrupt mode (even if the corresponding EXTI Interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see *Table 153: STM32U575/585 vector table*). - any EXTI line configured in event mode (see *Section 17.3: EXTI functional description*) - any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request
	Note: All peripheral clocks must be enabled to allow this peripheral to generate a wakeup from Stop interrupt ([PERIPH]EN, [PERIPH]SMEN and [PERIPH]AMEN bits must be set in the RCC, and a functional independent clock must be selected).
Wakeup latency	Longest wakeup time between: MSIS or HSI16 wakeup time and regulator wakeup time from low-power mode + Flash wakeup time from Stop 2 mode.

10.7.9 Stop 3 mode

The Stop 3 mode is based on the Cortex-M33 Deepsleep mode combined with peripheral clock gating. In Stop 3 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled.

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduce consumption.

The BOR is always available in Stop 3 mode.

All other peripherals must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring RCC registers.

I/O states in Stop 3 mode

In the Stop 3 mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O.

Some I/Os (listed in *Section 13.3.1: General-purpose I/O (GPIO)*) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Stop 3 mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Stop 3 mode. PC14 and PC15 used for LSE are also functional. The 24 wakeup pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

Entering Stop 3 mode

The MCU enters the Stop 3 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 System Control register is set (see *Table 94* for details on how to enter the Stop 3 mode).

If the Flash memory programming is ongoing, the Stop 3 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 3 mode entry is delayed until the APB access is finished.

In Stop 3 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 30.3: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in the *RCC Backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

Exiting Stop 3 mode

The MCU exits the Stop 3 mode as described in *Exiting a low-power mode* (see *Table 94* for details on how to exit Stop 3 mode).

When exiting Stop 3 mode by issuing an interrupt or a wakeup event, HSI16 is selected as system clock if the STOPWUCK bit is set in *RCC clock configuration register 1 (RCC_CFGR1)*. MSIS is selected as system clock if STOPWUCK is cleared. The MSIS selection allows a wakeup at higher frequency (up to 24 MHz).

When exiting the Stop 3 mode, the MCU is in Run mode, range 4.

Table 94. Stop 3 mode

Stop 3 mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS =“011 in PWR_CR1 – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 011 in PWR_CR1 – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wakeup source, cleared
	Note: To enter Stop 3 mode, all WUFx, and the RTC/TAMP flags generating wakeup interrupts must be cleared. Otherwise, the Stop 3 mode entry procedure is completed but the Stop 3 is exited immediately after entry.
Mode exit	WKUPx pin edge, RTC/TAMP event/interrupt, NRST pin external reset, IWDG reset, BOR reset
Wakeup latency	Longest wakeup time between: MSIS or HSI16 wakeup time and regulator wakeup time from low-power mode + Flash wakeup time from Stop 3 mode.

10.7.10 Standby mode

The lowest power mode in which the BOR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the Backup domain and Standby circuitry (see *Figure 29: Power supply overview*). SRAM2 content can be partially or fully preserved depending on RRSB1 and RRSB2 bits configuration in PWR_CR1. In this case, the low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The ULPMEN bit in the PWR_CR1 register must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode.

I/O states in Standby mode

In the Standby mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O.

Some I/Os (listed in *Section 13.3.1: General-purpose I/O (GPIO)*) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. The 24 wakeup pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

Entering Standby mode

The MCU enters the Standby mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 95* for details on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 52.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in *RCC Backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPRE bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

Exiting Standby mode

The MCU exits the Standby mode as described in *Exiting a low-power mode*. The SBF status flag in the *PWR status register (PWR_SR)* indicates that the MCU was in Standby mode. All registers are reset after wakeup from Standby except for *PWR control register 3 (PWR_CR3)* (see *Table 95* for more details on how to exit Standby mode).

When exiting Standby mode, I/Os that were configured with pull-up or pull-down during Standby through PWR_PUCRx or PWR_PDCRx, keep this configuration upon exiting Standby mode until the APC bit in PWR_CR3 is cleared. Once APC is cleared, the I/Os are either configured to their reset values or to the pull-up/pull-down state according to the GPIOx_PUPDR registers. The content of the PWR_PUCRx or PWR_PDCRx registers is not lost and can be re-used for a sub-sequent entering into Standby mode.

Some I/Os (listed in *Section 13.3.1: General-purpose I/O (GPIO)*) are used for JTAG/SW debug and have internal pull-up or pull-down activated after reset so is configured at this reset value, as well when exiting Standby mode.

For I/Os, with a pull-up or pull-down pre-defined after reset (some JTAG/SW I/Os) or with the GPIOx_PUPDR programming done after exiting from Standby, in case those programming is different from the PWR_PUCRx or PWR_PDCRx programmed value during Standby, both a pull-down and pull-up are applied until APC is cleared, releasing the PWR_PUCRx or PWR_PDCRx programmed value.

Table 95. Standby mode

Standby mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 10x in PWR_CR1 (1) – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 10x in PWR_CR1(1) – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wakeup source, cleared
Mode exit	WKUPx pin edge, RTC/TAMP event/interrupt, NRST pin external reset, IWDG reset, BOR reset
Wakeup latency	Reset phase

1. The Standby mode is also entered if LPMS = 11X in PWR_CR1 with BREN = 1 in PWR_BDCR1.

10.7.11 Shutdown mode

The lowest power consumption is reached in Shutdown mode. It is based on the Deepsleep mode with the voltage regulator disabled. The core domain is consequently powered off. The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the Backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

I/O states in Shutdown mode

In the Shutdown mode, I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers (x=A,B,C,D,E,F,G,H)), or with a pull-down (see PWR_PDCRx registers (x=A,B,C,D,E,F,G,H)), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

Some I/Os (listed in *Section 13.3.1: General-purpose I/O (GPIO)*) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Shutdown mode setting to 1 their respective bit in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. The 24 wakeup pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

Entering Shutdown mode

The MCU enters the Shutdown mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 96* for details on how to enter Shutdown mode).

In Shutdown mode, the following features can be selected by programming individual control bits:

- The real-time clock (RTC) is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR). Caution: in case of V_{DD} power-down, the RTC content is lost.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in the Backup domain control register (RCC_BDCR).

Caution: The Shutdown mode cannot be entered if the BREN bit is set in the *PWR Backup domain control register 1 (PWR_BDCR1)*. If BREN = 1, the Standby mode is entered instead of Shutdown mode.

Exiting Shutdown mode

The MCU exits the Shutdown mode as described in *Exiting a low-power mode*. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the Backup domain) are reset after a wakeup from Shutdown (see *Table 96* for more details on how to exit Shutdown mode).

When exiting Shutdown mode, I/Os that were configured with pull-up or pull-down during Shutdown through registers PWR_PUCRx or PWR_PDCRx lose their configuration and are configured in floating state or to their pull-up pull-down reset value (for some I/Os listed in *Section 13.3.1: General-purpose I/O (GPIO)*).

Table 96. Shutdown mode

Shutdown mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 11X in PWR_CR1 with BREN = 0 in PWR_BDCR1 – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXT = 1 – No interrupt pending – LPMS = 11X in PWR_CR1 – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wakeup source, cleared
Mode exit	WKUPx pin edge, RTC/TAMP event/interrupt, NRST pin external reset
Wakeup latency	Reset phase

10.7.12 Power modes output pins

In order to help the debug, three signals are available as device pins alternate functions:

- **CSLEEP**

  When set, CSLEEP indicates that the CPU is in Sleep mode: WFI or WFE has been executed.

  When cleared, CSLEEP indicates that the CPU is in Run mode.

- **CDSTOP**

  When set, CDSTOP indicates that the CPU domain (CD) is in CStop mode, meaning that the following conditions are filled:

  – WFI or WFE has been executed with CPU SLEEPDEEP = 1.

  – No AHB/APB clock is running in the CPU domain.

  When cleared, CDSTOP indicates that the CPU domain is not in CStop mode: AHB/APB clocks run in the CPU domain.

- **SRDSTOP**

  When set, SRDSTOP indicates that the SmartRun domain (SRD) is in DStop mode, meaning that the following conditions are filled:

  – WFI or WFE has been executed with CPU SLEEPDEEP = 1.

  – No AHB/APB clock is running in the SRD domain.

  When cleared, SRDSTOP indicates that the SmartRun domain is not in DStop mode: AHB/APB clocks run in the SRD domain.

Note: The AHB/APB clocks run after WFI or WFE has been executed if an autonomous peripheral requests its bus clock in Stop mode. The peripherals bus clock request can delay or prevent the device to enter low-power modes (refer to Section 10.7.2: Low-power background autonomous mode (LPBAM) and Section 10.7.4: Low-power modes).

The table below explains the MCU power mode depending on these signals states.

Table 97. Power modes output states versus MCU power modes

CSLEEP	CDSTOP	SRDSTOP	MCU power modes(1)
0	0	0	Run mode
1	0	0	Sleep mode or Stop 0 or Stop 1 mode, with AHB/APB clocks running in CPU domain (CD) and SmartRun domain (SRD)
1	1	0	Stop 0, Stop 1 or Stop 2 mode, with AHB/APB clocks running in SmartRun domain (SRD)
1	1	1	Stop 0, Stop 1, or Stop 2 mode

1. CSLEEP, CDSTOP and SRDSTOP are generated in core domain, consequently they are not driven in Stop 3, Standby and Shutdown modes.

10.8 PWR security and privileged protection

10.8.1 PWR security protection

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, some PWR register fields can be secured against non-secure access.

The PWR TrustZone security allows the following features to be secured through the PWR_SECCFGR register:

- Low-power mode
- Wake-up (WKUP) pins
- Voltage detection and monitoring
- V_{BAT} mode
- I/Os pull-up/pull-down configuration

Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC: the voltage scaling (VOS) configuration and the regulator booster (BOOSTEN) are secure.
- A GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode is secure.
- The UCPD1 is secure in the GTZC: the PWR_UCPDR register is secure.

Table 98 gives a summary of the PWR secured bits following the security configuration bit in PWR_SECCFGR. As soon as at least one function is configured to be secure, the PWR clock control is also secure in the RCC.

A non-secure access to a secure-protected register bit is denied:

- The secured bits are not written (WI) with a non-secure write access.
- The secured bits are read as 0 (RAZ) with a non-secure read access.

A non-secure write access to PWR_SECCFGR is WI and generates an illegal access event and an interrupt if enabled in the GTZC. It can be read with a non-secure read access.

When the TrustZone security is disabled (TZEN = 0), PWR_SECCFGR is RAZ/WI and all other registers are non-secure.

Table 98. PWR Security configuration summary

Secure configuration register	Security configuration bit	Register name	Secured bits	Non-secure access on secure bits
PWR_SECCFGR	Not applicable(1)	PWR_SECCFGR	All bits	Read OK. WI and illegal access event
PWR_SECCFGR	At least one bit is set	PWR_PRIVCFGR	SPRIV	Read OK. WI
PWR_SECCFGR	LPMSEC	PWR_CR1	All bits	RAZ/WI
		PWR_CR2	All bits	
		PWR_SR	CSSF	WI

Table 98. PWR Security configuration summary (continued)

Secure configuration register	Security configuration bit	Register name	Secured bits	Non-secure access on secure bits
PWR_SECCFGR	VDMSEC	PWR_CR3	All bits	RAZ/WI
		PWR_SVMCR	All bits	RAZ/WI
PWR_SECCFGR	VBSEC	PWR_BDCR1	All bits	RAZ/WI
		PWR_BDCR2	All bits	RAZ/WI
		PWR_DBPR	All bits	RAZ/WI
PWR_SECCFGR	APCSEC	PWR_APCR	All bits	RAZ/WI
PWR_SECCFGR	WUPxSEC (x = 1 to 8)	PWR_WUCR1	WUPENx	RAZ/WI
		PWR_WUCR2	WUPPx	RAZ/WI
		PWR_WUCR3	WUSELx	RAZ/WI
		PWR_WUSCR	CWUFx	WI
GTZC_TZSC_ SECCFGR	UCPD1SEC	PWR_UCPDR	All bits	RAZ/WI
RCC_SECCFGR	SYSCLKSEC	PWR_VOSR	VOS[1:0], BOOSTEN	RAZ/WI
GPIOx_SECCFGR (x=A,B..I)	SECy (y=0..15)	PWR_PUCRx (x = A to I)	PUy (y = 0 to 15)	RAZ/WI
		PWR_PDCRx (x = A to I)	PDy (y = 0 to 15)	RAZ/WI

1. PWR_SECCFGR is always secure.

10.8.2 PWR privileged protection

By default, after a reset, all PWR registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR that can be written with privileged access only. PWR_PRIVCFGR can be read by secure and non secure, privileged and unprivileged accesses.

The SPRIV bit in PWR_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all PWR secure functions (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in *Table 98: PWR Security configuration summary*).

When the SPRIV bit is set in PWR_PRIVCFGR:

- The PWR secure bits can be written only with privileged access, including PWR_SECCFGR.
- The PWR secure bits can be read only with privileged access except PWR_SECCFGR and PWR_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit of PWR_PRIVCFGR can be written with privileged access only, secure or non-secure. This bit configures the privileged access of all PWR securable functions that are configured as non-secure (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in *Table 98: PWR Security configuration summary*)).

When the NSPRIV bit is set in PWR_PRIVCFGR:

- The PWR securable bits that are configured as non-secure, can be written only with privileged access.
- The PWR securable bits that are configured as non-secure, can be read only with privileged access except PWR_PRIVCFGR that can be read by privileged or unprivileged accesses.
- The VOSRDY and BOOSTRDY bits in PWR_VOSR, PWR_SR, PWR_SVMSR, PWR_BDSR and PWR_WUSR, can be read with privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

10.9 PWR interrupts

The table below gives a summary of the interrupt sources and the way to control them.

Table 99. PWR interrupt requests

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep, Stop 0, 1, 2 modes	Exit Stop 3, Standby, Shutdown modes
PWR_S3WU(1)	Wakeup interrupt flag	WUFx (x = 1 to 8)	WUPENx (x = 1 to 8)	Write CWUFx = 1 (x = 1 to 8)	No	Yes(2)
PVD_PVM	Programmable voltage detector through EXTI line 16	PVDO	EXTI line 16 enabled	Write EXTI PIF16 = 1	Yes	No
	USB supply voltage monitor through EXTI line 19	VDDUSBRDY	EXTI line 19 enabled	Write EXTI PIF19 = 1	Yes	No
	V_{DDIO2} supply voltage monitor through EXTI line 20	VDDIO2RDY	EXTI line 20 enabled	Write EXTI PIF20 = 1		
	Analog supply voltage monitor1 through EXTI line 21	VDDA1RDY	EXTI line 21 enabled	Write EXTI PIF21 = 1		
	Analog supply voltage monitor2 through EXTI line 22	VDDA2RDY	EXTI line 22 enabled	Write EXTI PIF22 = 1		

1. The PWR_S3WU interrupt is generated only when the device is in Stop 3 mode (not applicable in Run, Sleep, Stop 0, Stop 1 and Stop 2 modes).
2. Only an interrupt can wake up from Stop 3 mode (not possible with an event).

10.10 PWR registers

10.10.1 PWR control register 1 (PWR_CR1)

This register is protected against non-secure access when LPMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x00

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	SRAM4PD	SRAM3PD	SRAM2PD	SRAM1PD	ULPMEN	RRSB2	RRSB1	Res.	Res.	LPMS[2:0]		
				rw	rw	rw	rw	rw	rw	rw			rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SRAM4PD**: SRAM4 power down
This bit is used to reduce the consumption by powering off the SRAM4.
0: SRAM4 powered on
1: SRAM4 powered off

Bit 10 **SRAM3PD**: SRAM3 power down
This bit is used to reduce the consumption by powering off the SRAM3.
0: SRAM3 powered on
1: SRAM3 powered off

Bit 9 **SRAM2PD**: SRAM2 power down
This bit is used to reduce the consumption by powering off the SRAM2.
0: SRAM2 powered on
1: SRAM2 powered off

Bit 8 **SRAM1PD**: SRAM1 power down
This bit is used to reduce the consumption by powering off the SRAM1.
0: SRAM1 powered on
1: SRAM1 powered off

Bit 7 **ULPMEN**: BOR ultra-low power mode
This bit is used to reduce the consumption by configuring the BOR in discontinuous mode.
0: BOR operating in continuous (normal) mode in Standby mode
1: BOR operating in discontinuous (ultra-low power) mode in Standby mode

Caution: This bit must be set to reach the lowest power consumption in Standby mode.

Bit 6 **RRSB2**: SRAM2 page 2 retention in Stop 3 and Standby modes

This bit is used to keep the SRAM2 page 2 content in Stop 3 and Standby modes. The SRAM2 page 2 corresponds to the last 56 Kbytes of the SRAM2 (from SRAM2 base address + 0x2000 to SRAM2 base address + 0xFFFF).

0: SRAM2 page2 content not retained in Stop3 and Standby modes

1: SRAM2 page2 content retained in Stop 3 and Standby modes

Note: This bit has no effect in Shutdown mode.
The backup SRAM is also retained when this bit is set.

Bit 5 **RRSB1**: SRAM2 page 1 retention in Stop 3 and Standby modes

This bit is used to keep the SRAM2 page 1 content in Stop 3 and Standby modes. The SRAM2 page 1 corresponds to the first 8 Kbytes of the SRAM2 (from SRAM2 base address to SRAM2 base address + 0x1FFF).

0: SRAM2 page1 content not retained in Stop 3 and Standby modes

1: SRAM2 page1 content retained in Stop 3 and Standby modes

Note: This bit has no effect in Shutdown mode.
The backup SRAM is also retained when this bit is set.

Bits 4:3 Reserved, must be kept at reset value.

Bits 2:0 **LPMS[2:0]**: Low-power mode selection

These bits select the low-power mode entered when the CPU enters the Deepsleep mode.

000: Stop 0 mode

001: Stop 1 mode

010: Stop 2 mode

011: Stop 3 mode

10x: Standby mode (Standby mode also entered if LPMS = 11X in PWR_CR1 with BREN = 1 in PWR_BDCR1)

11x: Shutdown mode if BREN = 0 in PWR_BDCR1

10.10.2 PWR control register 2 (PWR_CR2)

This register is protected against non-secure access when LPMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Address offset: 0x04

Reset value: 0x0000 0000

	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw		rw	rw	rw

Bit 31 **SRDRUN**: SmartRun domain in Run mode
0: SmartRun domain AHB3 and APB3 clocks disabled by default in Stop 0,1, 2 modes
1: SmartRun domain AHB3 and APB3 clocks kept enabled in Stop 0,1, 2 modes

Bits 30:24 Reserved, must be kept at reset value.

Bit 23 **SRAM3PDS8**: SRAM3 page 8 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 8 content retained in Stop modes
1: SRAM3 page 8 content lost in Stop modes

Bit 22 **SRAM3PDS7**: SRAM3 page 7 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 7 content retained in Stop modes
1: SRAM3 page 7 content lost in Stop modes

Bit 21 **SRAM3PDS6**: SRAM3 page 6 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 6 content retained in Stop modes
1: SRAM3 page 6 content lost in Stop modes

Bit 20 **SRAM3PDS5**: SRAM3 page 5 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 5 content retained in Stop modes
1: SRAM3 page 5 content lost in Stop modes

Bit 19 **SRAM3PDS4**: SRAM3 page 4 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 4 content retained in Stop modes
1: SRAM3 page 4 content lost in Stop modes

Bit 18 **SRAM3PDS3**: SRAM3 page 3 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 3 content retained in Stop modes
1: SRAM3 page 3 content lost in Stop modes

Bit 17 **SRAM3PDS2**: SRAM3 page 2 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 2 content retained in Stop modes
1: SRAM3 page 2 content lost in Stop modes

Bit 16 **SRAM3PDS1**: SRAM3 page 1 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM3 page 1 content retained in Stop modes
1: SRAM3 page 1 content lost in Stop modes

Bit 15 Reserved, must be kept at reset value.

Bit 14 **FLASHFWU**: Flash memory fast wakeup from Stop 0 and Stop 1 modes
This bit is used to obtain the best trade-off between low-power consumption and wakeup time when exiting the Stop 0 or Stop 1 modes.
When this bit is set, the Flash memory remains in normal mode in Stop 0 and Stop 1 modes, which offers a faster startup time with higher consumption.
0: Flash memory enters low-power mode in Stop 0 and Stop 1 modes (lower-power consumption).
1: Flash memory remains in normal mode in Stop 0 and Stop 1 modes (faster wakeup time).

Bit 13 **SRAM4FWU**: SRAM4 fast wakeup from Stop 0, Stop 1 and Stop 2 modes
This bit is used to obtain the best trade-off between low-power consumption and wakeup time. SRAM4 wakeup time increases the wakeup time when exiting Stop 0, 1 and 2 modes, and also increases the LPDMA access time to SRAM4 during Stop modes.
0: SRAM4 enters low-power mode in Stop 0, 1 and 2 modes (source biasing for lower-power consumption).
1: SRAM4 remains in normal mode in Stop 0, 1 and 2 modes (higher consumption but no SRAM4 wakeup time).

Bit 12 **PKARAMPDS**: PKA SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
0: PKA SRAM content retained in Stop modes
1: PKA SRAM content lost in Stop modes

Bit 11 **PRAMPDS**: FMAC, FDCAN and USB peripherals SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
0: FMAC, FDCAN and USB peripherals SRAM content retained in Stop modes
1: FMAC, FDCAN and USB peripherals SRAM content lost in Stop modes

Bit 10 **DMA2DRAMPDS**: DMA2D SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
0: DMA2D SRAM content retained in Stop modes
1: DMA2D SRAM content lost in Stop modes

Bit 9 **DC1RAMPDS**: DCACHE1 SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
0: DCACHE1 SRAM content retained in Stop modes
1: DCACHE1 SRAM content lost in Stop modes

Bit 8 **ICRAMPDS**: ICACHE SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
0: ICACHE SRAM content retained in Stop modes
1: ICACHE SRAM content lost in Stop modes

Bit 7 Reserved, must be kept at reset value.

Bit 6 **SRAM4PDS**: SRAM4 power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM4 content retained in Stop modes
1: SRAM4 content lost in Stop modes

Bit 5 **SRAM2PDS2**: SRAM2 page 2 (56 Kbytes) power-down in Stop modes (Stop 0, 1, 2)
0: SRAM2 page 2 content retained in Stop modes
1: SRAM2 page 2 content lost in Stop modes
Note: The SRAM2 page 2 retention in Stop 3 is controlled by RRSB2 bit in PWR_CR1.

Bit 4 **SRAM2PDS1**: SRAM2 page 1 (8 Kbytes) power-down in Stop modes (Stop 0, 1, 2)
0: SRAM2 page 1 content retained in Stop modes
1: SRAM2 page 1 content lost in Stop modes
Note: The SRAM2 page 1 retention in Stop 3 is controlled by RRSB1 bit in PWR_CR1.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SRAM1PDS3**: SRAM1 page 3 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM1 page 3 content retained in Stop modes
1: SRAM1 page 3 content lost in Stop modes

Bit 1 **SRAM1PDS2**: SRAM1 page 2 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM1 page 2 content retained in Stop modes
1: SRAM1 page 2 content lost in Stop modes

Bit 0 **SRAM1PDS1**: SRAM1 page 1 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
0: SRAM1 page 1 content retained in Stop modes
1: SRAM1 page 1 content lost in Stop modes

10.10.3 PWR control register 3 (PWR_CR3)

This register is protected against non-secure access when VDMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x08

Power-on reset value: 0x0000 0000

Exit from Standby modes: not affected

System reset: not affected, except REGSEL that is cleared to 0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSTEN**: Fast soft start
- 0: LDO/SMPS fast startup disabled (limited inrush current)
- 1: LDO/SMPS fast startup enabled

Bit 1 **REGSEL**: Regulator selection
- 0: LDO selected
- 1: SMPS selected

Note: REGSEL is reserved and must be kept at reset value in packages without SMPS.

Bit 0 Reserved, must be kept at reset value.

10.10.4 PWR voltage scaling register (PWR_VOSR)

Some register fields are protected against non-secure access depending on RCC_SECCFGR.

These fields can be protected against unprivileged access depending on PWR_PRIVCFGR.

Address offset: 0x0C

Reset value: 0x0000 8000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

VOSRDY	BOOSTRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r														

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **BOOSTEN**: EPOD booster enable

This bit is protected against non-secure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

This bit must be set in range 1 and range 2 before increasing the system clock frequency above 55 MHz.

This bit is reset when going into Stop modes (0, 1, 2, 3).

0: Booster disabled

1: Booster enabled

Bits 17:16 **VOS[1:0]**: Voltage scaling range selection

This field is protected against non-secure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

00: Range 4 (lowest power)

01: Range 3

10: Range 2

11: Range 1 (highest frequency)

Bit 15 **VOSRDY:** Ready bit for V_{CORE} voltage scaling output selection

0: Not ready, voltage level < VOS selected level

1: Ready, voltage level ≥ VOS selected level

Bit 14 **BOOSTRDY:** EPOD booster ready

This bit is set to 1 by hardware when the power booster startup time is reached. The system clock frequency can be switched higher than 55 MHz only after this bit is set.

0: Power booster not ready

1: Power booster ready

Bits 13:0 Reserved, must be kept at reset value.

10.10.5 PWR supply voltage monitoring control register (PWR_SVMCR)

This register is protected against non-secure access when VDMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDLS[2:0]			PVDE	Res.	Res.	Res.	Res.
								rw	rw	rw	rw				

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ASV**: V_{DDA} independent analog supply valid
This bit is used to validate the V_{DDA} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the analog peripherals. If V_{DDA} is not always present in the application, the V_{DDA} voltage monitor can be used to determine whether this supply is ready or not.
0: V_{DDA} not present: logical and electrical isolation is applied to ignore this supply.
1: V_{DDA} valid

Bit 29 **IO2SV**: V_{DDIO2} independent I/Os supply valid
This bit is used to validate the V_{DDIO2} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PG[15:2]. If V_{DDIO2} is not always present in the application, the V_{DDIO2} voltage monitor can be used to determine whether this supply is ready or not.
0: V_{DDIO2} not present: logical and electrical isolation is applied to ignore this supply.
1: V_{DDIO2} valid

Bit 28 **USV**: V_{DDUSB} independent USB supply valid
This bit is used to validate the V_{DDUSB} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USB OTG peripheral. If V_{DDUSB} is not always present in the application, the V_{DDUSB} voltage monitor can be used to determine whether this supply is ready or not.
0: V_{DDUSB} not present: logical and electrical isolation is applied to ignore this supply.
1: V_{DDUSB} valid

Bit 27 **AVM2EN**: V_{DDA} independent analog supply voltage monitor 2 enable (1.8 V threshold)
0: V_{DDA} voltage monitor 2 disabled
1: V_{DDA} voltage monitor 2 enabled

Bit 26 **AVM1EN**: V_{DDA} independent analog supply voltage monitor 1 enable (1.6 V threshold)
0: V_{DDA} voltage monitor 1 disabled
1: V_{DDA} voltage monitor 1 enabled

Bit 25 **IO2VMEN**: V_{DDIO2} independent I/Os voltage monitor enable
0: V_{DDIO2} voltage monitor disabled
1: V_{DDIO2} voltage monitor enabled

Bit 24 **UVMEN**: V_{DDUSB} independent USB voltage monitor enable
0: V_{DDUSB} voltage monitor disabled
1: V_{DDUSB} voltage monitor enabled

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:5 **PVDLS[2:0]**: Programmable voltage detector (PVD) level selection
These bits select the voltage threshold detected by the PVD:
000: V_{PVD0} around 2.0 V
001: V_{PVD1} around 2.2 V
010: V_{PVD2} around 2.4 V
011: V_{PVD3} around 2.5 V
100: V_{PVD4} around 2.6 V
101: V_{PVD5} around 2.8 V
110: V_{PVD6} around 2.9 V
111: External input analog voltage PVD_IN (compared internally to VREFINT)

Bit 4 **PVDE**: Programmable voltage detector enable
0: PVD disabled
1: PVD enabled

Bits 3:0 Reserved, must be kept at reset value.

10.10.6 PWR wakeup control register 1 (PWR_WUCR1)

Each register bit WUPENx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 in PWR_SECCFGR.

Each bit WUPENx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV =1 .

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x14

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

11: WKUP0_3

10.10.9 PWR Backup domain control register 1 (PWR_BDCR1)

This register is write-protected when DBP is cleared in PWR_DBPR.

This register is protected against non-secure access when VBSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VBSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x20

Backup domain reset value: 0x0000 0000

Power-on reset: not affected

Exit from Standby modes: not affected

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	Res.	Res.	Res.	BREN
											rw				rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **MONEN**: Backup domain voltage and temperature monitoring enable
0: Backup domain voltage and temperature monitoring disabled
1: Backup domain voltage and temperature monitoring enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BREN:** Backup RAM retention in Standby and V_{BAT} modes
When this bit is set, the backup RAM content is kept in Standby(1) and V_{BAT} modes.
If BREN is reset, the backup RAM can still be used in Run, Sleep and Stop modes. However, its content is lost in Standby, Shutdown and V_{BAT} modes. This bit can be written only when the regulator is LDO, which must be configured before switching to SMPS.
0: Backup RAM content lost in Standby(1) and V_{BAT} modes
1: Backup RAM content preserved in Standby and V_{BAT} modes
Note: Backup RAM cannot be preserved in Shutdown mode.

1. The Backup SRAM content is lost in Standby mode without SRAM2 retention. If either RRSB1 or RRSB2 bit is set in Standby mode, the backup SRAM is also retained.

10.10.10 PWR Backup domain control register 2 (PWR_BDCR2)

This register is protected against non-secure access when VBSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VBSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x24

Power-on reset value: 0x0000 0000

Exit from Standby modes: not affected

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBRS	VBE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **VBRS**: V_{BAT} charging resistor selection
0: Charge V_{BAT} through a 5 kΩ resistor
1: Charge V_{BAT} through a 1.5 kΩ resistor

Bit 0 **VBE**: V_{BAT} charging enable
0: V_{BAT} battery charging disabled
1: V_{BAT} battery charging enabled

10.10.11 PWR disable Backup domain register (PWR_DBPR)

This register is protected against non-secure access when VBSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VBSEC = 0 and NSPRIV = 1.

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBP
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DBP**: Disable Backup domain write protection

In reset state, all registers and SRAM in Backup domain are protected against parasitic write access. This bit must be set to enable the write access to these registers.

0: Write access to Backup domain disabled

1: Write access to Backup domain enabled

10.10.12 PWR USB Type-C and Power Delivery register (PWR_UCPDR)

This register is protected against non-secure access when UCPD1SEC = 1 in TZSC_SECCFGR.

This register is protected against unprivileged access when UCPD1SEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when UCPD1SEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x2C

Reset value: 0x0000 0000

(reset value not affected by exit from Standby modes)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UCPD_STBY	UCPD_DBDIS
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **UCPD_STBY**: UCPD Stop 3 and Standby modes

When set, this bit is used to memorize the UCPD configuration in Stop 3 and Standby modes. This bit must be written to 1 just before entering Stop 3 or Standby mode when using UCPD. It must be written to 0 after exiting Stop 3 or Standby mode and before writing any UCPD registers.

Bit 0 **UCPD_DBDIS**: UCPD dead battery disable

After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to handover control to the UCPD (the UCPD must be initialized before doing the disable).

0: UCPD dead battery pull-down behavior enabled on UCPDx_CC1 and UCPDx_CC2 pins

1: UCPD dead battery pull-down behavior disabled on UCPDx_CC1 and UCPDx_CC2 pins

10.10.13 PWR security configuration register (PWR_SECCFGR)

This register can be written only when the access is secure. It can be read by secure or non-secure access.

This register is write-protected against unprivileged write access when SPRIV = 1 in PWR_PRIVCFGR.

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **APCSEC**: Pull-up/pull-down secure protection

0: PWR_APCR can be read and written with secure or non-secure access.

1: PWR_APCR can be read and written only with secure access.

Bit 14 **VBSEC**: Backup domain secure protection

0: PWR_BDCR1, PWR_BDCR2 and PWR_DBPR can be read and written with secure or non-secure access.

1: PWR_BDCR1, PWR_BDCR2 and PWR_DBPR can be read and written only with secure access.

Bit 13 **VDMSEC**: Voltage detection and monitoring secure protection

0: PWR_SVMCR and PWR_CR3 can be read and written with secure or non-secure access.

1: PWR_SVMCR and PWR_CR3 can be read and written only with secure access.

Bit 12 **LPMSEC**: Low-power modes secure protection

0: PWR_CR1, PWR_CR2 and CSSF in the PWR_SR can be read and written with secure or non-secure access.

1: PWR_CR1, PWR_CR2, and CSSF in the PWR_SR can be read and written only with secure access.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **WUP8SEC**: WUP8 secure protection

0: Bits related to the WKUP8 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP8 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 6 **WUP7SEC**: WUP7 secure protection

0: Bits related to the WKUP7 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP7 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 5 **WUP6SEC**: WUP6 secure protection

0: Bits related to the WKUP6 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP6 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 4 **WUP5SEC**: WUP5 secure protection

0: Bits related to the WKUP5 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP5 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 3 **WUP4SEC**: WUP4 secure protection

0: Bits related to the WKUP4 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP4 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 2 **WUP3SEC**: WUP3 secure protection

0: Bits related to the WKUP3 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP3 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 1 **WUP2SEC**: WUP2 secure protection

0: Bits related to the WKUP2 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP2 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

Bit 0 **WUP1SEC**: WUP1 secure protection

0: Bits related to the WKUP1 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.

1: Bits related to the WKUP1 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

10.10.14 PWR privilege control register (PWR_PRIVCFGR)

This register can be written only when the access is privileged. It can be read by privileged or unprivileged access.

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: PWR non-secure functions privilege configuration

This bit is set and reset by software. It can be written only by privileged access, secure or non-secure.

0: Read and write to PWR non-secure functions can be done by privileged or unprivileged access.

1: Read and write to PWR non-secure functions can be done by privileged access only.

Bit 0 **SPRIV**: PWR secure functions privilege configuration

This bit is set and reset by software. It can be written only by a secure privileged access.

0: Read and write to PWR secure functions can be done by privileged or unprivileged access.

1: Read and write to PWR secure functions can be done by privileged access only.

10.10.15 PWR status register (PWR_SR)

Some register fields are protected against non-secure access depending on PWR_SECCFGR.

Some register fields are protected against unprivileged access depending on PWR_PRIVCFGR.

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	CSSF
													r	r	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **SBF**: Standby flag

This bit is set by hardware when the device enters the Standby mode, and is cleared by writing 1 to the CSSF bit, or by a power-on reset. It is not cleared by the system reset.

0: The device did not enter Standby mode.

1: The device entered Standby mode.

Bit 1 **STOPF**: Stop flag

This bit is set by hardware when the device enters a Stop mode, and is cleared by software by writing 1 to the CSSF bit.

0: The device did not enter any Stop mode.

1: The device entered a Stop mode.

Bit 0 **CSSF**: Clear Stop and Standby flags

This bit is protected against non-secure access when LPMSEC = 1 in PWR_SECCFGR.

This bit is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Writing 1 to this bit clears the STOPF and SBF flags.

10.10.16 PWR supply voltage monitoring status register (PWR_SVMSR)

Address offset: 0x3C

Reset value: 0x0000 8000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	VDDA2RDY	VDDA1RDY	VDDIO2RDY	VDDUSBRDY	Res.	Res.	Res.	Res.	Res.	Res.	ACTVOS[1:0]	
				r	r	r	r							r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACTVOSRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	Res.	REGS	Res.
r											r			r	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **VDDA2RDY**: V_{DDA} ready versus 1.8 V voltage monitor

0: V_{DDA} is below the threshold of the V_{DDA} voltage monitor 2 (around 1.8 V).

1: V_{DDA} is equal or above the threshold of the V_{DDA} voltage monitor 2 (around 1.8 V).

Bit 26 **VDDA1RDY**: V_{DDA} ready versus 1.6V voltage monitor

0: V_{DDA} is below the threshold of the V_{DDA} voltage monitor 1 (around 1.6 V).

1: V_{DDA} is equal or above the threshold of the V_{DDA} voltage monitor 1 (around 1.6 V).

Bit 25 **VDDIO2RDY**: V_{DDIO2} ready

0: V_{DDIO2} is below the threshold of the V_{DDIO2} voltage monitor.

1: V_{DDIO2} is equal or above the threshold of the V_{DDIO2} voltage monitor.

Bit 24 **VDDUSBRDY**: V_{DDUSB} ready

0: V_{DDUSB} is below the threshold of the V_{DDUSB} voltage monitor.

1: V_{DDUSB} is equal or above the threshold of the V_{DDUSB} voltage monitor.

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **ACTVOS[1:0]**: VOS currently applied to V_{CORE}
This field provides the last VOS value.
00: Range 4 (lowest power)
01: Range 3
10: Range 2
11: Range 1 (highest frequency)

Bit 15 **ACTVOSRDY**: Voltage level ready for currently used VOS
0: V_{CORE} is above or below the current voltage scaling provided by ACTVOS[1:0].
1: V_{CORE} is equal to the current voltage scaling provided by ACTVOS[1:0]

Bits 14:5 Reserved, must be kept at reset value.

Bit 4 **PVDO**: Programmable voltage detector output
0: V_{DD} is equal or above the PVD threshold selected by PVDLS[2:0].
1: V_{DD} is below the PVD threshold selected by PVDLS[2:0].

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **REGS**: Regulator selection
0: LDO selected
1: SMPS selected

Bit 0 Reserved, must be kept at reset value.

10.10.17 PWR Backup domain status register (PWR_BDSR)

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x40

Backup domain reset value: 0x0000 0000

Power-on reset: not affected

Exit from Standby modes: not affected
System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEMPH	TEMPL	VBATH	Res.
												r	r	r	

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **TEMPH**: Temperature level monitoring versus high threshold
0: Temperature < high threshold
1: Temperature ≥ high threshold

Bit 2 **TEMPL**: Temperature level monitoring versus low threshold
0: Temperature > low threshold
1: Temperature ≤ low threshold

Bit 1 **VBATH**: Backup domain voltage level monitoring versus high threshold
0: Backup domain voltage level < high threshold
1: Backup domain voltage level ≥ high threshold

Bit 0 Reserved, must be kept at reset value.

10.10.18 PWR wakeup status register (PWR_WUSR)

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x44

Reset value: 0x0000 0000

(reset value not affected by exit from Standby modes)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WUF8	WUF7	WUF6	WUF5	WUF4	WUF3	WUF2	WUF1
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WUF8**: Wakeup flag 8
This bit is set when a wakeup event is detected on WKUP8 pin. This bit is cleared by writing 1 in the CWUF8 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN8 = 0.
If WUSEL = 11, this bit is cleared by hardware when all internal wakeup source are cleared.

Bit 6 **WUF7**: Wakeup flag 7
This bit is set when a wakeup event is detected on WKUP7 pin. This bit is cleared by writing 1 in the CWUF7 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN7 = 0.
If WUSEL = 11, this bit is cleared by hardware when all internal wakeup source are cleared.

Bit 5 **WUF6**: Wakeup flag 6
This bit is set when a wakeup event is detected on WKUP6 pin. This bit is cleared by writing 1 in the CWUF6 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN6 = 0.
If WUSEL = 11, this bit is cleared by hardware when all internal wakeup source are cleared.

Bit 4 **WUF5**: Wakeup flag 5
This bit is set when a wakeup event is detected on WKUP5 pin. This bit is cleared by writing 1 in the CWUF5 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN5 = 0.

Bit 3 **WUF4**: Wakeup flag 4
This bit is set when a wakeup event is detected on WKUP4 pin. This bit is cleared by writing 1 in the CWUF4 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN4 = 0.

Bit 2 **WUF3**: Wakeup flag 3
This bit is set when a wakeup event is detected on WKUP3 pin. This bit is cleared by writing 1 in the CWUF3 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN3 = 0.

Bit 1 **WUF2**: Wakeup flag 2

This bit is set when a wakeup event is detected on WKUP2 pin. This bit is cleared by writing 1 in the CWUF2 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN2 = 0.

Bit 0 **WUF1**: Wakeup flag 1

This bit is set when a wakeup event is detected on WKUP1 pin. This bit is cleared by writing 1 in the CWUF1 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN1 = 0.

10.10.19 PWR wakeup status clear register (PWR_WUSCR)

Each register bit CWUFx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 in PWR_SECCFGR.

Each bit CWUFx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **CWUF8**: Wakeup flag 8

Writing 1 to this bit clears the WUF8 flag in PWR_WUSR.

Bit 6 **CWUF7**: Wakeup flag 7

Writing 1 to this bit clears the WUF7 flag in PWR_WUSR.

Bit 5 **CWUF6**: Wakeup flag 6

Writing 1 to this bit clears the WUF6 flag in PWR_WUSR.

Bit 4 **CWUF5**: Wakeup flag 5

Writing 1 to this bit clears the WUF5 flag in PWR_WUSR.

Bit 3 **CWUF4**: Wakeup flag 4

Writing 1 to this bit clears the WUF4 flag in PWR_WUSR.

Bit 2 **CWUF3**: Wakeup flag 3

Writing 1 to this bit clears the WUF3 flag in PWR_WUSR.

Bit 1 **CWUF2**: Wakeup flag 2

Writing 1 to this bit clears the WUF2 flag in PWR_WUSR.

Bit 0 **CWUF1**: Wakeup flag 1

Writing 1 to this bit clears the WUF1 flag in PWR_WUSR.

10.10.20 PWR apply pull configuration register (PWR_APCR)

This register is protected against non-secure access when APCSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when APCSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when APCSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x4C

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APC
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **APC**: Apply pull-up and pull-down configuration

When this bit is set, the I/O pull-up and pull-down configurations defined in PWR_PUCRx and PWR_PDCRx are applied. When this bit is cleared, PWR_PUCRx and PWR_PDCRx are not applied to the I/Os.

10.10.21 PWR port A pull-up control register (PWR_PUCRA)

Each register bit PUy is protected against non-secure access when SECy = 1 in GPIOA_SECCFGR.

Each register bit PUy is protected against unprivileged access when SECy = 1 in GPIOA_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x50

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **PU15**: Port A pull-up bit 15
When set, this bit activates the pull-up on PA15 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD15 bit is also set.

Bit 14 Reserved, must be kept at reset value.

Bits 13:0 **PUy**: Port A pull-up bit y (y = 13 to 0)
When set, each bit activates the pull-up on PAy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.

10.10.22 PWR port A pull-down control register (PWR_PDCRA)

Each register bit PDy is protected against non-secure access when SECy = 1 in GPIOA_SECCFGR.

Each register bit PDy is protected against unprivileged access when SECy = 1 in GPIOA_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PDy**: Port I pull-down bit y (y = 7 to 0)

When set, each bit activates the pull-down on PIy when the APC bit is set in PWR_APCR.

11 Reset and clock control (RCC)

11.1 Introduction

The reset and clock control (RCC) manages the different kind of reset, and generates all clocks for the bus and peripherals.

11.2 RCC pins and internal signals

The table below lists the RCC inputs and output signals connected to package pins or balls.

Table 101. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO	O	Output clock for external devices
LSCO	O	Low-speed output clock for external devices
AUDIOCLK	I	External kernel clock input for SAI1, SAI2, MDF1 and ADF1

11.3 RCC reset functional description

There are three types of reset:

- a system reset
- a power reset
- a Backup domain reset

11.3.1 Power reset

A power reset is generated when one of the following events occurs:

- a Brownout reset (BOR)
- when exiting Standby mode
- when exiting Shutdown mode

A BOR sets all registers to their reset values except the ones in the Backup domain.

When exiting Standby mode, all registers in the core domain are set to their reset value. Registers outside the core domain (RTC, TAMP, WKUP, IWDG, and Standby/Shutdown mode control) are not impacted.

When exiting Shutdown mode, a Brownout reset is generated, resetting all registers except those in the Backup domain.

11.3.2 System reset

A system reset sets all registers to their reset values except the reset flags in *RCC control/status register (RCC_CSR)* and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:

- a low level on the NRST pin (external reset)
- a window watchdog event (WWDG reset)
- an independent watchdog event (IWDG reset)
- a software reset (SW reset) (see *Software reset*)
- a low-power mode security reset (see *Low-power mode security reset*)
- an option-byte loader reset (see *Option byte loader reset*)
- a Brownout reset

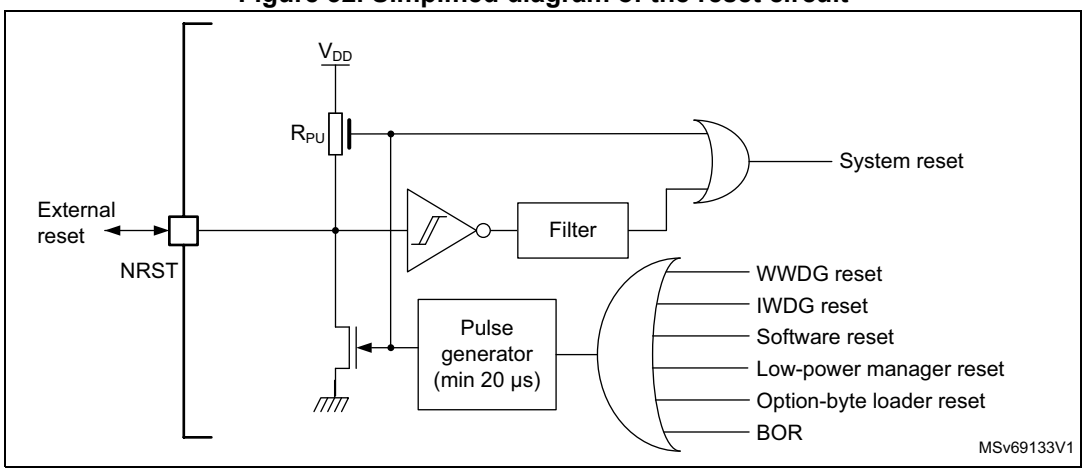
The reset source can be identified by checking the reset flags in *RCC control/status register (RCC_CSR)*.

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected via the boot option bytes.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case on an internal reset, the internal pull-up R_{PU} is deactivated in order to save the power consumption through the pull-up resistor.

Figure 32. Simplified diagram of the reset circuit



Software reset

The SYSRESETREQ bit in Cortex-M33 application interrupt and reset control register must be set to force a software reset on the device.

Low-power mode security reset

To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

- Entering Standby mode: this type of reset is enabled by resetting NRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
- Entering Stop mode: this type of reset is enabled by resetting NRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.
- Entering Shutdown mode: this type of reset is enabled by resetting NRST_SHDW bit in user option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the user option bytes, refer to *Section 7.4.1: Option bytes description*.

Option byte loader reset

The option byte loader reset is generated when the OBL_LAUNCH bit is set in the FLASH_NSCR register. This bit is used to launch the option byte loading by software.

11.3.3 Backup domain reset

The Backup domain has two specific resets.

A Backup domain reset is generated when one of the following events occurs:

- a software reset, triggered by setting the BDRST bit in the *RCC Backup domain control register (RCC_BDCR)*
- a V_{DD} or V_{BAT} power on, if both supplies have previously been powered off

A Backup domain reset affects the LSE oscillator, the RTC, the backup registers, the backup SRAM, the SRAM2, all secrets protected by tamper (refer to *Table 528: TAMP interconnection*) and the RCC_BDCR register.

11.4 RCC clocks functional description

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI16: high-speed internal 16 MHz RC oscillator clock
- MSIS: multi-speed internal RC oscillator clock
- HSE: high-speed external crystal or clock, from 4 to 50 MHz
- PLL1 clock

The MSIS is used as system clock source after startup from reset, configured at 4 MHz.

The devices have the following additional clock sources:

- MSIK: multi-speed internal RC oscillator clock used for peripherals kernel clocks
- LSI: 32 kHz/250 Hz low-speed internal RC that drives the independent watchdog and optionally the RTC used for auto-wakeup from Stop and Standby modes
- LSE: 32.768 kHz low-speed external crystal or clock that optionally drives the real-time clock (rtc_ck)
- HSI48: internal 48 MHz RC that potentially drives the OTG_FS, the SDMMC and the RNG
- SHSI: secure high-speed internal 48 MHz RC that drives the SAES
- PLL2 and PLL3 clocks

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of the AHB and APB domains is 160 MHz.

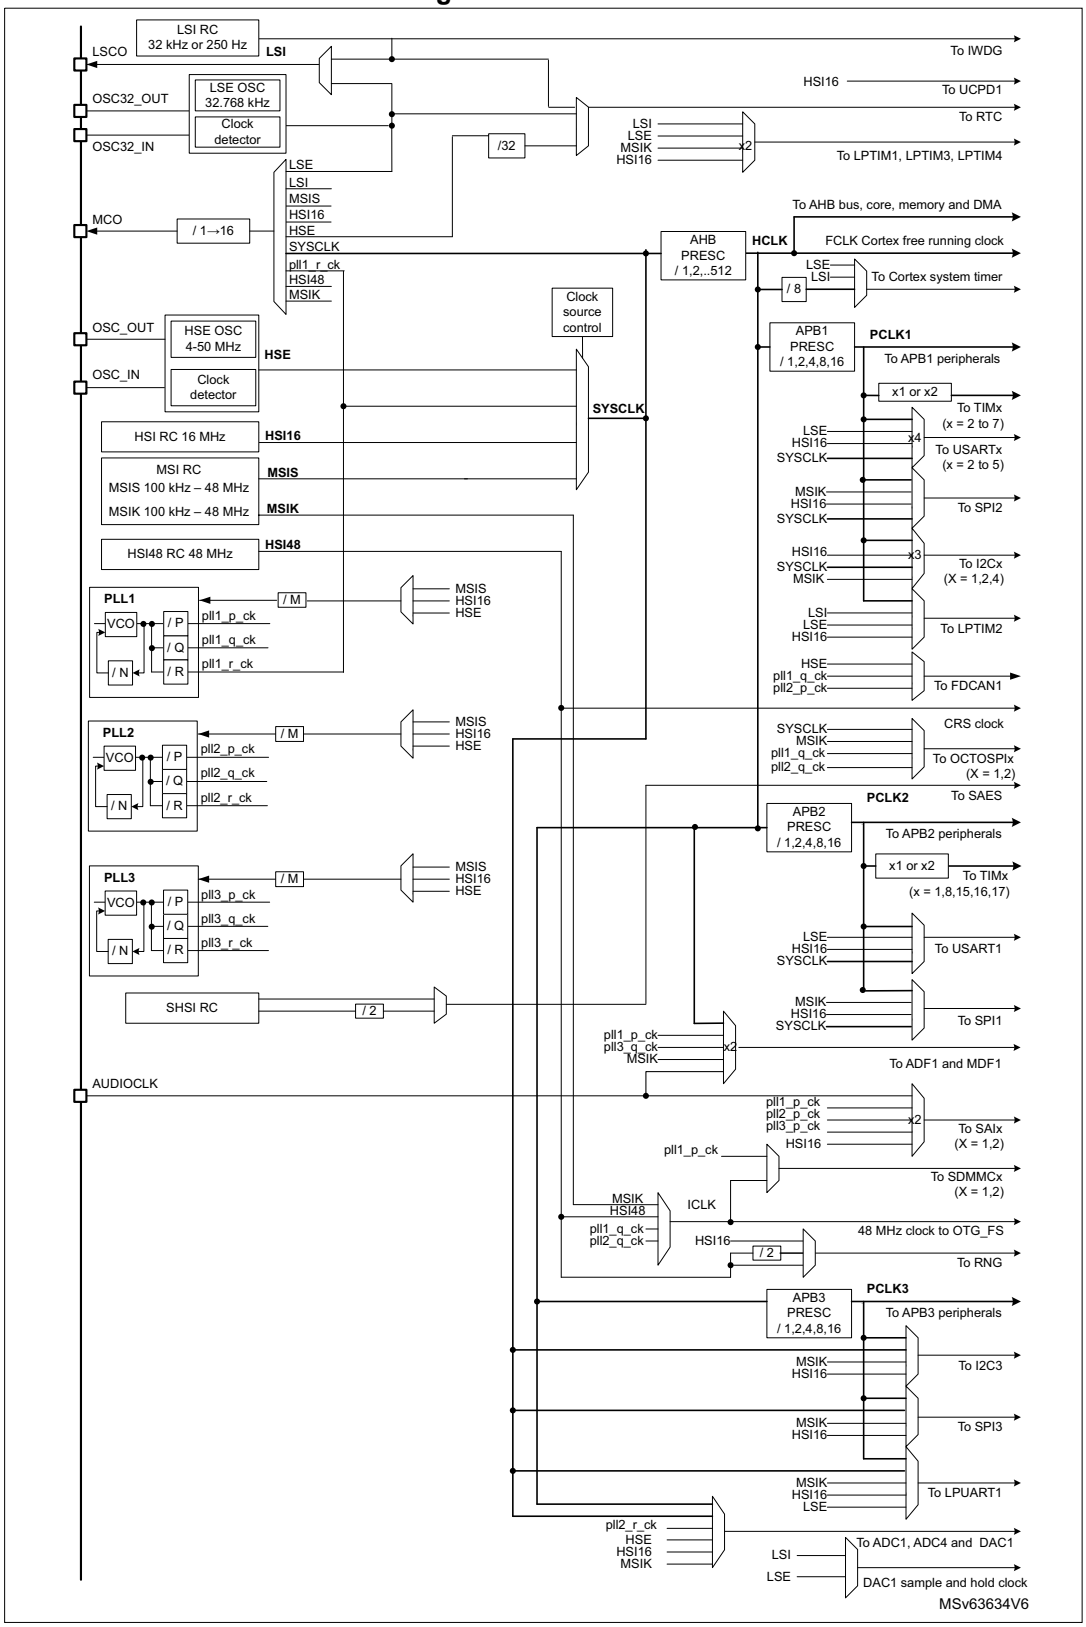
All the peripheral clocks are derived from their bus clock (HCLK, PCLK1, PCLK2 or PCLK3) except the following ones that receive an independent kernel clock. This kernel clock can be selected by software between several sources thanks to RCC_CCIPRx registers (x = 1,2,3): OTG_FS, SDMMCx (x = 1,2), RNG, ADCx (x = 1,4), DAC1, U(S)ARTx (x = 1 to 5), LPUART1, I2Cx (x = 1 to 4), SPIx (x = 1 to 3), OCTOSPIx (x = 1,2), SAIx (x = 1,2), MDF1, ADF1, FDCAN1, LPTIMx (x = 1 to 4), SAES.

In addition, the RTC kernel clock is selected by software in RCC_BDCR. The IWDG clock is always the LSI 32 kHz clock.

The RCC feeds the Cortex system timer (SysTick) external clock with the AHB clock (HCLK) divided by eight, or LSE or LSI. The SysTick can work either with this clock or directly with the Cortex clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex-M33 free-running clock.

Figure 33. Clock tree



11.4.1 HSE clock

The high-speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

Figure 34. HSE/ LSE clock sources

Clock source	Hardware configuration
External clock	Crystal/ceramic resonators	
External crystal/ceramic resonator (HSE crystal)

The 4 to 50 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in *Figure 34*. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the *RCC clock control register (RCC_CR)* indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt enable register (RCC_CIER)*.

The HSE crystal can be switched on and off using the HSEON bit in the *RCC clock control register (RCC_CR)*.

External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 50 MHz. This mode is selected by setting the HSEBYP and HSEON bits in the *RCC clock control register (RCC_CR)*. The external clock signal (square, sinus or triangle) with ~40-60 % duty cycle depending on the frequency (refer to the datasheet) must drive the OSC_IN pin while the OSC_OUT pin can be used a GPIO (see *Figure 34*).

11.4.2 HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator. However, even with calibration, the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wakeup from Stop modes (Stop 0, Stop 1, Stop 2 or Stop 3). Refer to *Section 11.8.6: RCC clock configuration register 1 (RCC_CFGR1)*. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to *Section 11.4.11: Clock security system (CSS)*.

Calibration

The RC oscillator frequencies may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at T_A = 25°C.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the *RCC internal clock sources calibration register 3 (RCC_ICSCR3)*.

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. The HSI16 frequency can be trimmed in the application using the HSITRIM[6:0] in the *RCC internal clock sources calibration register 3 (RCC_ICSCR3)*.

For more details on how to measure the HSI16 frequency variation, refer to *Section 11.4.19: Internal/external clock measurement with TIM15/TIM16/TIM17*.

The HSIRDY flag in the *RCC clock control register (RCC_CR)* indicates if the HSI16 RC is stable or not. At startup, the HSI16 RC output clock is not released until this bit is set by hardware.

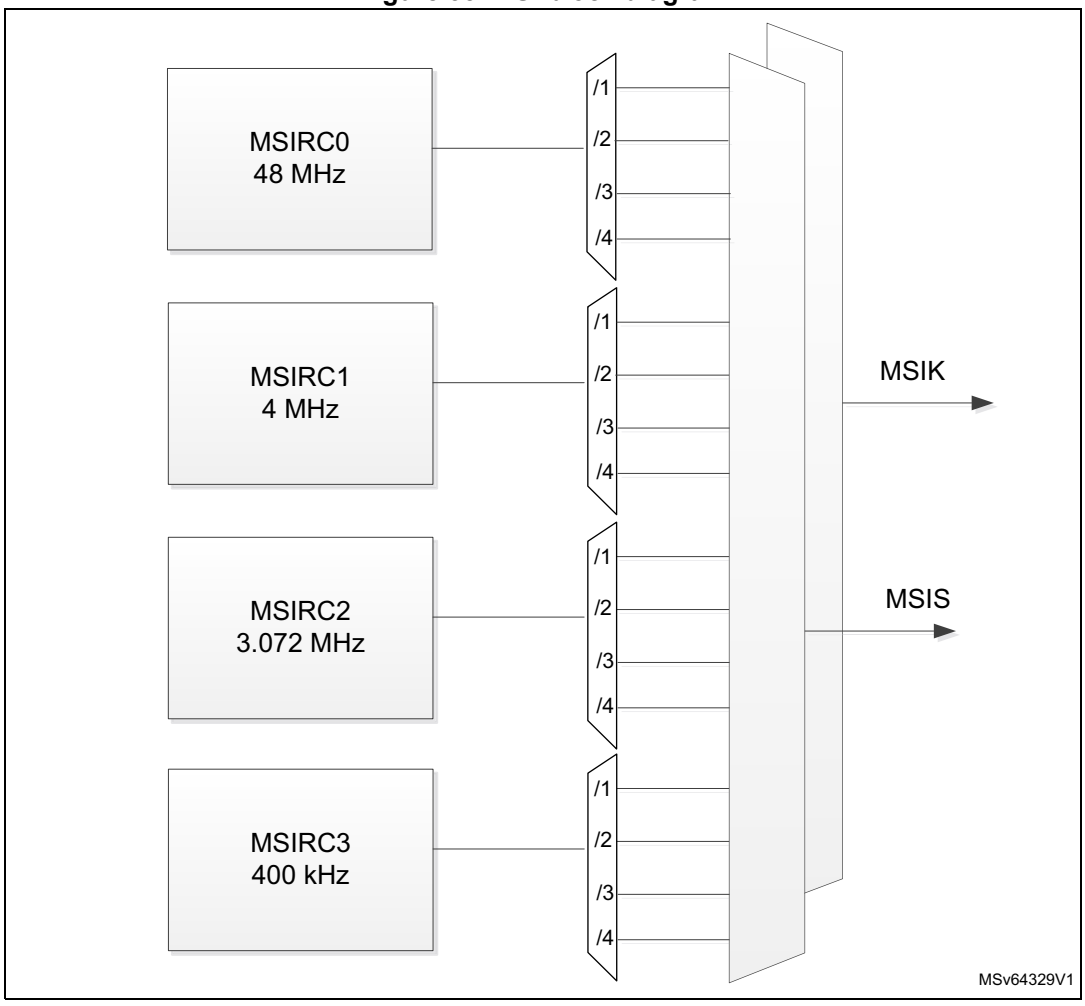
The HSI16 RC can be switched on and off using the HSION bit in the *RCC clock control register (RCC_CR)*.

The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to *Section 11.4.11: Clock security system (CSS)*.

11.4.3 MSI (MSIS and MSIK) clocks

The MSI is made of four internal RC oscillators: MSIRC0 at 48 MHz, MSIRC1 at 4 MHz, MSIRC2 at 3.072 MHz and MSIRC3 at 400 kHz. Each oscillator feeds a prescaler providing a division by 1, 2, 3 or 4. Two output clocks are generated from these divided oscillators: MSIS, that can be selected as system clock, and MSIK, that can be selected by some peripherals as kernel clock.

Figure 35. MSI block diagram



MSIS and MSIK frequency range can be adjusted by software, by using respectively the MSISRANGE[3:0] and MSIKRANGE[3:0] fields in the *RCC internal clock sources calibration*

register 1 (RCC_ICSCR1), with MSIRGSEL = 1. Sixteen frequency ranges are available, generated from the four internal RCs, as shown in the table below.

Table 102. MSIS and MSIK ranges per internal MSIRCs

MSIRC0	MSIRC1	MSIRC2	MSIRC3
Range 0: 48 MHz	Range 4: 4 MHz	Range 8: 3.072 MHz	Range 12: 400 kHz
Range 1: 24 MHz	Range 5: 2 MHz	Range 9: 1.536 MHz	Range 13: 200 kHz
Range 2: 16 MHz	Range 6: 1.33 MHz	Range 10: 1.024 MHz	Range 14: 133 kHz
Range 3: 12 MHz	Range 7: 1 MHz	Range 11: 0.768 MHz	Range 15: 100 kHz

The MSIS clock is used as system clock after restart from Reset, wakeup from Standby and Shutdown low-power modes. After restart from Reset or when exiting Shutdown mode, the MSIS and MSIK frequencies are set to their default value 4 MHz. The frequency range at wakeup from Standby mode can be adjusted by software, using respectively the MSISSRANGE[3:0] and MSIKSRANGE[3:0] fields with MSIRGSEL=0. Refer to *Section 11.8.50: RCC control/status register (RCC_CSR)*.

The MSIS clock can be selected as system clock after a wakeup from Stop mode (Stop 0, Stop 1, Stop 2 or Stop 3) depending on STOPWUCK in the *RCC clock control register (RCC_CR)*. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to *Section 11.4.11: Clock security system (CSS)*.

The MSI oscillator has the advantage of providing a low-cost (no external components) low-power clock source. In addition, when used in PLL-mode with the LSE, the MSI provides a very accurate clock source that can be used by the OTG_FS peripheral, and feeds the PLL.

The MSISRDY and MSIKRDY flags in the *RCC clock control register (RCC_CR)* indicate whether the MSIS and MSIK RC are stable or not. At startup, the MSIS and MSIK RC output clocks are not released until their respective bit is set by hardware. The MSIS and MSIK RC can be switched on and off by using the MSISON and MSIKON bits in the *RCC clock control register (RCC_CR)*.

Hardware auto calibration with LSE (PLL-mode)

When a 32.768 kHz external oscillator is present in the application, it is possible to configure either the MSIS or the MSIK in a PLL-mode. This mode is enabled:

- for MSIS by setting the MSIPLLEN bit with MSIPLLSEL = 1 in the *RCC clock control register (RCC_CR)*
- for MSIK by setting the MSIPLLEN bit with MSIPLLSEL = 0

In case MSIS and MSIK ranges are generated from the same MSIRC source, the PLL-mode is applied on both MSIS and MSIK. When configured in PLL-mode, the MSIS or MSIK automatically calibrates itself thanks to the LSE. This mode is available for all MSI frequency ranges. At 48 MHz, the MSIK in PLL-mode can be used for the OTG_FS device, avoiding the need of an external high-speed crystal.

If LSE clocks pulses are stopped, the MSI PLL-mode is automatically unlocked, and the MSI accuracy is consequently degraded. On all STM32U575/585 revisions except rev. X, the MSI PLL-mode unlock event is connected to an EXTI line: this is used to generate an event or interrupt supporting wakeup from Stop 0, Stop 1, or Stop 2 mode (see *Table 107: Interrupt sources and control* and *Table 156: EXTI line connections*).

MSI PLL-mode stabilization time

When MSIPLLEN = 1, the final accuracy after enabling the MSI (by writing MSISON = 1 or MSIKON = 1 or following a peripheral clock request in Stop mode) is reached after a stabilization time t_{STAB}(MSI) when MSIPLLFAST = 0. This stabilization time is needed even if the LSE is kept enable. Refer to datasheet for t_{STAB}(MSI) value.

If MSIPLLEN = 1 with MSIPLLFAST =1 , the MSI oscillator is kept powered on when a request to switch it off is received (either by writing MSISON = 0 and MSIKON =0 , or because no peripheral requests this clock in Stop mode). In this case the MSI PLL-mode accuracy is kept when the MSI is switched on again, providing that the t_{STAB}(MSI) stabilization time is reached before switching off the MSI. This mode can be used for autonomous peripherals requiring accuracy in Stop mode, with an extra consumption as the oscillator remains powered on, but gated off when disabled.

Software calibration

The MSIRCx (x = 0 to 3) oscillators frequency may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at an ambient temperature, T_A = 25 °C. After reset, the factory calibration value is loaded in the MSICALx[4:0] bits (x = 0 to 3) in the *RCC internal clock sources calibration register 1 (RCC_ICSCR1)*. If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. The MSIRCx frequency can be trimmed in the application by using the MSITRIMx[4:0] bits (x = 0 to 3) in the RCC_ICSCR register.

Note: The final accuracy after applying the calibration value is reached after a stabilization time. This stabilization time is needed after reset of exiting Standby or Shutdown mode. It is also needed when switching from PLL-mode to normal mode.

The hardware auto calibration with LSE must not be used in conjunction with software calibration.

For more details on how to measure the MSI frequency variation, refer to *Section 11.4.19: Internal/external clock measurement with TIM15/TIM16/TIM17*.

11.4.4 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB and for random number generator (RNG) as well as SDMMC.

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the OTG_FS SOF signal, the LSE or an external signal to automatically and quickly adjust the oscillator frequency on-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency that is subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral, refer to *Section 12: Clock recovery system (CRS)*.

The HSI48RDY flag in the RCC_CR register indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the RCC_CR register.

11.4.5 SHSI clock

The SHSI is an internal securable RC oscillator dedicated to clock the SAES. The SHSIRDY flag in the *RCC clock control register (RCC_CR)* indicates if the SHSI RC is stable or not. At startup, the SHSI RC output clock is not released until this bit is set by hardware.

The SHSI RC can be switched on and off using the SHSION bit in the *RCC clock control register (RCC_CR)*.

11.4.6 PLL

The RCC features three PLLs:

- a main PLL, PLL1, that is generally used to provide clocks to the CPU and to some peripherals
- two dedicated PLL2 and PLL3, that are used to generate the kernel clock for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:

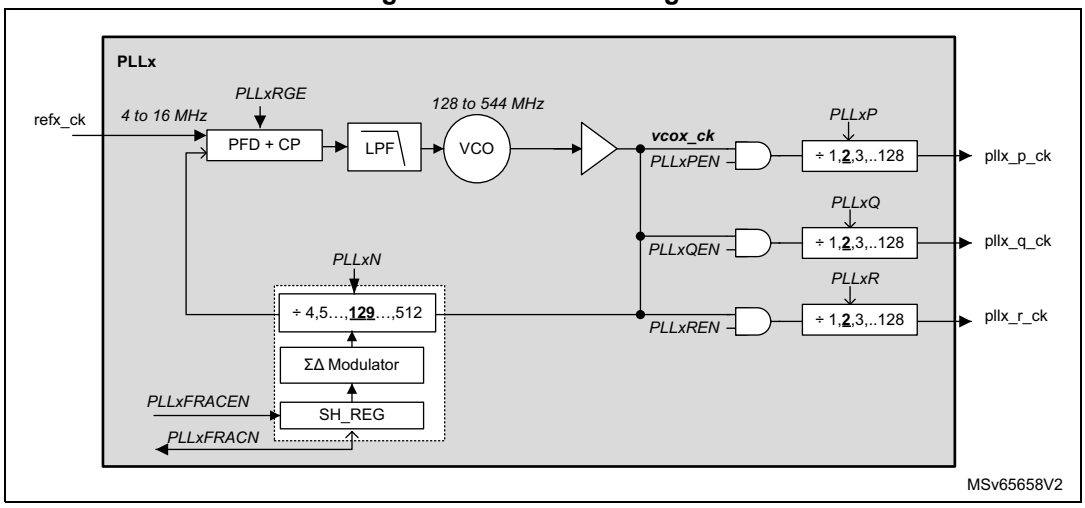
- Input frequency range: 4 to 16 MHz
- Capability to work either in integer or Fractional mode
- 13-bit sigma-delta (ΣΔ) modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm
- The ΣΔ modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
- Each PLL offers three outputs with post-dividers.

The PLLs are controlled via the registers RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLxCFGR and RCC_CR (x = 1,2,3).

The frequency of the reference clock provided to the PLLs (refx_ck) must range from 4 to 16 MHz. The user application must program properly the PLLxM (x = 1,2,3) dividers in the *RCC PLL1 configuration register (RCC_PLL1CFGR)*, *RCC PLL2 configuration register (RCC_PLL2CFGR)* and *RCC PLL3 configuration register (RCC_PLL3CFGR)* in order to match this condition. In addition, PLLxRGE must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

To reduce the power consumption, it is recommended to configure the VCOx output to the lowest frequency.

Figure 36. PLL block diagram



PLLxN loop divider must be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLx operates in integer mode when PLLxFRACEN = 0, and the PLL is enabled with PLLxON. The fractional mode can be enabled at any time by setting PLLxFRACN to the required value, and subsequently setting PLLxFRACEN from 0 to 1. The ∑Δ modulator is designed to minimize the jitter impact while allowing very small step frequency adjustments. To update the fractional value, first set PLLxFRACEN to 0 before updating the PLLxFRACN value, and subsequently set PLLxFRACEN to 1. The old PLLxFRACN value is kept used until the new value is activated by setting PLLxFRACEN from 0 to 1. PLLxFRACN must only be updated by software when PLLxFRACEN = 0.

The PLLs can be enabled by setting PLLxON to 1 in the *RCC clock control register (RCC_CR)*. The PLLxRDY bit indicates that the PLL is ready (meaning locked).

Note: Before enabling the PLLx, make sure that the reference frequency (refx_ck) provided to the PLL is stable. The following PLLx parameters cannot be changed once the PLLx is enabled: PLLxSRC, PLLxN, PLLxRGE, PLLxP, PLLxQ, and PLLxR.

The hardware prevents writing PLLxON to 0 if the PLL is currently used to deliver the system clock.

The following PLL parameters cannot be changed once the PLL is enabled: PLLxN, PLLxRGE, PLLxP, PLLxQ, and PLLxR.

To insure an optimal behavior of the PLL when one of the post-dividers (PLLxP, PLLxQ or PLLxR) is not used, the application must clear the enable bit (PLLxPEN, PLLxQEN, PLLxREN), and configure the corresponding post-dividers to their minimum value (PLLxR = 1, PLLxP = 0, or PLLxQ = 0).

If the above rules are not respected, the PLL output frequency is not guaranteed.

Output frequency computation

When the PLL operates in integer mode (SH_REG = 0), the VCO frequency (F_{VCO}) is given by the following formula (x = 1, 2, 3):

$$F_{VCOx} = F_{refx\_ck} \times PLLxN$$

When the PLLx operates in fractional mode, the PLLxFRACN value can be changed on-the-fly without disturbing the PLLx output.

This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

$$F_{VCOx} = F_{refx\_ck} \times \left(PLLxN + \frac{PLLxFRACN}{2^{(13)}} \right)$$

For both integer and fractional mode, the PLLx output frequency is given by the following formula:

$$F_{pllx\_y\_ck} = (F_{VCOx} / (PLLxy + 1)) \text{ with y = P, Q or R}$$

The PLLs are disabled by hardware:

- when the system enters Stop or Standby mode
- when an HSE failure occurs, when HSE or PLL (clocked by HSE) are used as system clock

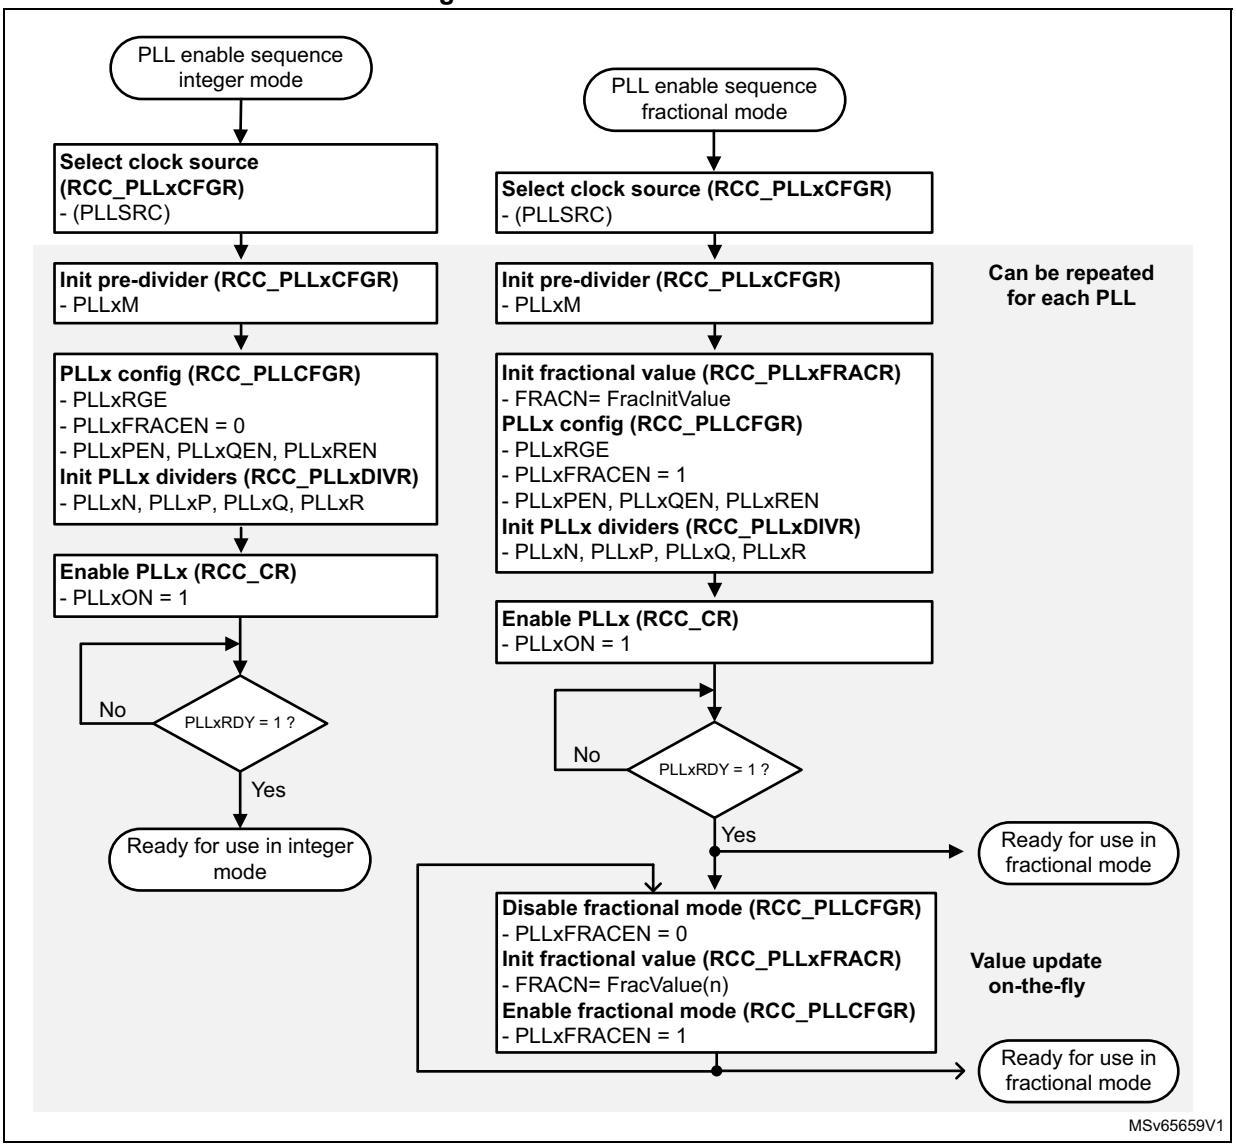
The fractional information used by the PLL is reset when disabling the PLL.

PLL initialization phase

Here below the recommended PLL initialization sequence in integer and fractional mode. The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Initialize the PLL registers according to the required frequency.
   - For integer mode, set PLLxFRACEN to 0 in the *RCC PLL1 configuration register (RCC_PLL1CFGR)*, *RCC PLL2 configuration register (RCC_PLL2CFGR)* and *RCC PLL3 configuration register (RCC_PLL3CFGR)*.
   - For fractional mode, set PLLxFRACN to the required initial value (FracInitValue) and then set PLLxFRACEN to 1.
2. Once the PLLxON bit is set to 1, the application must wait until PLLxRDY is set to 1. As long as PLLxRDY = 0, PLLxFRACEN must not be altered.
3. Once the PLLxRDY bit is set to 1, the PLLx is ready to be used.
4. If the application intends to tune the PLLx frequency on-the-fly, then:
   a) PLLxFRACEN must be set to 0 to update the PLLxFRACN value while keeping the PLL running.
   b) A new value can be uploaded into PLLxFRACN (FracValue(n).
   c) PLLxFRACEN must be set to 1 to activate the new programed value in PLLxFRACN, that is taken into account by the PLL.

Figure 37. PLL initialization flow



Note: When the PLLxRDY goes to 1, it means that the difference between the PLLx output frequency and the target value is lower than ± 2 %.

11.4.7 LSE clock

The LSE crystal is a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in *RCC Backup domain control register (RCC_BDCR)*. If the LSE is used by other peripherals of functions than RTC, TAMP, and LSECSS, the LSESYSEN bit must be also be set in *RCC Backup domain control register (RCC_BDCR)* (refer to *Section : LSE when used by peripherals other than RTC/TAMP, and RCC functions*).

The crystal oscillator driving strength is configured using the LSEDRV[1:0] bits, according to crystal specification, to obtain the best compromise between robustness and short start-up time on one side and low-power-consumption on the other side. The LSE drive must be programmed before enabling the LSE.

The LSERDY flag in the *RCC Backup domain control register (RCC_BDCR)* indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt enable register (RCC_CIER)*.

External source (LSE bypass)

In this mode, an external clock source must be provided. This mode is selected by setting the LSEBYP and LSEON bits in the *RCC Backup domain control register (RCC_BDCR)*. The external clock signal (square, sinus or triangle) with ~50 % duty cycle, must drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO (see *Figure 34*).

LSE when used by peripherals other than RTC/TAMP, and RCC functions

By default, when enabled, the LSE is sent only to RTC and TAMP (assuming that RTCSEL = 01).

It the LSE is needed for other peripherals (such as peripheral clock or trigger source), or if the LSE is used by a RCC function (such as LSCO, MCO, MSI PLL mode), the sequence below must be done:

1. Set the LSEON in RCC_BDCR and wait the LSE clock ready bit (LSERD = 1 in *RCC Backup domain control register (RCC_BDCR)*.
2. Set the LSESYSEN bit in RCC_BDCR.
3. Wait the LSESYS clock is ready (LSESYSRDY = 1 in RCC_BDCR).

The LSE consumption is increased when LSESYSEN = 1.

11.4.8 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby modes for the independent watchdog (IWDG) and RTC. The clock frequency is either 32 kHz or 250 Hz depending on the LSIPREDIV bit in *RCC Backup domain control register (RCC_BDCR)*. Setting LSIPREDIV allows a lower consumption (refer to the electrical characteristics section of the datasheet for more details).

When the IWDG is enabled or when the RTC or TAMP is clocked by the LSI, the LSIPREDIV cannot be changed anymore.

The LSI RC can be switched on and off using the LSION bit in the *RCC Backup domain control register (RCC_BDCR)*.

The LSIRDY flag in the *RCC Backup domain control register (RCC_BDCR)* indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt enable register (RCC_CIER)*.

11.4.9 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):

- MSIS oscillator
- HSI16 oscillator
- HSE oscillator
- PLL

The system clock maximum frequency is 160 MHz. After a system reset, the MSIS oscillator, at 4 MHz, is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in the *RCC clock control register (RCC_CR)* indicate which clocks are ready and which clock is currently used as a system clock.

The table below gives the different bus frequencies depending on the product voltage range.

Table 103. Bus maximum frequency

Product voltage range	AHB1/AHB2/AHB3/APB1/APB2/APB3
Range 1	160 MHz
Range 2	110 MHz
Range 3	55 MHz
Range 4	25 MHz

11.4.10 Clock source frequency versus voltage scaling

The table below gives the different clock source frequencies depending on the product voltage range.

Table 104. Clock source maximum frequency

Product voltage range	Clock frequency					
	MSIS MSIK	HSI16	HSI48	SHSI	HSE	PLL outputs (VCO min to max)
Range 1	All ranges	Allowed	Allowed	Allowed	50 MHz	208 MHz(1) (128 to 544 MHz)
Range 2	All ranges	Allowed	Allowed	Allowed	50 MHz	110 MHz (128 to 544 MHz)
Range 3	All ranges	Allowed	Allowed	Allowed	50 MHz	55 MHz (128 to 330 MHz)
Range 4	Up to 24 MHz range	Allowed	Allowed (divided by 2)	Allowed (divided by 2)	25 MHz	Not allowed

1. Max frequency can vary depending on peripherals connected to PLL outputs.

11.4.11 Clock security system (CSS)

The CSS can be activated by software. In this case, the clock detector is enabled after the HSE oscillator wakeup time, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled. A clock failure event is sent to some timers break input and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI). This allows the MCU to perform rescue operations. The CSSI is linked to the Cortex-M33 NMI (non-maskable interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSSI occurs and a NMI is automatically generated. The NMI is executed indefinitely unless the CSSI pending bit is cleared. As a consequence, in the NMI ISR, the user must clear the CSSI by setting the CSSC bit in the RCC clock interrupt clear register (RCC_CICR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the MSIS or the HSI16 oscillator depending on the STOPWUCK configuration in the *RCC clock control register (RCC_CR)*, and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

11.4.12 Clock security system on LSE

A clock security system on LSE can be activated by software writing the LSECSSON bit in the *RCC Backup domain control register (RCC_BDCR)*. This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE is working in all modes including VBAT. It works also under system reset (excluding power-on reset).

The clock security system on LSE detects when the LSE disappears or in case of over frequency. In addition, the glitches on LSE can be filtered by setting LSEGFON. LSEGFON must be written when the LSE is disabled (LSEON = 0 and LSERDY = 0).

If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC but no hardware action is made to the registers. If the MSI was in PLL-mode, this mode is disabled.

The CSS on LSE detection event is connected to the internal tamper 3 of the TAMP peripheral:

- On STM32U575/585 rev.X devices, the internal tamper 3 must be enabled (ITAMP3E = 1 in TAMP_CR1 register), and the associated interrupt enabled (ITAMP3IE in TAMP_IER) in order to wake up from the low-power modes. This erases also the TAMP backup registers and backup SRAM, unless ITAMP3NOER = 1 in TAMP_CR3 (see *Section 55: Tamper and backup registers (TAMP)* for more details).
- On all other STM32U575/585 revisions, the CSS on LSE detection event is also connected to an EXTI line: this is used to generate an event or interrupt supporting wakeup from Stop 0, Stop 1, or Stop 2 mode, without requiring to enable tamper detection (see *Table 107: Interrupt sources and control* and *Table 156: EXTI line connections*).

In case of CSS on LSE detection event (LSECSSD = 1 in the RCC_BDCR), the software must then disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take any required action to secure the application.

Refer to datasheet for CSS on LSE electrical characteristics.

11.4.13 ADC and DAC clocks

The ADC and DAC kernel clock source is selected thanks to ADCDACSEL[2:0] in the *RCC peripherals independent clock configuration register 3 (RCC_CCIPR3)*. The ADC clock ratio must be around 50 %. For this reason, the AHB clock, when selected as ADC clock, must not be divided with HPRE prescaler. If pll2_r_ck is selected as ADC clock, the PLL2R division factor must be even (division by 2 or 4 for example).

If the application requires that the ADC or DAC is precisely triggered by a TIMx timer without any uncertainty, the HCLK must be selected as ADC and DAC kernel clock source. The other clock sources are asynchronous to TIMx timers therefore an uncertainty of the trigger instant is added by the resynchronization between the two clock domains. The LPTIMx timers are also asynchronous.

The DAC requires an additional low-power clock (LSI or LSE) to operate in sample and hold mode, available in Stop mode. This clock is selected with DAC1SEL in the RCC_CCIPR3.

11.4.14 RTC and TAMP clock

The RTCCLK clock source is used by RTC and TAMP, and can be either the HSE / 32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in the *RCC Backup domain control register (RCC_BDCR)*. This selection cannot be modified without resetting the Backup domain. The system must always be configured so as to get a PCLK frequency greater then or equal to the RTCCLK frequency for a proper operation of the RTC. The TAMP does not require any kernel clock if only the backup registers are used, with tampers in edge detection mode. All other tamper detection modes require a kernel clock (refer to *Section 55: Tamper and backup registers (TAMP)* for more details).

The LSE and the LSI clocks are in the Backup domain, whereas the HSE clock is not. Consequently:

- If LSE or LSI is selected as RTC and TAMP clock, these peripherals continue to work even if the V_{DD} supply is switched off, provided the V_{BAT} supply is maintained.
- If the HSE clock divided by a prescaler is used as the RTC or TAMP clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the internal voltage regulator is powered off (removing power from the core domain). Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

If the LSE is needed only for the RTC or TAMP, LSESYSEN must be kept at reset value to get the lowest consumption.

11.4.15 Timer clock

The timer clock frequencies are automatically defined by hardware.

There are two cases:

- If the APB prescaler equals 1, the timer clock frequencies are set to the APB domain frequency.
- Otherwise, they are set to twice (×2) the APB domain frequency.

11.4.16 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced on and cannot be disabled. After the LSI oscillator temporization, the LSI 32 kHz clock is provided to the IWDG.

11.4.17 OCTOSPI clock

The OCTOSPIx kernel clock, selected by OCTOSPIxSEL[1:0], can be up to 200 MHz when pll1_q_ck is used.

11.4.18 Clock-out capability

- **MCO**

  The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. One of the following clock signals can be selected as MCO clock.

  – LSI
  – LSE
  – SYSCLK
  – HSI16
  – HSI48
  – HSE
  – PLLCLK
  – MSIS
  – MSIK

  The selection is controlled by the MCOSEL[3:0] bits in the *RCC clock control register (RCC_CR)*. The selected clock can be divided with the MCOPRE[2:0] field in the *RCC clock control register (RCC_CR)*.

- **LSCO**

  Another output (LSCO) allows one of the low-speed clocks below to be output onto the external LSCO pin:

  – LSI
  – LSE

  This output remains available in all Stop modes, Standby and Shutdown modes. This output is not available in VBAT mode. The selection is controlled by the LSCOSEL bit and enabled with the LSCOEN in the *RCC Backup domain control register (RCC_BDCR)*.

The MCO clock output requires the corresponding alternate function selected on the MCO pin.

11.4.19 Internal/external clock measurement with TIM15/TIM16/TIM17

The frequency of all on-board clock sources can be indirectly measured by mean of the TIM15, TIM16 or TIM17 channel 1 input capture and LPTIM1 or LPTIM2 channel 2 input capture.

HSI16 and MSI calibration using LSE

The primary purpose of connecting the LSE to the channel 1 input capture of TIM15, TIM16 and TIM17, and to the channel 2 input capture of LPTIM2, is to be able to precisely measure the HSI16 and MSI system clocks (for this, either HSI16 or MSIS must be used as system clock source). The number of HSI16 (MSIS respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppms), the internal clock frequency can be determined with the same resolution, and the source can be trimmed to compensate the manufacturing, process, temperature and/or voltage related frequency deviations.

The four oscillators of MSI and HSI16 oscillator have dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (such as the HSI16/LSE ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

Note: When the LSE is available, the MSI can be automatically trimmed by LSE using the PLL-mode.

HSI16 and MSI calibration using HSE

If the HSE is available, it can be used as system clock and the timer input capture must be connected either to MSI (divided by 1024 or by 4) or to HSI/256. The timers 16 and 17 channel 1 input capture, as well and the LPTIM2 input capture 2, are connected to the divided oscillator only when TIMICSEL[2:0] is different from 0xx in the *RCC peripherals independent clock configuration register 1 (RCC_CCIPR1)*.

Considering that the timers counter is 16-bit, and that the ratio between HSE and the input capture signal must be the highest possible, a division by 1024 must be selected when the MSIRC0, MSIRC1 or MSIRC2 is measured, and a division by 4 when the MSIRC4 is measured.

LSI calibration

The calibration of the LSI follows the same principle, but changing the reference clock. The LSI clock must be connected to the channel 1 input capture of the TIM16 or TIM17, or to the channel 2 input capture of the LPTIM1. Then defining the HSE as system clock source, the number of its clock counts between consecutive edges of the LSI signal, provides a measure of the internal low-speed clock period.

The basic concept consists in providing a relative measurement (such as the HSE/LSI ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

11.4.20 Peripherals clock gating and autonomous mode

Peripherals clock gating in Run mode

Each peripheral clock can be enabled by the corresponding EN bit in the RCC_AHBxENR and RCC_APBxENR registers.

When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.

The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, there the clock is active after 2 cycles of the peripheral bus clock.

Caution: Just after enabling the clock for a peripheral, the software must wait for these 2 clock cycles before accessing the peripheral registers.

Peripherals clock gating in Sleep and Stop modes

When a peripheral is enabled, its clock can be automatically gated off when the device is in Sleep mode, by clearing the peripheral SMEN bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers. Both EN and SMEN bit of the peripheral must be set to keep the clock on in Sleep mode.

The SMEN bit of the peripheral is also used to allow peripheral clocking in Stop 0 and Stop 1 modes, upon peripheral request.

When the clock is requested by a peripheral, this clock is distributed to all enabled peripherals. Therefore the SMEN bit must be cleared before entering Stop mode, if the peripheral is not used in Stop mode.

Caution: The SMEN bit of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop mode. This is not necessary when the peripheral wakeup interrupt is generated though the EXTI.

Peripherals clock gating and autonomous mode in Stop 0/1/2 modes

Some peripherals support autonomous mode (refer to *Table 105: Autonomous peripherals*). These peripherals are able to generate a kernel clock request and a AHB/APB bus clock request when they need, in order to operate and update their status register even in Stop mode. Depending on the peripheral configuration, either a DMA request or an interrupt can be associated to the peripheral event.

Upon an AHB or APB bus clock request from an autonomous peripheral, either MSI or HSI16 oscillator is woken up, depending on the oscillator selected by STOPWUCK in the *RCC clock configuration register 1 (RCC_CFGR1)*.

If the autonomous peripheral is configured with DMA requests enabled, a data transfer is performed thanks to the AHB/APB clock. The bus clocks as well as the oscillator (HSI16 or MSI) are automatically switched off as soon as the transfer is finished, if no other peripheral requests it. The device automatically goes back in Stop mode.

If the autonomous peripheral is configured with interrupt enabled, the interrupt wakes up the device into Run mode.

The autonomous peripherals mapped on AHB3 or APB3 belong to the SmartRun domain and are autonomous in Stop 0, Stop 1 and Stop 2 with the LPDMA1 and SRAM4.

The autonomous peripherals mapped on AHB1, AHB2, APB1 and APB2, belong to the CPU domain and are autonomous in Stop 0 and Stop 1 only with the GPDMA1 and SRAM1, SRAM2, SRAM3 or SRAM4.

The table below shows the list of peripherals with autonomous mode capability.

Table 105. Autonomous peripherals

Domain	Peripheral	Autonomous in Stop 0, 1 modes	Autonomous in Stop 2 mode	Associated DMA	Associated SRAM
CPU domain (CD)	U(S)ARTx (x = 1 to 5)	Yes(1)	No	GPDMA1	SRAM1 SRAM2 SRAM3 SRAM4(2)
	SPIx (x = 1,2)				
	I2Cx (x = 1,2,4)				
	LPTIM2				
	MDF1				
	GPDMA1			-	
SmartRun domain (SRD)	LPUART1	Yes (3)	Yes(3)	LPDMA1	SRAM4
	SPI3				
	I2C3				
	LPTIMx (x = 1,3,4)				
	ADF1				
	DAC1				
	ADC4				
	LPDMA1			-	

1. Enabled if both xxEN and xxSMEN bits of the peripheral are set (xx = instance name)
2. SRAM4 belongs to SmartRun domain (SRD) but can be addressed by GPDMA 1 in Stop 0 and Stop 1 modes.
3. Enabled if all xxEN, xxSMEN and xxAMEN bits of the peripheral are set (xx = instance name)

For peripherals in CPU domain, the autonomous mode is enabled in Stop 0 and Stop 1 modes if both xxEN and xxSMEN bits of the peripheral are set.

For peripherals in SmartRun domain, the autonomous mode is enabled in Stop 0, Stop 1 and Stop 2 modes if both xxEN and xxSMEN bits of the peripheral are set, plus the xxAMEN bit of the peripheral in the *RCC SmartRun domain peripheral autonomous mode register (RCC_SRDAMR)*.

If an autonomous peripheral requests its kernel clock in Stop 0, Stop 1 or Stop 2 mode, the internal oscillator (HSI16 or MSI) is woken up if it was off, and the kernel clock is propagated only to the peripheral requesting it. When the peripheral releases its kernel clock request, the HSI16 or MSI is switched off if no other peripheral requests it.

If an autonomous peripheral belonging to CPU domain requests its bus clock (AHB1, AHB2, APB1 or APB2 clock) in Stop 0 or Stop 1 mode, the internal oscillator (HSI16 or MSI depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and the system clock is propagated to all peripherals configured with both xxEN and xxSMEN bits set.

If an autonomous peripheral belonging to SmartRun domain requests its bus clock (AHB3 or APB3 clock) in Stop 0, Stop 1 or Stop 2 mode, the internal oscillator (HSI16 or MSI depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and the HCLK3/PCLK3 clocks are propagated to all peripherals of the SmartRun domain configured with xxEN, xxSMEN and xxAMEN set.

Caution: The AMEN bit of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop mode. This is not necessary when the peripheral wakeup interrupt is generated though the EXTI.

Note: MSIK or HSI16 can be forced to remain ON in Stop 0, Stop 1 or Stop 2 mode, by configuring MSIKERON or HSIKERON is the RCC_CR. In this case, the oscillator is propagated only to the kernel clock of the enabled autonomous peripherals with this oscillator selected as kernel clock. This allows the peripheral baudrates or conversion rates increase, as there is no need to wait for the oscillator wakeup time when the peripheral requests its kernel clock.

The LSE or LSI selected as peripheral kernel clock remains always ON in Stop modes.

The AHB3 and APB3 clocks can be forced to remain ON by setting the SRDRUN bit in the PWR_CR2 register. This allows the LPDMA1 latency to be improved as there is no need to wait for the oscillator wakeup time when the peripheral requests its bus clock.

11.5 RCC security and privilege functional description

11.5.1 RCC TrustZone security protection modes

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, the RCC is able to secure RCC configuration and status bits from being modified by non-secure accesses.

This is configured through the *RCC secure configuration register (RCC_SECCFGR)* to prevent non-secure access to read or modify the following features:

- HSE, HSE-CSS, HSI, MSI, LSI, LSE, LSE-CSS, LSCO, HSI48 configuration and status bits
- PLL1, PLL2, PLL3, AHB and APB prescalers configuration and status bits
- system clock (SYSCLK) and ICLK source clock selection and status bits
- MCO clock output configuration and STOPWUCK and STOPKERWUCK bit
- Remove reset flag RMVF configuration

If SPRIV is set in the *RCC privilege configuration register (RCC_PRIVCFGR)*, the RCC_SECCFGR register can be written only by secure and privileged access. If SPRIV is cleared in RCC_PRIVCFGR, RCC_SECCFGR can be written only by secure access, privileged or unprivileged.

RCC_SECCFGR can be read by secure, non-secure, privileged and unprivileged access.

When a peripheral is configured as secure, its related clock, reset, clock source selection and clock enable during low-power modes control bits, are also secure in the RCC_AHBxENR, RCC_APBxENR, RCC_AHBxSMEN, RCC_APBxSMEN, RCC_SRDAMEN, RCC_CCIPR1, RCC_CCIPR2, RCC_CCIPR3 and RCC_BDCR registers.

The SHSI configuration and status bits are secured wen the SAES is configured as secure.

BDRST in RCC_BDCR is secure when at least one function is secure in RTC or TAMP.

A peripheral is secure when:

- For securable peripherals by TZSC (TrustZone security controller), the SEC security bit corresponding to this peripheral is set in the GTZC TZSC secure configuration registers.
- For TrustZone-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.

Table 106 summarizes the RCC secured bits following the security configuration bit in the RCC_SECCFGR register.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and non-secure bits:

- Secured bits: read and write operations are only allowed by a secure access. Non-secure read returns 0 and write accesses are ignored. No illegal access event is generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.
- A non-secure write access to RCC_SECCFGR is ignored and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in the GTZC TZIC registers. RCC_SECCFGR can be read by secure or non-secure access.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers are non-secure. RCC_SECCFGR write accesses are ignored.

Table 106. RCC security configuration summary

Configuration bit in RCC_SECCFGR	Secured bits	Corresponding register

1. TRIM field of the HSI48 is located in CRS peripheral. Be sure to secure it using CRSSEC bit in GTZC1 TZSC secure configuration register 1.

11.5.2 RCC privilege protection modes

By default, after reset, all RCC registers can be read or written with both privileged and unprivileged access except *RCC privilege configuration register (RCC_PRIVCFGR)* that can be written with privileged access only. RCC_PRIVCFGR can be read by secure and non secure, privileged and unprivileged access.

The SPRIV bit in RCC_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all RCC secure functions (as defined by *RCC secure configuration register (RCC_SECCFGR)* or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the SPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC secure bits is possible only with privileged access, including RCC_SECCFGR.
- The RCC secure bits can be read only with privileged access except RCC_SECCFGR and RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit in RCC_PRIVCFGR can be written with privileged access only, secure or non-secure. This bit configures the privileged access of all RCC non-secure functions (as defined by RCC_SECCFGR, or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the NSPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC non-secure bits is possible only with privileged access.
- The RCC non-secure bits can be read only with privileged access except RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

11.6 RCC low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep mode stops the CPU clock. The memory interface clocks (Flash memory, caches and all SRAM interfaces) can be stopped by software during Sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.
- Stop modes (Stop 0, Stop 1, Stop 2, Stop 3) stop all the clocks in the core domain and disable the PLLs, HSI16, HSI48, SHSI, MSI and HSE oscillators. However, HSI16 or MSI can be switched ON if the peripheral requests it for autonomous mode purpose, or to generate a wakeup interrupt (see *Section 11.4.20: Peripherals clock gating and autonomous mode* for more details). LSI and LSE remain active in Stop modes.
- Standby and Shutdown modes stop all the clocks in the core domain and disable the PLLs, HSI16, HSI48, SHSI, MSI and HSE oscillators.

The CPU Deepsleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in the DBGMCU_CR register.

When exiting Stop modes (Stop 0, Stop 1, Stop 2 or Stop 3), the system clock is either MSIS or HSI16, depending on the software configuration of STOPWUCK in the *RCC clock configuration register 1 (RCC_CFGR1)*. The frequency (range and user trim) of the MSIS and MSIK oscillators is the one configured before entering Stop mode, except if above 24 MHz. In this case, the MSIS or MSIK range is the 24 MHz range. The user trim of HSI16 is kept. If MSI is in PLL-mode before entering Stop mode with MSIPLLFAST = 0, the PLL-mode stabilization time must be waited for after wakeup even if the LSE was kept ON during the Stop mode. The PLL-mode accuracy is kept after wakeup from Stop 0, Stop 1 or Stop 2 mode without stabilization time if MSIPLLFAST = 1. The MSIPLLFAST bit has no effect when exiting Stop 3 mode.

The other internal oscillator can be automatically woken up in addition to the one used by the system clock, in order to avoid waiting for the other oscillator wakeup time when the device is back in Run mode. This is done thanks to STOPKERWUCK in RCC_CFGR1.

When leaving the Standby and Shutdown modes, the system clock is MSIS. The MSIS and MSIK frequency at wakeup from Standby mode is configured with MSISSRANGE and MSIKSRANGE in RCC_CSR, from 1 to 4 MHz. The MSI frequency at wakeup from Shutdown mode is 4 MHz. The user trim is lost.

If a Flash memory programming operation is ongoing, Stop, Standby or Shutdown mode entry is delayed until the Flash memory interface access is finished. If an access to the APB domain is ongoing, Stop, Standby or Shutdown mode entry is delayed until the APB access is finished. If an autonomous peripheral generates a system clock request, Stop, Standby or Shutdown mode entry is delayed until the system clock request is released.

11.7 RCC interrupts

The table below summarizes the interrupt sources and the way to control them.

Table 107. Interrupt sources and control

Interrupt vector	Interrupt event flag	Description	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby, Shutdown modes
RCC	LSIRDYF	LSI ready	LSIRDYIE and LSISEC = 0	Set LSIRDYC to 1	Yes	No
	LSERDYF	LSE ready	LSERDYIE and LSESEC = 0	Set LSERDYC to 1	Yes	No
	HSIDRYF	HSI ready	HSIDRYIE and HSISEC = 0	Set HSIRDYC to 1	Yes	No
	HSERDYF	HSE ready	HSERDYIE and HSESEC = 0	Set HSERDYC to 1	Yes	No
	MSISRDYF	MSIS ready	MSISRDYIE and MSISEC = 0	Set MSISRDYC to 1	Yes	No
	MSIKRDYF	MSIK ready	MSIKRDYIE and MSISEC = 0	Set MSIKRDYC to 1	Yes	No
	SHSIRDYF	SHSI ready	SHSIRDYIE and SAESSEC = 0 (in GTZC)	Set SHSIRDYC to 1	Yes	No
	HSI48RDYF	HSI48 ready	HSI48RDYIE and HSI48SEC = 0	Set HSI48RDYC to 1	Yes	No
	PLL1RDYF	PLL1 ready	PLL1RDYIE and PLL1SEC = 0	Set PLL1RDYC to 1	Yes	No
	PLL2RDYF	PLL2 ready	PLL2RDYIE and PLL2SEC = 0	Set PLL2RDYC to 1	Yes	No
	PLL3RDYF	PLL3 ready	PLL3RDYIE and PLL3SEC = 0	Set PLL3DYC to 1	Yes	No
RCC_S(1)	LSIRDYF	LSI ready	LSIRDYIE and LSISEC = 1	Set LSIRDYC to 1	Yes	No
	LSERDYF	LSE ready	LSERDYIE and LSESEC = 1	Set LSERDYC to 1	Yes	No
	HSIDRYF	HSI ready	HSIDRYIE and HSISEC = 1	Set HSIRDYC to 1	Yes	No
	HSERDYF	HSE ready	HSERDYIE and HSESEC = 1	Set HSERDYC to 1	Yes	No
	MSISRDYF	MSIS ready	MSISRDYIE and MSISEC = 1	Set MSISRDYC to 1	Yes	No
	MSIKRDYF	MSIK ready	MSIKRDYIE and MSISEC = 1	Set MSIKRDYC to 1	Yes	No

Table 107. Interrupt sources and control (continued)

Interrupt vector	Interrupt event flag	Description	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby, Shutdown modes
RCC_S(1)	SHSIRDYF	SHSI ready	SHSIRDYIE and SAESSEC(2) = 1	Set SHSIRDYC to 1	Yes	No
	HSI48RDYF	HSI48 ready	HSI48RDYIE and HSI48SEC = 1	Set HSI48RDYC to 1	Yes	No
	PLL1RDYF	PLL1 ready	PLL1RDYIE and PLL1SEC = 1	Set PLL1RDYC to 1	Yes	No
	PLL2RDYF	PLL2 ready	PLL2RDYIE and PLL2SEC = 1	Set PLL2RDYC to 1	Yes	No
	PLL3RDYF	PLL3 ready	PLL3RDYIE and PLL3SEC = 1	Set PLL3RDYC to 1	Yes	No
TAMP	ITAMP3F(3)	LSE CSS failure	LSECSSON and ITAMP3E(3) and ITAMP3IE(3)	Set CITAMP3F(3) to 1	Yes	Yes
NMI	HSECSSF	HSE CSS failure	-(4)	Set HSECSSC to 1	Yes	No
LSECSS(5)	Through EXTI	LSE CSS failure	Through EXTI	Through EXTI	Yes	Yes(6)/No
MSI_PLL_UNLOCK(5)	Through EXTI	MSI PLL-mode unlock(7)	Through EXTI	Through EXTI	Yes	Yes(6)/No

1. The RCC secure interrupt vector is used only when TrustZone is enabled.
2. The SAESSEC bit is in the GTZC peripheral.
3. The LSE CSS failure event (LSECSSD) is connected to TAMP internal tamper 3. In order to get the interrupt associated to this event, the internal tamper 3 must be enabled, and the internal tamper 3 interrupt must be enabled. The ITAMP3F, ITAMP3E, ITAMP3IE and CITAMP3F bits are in the TAMP peripheral. Consequently, the LSE CSS tamper interrupt erases or blocks the device secrets as described in *Table 528: TAMP interconnection*.
4. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).
5. Not available in STM32U575/585 rev. X. Available in all other STM32U575/585 revisions.
6. This interrupt can wake up from Stop 0, Stop 1, and Stop 2 modes only.
7. This interrupt indicates that the MSI has left the PLL_mode, due to LSE missing pulses. As a consequence, the MSI frequency accuracy is degraded.

11.8 RCC registers

11.8.1 RCC clock control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 0035

HSEBYP and HSEEXT are cleared upon power-on reset. They are not affected upon other types of reset.

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PLL3 RDY	PLL3ON	PLL2 RDY	PLL2ON	PLL1 RDY	PLL1ON	Res.	Res.	Res.	HSEEXT	CSSON	HSEBYP	HSE RDY	HSEON
		r	rw	r	rw	r	rw				rw	rs	rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SHSIRDY	SHSION	HSI48RDY	HSI48ON	Res.	HSIRDY	HSIKERON	HSION	MSIPLLFAST	MSIPLLSEL	MSIKRDY	MSIKON	MSIPLLEN	MSISRDY	MSIKERON	MSISON
r	rw	r	rw		r	rw	rw	rw	rw	r	rw	rw	r	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **PLL3RDY**: PLL3 clock ready flag
Set by hardware to indicate that the PLL3 is locked.
0: PLL3 unlocked
1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable
Set and cleared by software to enable PLL3.
Cleared by hardware when entering Stop, Standby or Shutdown mode.
0: PLL3 OFF
1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag
Set by hardware to indicate that the PLL2 is locked.
0: PLL2 unlocked
1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable
Set and cleared by software to enable PLL2.
Cleared by hardware when entering Stop, Standby or Shutdown mode.
0: PLL2 OFF
1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag
Set by hardware to indicate that the PLL1 is locked.
0: PLL1 unlocked
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable

Set and cleared by software to enable the main PLL.

Cleared by hardware when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the PLL1 clock is used as the system clock.

0: PLL1 OFF

1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: HSE external clock bypass mode

Set and reset by software to select the external clock mode in bypass mode. External clock mode must be configured with HSEON bit to be used by the device. This bit can be written only if the HSE oscillator is disabled. This bit is active only if the HSE bypass mode is enabled.

0: external HSE clock analog mode

1: external HSE clock digital mode (through I/O Schmitt trigger)

Bit 19 **CSSON**: Clock security system enable

Set by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.

0: clock security system OFF (clock detector OFF)

1: clock security system ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18 **HSEBYP**: HSE crystal oscillator bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE crystal oscillator not bypassed

1: HSE crystal oscillator bypassed with external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE oscillator not ready

1: HSE oscillator ready

Note: Once the HSEON bit is cleared, HSERDY goes low after six HSE clock cycles.

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE oscillator when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.

0: HSE oscillator OFF

1: HSE oscillator ON

Bit 15 **SHSIRDY**: SHSI clock ready flag

Set by hardware to indicate that the SHSI oscillator is stable. This bit is set only when SHSI is enabled by software by setting SHSION.

0: SHSI oscillator not ready

1: SHSI oscillator ready

Note: Once the SHSION bit is cleared, SHSIRDY goes low after six SHSI clock cycles.

Bit 14 **SHSION**: SHSI clock enable
Set and cleared by software.
Cleared by hardware to stop the SHSI when entering in Stop, Standby or Shutdown modes.
0: SHSI oscillator OFF
1: SHSI oscillator ON

Bit 13 **HSI48RDY**: HSI48 clock ready flag
Set by hardware to indicate that HSI48 oscillator is stable. This bit is set only when HSI48 is enabled by software by setting HSI48ON.
0: HSI48 oscillator not ready
1: HSI48 oscillator ready

Bit 12 **HSI48ON**: HSI48 clock enable
Set and cleared by software.
Cleared by hardware to stop the HSI48 when entering in Stop, Standby or Shutdown modes.
0: HSI48 oscillator OFF
1: HSI48 oscillator ON

Bit 11 Reserved, must be kept at reset value.

Bit 10 **HSIRDY**: HSI16 clock ready flag
Set by hardware to indicate that HSI16 oscillator is stable. This bit is set only when HSI16 is enabled by software by setting HSION.
0: HSI16 oscillator not ready
1: HSI16 oscillator ready
Note: Once the HSION bit is cleared, HSIRDY goes low after six HSI16 clock cycles.

Bit 9 **HSIKERON**: HSI16 enable for some peripheral kernels
Set and cleared by software to force HSI16 ON even in Stop modes. Keeping the HSI16 ON in Stop mode allows the communication speed not to be reduced by the HSI16 startup time. This bit has no effect on HSION value.
Refer to *Peripherals clock gating and autonomous mode* for more details.
The HSIKERON must be configured at 0 before entering Stop 3 mode.
0: No effect on HSI16 oscillator
1: HSI16 oscillator forced ON even in Stop mode

Bit 8 **HSION**: HSI16 clock enable
Set and cleared by software.
Cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby or Shutdown mode.
Set by hardware to force the HSI16 oscillator ON when STOPWUCK = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator.
This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.
0: HSI16 oscillator OFF
1: HSI16 oscillator ON

Bit 7 **MSIPLLFAST:** MSI PLL mode fast startup
Set and reset by software to enable/disable the fast PLL mode start-up of the MSI clock source. This bit is used only if PLL mode is selected (MSIPLLEN = 1).

Caution: The fast start-up feature is not active the first time the PLL mode is selected. The fast start-up is active when the MSI in PLL mode returns from switch off.

0: MSI PLL normal start-up
1: MSI PLL fast start-up

Bit 6 **MSIPLLSEL:** MSI clock with PLL mode selection

Set and cleared by software to select which MSI output clock uses the PLL mode. This bit can be written only when the MSI PLL mode is disabled (MSIPLLEN = 0).

0: PLL mode applied to MSIK (MSI kernel) clock output

1: PLL mode applied to MSIS (MSI system) clock output

Note: If the MSI kernel clock output uses the same oscillator source than the MSI system clock output, then the PLL mode is applied to both clock outputs.

Bit 5 **MSIKRDY**: MSIK clock ready flag

Set by hardware to indicate that the MSIK is stable. This bit is set only when MSI kernel oscillator is enabled by software by setting MSIKON.

0: MSIK (MSI kernel) oscillator not ready

1: MSIK (MSI kernel) oscillator ready

Note: Once the MSIKON bit is cleared, MSIKRDY goes low after six MSIK oscillator clock cycles.

Bit 4 **MSIKON**: MSIK clock enable

Set and cleared by software.

Cleared by hardware to stop the MSIK when entering Stop, Standby or Shutdown mode.

Set by hardware to force the MSIK oscillator ON when exiting Standby or Shutdown mode.

Set by hardware to force the MSIK oscillator ON when STOPWUCK = 0 or STOPKERWUCK = 0 when exiting Stop modes or in case of a failure of the HSE oscillator.

0: MSIK (MSI kernel) oscillator disabled

1: MSIK (MSI kernel) oscillator enabled

Bit 3 **MSIPLLEN**: MSI clock PLL-mode enable

Set and cleared by software to enable/disable the PLL part of the MSI clock source.

MSIPLLEN must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware). A hardware protection prevents from enabling MSIPLLEN if LSE is not ready.

This bit is cleared by hardware when LSE is disabled (LSEON = 0) or when the CSS on LSE detects a LSE failure (see RCC_CSR).

0: MSI PLL-mode OFF

1: MSI PLL-mode ON

Bit 2 **MSISRDY**: MSIS clock ready flag

Set by hardware to indicate that the MSIS oscillator is stable. This bit is set only when MSIS is enabled by software by setting MSISON.

0: MSIS (MSI system) oscillator not ready

1: MSIS (MSI system) oscillator ready

Note: Once the MSISON bit is cleared, MSISRDY goes low after six MSIS clock cycles.

Bit 1 **MSIKERON**: MSI enable for some peripheral kernels

Set and cleared by software to force MSI ON even in Stop modes. Keeping the MSI ON in Stop mode allows the communication speed not to be reduced by the MSI startup time. This bit has no effect on MSISON and MSIKON values (see *Peripherals clock gating and autonomous mode* for more details).

The MSIKERON must be configured at 0 before entering Stop 3 mode.

0: No effect on MSI oscillator

1: MSI oscillator forced ON even in Stop mode

Bit 0 **MSISON**: MSIS clock enable

Set and cleared by software.

Cleared by hardware to stop the MSIS oscillator when entering Stop, Standby or Shutdown mode.

Set by hardware to force the MSIS oscillator ON when exiting Standby or Shutdown mode.

Set by hardware to force the MSIS oscillator ON when STOPWUCK = 0 when exiting Stop modes or in case of a failure of the HSE oscillator.

Set by hardware when used directly or indirectly as system clock.

0: MSIS (MSI system) oscillator OFF

1: MSIS (MSI system) oscillator ON

11.8.2 RCC internal clock sources calibration register 1 (RCC_ICSCR1)

Address offset: 0x008

Reset value: 0x440X XXXX

X is factory-programmed.

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSISRANGE[3:0]				MSIKRANGE[3:0]				MSIRGSEL	MSIBIAS	Res.	Res.	MSICAL0[4:1]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSICAL0[0]	MSICAL1[4:0]					MSICAL2[4:0]					MSICAL3[4:0]				
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 **MSISRANGE[3:0]**: MSIS clock ranges

These bits are configured by software to choose the frequency range of MSIS oscillator when MSIRGSEL is set. 16 frequency ranges are available:
0000: range 0 around 48 MHz
0001: range 1 around 24 MHz
0010: range 2 around 16 MHz
0011: range 3 around 12 MHz
0100: range 4 around 4 MHz (reset value)
0101: range 5 around 2 MHz
0110: range 6 around 1.33 MHz
0111: range 7 around 1 MHz
1000: range 8 around 3.072 MHz
1001: range 9 around 1.536 MHz
1010: range 10 around 1.024 MHz
1011: range 11 around 768 kHz
1100: range 12 around 400 kHz
1101: range 13 around 200 kHz
1110: range 14 around 133 kHz
1111: range 15 around 100 kHz

Note: MSISRANGE can be modified when MSIS is OFF (MSISON = 0) or when MSIS is ready (MSISRDY = 1). MSISRANGE must NOT be modified when MSIS is ON and NOT ready (MSISON = 1 and MSISRDY = 0)

MSISRANGE is kept when the device wakes up from Stop mode, except when the MSIS range is above 24 MHz. In this case MSISRANGE is changed by hardware into range 2 (24 MHz).

Bits 27:24 **MSIKRANGE[3:0]**: MSIK clock ranges

These bits are configured by software to choose the frequency range of MSIK oscillator when MSIRGSEL is set. 16 frequency ranges are available:
0000: range 0 around 48 MHz
0001: range 1 around 24 MHz
0010: range 2 around 16 MHz
0011: range 3 around 12 MHz
0100: range 4 around 4 MHz (reset value)
0101: range 5 around 2 MHz
0110: range 6 around 1.33 MHz
0111: range 7 around 1 MHz
1000: range 8 around 3.072 MHz
1001: range 9 around 1.536 MHz
1010: range 10 around 1.024 MHz
1011: range 11 around 768 kHz
1100: range 12 around 400 kHz
1101: range 13 around 200 kHz
1110: range 14 around 133 kHz
1111: range 15 around 100 kHz

Note: MSIKRANGE can be modified when MSIK is OFF (MSISON = 0) or when MSIK is ready (MSIKRDY = 1). MSIKRANGE must NOT be modified when MSIK is ON and NOT ready (MSIKON = 1 and MSIKRDY = 0)

MSIKRANGE is kept when the device wakes up from Stop mode, except when the MSIK range is above 24 MHz. In this case MSIKRANGE is changed by hardware into range 2 (24 MHz).

Bit 23 **MSIRGSEL**: MSI clock range selection

Set by software to select the MSIS and MSIK clocks range with MSISRANGE[3:0] and MSIKRANGE[3:0]. Write 0 has no effect.

After exiting Standby or Shutdown mode, or after a reset, this bit is at 0 and the MSIS and MSIK ranges are provided by MSISSRANGE[3:0] and MSIKSRANGE[3:0] in RCC_CSR.

0: MSIS/MSIK ranges provided by MSISSRANGE[3:0] and MSIKSRANGE[3:0] in RCC_CSR

1: MSIS/MSIK ranges provided by MSISRANGE[3:0] and MSIKRANGE[3:0] in RCC_ICSCR1

Bit 22 **MSIBIAS**: MSI bias mode selection

Set by software to select the MSI bias mode. By default, the MSI bias is in continuous mode in order to maintain the output clocks accuracy. Setting this bit reduces the MSI consumption when the regulator is in range 4, or when the device is in Stop 1 or Stop 2 mode, but it decreases the MSI accuracy

0: MSI bias continuous mode (clock accuracy fast settling time)

1: MSI bias sampling mode when the regulator is in range 4, or when the device is in Stop 1 or Stop 2 (ultra-low-power mode)

Bits 21:20 Reserved, must be kept at reset value.

Bits 19:15 **MSICAL0[4:0]**: MSIRC0 clock calibration for MSI ranges 0 to 3

These bits are initialized at startup with the factory-programmed MSIRC0 calibration trim value for ranges 0 to 3. When MSITRIM0 is written, MSICAL0 is updated with the sum of MSITRIM0[4:0] and the factory-programmed calibration trim value MSIRC0[4:0].

Caution: There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

Bits 14:10 **MSICAL1[4:0]**: MSIRC1 clock calibration for MSI ranges 4 to 7

These bits are initialized at startup with the factory-programmed MSIRC1 calibration trim value for ranges 4 to 7. When MSITRIM1 is written, MSICAL1 is updated with the sum of MSITRIM1[4:0] and the factory calibration trim value MSIRC1[4:0].

Caution: There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

Bits 9:5 **MSICAL2[4:0]**: MSIRC2 clock calibration for MSI ranges 8 to 11

These bits are initialized at startup with the factory-programmed MSIRC2 calibration trim value for ranges 8 to 11. When MSITRIM2 is written, MSICAL2 is updated with the sum of MSITRIM2[4:0] and the factory calibration trim value MSIRC2[4:0].

Caution: There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

Bits 4:0 **MSICAL3[4:0]**: MSIRC3 clock calibration for MSI ranges 12 to 15

These bits are initialized at startup with the factory-programmed MSIRC3 calibration trim value for ranges 12 to 15. When MSITRIM3 is written, MSICAL3 is updated with the sum of MSITRIM3[4:0] and the factory calibration trim value MSIRC2[4:0].

Caution: There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

11.8.3 RCC internal clock sources calibration register 2 (RCC_ICSCR2)

Address offset: 0x00C

Reset value: 0x0008 4210

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MSITRIM0[4:1]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSITRIM0[0]	MSITRIM1[4:0]					MSITRIM2[4:0]					MSITRIM3[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:15 **MSITRIM0[4:0]**: MSI clock trimming for ranges 0 to 3

These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC0[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 14:10 **MSITRIM1[4:0]**: MSI clock trimming for ranges 4 to 7

These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC1[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 9:5 **MSITRIM2[4:0]**: MSI clock trimming for ranges 8 to 11

These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC2[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 4:0 **MSITRIM3[4:0]**: MSI clock trimming for ranges 12 to 15

These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC3[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Note: The hardware auto calibration with LSE must not be used in conjunction with software calibration.

11.8.4 RCC internal clock sources calibration register 3 (RCC_ICSCR3)

Address offset: 0x010

Reset value: 0x0010 0XXX

X is factory-programmed.

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **HSITRIM[4:0]**: HSI clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSICAL[11:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the HSI.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

These bits are initialized at startup with the factory-programmed HSI calibration trim value. When HSITRIM is written, HSICAL is updated with the sum of HSITRIM and the factory trim value.

11.8.5 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x014

Reset value: 0x0000 0XXX

X is factory-programmed.

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[8:0]								
							r	r	r	r	r	r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **HSI48CAL[8:0]**: HSI48 clock calibration

These bits are initialized at startup with the factory-programmed HSI48 calibration trim value.

11.8.6 RCC clock configuration register 1 (RCC_CFGR1)

Address offset: 0x01C

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2; word, half-word and byte access

1 or 2 wait states are inserted only if the access occurs during clock source switch.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	MCOPRE[2:0]			MCOSEL[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

										rw	rw	r	r	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **MCOPRE[2:0]**: microcontroller clock output prescaler
Set and cleared by software.
It is highly recommended to change this prescaler before MCO output is enabled.
000: MCO divided by 1
001: MCO divided by 2
010: MCO divided by 4
011: MCO divided by 8
100: MCO divided by 16
Others: not allowed

Bits 27:24 **MCOSEL[3:0]**: microcontroller clock output
Set and cleared by software.
0000: MCO output disabled, no clock on MCO
0001: SYSCLK system clock selected
0010: MSIS clock selected
0011: HSI16 clock selected
0100: HSE clock selected
0101: Main PLL clock pll1_r_ck selected
0110: LSI clock selected
0111: LSE clock selected
1000: Internal HSI48 clock selected
1001: MSIK clock selected
Others: reserved

Note: This clock output may have some truncated cycles at startup or during MCO clock source switching.

Bits 23:6 Reserved, must be kept at reset value.

Bit 5 **STOPKERWUCK:** wakeup from Stop kernel clock automatic enable selection
Set and cleared by software to enable automatically another oscillator when exiting Stop mode. This oscillator can be used as independent kernel clock by peripherals.
0: MSIK oscillator automatically enabled when exiting Stop mode
1: HSI16 oscillator automatically enabled when exiting Stop mode

Bit 4 **STOPWUCK:** wakeup from Stop and CSS backup clock selection
Set and cleared by software to select the system clock used when exiting Stop mode.
The selected clock is also used as emergency clock for the clock security system on HSE.
Warning: STOPWUCK must not be modified when the CSS is enabled by HSECSSON bit in RCC_CR and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW = 10).
0: MSIS oscillator selected as wakeup from stop clock and CSS backup clock
1: HSI16 oscillator selected as wakeup from stop clock and CSS backup clock

Bits 3:2 **SWS[1:0]**: system clock switch status
Set and cleared by hardware to indicate which clock source is used as system clock.
00: MSIS oscillator used as system clock
01: HSI16 oscillator used as system clock
10: HSE used as system clock
11: PLL pll1_r_ck used as system clock

Bits 1:0 **SW[1:0]**: system clock switch
Set and cleared by software to select system clock source (SYSCLK).
Configured by hardware to force MSIS oscillator selection when exiting Standby or Shutdown mode. Configured by hardware to force MSIS or HSI16 oscillator selection when exiting Stop mode or in case of HSE oscillator failure, depending on STOPWUCK value.
00: MSIS selected as system clock
01: HSI16 selected as system clock
10: HSE selected as system clock
11: PLL pll1_r_ck selected as system clock

11.8.7 RCC clock configuration register 2 (RCC_CFGR2)

Address offset: 0x020

Reset value: 0x0000 0000

Access: word, half-word and byte access

1 or 2 wait states are inserted only if the access occurs during clock source switch.

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	PPRE2[2:0]			Res.	PPRE1[2:0]			HPRE[3:0]			
					rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **APB2DIS**: APB2 clock disable

This bit can be set in order to further reduce power consumption, when none of the APB2 peripherals are used and when their clocks are disabled in RCC_APB2ENR. When this bit is set, all the APB2 peripherals clocks are off.

0: APB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB2 clock disabled

Bit 19 **APB1DIS**: APB1 clock disable

This bit can be set in order to further reduce power consumption, when none of the APB1 peripherals (except IWDG) are used and when their clocks are disabled in RCC_APB1ENR. When this bit is set, all the APB1 peripherals clocks are off, except for IWDG.

0: APB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB1 clock disabled

Bit 18 **AHB2DIS2**: AHB2_2 clock disable

This bit can be set in order to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR2 are used and when their clocks are disabled in RCC_AHB2ENR2. When this bit is set, all the AHB2 peripherals clocks from RCC_AHB2EBNR2 are off.

0: AHB2_2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB2_2 clock disabled

Bit 17 **AHB2DIS1**: AHB2_1 clock disable

This bit can be set in order to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR1 (except SRAM2 and SRAM3) are used and when their clocks are disabled in RCC_AHB2ENR1. When this bit is set, all the AHB2 peripherals clocks from RCC_AHB2ENR1 are off, except for SRAM2 and SRAM3.

0: AHB2_1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB2_1 clock disabled

Bit 16 **AHB1DIS**: AHB1 clock disable

This bit can be set in order to further reduce power consumption, when none of the AHB1 peripherals (except those listed hereafter) are used and when their clocks are disabled in RCC_AHB1ENR. When this bit is set, all the AHB1 peripherals clocks are off, except for FLASH, BKPSRAM, ICACHE, DCACHE1 and SRAM1.

0: AHB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB1 clock disabled

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE2[2:0]**: APB2 prescaler

Set and cleared by software to control the division factor of the APB2 clock (PCLK2).

0xx: PCLK2 not divided

100: PCLK2 divided by 2

101: PCLK2 divided by 4

110: PCLK2 divided by 8

111: PCLK2 divided by 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE1[2:0]:** APB1 prescaler

Set and cleared by software to control the division factor of the APB1 clock (PCLK1).

0xx: PCLK1 not divided

100: PCLK1 divided by 2

101: PCLK1 divided by 4

110: PCLK1 divided by 8

111: PCLK1 divided by 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler

Set and cleared by software to control the division factor of the AHB clock (HCLK).

Caution: Depending on the device voltage range, the software must set these bits correctly to ensure that the system frequency does not exceed the maximum allowed frequency (for more details, refer to *Table 103: Bus maximum frequency*). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value is taken into account.

0xxx: SYSCLK not divided

1000: SYSCLK divided by 2

1001: SYSCLK divided by 4

1010: SYSCLK divided by 8

1011: SYSCLK divided by 16

1100: SYSCLK divided by 64

1101: SYSCLK divided by 128

1110: SYSCLK divided by 256

1111: SYSCLK divided by 512

11.8.8 RCC clock configuration register 3 (RCC_CFGR3)

Address offset: 0x024

Reset value: 0x0000 0000

Access: word, half-word and byte access

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **APB3DIS**: APB3 clock disable

This bit can be set in order to further reduce power consumption, when none of the APB3 peripherals from RCC_APB3ENR are used and when their clocks are disabled in RCC_APB3ENR. When this bit is set, all the APB3 peripherals clocks are off.

0: APB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB3 clock disabled

Bit 16 **AHB3DIS**: AHB3 clock disable

This bit can be set in order to further reduce power consumption, when none of the AHB3 peripherals (except SRAM4) are used and when their clocks are disabled in RCC_AHB3ENR. When this bit is set, all the AHB3 peripherals clocks are off, except for SRAM4.

0: AHB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB3 clock disabled

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE3[2:0]**: APB3 prescaler

Set and cleared by software to control the division factor of the APB3 clock (PCLK3).

0xx: HCLK not divided

100: HCLK divided by 2

101: HCLK divided by 4

110: HCLK divided by 8

111: HCLK divided by 16

Bits 3:0 Reserved, must be kept at reset value.

11.8.9 RCC PLL1 configuration register (RCC_PLL1CFGR)

Address offset: 0x028

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL1REN**: PLL1 DIVR divider output enable

Set and reset by software to enable the pll1_r_ck output of the PLL1.

To save power, PLL1RENPLL2REN and PLL1R bits must be set to 0 when the pll1_r_ck is not used.

This bit can be cleared only when the PLL1 is not used as SYSCLK.

0: pll1_r_ck output disabled

1: pll1_r_ck output enabled

Bit 17 **PLL1QEN**: PLL1 DIVQ divider output enable
Set and reset by software to enable the pll1_q_ck output of the PLL1.
To save power, PLL1QEN and PLL1Q bits must be set to 0 when the pll1_q_ck is not used.
0: pll1_q_ck output disabled
1: pll1_q_ck output enabled

Bit 16 **PLL1PEN**: PLL1 DIVP divider output enable
Set and reset by software to enable the pll1_p_ck output of the PLL1.
To save power, PLL1PEN and PLL1P bits must be set to 0 when the pll1_p_ck is not used.
0: pll1_p_ck output disabled
1: pll1_p_ck output enabled

Bits 15:12 **PLL1MBOOST[3:0]**: Prescaler for EPOD booster input clock
Set and cleared by software to configure the prescaler of the PLL1, used for the EPOD booster. The EPOD booster input frequency is PLL1 input clock frequency/PLL1MBOOST.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0) and EPOD Boost mode is disabled (see *Section 10: Power control (PWR)*).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 4
0011: division by 6
0100: division by 8
0101: division by 10
0110: division by 12

1000: division by 16
others: reserved

Bits 11:8 **PLL1M[3:0]**: Prescaler for PLL1
Set and cleared by software to configure the prescaler of the PLL1. The VCO1 input frequency is PLL1 input clock frequency/PLL1M.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3
...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL1FRACEN**: PLL1 fractional latch enable
Set and reset by software to latch the content of PLL1FRACN into the ΣΔ modulator.
In order to latch the PLL1FRACN value into the ΣΔ modulator, PLL1FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL1FRACN into the modulator (see *PLL initialization phase* for details).

Bits 3:2 **PLL1RGE[1:0]**: PLL1 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL1.
This bit must be written before enabling the PLL1.
00-01-10: PLL1 input (ref1_ck) clock range frequency between 4 and 8 MHz
11: PLL1 input (ref1_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL1SRC[1:0]**: PLL1 entry clock source

Set and cleared by software to select PLL1 clock source. These bits can be written only when the PLL1 is disabled.
In order to save power, when no PLL1 is used, the value of PLL1SRC must be 0.
00: No clock sent to PLL1
01: MSIS clock selected as PLL1 clock entry
10: HSI16 clock selected as PLL1 clock entry
11: HSE clock selected as PLL1 clock entry

11.8.10 RCC PLL2 configuration register (RCC_PLL2CFGR)

Address offset: 0x02C

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL2REN**: PLL2 DIVR divider output enable

Set and reset by software to enable the pll2_r_ck output of the PLL2.
To save power, PLL2REN and PLL2R bits must be set to 0 when the pll2_r_ck is not used.
0: pll2_r_ck output disabled
1: pll2_r_ck output enabled

Bit 17 **PLL2QEN**: PLL2 DIVQ divider output enable

Set and reset by software to enable the pll2_q_ck output of the PLL2.
To save power, PLL2QEN and PLL2Q bits must be set to 0 when the pll2_q_ck is not used.
0: pll2_q_ck output disabled
1: pll2_q_ck output enabled

Bit 16 **PLL2PEN:** PLL2 DIVP divider output enable

Set and reset by software to enable the pll2_p_ck output of the PLL2.
To save power, PLL2PEN and PLL2P bits must be set to 0 when the pll2_p_ck is not used.
0: pll2_p_ck output disabled
1: pll2_p_ck output enabled

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL2M[3:0]**: Prescaler for PLL2

Set and cleared by software to configure the prescaler of the PLL2. The VCO2 input frequency is PLL2 input clock frequency/PLL2M.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3
...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL2FRACEN**: PLL2 fractional latch enable

Set and reset by software to latch the content of PLL2FRACN into the ΣΔ modulator.
In order to latch the PLL2FRACN value into the ΣΔ modulator, PLL2FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL2FRACN into the modulator (see *PLL initialization phase* for details).

Bits 3:2 **PLL2RGE[1:0]**: PLL2 input frequency range

Set and reset by software to select the proper reference frequency range used for PLL2. This bit must be written before enabling the PLL2.
00-01-10: PLL2 input (ref2_ck) clock range frequency between 4 and 8 MHz
11: PLL2 input (ref2_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL2SRC[1:0]**: PLL2 entry clock source

Set and cleared by software to select PLL2 clock source. These bits can be written only when the PLL2 is disabled.
In order to save power, when no PLL2 is used, the value of PLL2SRC must be 0.
00: No clock sent to PLL2
01: MSIS clock selected as PLL2 clock entry
10: HSI16 clock selected as PLL2 clock entry
11: HSE clock selected as PLL2 clock entry

11.8.11 RCC PLL3 configuration register (RCC_PLL3CFGR)

Address offset: 0x030

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL3REN**: PLL3 DIVR divider output enable
Set and reset by software to enable the pll3_r_ck output of the PLL3.
To save power, PLL3REN and PLL3R bits must be set to 0 when the pll3_r_ck is not used.
0: pll3_r_ck output disabled
1: pll3_r_ck output enabled

Bit 17 **PLL3QEN**: PLL3 DIVQ divider output enable
Set and reset by software to enable the pll3_q_ck output of the PLL3.
To save power, PLL3QEN and PLL3Q bits must be set to 0 when the pll3_q_ck is not used.
0: pll3_q_ck output disabled
1: pll3_q_ck output enabled

Bit 16 **PLL3PEN:** PLL3 DIVP divider output enable
Set and reset by software to enable the pll3_p_ck output of the PLL3.
To save power, PLL3PEN and PLL3P bits must be set to 0 when the pll3_p_ck is not used.
0: pll3_p_ck output disabled
1: pll3_p_ck output enabled

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL3M[3:0]**: Prescaler for PLL3
Set and cleared by software to configure the prescaler of the PLL3. The VCO3 input frequency is PLL3 input clock frequency/PLL3M.
This bit can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3
...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of PLL3FRACN into the ΣΔ modulator.
In order to latch the PLL3FRACN value into the ΣΔ modulator, PLL3FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL3FRACN into the modulator (see *PLL initialization phase* for details).

Bits 3:2 **PLL3RGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
This bit must be written before enabling the PLL3.
00-01-10: PLL3 input (ref3_ck) clock range frequency between 4 and 8 MHz
11: PLL3 input (ref3_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL3SRC[1:0]**: PLL3 entry clock source
Set and cleared by software to select PLL3 clock source. These bits can be written only when the PLL3 is disabled.
In order to save power, when no PLL3 is used, the value of PLL3SRC must be 00.
00: No clock sent to PLL3
01: MSIS clock selected as PLL3 clock entry
10: HSI16 clock selected as PLL3 clock entry
11: HSE clock selected as PLL3 clock entry

11.8.12 RCC PLL1 dividers register (RCC_PLL1DIVR)

Address offset: 0x034

Reset value: 0x0101 0280

Access: no wait state; word, half-word and byte access

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **PLL1R[6:0]**: PLL1 DIVR division factor

Set and reset by software to control the frequency of the pll1_r_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
Only division by 1 and even division factors are allowed.
0000000: Not allowed
0000001: pll1_r_ck = vco1_ck / 2 (default after reset)
0000010: pll1_r_ck = vco1_ck / 3
0000011: pll1_r_ck = vco1_ck / 4
...
1111111: pll1_r_ck = vco1_ck / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **PLL1Q[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the pll1_q_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_q_ck = vco1_ck
0000001: pll1_q_ck = vco1_ck / 2 (default after reset)
0000010: pll1_q_ck = vco1_ck / 3
0000011: pll1_q_ck = vco1_ck / 4
...
1111111: pll1_q_ck = vco1_ck / 128

Bits 15:9 **PLL1P[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the pll1_p_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_p_ck = vco1_ck
0000001: pll1_p_ck = vco1_ck / 2 (default after reset)
0000010: pll1_p_ck = vco1_ck
0000011: pll1_p_ck = vco1_ck / 4
...
1111111: pll1_p_ck = vco1_ck / 128

Bits 8:0 **PLL1N[8:0]**: Multiplication factor for PLL1 VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits can be written only when the PLL is disabled (PLL1ON = 0 and PLL1RDY = 0).

0x003: PLL1N = 4

0x004: PLL1N = 5

0x005: PLL1N = 6

...

0x080: PLL1N = 129 (default after reset)

...

0x1FF: PLL1N = 512

Others: reserved

VCO output frequency = F_{ref1_ck} x PLL1N, when fractional value 0 has been loaded into PLL1FRACN, with:

- PLL1N between 4 and 512
- input frequency F_{ref1_ck} between 4 and 16 MHz

11.8.13 RCC PLL1 fractional divider register (RCC_PLL1FRACR)

Address offset: 0x038

Reset value: 0x0000 0000

Access: no wait state; word and half-word access

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **PLL1FRACN[12:0]**: Fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

VCO output frequency = F_{ref1_ck} x $\left(\text{PLL1N} + (\text{PLL1FRACN} / 2^{13})\right)$, with:

- PLL1N must be between 4 and 512.
- PLL1FRACN can be between 0 and 2^{13}- 1.
- The input frequency F_{ref1_ck} must be between 4 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into PLL1FRACN.
- Set the bit PLL1FRACEN to 1.

Bits 2:0 Reserved, must be kept at reset value.

11.8.14 RCC PLL2 dividers configuration register (RCC_PLL2DIVR)

Address offset: 0x03C

Reset value: 0x0101 0280

Access: no wait state; word, half-word and byte access

Set and reset by software to control the frequency of the pll3_r_ck clock.
These bits can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
0000000: pll3_r_ck = vco3_ck
0000001: pll3_r_ck = vco3_ck / 2 (default after reset)
0000010: pll3_r_ck = vco3_ck / 3
0000011: pll3_r_ck = vco3_ck / 4
...
1111111: pll3_r_ck = vco3_ck / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **PLL3Q[6:0]**: PLL3 DIVQ division factor

Set and reset by software to control the frequency of the pll3_q_ck clock.
These bits can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
0000000: pll3_q_ck = vco3_ck
0000001: pll3_q_ck = vco3_ck / 2 (default after reset)
0000010: pll3_q_ck = vco3_ck / 3
0000011: pll3_q_ck = vco3_ck / 4
...
1111111: pll3_q_ck = vco3_ck / 128

Bits 15:9 **PLL3P[6:0]**: PLL3 DIVP division factor

Set and reset by software to control the frequency of the pll3_p_ck clock.
These bits can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).

0000000: pll3_p_ck = vco3_ck
0000001: pll3_p_ck = vco3_ck / 2 (default after reset)
0000010: pll3_p_ck = vco3_ck / 3
0000011: pll3_p_ck = vco3_ck / 4
...
1111111: pll3_p_ck = vco3_ck / 128

Bits 8:0 **PLL3N[8:0]**: Multiplication factor for PLL3 VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits can be written only when the PLL is disabled (PLL3ON = 0 and PLL3RDY = 0).

0x003: PLL3N = 4

0x004: PLL3N = 5

0x005: PLL3N = 6

...

0x080: PLL3N = 129 (default after reset)

...

0x1FF: PLL3N = 512

Others: reserved

VCO output frequency = F_{ref3_ck} x PLL3N, when fractional value 0 has been loaded into PLL3FRACN, with:

- PLL3N between 4 and 512
- input frequency F_{ref3_ck} between 4 and 16MHz

11.8.17 RCC PLL3 fractional divider register (RCC_PLL3FRACR)

Address offset: 0x048

Reset value: 0x0000 0000

Access: no wait state; word and half-word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLL3FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **PLL3FRACN[12:0]**: Fractional part of the multiplication factor for PLL3 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL3 VCO.

VCO output frequency = F_{ref3_ck} x $\left(\text{PLL3N} + (\text{PLL3FRACN} / 2^{13})\right)$, with:

- PLL3N must be between 4 and 512.
- PLL3FRACN can be between 0 and 2^{13} - 1.
- The input frequency F_{ref3_ck} must be between 4 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL3FRACEN to 0.
- Write the new fractional value into PLL3FRACN.
- Set the bit PLL3FRACEN to 1.

Bits 2:0 Reserved, must be kept at reset value.

11.8.18 RCC clock interrupt enable register (RCC_CIER)

Address offset: 0x050

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SHSIRDYIE**: SHSI ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the SHSI oscillator stabilization.
0: SHSI ready interrupt disabled
1: SHSI ready interrupt enabled

Bit 11 **MSIKRDYIE**: MSIK ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the MSIK oscillator stabilization.
0: MSIK ready interrupt disabled
1: MSIK ready interrupt enabled

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYIE**: PLL3 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLL3 lock.
0: PLL3 lock interrupt disabled
1: PLL3 lock interrupt enabled

Bit 7 **PLL2RDYIE**: PLL2 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLL2 lock.
0: PLL2 lock interrupt disabled
1: PLL2 lock interrupt enabled

Bit 6 **PLL1RDYIE**: PLL ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled
1: PLL1 lock interrupt enabled

Bit 5 **HSI48RDYIE**: HSI48 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.
0: HSI48 ready interrupt disabled
1: HSI48 ready interrupt enabled

Bit 4 **HSERDYIE**: HSE ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.

0: HSE ready interrupt disabled

1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI16 ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by the HSI16 oscillator stabilization.

0: HSI16 ready interrupt disabled

1: HSI16 ready interrupt enabled

Bit 2 **MSISRDYIE**: MSIS ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by the MSIS oscillator stabilization.

0: MSIS ready interrupt disabled

1: MSIS ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.

0: LSE ready interrupt disabled

1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by the LSI oscillator stabilization.

0: LSI ready interrupt disabled

1: LSI ready interrupt enabled

11.8.19 RCC clock interrupt flag register (RCC_CIFR)

Address offset: 0x054

Reset value: 0x0000 0000

Access: no wait state, word; half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	SHSIRDYF	MSIKRDYF	CSSF	Res.	PLL3RDYF	PLL2RDYF	PLL1RDYF	HSI48RDYF	HSERDYF	HSIRDYF	MSISRDYF	LSERDYF	LSIRDYF
			r	r	r		r	r	r	r	r	r	r	r	r

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SHSIRDYF**: SHSI ready interrupt flag

Set by hardware when the SHSI clock becomes stable and SHSIRDYIE is set.

Cleared by software setting the SHSIRDYC bit.

0: No clock ready interrupt caused by the SHSI oscillator

1: Clock ready interrupt caused by the SHSI oscillator

Bit 11 **MSIKRDYF**: MSIK ready interrupt flag
Set by hardware when the MSIK clock becomes stable and MSIKRDYIE is set.
Cleared by software setting the MSIKRDYC bit.
0: No clock ready interrupt caused by the MSIK oscillator
1: Clock ready interrupt caused by the MSIK oscillator

Bit 10 **CSSF**: Clock security system interrupt flag
Set by hardware when a failure is detected in the HSE oscillator.
Cleared by software setting the CSSC bit.
0: No clock security interrupt caused by HSE clock failure
1: Clock security interrupt caused by HSE clock failure

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYF**: PLL3 ready interrupt flag
Set by hardware when the PLL3 locks and PLL3RDYIE is set.
Cleared by software setting the PLL3RDYC bit.
0: No clock ready interrupt caused by PLL3 lock
1: Clock ready interrupt caused by PLL3 lock

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
Cleared by software setting the PLL2RDYC bit.
0: No clock ready interrupt caused by PLL2 lock
1: Clock ready interrupt caused by PLL2 lock

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
Cleared by software setting the PLL1RDYC bit.
0: No clock ready interrupt caused by PLL1 lock
1: Clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
Cleared by software setting the HSI48RDYC bit.
0: No clock ready interrupt caused by the HSI48 oscillator
1: Clock ready interrupt caused by the HSI48 oscillator

Bit 4 **HSERDYF**: HSE ready interrupt flag
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
Cleared by software setting the HSERDYC bit.
0: No clock ready interrupt caused by the HSE oscillator
1: Clock ready interrupt caused by the HSE oscillator

Bit 3 **HSIRDYF**: HSI16 ready interrupt flag
Set by hardware when the HSI16 clock becomes stable and HSIRDYIE is set in a response to setting the HSION (see RCC_CR). When HSION is not set but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSIRDYC bit.
0: No clock ready interrupt caused by the HSI16 oscillator
1: Clock ready interrupt caused by the HSI16 oscillator

Bit 2 **MSISRDYF**: MSIS ready interrupt flag
Set by hardware when the MSIS clock becomes stable and MSISRDYIE is set.
Cleared by software setting the MSISRDYC bit.
0: No clock ready interrupt caused by the MSIS oscillator
1: Clock ready interrupt caused by the MSIS oscillator

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
Cleared by software setting the LSERDYC bit.
0: No clock ready interrupt caused by the LSE oscillator
1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
Cleared by software setting the LSIRDYC bit.
0: No clock ready interrupt caused by the LSI oscillator
1: Clock ready interrupt caused by the LSI oscillator

11.8.20 RCC clock interrupt clear register (RCC_CICR)

Address offset: 0x058

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	SHSIRDYC	MSIKRDYC	CSSC	Res.	PLL3RDYC	PLL2RDYC	PLL1RDYC	HSI48RDYC	HSERDYC	HSIRDYC	MSISRDYC	LSERDYC	LSIRDYC
			w	w	w		w	w	w	w	w	w	w	w	w

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SHSIRDYC**: SHSI oscillator ready interrupt clear
Writing this bit to 1 clears the SHSIRDYF flag. Writing 0 has no effect.

Bit 11 **MSIKRDYC**: MSIK oscillator ready interrupt clear
Writing this bit to 1 clears the MSIKRDYF flag. Writing 0 has no effect.

Bit 10 **CSSC**: Clock security system interrupt clear
Writing this bit to 1 clears the CSSF flag. Writing 0 has no effect.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYC**: PLL3 ready interrupt clear
Writing this bit to 1 clears the PLL3RDYF flag. Writing 0 has no effect.

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Writing this bit to 1 clears the PLL2RDYF flag. Writing 0 has no effect.

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Writing this bit to 1 clears the PLL1RDYF flag. Writing 0 has no effect.

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Writing this bit to 1 clears the HSI48RDYF flag. Writing 0 has no effect.

Bit 4 **HSERDYC**: HSE ready interrupt clear
Writing this bit to 1 clears the HSERDYF flag. Writing 0 has no effect.

Bit 3 **HSIRDYC**: HSI16 ready interrupt clear
Writing this bit to 1 clears the HSIRDYF flag. Writing 0 has no effect.

Bit 2 **MSISRDYC**: MSIS ready interrupt clear
Writing this bit to 1 clears the MSISRDYF flag. Writing 0 has no effect.

Bit 1 **LSERDYC**: LSE ready interrupt clear
Writing this bit to 1 clears the LSERDYF flag. Writing 0 has no effect.

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Writing this bit to 1 clears the LSIRDYF flag. Writing 0 has no effect.

11.8.21 RCC AHB1 peripheral reset register (RCC_AHB1RSTR)

Address offset: 0x060

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **VREFRST**: VREFBUF reset
Set and cleared by software.
0: No effect
1: Reset VREFBUF

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **COMPRST**: COMP reset
Set and cleared by software.
0: No effect
1: Reset COMP

Bit 14 **OPAMPRST**: OPAMP reset
Set and cleared by software.
0: No effect
1: Reset OPAMP

Bit 13 **LPTIM4RST**: LPTIM4 reset
Set and cleared by software.
0: No effect
1: Reset LPTIM4

Bit 12 **LPTIM3RST**: LPTIM3 reset
Set and cleared by software.
0: No effect
1: Reset LPTIM3

Bit 11 **LPTIM1RST**: LPTIM1 reset
Set and cleared by software.
0: No effect
1: Reset LPTIM1

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3RST**: I2C3 reset
Set and cleared by software.
0: No effect
1: Reset I2C3

Bit 6 **LPUART1RST**: LPUART1 reset
Set and cleared by software.
0: No effect
1: Reset LPUART1

Bit 5 **SPI3RST**: SPI3 reset
Set and cleared by software.
0: No effect
1: Reset SPI3

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGRST**: SYSCFG reset
Set and cleared by software.
0: No effect
1: Reset SYSCFG

Bit 0 Reserved, must be kept at reset value.

11.8.29 RCC AHB1 peripheral clock enable register (RCC_AHB1ENR)

Address offset: 0x088

Reset value: 0xD000 0100

Access: no wait state; word, half-word and byte access

Note: When the peripheral clock is not active, the peripheral registers read or write access is not supported.

Bit 31 **SRAM1EN**: SRAM1 clock enable
Set and reset by software.
0: SRAM1 clock disabled
1: SRAM1 clock enabled

Bit 30 **DCACHE1EN**: DCACHE1 clock enable
Set and reset by software.
0: DCACHE1 clock disabled
1: DCACHE1 clock enabled
Note: DCACHE1 clock must be enabled when external memories are accessed through OCTOSPI1, OCTOSPI2, or FSMC, even if the DCACHE1 is bypassed.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **BKPSRAMEN**: BKPSRAM clock enable
Set and reset by software.
0: BKPSRAM clock disabled
1: BKPSRAM clock enabled

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **GTZC1EN**: GTZC1 clock enable
Set and reset by software.
0: GTZC1 clock disabled
1: GTZC1 clock enabled

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **DMA2DEN**: DMA2D clock enable
Set and cleared by software.
0: DMA2D clock disabled
1: DMA2D clock enabled

Bit 17 **RAMCFGEN**: RAMCFG clock enable
Set and cleared by software.
0: RAMCFG clock disabled
1: RAMCFG clock enabled

Bit 16 **TSCEN**: Touch sensing controller clock enable
Set and cleared by software.
0: TSC clock disabled
1: TSC clock enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CRCEN**: CRC clock enable
Set and cleared by software.
0: CRC clock disabled
1: CRC clock enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHEN**: FLASH clock enable
Set and cleared by software. This bit can be disabled only when the Flash memory is in power down mode.
0: FLASH clock disabled
1: FLASH clock enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **MDF1EN**: MDF1 clock enable
Set and reset by software.
0: MDF1 clock disabled
1: MDF1 clock enabled

Bit 2 **FMACEN**: FMAC clock enable
Set and reset by software.
0: FMAC clock disabled
1: FMAC clock enabled

Bit 1 **CORDICEN**: CORDIC clock enable
Set and cleared by software.
0: CORDIC clock disabled
1: CORDIC clock enabled

Bit 0 **GPDMA1EN**: GPDMA1 clock enable
Set and cleared by software.
0: GPDMA1 clock disabled
1: GPDMA1 clock enabled

11.8.30 RCC AHB2 peripheral clock enable register 1 (RCC_AHB2ENR1)

Address offset: 0x08C

Reset value: 0xC000 0000

Access: no wait state, word, half-word and byte access

Note: When the peripheral clock is not active, the peripheral registers read or write access is not supported.

Bit 5 **SPI3EN**: SPI3 clock enable
Set and cleared by software.
0: SPI3 clock disabled
1: SPI3 clock enabled

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGEN**: SYSCFG clock enable
Set and cleared by software.
0: SYSCFG clock disabled
1: SYSCFG clock enabled

Bit 0 Reserved, must be kept at reset value.

11.8.37 RCC AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR)

Address offset: 0x0B0

Reset value: 0xFFFF FFFF

Access: no wait state, word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to *Section 11.4.20: Peripherals clock gating and autonomous mode*).

1: SRAM1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 30 **DCACHE1SMEN**: DCACHE1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DCACHE1 clocks disabled by the clock gating during Sleep and Stop modes
1: DCACHE1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 29 **ICACHESMEN**: ICACHE clocks enable during Sleep and Stop modes
Set and cleared by software.
0: ICACHE clocks disabled by the clock gating during Sleep and Stop modes
1: ICACHE clocks enabled by the clock gating during Sleep and Stop modes

Bit 28 **BKPSRAMSMEN**: BKPSRAM clocks enable during Sleep and Stop modes
Set and cleared by software
0: BKPSRAM clocks disabled by the clock gating during Sleep and Stop modes
1: BKPSRAM clocks enabled by the clock gating during Sleep and Stop modes

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **GTZC1SMEN**: GTZC1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: GTZC1 clocks disabled by the clock gating during Sleep and Stop modes
1: GTZC1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **DMA2DSMEN**: DMA2D clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DMA2D clocks disabled by the clock gating during Sleep and Stop modes
1: DMA2D clocks enabled by the clock gating during Sleep and Stop modes

Bit 17 **RAMCFGSMEN**: RAMCFG clocks enable during Sleep and Stop modes
Set and cleared by software.
0: RAMCFG clocks disabled by the clock gating during Sleep and Stop modes
1: RAMCFG clocks enabled by the clock gating during Sleep and Stop modes

Bit 16 **TSCSMEN**: TSC clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TSC clocks disabled by the clock gating during Sleep and Stop modes
1: TSC clocks enabled by the clock gating during Sleep and Stop modes

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CRCSMEN**: CRC clocks enable during Sleep and Stop modes
Set and cleared by software.
0: CRC clocks disabled by the clock gating during Sleep and Stop modes
1: CRC clocks enabled by the clock gating during Sleep and Stop modes

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHSMEN**: FLASH clocks enable during Sleep and Stop modes
Set and cleared by software.
0: FLASH clocks disabled by the clock gating during Sleep and Stop modes
1: FLASH clocks enabled by the clock gating during Sleep and Stop modes

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **MDF1SMEN**: MDF1 clocks enable during Sleep and Stop modes.
Set and cleared by software.
0: MDF1 clocks disabled by the clock gating during Sleep and Stop modes
1: MDF1 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 2 **FMACSMEN**: FMAC clocks enable during Sleep and Stop modes.
Set and cleared by software.
0: FMAC clocks disabled by the clock gating during Sleep and Stop modes
1: FMAC clocks enabled by the clock gating during Sleep and Stop modes

Bit 1 **CORDICSMEN**: CORDIC clocks enable during Sleep and Stop modes
Set and cleared by software during Sleep mode.
0: CORDIC clocks disabled by the clock gating during Sleep and Stop modes
1: CORDIC clocks enabled by the clock gating during Sleep and Stop modes

Bit 0 **GPDMA1SMEN**: GPDMA1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: GPDMA1 clocks disabled by the clock gating during Sleep and Stop modes
1: GPDMA1 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

11.8.38 RCC AHB2 peripheral clocks enable in Sleep and Stop modes register 1 (RCC_AHB2SMENR1)

Address offset: 0x0B4

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to *Section 11.4.20: Peripherals clock gating and autonomous mode*).

1: OTFDEC1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 22 Reserved, must be kept at reset value.

Bit 21 **OCTOSPIMSMEN**: OCTOSPIM clocks enable during Sleep and Stop modes
Set and cleared by software.
0: OCTOSPIM clocks disabled by the clock gating during Sleep and Stop modes
1: OCTOSPIM clocks enabled by the clock gating during Sleep and Stop modes

Bit 20 **SAESSMEN:** SAES accelerator clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SAES clocks disabled by the clock gating during Sleep and Stop modes
1: SAES clocks enabled by the clock gating during Sleep and Stop modes

Bit 19 **PKASMEN**: PKA clocks enable during Sleep and Stop modes
Set and cleared by software.
0: PKA clocks disabled by the clock gating during Sleep and Stop modes
1: PKA clocks enabled by the clock gating during Sleep and Stop modes

Bit 18 **RNGSMEN:** Random number generator (RNG) clocks enable during Sleep and Stop modes
Set and cleared by software.
0: RNG clocks disabled by the clock gating during Sleep and Stop modes
1: RNG clocks enabled by the clock gating during Sleep and Stop modes

Bit 17 **HASHSMEN**: HASH clock enable during Sleep and Stop modes
Set and cleared by software
0: HASH clocks disabled by the clock gating during Sleep and Stop modes
1: HASH clocks enabled by the clock gating during Sleep and Stop modes

Bit 16 **AESSMEN**: AES clock enable during Sleep and Stop modes
Set and cleared by software
0: AES clocks disabled by the clock gating during Sleep and Stop modes
1: AES clocks enabled by the clock gating during Sleep and Stop modes

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OTGSMEN:** OTG_FS clocks enable during Sleep and Stop modes
Set and cleared by software.
0: OTG_FS clocks disabled by the clock gating during Sleep and Stop modes
1: OTG_FS clocks enabled by the clock gating during Sleep and Stop modes

Bit 13 Reserved, must be kept at reset value.

Bit 12 **DCMI_PSSISMEN:** DCMI and PSSI clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DCMI and PSSI clocks disabled by the clock gating during Sleep and Stop modes
1: DCMI and PSSI clocks enabled by the clock gating during Sleep and Stop modes

Bit 11 Reserved, must be kept at reset value.

Bit 10 **ADC1SMEN:** ADC1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: ADC1 clocks disabled by the clock gating during Sleep and Stop modes
1: ADC1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 9 Reserved, must be kept at reset value.

Bit 8 **GPIOISMEN:** IO port I clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port I clocks disabled by the clock gating during Sleep and Stop modes
1: IO port I clocks enabled by the clock gating during Sleep and Stop modes

Bit 24 **CRSSMEN**: CRS clock enable during Sleep and Stop modes
Set and cleared by software.
0: CRS clocks disabled by the clock gating during Sleep and Stop modes
1: CRS clocks enabled by the clock gating during Sleep and Stop modes

Bit 23 Reserved, must be kept at reset value.

Bit 22 **I2C2SMEN**: I2C2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: I2C2 clocks disabled by the clock gating during Sleep and Stop modes
1: I2C2 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 21 **I2C1SMEN**: I2C1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: I2C1 clocks disabled by the clock gating during Sleep and Stop modes
1: I2C1 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 20 **UART5SMEN**: UART5 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: UART5 clocks disabled by the clock gating during Sleep and Stop modes
1: UART5 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 19 **UART4SMEN**: UART4 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: UART4 clocks disabled by the clock gating during Sleep and Stop modes
1: UART4 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 18 **USART3SMEN**: USART3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: USART3 clocks disabled by the clock gating during Sleep and Stop modes
1: USART3 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 17 **USART2SMEN**: USART2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: USART2 clocks disabled by the clock gating during Sleep and Stop modes
1: USART2 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **SPI2SMEN**: SPI2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SPI2 clocks disabled by the clock gating during Sleep and Stop modes
1: SPI2 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGSMEN**: Window watchdog clocks enable during Sleep and Stop modes
Set and cleared by software. This bit is forced to 1 by hardware when the hardware WWDG option is activated.
0: Window watchdog clocks disabled by the clock gating during Sleep and Stop modes
1: Window watchdog clocks enabled by the clock gating during Sleep and Stop modes

Bits 10:6 Reserved, must be kept at reset value.

Bit 5 **TIM7SMEN**: TIM7 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM7 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM7 clocks enabled by the clock gating during Sleep and Stop modes

Bit 4 **TIM6SMEN**: TIM6 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM6 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM6 clocks enabled by the clock gating during Sleep and Stop modes

Bit 3 **TIM5SMEN**: TIM5 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM5 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM5 clocks enabled by the clock gating during Sleep and Stop modes

Bit 2 **TIM4SMEN**: TIM4 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM4 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM4 clocks enabled by the clock gating during Sleep and Stop modes

Bit 1 **TIM3SMEN**: TIM3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM3 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM3 clocks enabled by the clock gating during Sleep and Stop modes

Bit 0 **TIM2SMEN**: TIM2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM2 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM2 clocks enabled by the clock gating during Sleep and Stop modes

11.8.42 RCC APB1 peripheral clocks enable in Sleep and Stop modes register 2 (RCC_APB1SMENR2)

Address offset: 0x0C8

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to *Section 11.4.20: Peripherals clock gating and autonomous mode*).

						rw				rw				rw	

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1SMEN**: UCPD1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: UCPD1 clocks disabled by the clock gating during Sleep and Stop modes
1: UCPD1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCAN1SMEN**: FDCAN1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: FDCAN1 clocks disabled by the clock gating during Sleep and Stop modes
1: FDCAN1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **LPTIM2SMEN:** LPTIM2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM2 clocks disabled by the clock gating during Sleep and Stop modes
1: LPTIM2 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **I2C4SMEN**: I2C4 clocks enable during Sleep and Stop modes
Set and cleared by software
0: I2C4 clocks disabled by the clock gating during Sleep and Stop modes
1: I2C4 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 0 Reserved, must be kept at reset value.

11.8.43 RCC APB2 peripheral clocks enable in Sleep and Stop modes register (RCC_APB2SMENR)

Address offset: 0x0CC

Reset value: 0xFFFF FFFF

Access: word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to *Section 11.4.20: Peripherals clock gating and autonomous mode*).

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SAI2SMEN**: SAI2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SAI2 clocks disabled by the clock gating during Sleep and Stop modes
1: SAI2 clocks enabled by the clock gating during Sleep and Stop modes

Bit 21 **SAI1SMEN**: SAI1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SAI1 clocks disabled by the clock gating during Sleep and Stop modes
1: SAI1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TIM17SMEN**: TIM17 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM17 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM17 clocks enabled by the clock gating during Sleep and Stop modes

Bit 17 **TIM16SMEN**: TIM16 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM16 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM16 clocks enabled by the clock gating during Sleep and Stop modes

Bit 16 **TIM15SMEN**: TIM15 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM15 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM15 clocks enabled by the clock gating during Sleep and Stop modes

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1SMEN**: USART1clocks enable during Sleep and Stop modes
Set and cleared by software.
0: USART1clocks disabled by the clock gating during Sleep and Stop modes
1: USART1clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 13 T**IM8SMEN**: TIM8 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM8 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM8 clocks enabled by the clock gating during Sleep and Stop modes

Bit 12 **SPI1SMEN**: SPI1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SPI1 clocks disabled by the clock gating during Sleep and Stop modes
1: SPI1 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 11 **TIM1SMEN**: TIM1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM1 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 10:0 Reserved, must be kept at reset value.

11.8.44 RCC APB3 peripheral clock enable in Sleep and Stop modes register (RCC_APB3SMENR)

Address offset: 0x0D0

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to *Section 11.4.20: Peripherals clock gating and autonomous mode*).

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBSMEN**: RTC and TAMP APB clock enable during Sleep and Stop modes
Set and cleared by software.
0: RTC and TAMP APB clock disabled by the clock gating during Sleep and Stop modes
1: RTC and TAMP APB clock enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 20 **VREFSMEN**: VREFBUF clocks enable during Sleep and Stop modes
Set and cleared by software.
0: VREFBUF clocks disabled by the clock gating during Sleep and Stop modes
1: VREFBUF clocks enabled by the clock gating during Sleep and Stop modes

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **COMPSMEN**: COMP clocks enable during Sleep and Stop modes
Set and cleared by software.
0: COMP clocks disabled by the clock gating during Sleep and Stop modes
1: COMP clocks enabled by the clock gating during Sleep and Stop modes

Bit 14 **OPAMPSMEN**: OPAMP clocks enable during Sleep and Stop modes
Set and cleared by software.
0: OPAMP clocks disabled by the clock gating during Sleep and Stop modes
1: OPAMP clocks enabled by the clock gating during Sleep and Stop modes

Bit 13 **LPTIM4SMEN**: LPTIM4 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM4 clocks disabled by the clock gating during Sleep and Stop modes
1: LPTIM4 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 12 **LPTIM3SMEN**: LPTIM3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM3 clocks disabled by the clock gating during Sleep and Stop modes
1: LPTIM3 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 11 **LPTIM1SMEN**: LPTIM1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM1 clocks disabled by the clock gating during Sleep and Stop modes
1: LPTIM1 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3SMEN**: I2C3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: I2C3 clocks disabled by the clock gating during Sleep and Stop modes
1: I2C3 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 6 **LPUART1SMEN**: LPUART1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPUART1 clocks disabled by the clock gating during Sleep and Stop modes
1: LPUART1 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 5 **SPI3SMEN**: SPI3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SPI3 clocks disabled by the clock gating during Sleep and Stop modes
1: SPI3 clocks enabled by the clock gating during Sleep and Stop modes
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGSMEN**: SYSCFG clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SYSCFG clocks disabled by the clock gating during Sleep and Stop modes
1: SYSCFG clocks enabled by the clock gating during Sleep and Stop modes

Bit 0 Reserved, must be kept at reset value.

11.8.45 RCC SmartRun domain peripheral autonomous mode register (RCC_SRDAMR)

Address offset: 0x0D8

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **SRAM4AMEN**: SRAM4 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: SRAM4 autonomous mode disabled during Stop 0,1,2 mode
1: SRAM4 autonomous mode enabled during Stop 0,1,2 mode

Bit 30 Reserved, must be kept at reset value.

Bit 29 **ADF1AMEN**: ADF1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: ADF1 autonomous mode disabled during Stop 0,1,2 mode
1: ADF1 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 28 **LPDMA1AMEN**: LPDMA1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPDMA1 autonomous mode disabled during Stop 0,1,2 mode
1: LPDMA1 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 27 **DAC1AMEN**: DAC1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: DAC1 autonomous mode disabled during Stop 0,1,2 mode
1: DAC1 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 26 **LPGPIO1AMEN**: LPGPIO1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPGPIO1 autonomous mode disabled during Stop 0,1,2 mode
1: LPGPIO1 autonomous mode enabled during Stop 0,1,2 mode

Bit 25 **ADC4AMEN**: ADC4 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: ADC4 autonomous mode disabled during Stop 0,1,2 mode
1: ADC4 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 24:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBAMEN**: RTC and TAMP autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: RTC and TAMP autonomous mode disabled during Stop 0,1,2 mode
1: RTC and TAMP autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 20 **VREFAMEN**: VREFBUF autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: VREFBUF autonomous mode disabled during Stop 0,1,2 mode
1: VREFBUF autonomous mode enabled during Stop 0,1,2 mode

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **COMPAMEN**: COMP autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: COMP autonomous mode disabled during Stop 0,1,2 mode
1: COMP autonomous mode enabled during Stop 0,1,2 mode

Bit 14 **OPAMPAMEN**: OPAMP autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: OPAMP autonomous mode disabled during Stop 0,1,2 mode
1: OPAMP autonomous mode enabled during Stop 0,1,2 mode

Bit 13 **LPTIM4AMEN**: LPTIM4 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPTIM4 autonomous mode disabled during Stop 0,1,2 mode
1: LPTIM4 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 12 **LPTIM3AMEN**: LPTIM3 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPTIM3 autonomous mode disabled during Stop 0,1,2 mode
1: LPTIM3 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 11 **LPTIM1AMEN**: LPTIM1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPTIM1 autonomous mode disabled during Stop 0,1,2 mode
1: LPTIM1 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3AMEN**: I2C3 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: I2C3 autonomous mode disabled during Stop 0,1,2 mode
1: I2C3 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 6 **LPUART1AMEN**: LPUART1 autonomous mode enable in Stop 0,1, 2 mode
Set and cleared by software.
0: LPUART1 autonomous mode disabled during Stop 0,1,2 mode
1: LPUART1 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 5 **SPI3AMEN**: SPI3 autonomous mode enable in Stop 0,1, 2 mode
Set and cleared by software.
0: SPI3 autonomous mode disabled during Stop 0,1,2 mode
1: SPI3 autonomous mode enabled during Stop 0,1,2 mode
Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 4:0 Reserved, must be kept at reset value.

11.8.46 RCC peripherals independent clock configuration register 1 (RCC_CCIPR1)

Address offset: 0x0E0

Reset value: 0x0000 0000

Access: no wait states; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TIMICSEL[2:0]			Res.	ICLKSEL[1:0]		FDCAN1SEL[1:0]		SYSTICKSEL [1:0]		SPI1SEL[1:0]		LPTIM2SEL[1:0]		SPI2SEL[1:0]	
rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
I2C4SEL[1:0]		I2C2SEL[1:0]		I2C1SEL[1:0]		UART5SEL[1:0]		UART4SEL[1:0]		USART3SEL [1:0]		USART2SEL[1:0]		USART1SEL [1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **TIMICSEL[2:0]**: Clocks sources for TIM16,TIM17 and LPTIM2 internal input capture
When the TIMICSEL2 bit is set, the TIM16, TIM17 and LPTIM2 internal input capture can be connected either to HSI/256, MSI/4 or MSI/1024. Depending on TIMICSEL[1:0] value, MSI is either MSIK or MSIS.
When TIMICSEL2 is cleared, the HSI, MSIK and MSIS clock sources cannot be selected as TIM16, TIM17 or LPTIM2 internal input capture.
0xx: HSI, MSIK and MSIS dividers disabled
100: HSI/256, MSIS/1024 and MSIS/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
101: HSI/256, MSIS/1024 and MSIK/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
110: HSI/256, MSIK/1024 and MSIS/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
111: HSI/256, MSIK/1024 and MSIK/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
Note: The clock division must be disabled (TIMICSEL configured to 0xx) before selecting or changing a clock sources division.

Bit 28 Reserved, must be kept at reset value.

Bits 27:26 **ICLKSEL[1:0]**: intermediate clock source selection
These bits are used to select the clock source used by OTG_FS and SDMMC.
00: HSI48 clock selected
01: PLL2 “Q” (pll2_q_ck) selected
10: PLL1 “Q” (pll1_q_ck) selected
11: MSIK clock selected

Bits 25:24 **FDCAN1SEL[1:0]**: FDCAN1 kernel clock source selection
These bits are used to select the FDCAN1 kernel clock source.
00: HSE clock selected
01: PLL1“Q” (pll1_q_ck) selected
10: PLL2 “P” (pll2_p_ck) selected
11: reserved

Bits 23:22 **SYSTICKSEL[1:0]**: SysTick clock source selection
These bits are used to select the SysTick clock source.
00: HCLK/8 selected
01: LSI selected
10: LSE selected
11: reserved

Note: When LSE or LSI is selected, the AHB frequency must be at least four times higher than the LSI or LSE frequency. In addition, a jitter up to one HCLK cycle is introduced, due to the LSE or LSI sampling with HCLK in the SysTick circuitry.

Bits 21:20 **SPI1SEL[1:0]**: SPI1 kernel clock source selection
These bits are used to select the SPI1 kernel clock source.
00: PCLK2 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

Note: The SPI1 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 19:18 **LPTIM2SEL[1:0]**: Low-power timer 2 kernel clock source selection
These bits are used to select the LPTIM2 kernel clock source.
00: PCLK1 selected
01: LSI selected
10: HSI16 selected
11: LSE selected

Note: The LPTIM2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is LSI, LSE or HSI16 if HSIKERON = 1.

Bits 17:16 **SPI2SEL[1:0]**: SPI2 kernel clock source selection
These bits are used to select the SPI2 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

Note: The SPI2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 15:14 **I2C4SEL[1:0]**: I2C4 kernel clock source selection
These bits are used to select the I2C4 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected
Note: The I2C4 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 13:12 **I2C2SEL[1:0]**: I2C2 kernel clock source selection
These bits are used to select the I2C2 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected
Note: The I2C2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 11:10 **I2C1SEL[1:0]**: I2C1 kernel clock source selection
These bits are used to select the I2C1 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected
Note: The I2C1 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 9:8 **UART5SEL[1:0]**: UART5 kernel clock source selection
These bits are used to select the UART5 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: LSE selected
Note: The UART5 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

Bits 7:6 **UART4SEL[1:0]**: UART4 kernel clock source selection
This bits are used to select the UART4 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: LSE selected
Note: The UART4 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

Bits 5:4 **USART3SEL[1:0]**: USART3 kernel clock source selection
This bits are used to select the USART3 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: LSE selected
Note: The USART3 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

Bits 3:2 **USART2SEL[1:0]**: USART2 kernel clock source selection
This bits are used to select the USART2 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: LSE selected
Note: The USART2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

Bits 1:0 **USART1SEL[1:0]**: USART1 kernel clock source selection
This bits are used to select the USART1 kernel clock source.
00: PCLK2 selected
01: SYSCLK selected
10: HSI16 selected
11: LSE selected
Note: The USART1 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

11.8.47 RCC peripherals independent clock configuration register 2 (RCC_CCIPR2)

Address offset: 0x0E4

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OCTOSPISEL [1:0]		Res.	Res.	Res.	Res.
										rw	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **OCTOSPISEL[1:0]**: OCTOSPI1 and OCTOSPI2 kernel clock source selection
These bits are used to select the OCTOSPI1 and OCTOSPI2 kernel clock source.
00: SYSCLK selected
01: MSIK selected
10: PLL1 “Q” (pll1_q_ck) selected, can be up to 200 MHz
11: PLL2 “Q” (pll2_q_ck) selected, can be up to 200 MHz

Bits 19:15 Reserved, must be kept at reset value.

Bit 14 **SDMMCSEL**: SDMMC1 and SDMMC2 kernel clock source selection
This bit is used to select the SDMMC kernel clock source. It is recommended to change this bit only after reset and before enabling the SDMMC.
0: ICLK clock selected
1: PLL1 “P” (pll1_p_ck) selected, in case higher than 48 MHz is needed (for SDR50 mode)

Bits 13:12 **RNGSEL[1:0]**: RNGSEL kernel clock source selection
These bits are used to select the RNG kernel clock source.
00: HSI48 selected
01: HSI48 / 2 selected, can be used in range 4
10: HSI16 selected
11: reserved

Bit 11 **SAESSEL**: SAES kernel clock source selection
This bit is used to select the SAES kernel clock source.
0: SHSI selected
1: SHSI / 2 selected, can be used in range 4

Bits 10:8 **SAI2SEL[2:0]**: SAI2 kernel clock source selection
These bits are used to select the SAI2 kernel clock source.
000: PLL2 “P” (pll2_p_ck) selected
001: PLL3 “P” (pll3_p_ck) selected
010: PLL1 “P” (pll1_p_ck) selected
011: input pin AUDIOCLK selected
100: HSI16 clock selected
others: reserved
Note: If the selected clock is the external clock and this clock is stopped, a switch to another clock is impossible.

Bits 7:5 **SAI1SEL[2:0]**: SAI1 kernel clock source selection
These bits are used to select the SAI1 kernel clock source.
000: PLL2 “P” (pll2_p_ck) selected
001: PLL3 “P” (pll3_p_ck) selected
010: PLL1 “P” (pll1_p_ck) selected
011: input pin AUDIOCLK selected
100: HSI16 clock selected
others: reserved
Note: If the selected clock is the external clock and this clock is stopped, a switch to another clock is impossible.

Bits 4:3 Reserved, must be kept at reset value.

Bits 2:0 **MDF1SEL[2:0]**: MDF1 kernel clock source selection
These bits are used to select the MDF1 kernel clock source.
000: HCLK selected
001: PLL1 “P” (pll1_p_ck) selected
010: PLL3 “Q” (pll3_q_ck) selected
011: input pin AUDIOCLK selected
100: MSIK clock selected

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **ADF1SEL[2:0]**: ADF1 kernel clock source selection

These bits are used to select the ADF1 kernel clock source.
000: HCLK selected
001: PLL1 “P” (pll1_p_ck) selected
010: PLL3 “Q” (pll3_q_ck) selected
011: input pin AUDIOCLK selected
100: MSIK clock selected
others: reserved

Note: The ADF1 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is AUDIOCLK or MSIK.

Bit 15 **DAC1SEL**: DAC1 sample and hold clock source selection

This bit is used to select the DAC1 sample and hold clock source.
0: LSE selected
1: LSI selected

Bits 14:12 **ADCDACSEL[2:0]**: ADC1, ADC4 and DAC1 kernel clock source selection

These bits are used to select the ADC1, ADC4 and DAC1 kernel clock source.
000: HCLK clock selected
001: SYSCLK selected
010: PLL2 “R” (pll2_r_ck) selected
011: HSE clock selected
100: HSI16 clock selected
101: MSIK clock selected
others: reserved

Note: The ADC1, ADC4 and DAC1 are functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16 or MSIK (only ADC4 and DAC1 are functional in Stop 2 mode).

Bits 11:10 **LPTIM1SEL[1:0]**: LPTIM1 kernel clock source selection
These bits are used to select the LPTIM1 kernel clock source.
00: MSIK clock selected
01: LSI selected
10: HSI16 selected
11: LSE selected
Note: The LPTIM1 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIKERON = 1 or MSIK with MSIKERON = 1.

Bits 9:8 **LPTIM34SEL[1:0]**: LPTIM3 and LPTIM4 kernel clock source selection
These bits are used to select the LPTIM3 and LPTIM4 kernel clock source.
00: MSIK clock selected
01: LSI selected
10: HSI selected
11: LSE selected
Note: The LPTIM3 and LPTIM4 are functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIKERON = 1 or MSIK with MSIKERON = 1.

Bits 7:6 **I2C3SEL[1:0]**: I2C3 kernel clock source selection
These bits are used to select the I2C3 kernel clock source.
00: PCLK3 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected
Note: The I2C3 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16 or MSIK.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **SPI3SEL[1:0]**: SPI3 kernel clock source selection
These bits are used to select the SPI3 kernel clock source.
00: PCLK3 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected
Note: The SPI3 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16 or MSIK.

Bits 2:0 **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection
These bits are used to select the LPUART1 kernel clock source.
000: PCLK3 selected
001: SYSCLK selected
010: HSI16 selected
011: LSE selected
100: MSIK selected
others: reserved
Note: The LPUART1 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16, LSE or MSIK.

11.8.49 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x00F0

Backup domain reset value: 0x0000 0000

Reset by Backup domain reset except LSCOSEL, LSCOEN and BDRST that are reset only by Backup domain power-on reset.

Access: 0 ≤ wait state ≤ 3; word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

Note: The bits of this register are outside of the core domain. As a result, after reset, these bits are write-protected and the DBP bit in the PWR Backup domain control register 1 (PWR_BDCR1) must be set before these can be modified (see Section 10: Power control (PWR) for further information). These bits (except LSCOSEL, LSCOEN and BDRST) are only reset after a Backup domain reset (see Section 11.3.3: Backup domain reset). Any internal or external reset does not have any effect on these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	LSIPREDIV	LSIRDY	LSION	LSCOSEL	LSCOEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BDRST
			rw	rw	rw	rw	rw								rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	LSEGFON	LSESYSRDY	Res.	RTCSEL[1:0]		LSESYSEN	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw			rw	r		rw	rw	rw	r	rw	rw	rw	rw	r	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **LSIPREDIV**: Low-speed clock divider configuration

Set and cleared by software to enable the LSI division. This bit can be written only when the LSI is disabled (LSION = 0 and LSIRDY = 0). If the LSI was previously enabled, it is necessary to wait for at least 60 µs after clearing LSION bit (synchronization time for LSI to be really disabled), before writing LSIPREDIV. The LSIPREDIV cannot be changed if the LSI is used by the IWDG or by the RTC.

0: LSI not divided

1: LSI divided by 128

Bit 27 **LSIRDY**: LSI oscillator ready

Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles. This bit is set when the LSI is used by IWDG or RTC, even if LSION = 0.

0: LSI oscillator not ready

1: LSI oscillator ready

Bit 26 **LSION**: LSI oscillator enable

Set and cleared by software. The LSI oscillator is disabled 60 µs maximum after the LSION bit is cleared.

0: LSI oscillator OFF

1: LSI oscillator ON

Bit 25 **LSCOSEL**: Low-speed clock output selection
Set and cleared by software.
0: LSI clock selected
1: LSE clock selected

Bit 24 **LSCOEN**: Low-speed clock output (LSCO) enable
Set and cleared by software.
0: LSCO disabled
1: LSCO enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset
Set and cleared by software.
0: Reset not activated
1: Reset the entire Backup domain

Bit 15 **RTCEN**: RTC and TAMP clock enable
Set and cleared by software.
0: RTC and TAMP clock disabled
1: RTC and TAMP clock enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LSEGFON**: LSE clock glitch filter enable
Set and cleared by hardware to enable the LSE glitch filter. This bit can be written only when the LSE is disabled (LSEON = 0 and LSERDY = 0)
0: LSE glitch filter disabled
1: LSE glitch filter enabled

Bit 11 **LSESYSRDY**: LSE system clock (LSESYS) ready
Set and cleared by hardware to indicate when the LSE system clock is stable.When the LSESYSEN bit is set, the LSESYSRDY flag is set after two LSE clock cycles.
The LSE clock must be already enabled and stable (LSEON and LSERDY are set).
When the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.
0: LSESYS clock not ready
1: LSESYS clock ready

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: RTC and TAMP clock source selection
Set by software to select the clock source for the RTC and TAMP . Once the RTC and TAMP clock source has been selected, it cannot be changed anymore unless the Backup domain is reset, or unless a failure is detected on LSE (LSECSSD is set). The BDRST bit can be used to reset them.
00: No clock selected
01: LSE oscillator clock selected
10: LSI oscillator clock selected
11: HSE oscillator clock divided by 32 selected

Bit 7 **LSESYSEN**: LSE system clock (LSESYS) enable
Set by software to enable always the LSE system clock generated by RCC, which can be used by any peripheral when its source clock is the LSE, or at system level if one of LSCOSEL, MCO, or MSI PLL mode is needed.
0: LSE can be used only for RTC, TAMP, and CSS on LSE.
1: LSE can be used by any other peripheral or function.

Bit 6 **LSECSSD**: CSS on LSE failure Detection

Set by hardware to indicate when a failure is detected by the CCS on the external 32 kHz oscillator (LSE).

0: No failure detected on LSE

1: Failure detected on LSE

Bit 5 **LSECSSON**: CSS on LSE enable

Set by software to enable the CSS on LSE. LSECSSON must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected.

Once enabled, this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case, the software must disable the LSECSSON bit.

0: CSS on LSE OFF

1: CSS on LSE ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator drive capability

Set by software to modulate the drive capability of the LSE oscillator. This field can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).

00: ‘Xtal mode’ lower driving capability

01: ‘Xtal mode’ medium-low driving capability

10: ‘Xtal mode’ medium-high driving capability

11: ‘Xtal mode’ higher driving capability

Note: The oscillator is in ‘Xtal mode’ when it is not in bypass mode.

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and cleared by software to bypass oscillator in debug mode. This bit can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).

0: LSE oscillator not bypassed

1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.

0: LSE oscillator not ready

1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enable

Set and cleared by software.

0: LSE oscillator OFF

1: LSE oscillator ON

11.8.50 RCC control/status register (RCC_CSR)

Address offset: 0x0F4

Reset value: 0x0C00 4400

Reset by system reset, except reset flags by power reset only.

Access: 0 ≤ wait state ≤ 3; word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	BORRSTF	PINRSTF	OBLRSTF	Res.	RMVF	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	r	r	r	r	r		rw

MSISSRANGE[3:0]				MSIKSRANGE[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								

Bit 31 **LPWRRSTF**: Low-power reset flag

Set by hardware when a reset occurs due to Stop, Standby or Shutdown mode entry, whereas the corresponding NRST_STOP, NRST_STBY or NRST_SHDW option bit is cleared.

Cleared by writing to the RMVF bit.

0: No illegal low-power mode reset occurred

1: Illegal low-power mode reset occurred

Bit 30 **WWDGRSTF**: Window watchdog reset flag

Set by hardware when a window watchdog reset occurs.

Cleared by writing to the RMVF bit.

0: No window watchdog reset occurred

1: Window watchdog reset occurred

Bit 29 **IWDGRSTF**: Independent watchdog reset flag

Set by hardware when an independent watchdog reset domain occurs.

Cleared by writing to the RMVF bit.

0: No independent watchdog reset occurred

1: Independent watchdog reset occurred

Bit 28 **SFTRSTF**: Software reset flag

Set by hardware when a software reset occurs.

Cleared by writing to the RMVF bit.

0: No software reset occurred

1: Software reset occurred

Bit 27 **BORRSTF**: BOR flag

Set by hardware when a BOR occurs.

Cleared by writing to the RMVF bit.

0: No BOR occurred

1: BOR occurred

Bit 26 **PINRSTF**: NRST pin reset flag
Set by hardware when a reset from the NRST pin occurs.
Cleared by writing to the RMVF bit.
0: No reset from NRST pin occurred
1: Reset from NRST pin occurred

Bit 25 **OBLRSTF**: Option byte loader reset flag
Set by hardware when a reset from the option byte loading occurs.
Cleared by writing to the RMVF bit.
0: No reset from option byte loading occurred
1: Reset from option byte loading occurred

Bit 24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag
Set by software to clear the reset flags.
0: No effect
1: Clear the reset flags

Bits 22:16 Reserved, must be kept at reset value.

Bits 15:12 **MSISSRANGE[3:0]**:MSIS range after Standby mode
Set by software to chose the MSIS frequency at startup. This range is used after exiting Standby mode until MSIRGSEL is set. After a NRST pin or a power-on reset or when exiting Shutdown mode, the range is always 4 MHz. MSISSRANGE can be written only when MSIRGSEL = 1.
0100: range 4 around 4M Hz (reset value)
0101: range 5 around 2 MHz
0110: range 6 around 1.33 MHz
0111: range 7 around 1 MHz
1000: range 8 around 3.072 MHz
others: reserved
Note: Changing the MSISSRANGE does not change the current MSIS frequency.

Bits 11:8 **MSIKSRANGE[3:0]**:MSIK range after Standby mode
Set by software to chose the MSIK frequency at startup. This range is used after exiting Standby mode until MSIRGSEL is set. After a NRST pin or a power-on reset or when exiting Shutdown mode, the range is always 4 MHz. MSIKSRANGE can be written only when MSIRGSEL = 1.
0100: range 4 around 4M Hz (reset value)
0101: range 5 around 2 MHz
0110: range 6 around 1.33 MHz
0111: range 7 around 1 MHz
1000: range 8 around 3.072 MHz
others: reserved
Note: Changing the MSIKSRANGE does not change the current MSIK frequency.

Bits 7:0 Reserved, must be kept at reset value.

11.8.51 RCC secure configuration register (RCC_SECCFGR)

Address offset: 0x110

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

When the system is secure (TZEN = 1), this register can be written only by a secure privileged access if SPRIV = 1, and by a secure privileged or unprivileged access if SPRIV = 0. A non-secure write access generates an illegal access event and data is not written. This register can be read by secure or non-secure, privilege or unprivileged access.

When the system is not secure (TZEN = 0), this register is read as 0 and the register write is ignored.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **RMVFSEC**: Remove reset flag security
Set and reset by software.
0: non secure
1: secure

Bit 11 **HSI48SEC**: HSI48 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 10 **ICLKSEC**: intermediate clock source selection security
Set and reset by software.
0: non secure
1: secure

Bit 9 **PLL3SEC**: PLL3 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 8 **PLL2SEC**: PLL2 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 7 **PLL1SEC**: PLL1 clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 6 **PRESCSEC**: AHBx/APBx prescaler configuration bits security
Set and reset by software.
0: non secure
1: secure

Bit 5 **SYSCLKSEC**: SYSCLK clock selection, STOPWUCK bit, clock output on MCO configuration security
Set and reset by software.
0: non secure
1: secure

Bit 4 **LSESEC**: LSE clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 3 **LSISEC**: LSI clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 2 **MSISEC**: MSI clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

Bit 1 **HSESEC**: HSE clock configuration bits, status bits and HSE_CSS security
Set and reset by software.
0: non secure
1: secure

Bit 0 **HSISEC**: HSI clock configuration and status bits security
Set and reset by software.
0: non secure
1: secure

11.8.52 RCC privilege configuration register (RCC_PRIVCFGR)

Address offset: 0x114

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

This register can be written only by a privileged access. It can be read by privileged or unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: RCC non-secure functions privilege configuration

Set and reset by software. This bit can be written only by privileged access, secure or non-secure.

0: Read and write to RCC non-secure functions can be done by privileged or unprivileged access.

1: Read and write to RCC non-secure functions can be done by privileged access only.

Bit 0 **SPRIV**: RCC secure functions privilege configuration

Set and reset by software. This bit can be written only by a secure privileged access.

0: Read and write to RCC secure functions can be done by privileged or unprivileged access.

1: Read and write to RCC secure functions can be done by privileged access only.

12 Clock recovery system (CRS)

12.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output or it can be generated by user software.

12.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

12.3 CRS implementation

Table 109. CRS features

Feature	CRS1
TRIM width	7 bits

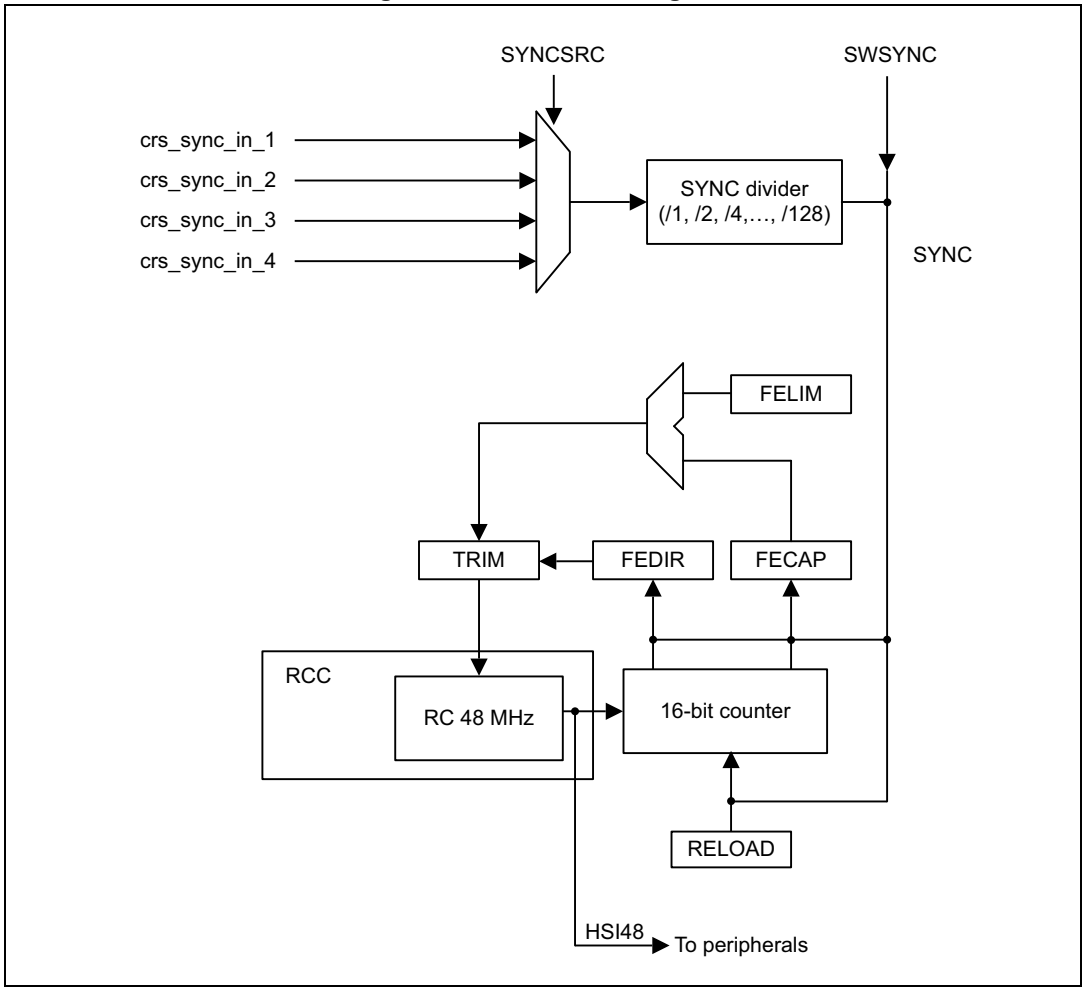
Table 110. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_sync_in_1	Input	00: GPIO AF selected as SYNC signal source
crs_sync_in_2	Input	01: LSE selected as SYNC signal source
crs_sync_in_3	Input	10: USB SOF selected as SYNC signal source (default)
crs_sync_in_4	Input	11: Reserved

12.4 CRS functional description

12.4.1 CRS block diagram

Figure 38. CRS block diagram



12.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from the LSE clock or the USB SOF signal. For a better robustness of the

SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the HSI48 clock) is implemented to filter out any glitches. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to *Section 12.7.2: CRS configuration register (CRS_CFGR)*.

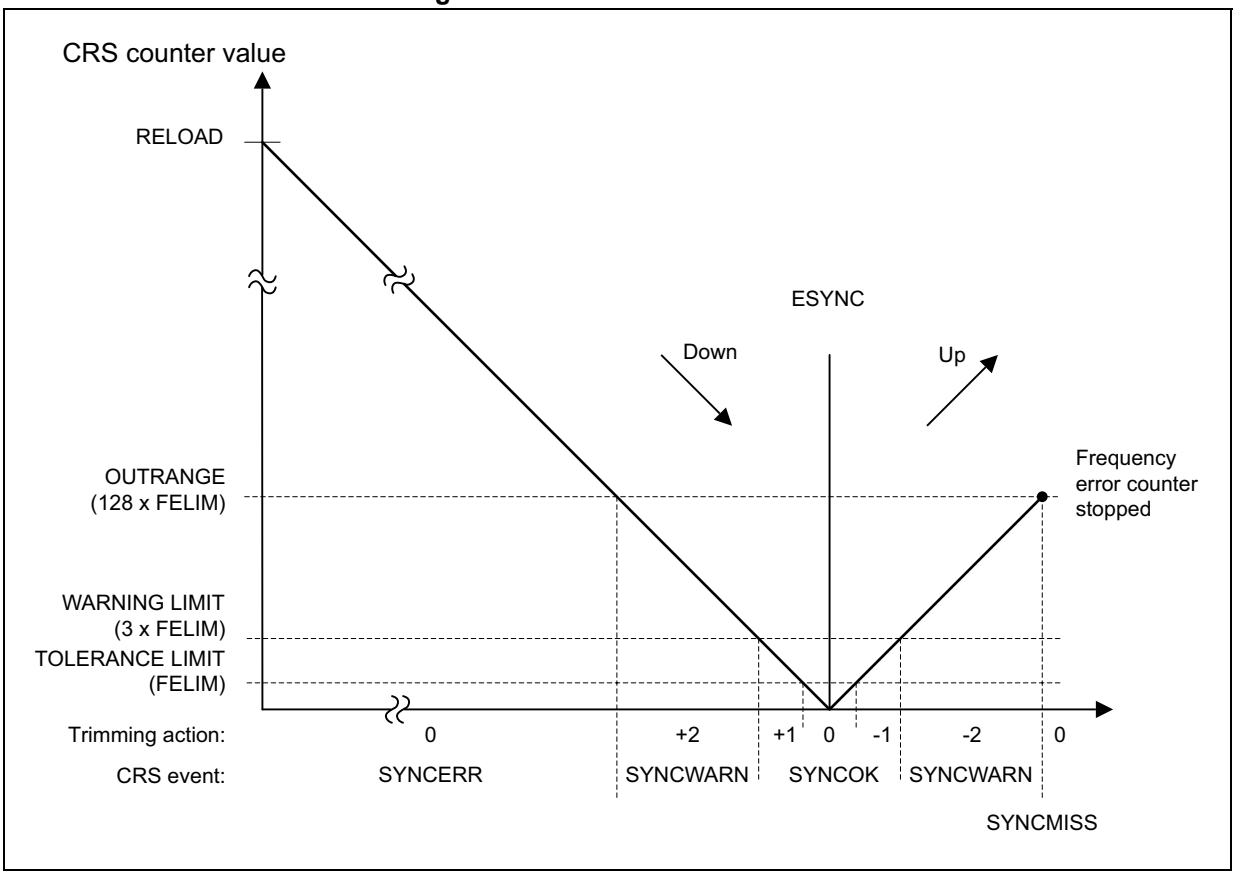
It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

12.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value must be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value must be decremented).

Figure 39. CRS counter behavior



12.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode

- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

12.4.5 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$ and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

12.5 CRS low-power modes

Table 111. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator restarted.
Standby	The CRS peripheral is powered down and must be reinitialized after exiting Standby mode.

12.6 CRS interrupts

Table 112. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

12.7 CRS registers

Refer to *Section 1.2 on page 104* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

12.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 X000 (X=4 for products supporting 7-bit TRIM width, otherwise X=2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TRIM[6:0]							SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNCIE	ERRIE	SYNC WARNIE	SYNC OKIE
	rw	rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **TRIM[6:0]**: HSI48 oscillator smooth trimming

The default value of the HSI48 oscillator smooth trimming is 64, which corresponds to the middle of the trimming interval.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 12.4.4* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable
0: SYNC warning (SYNCWARNF) interrupt disabled
1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable
0: SYNC event OK (SYNCOKF) interrupt disabled
1: SYNC event OK (SYNCOKF) interrupt enabled

12.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection
This bit is set and cleared by software to select the input polarity for the SYNC signal source.
0: SYNC active on rising edge (default)
1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection
These bits are set and cleared by software to select the SYNC signal source (see *Table 110: CRS internal input/output signals*):
00: crs_sync_in_1 selected as SYNC signal source
01: crs_sync_in_2 selected as SYNC signal source
10: crs_sync_in_3 selected as SYNC signal source
11: crs_sync_in_4 selected as SYNC signal source

Note: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.
000: SYNC not divided (default)
001: SYNC divided by 2
010: SYNC divided by 4
011: SYNC divided by 8
100: SYNC divided by 16
101: SYNC divided by 32
110: SYNC divided by 64
111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 12.4.4* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 12.4.3* for more details about counter behavior.

12.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 12.4.4* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.
0: Upcounting direction, the actual frequency is above the target.
1: Downcounting direction, the actual frequency is below the target.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No trimming error signalized
1: Trimming error signalized

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reached value FELIM * 128 and no SYNC was detected, meaning either that a SYNC pulse was missed or that the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, and that some other action has to be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signalized

1: SYNC missed error signalized

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signalized

1: SYNC error signalized

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signalized

1: Expected SYNC signalized

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signalized

1: Synchronization or trimming error signalized

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signalized

1: SYNC warning signalized

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signalized

1: SYNC event OK signalized

12.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

12.7.5 CRS register map

Table 113. CRS register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 115* for the register boundary addresses.

13 General-purpose I/Os (GPIO)

13.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16 bits reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL), a secure configuration register (GPIOx_SECCFGR) and a high-speed low-voltage register (GPIOx_HSLVR).

13.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone security support

13.3 GPIO functional description

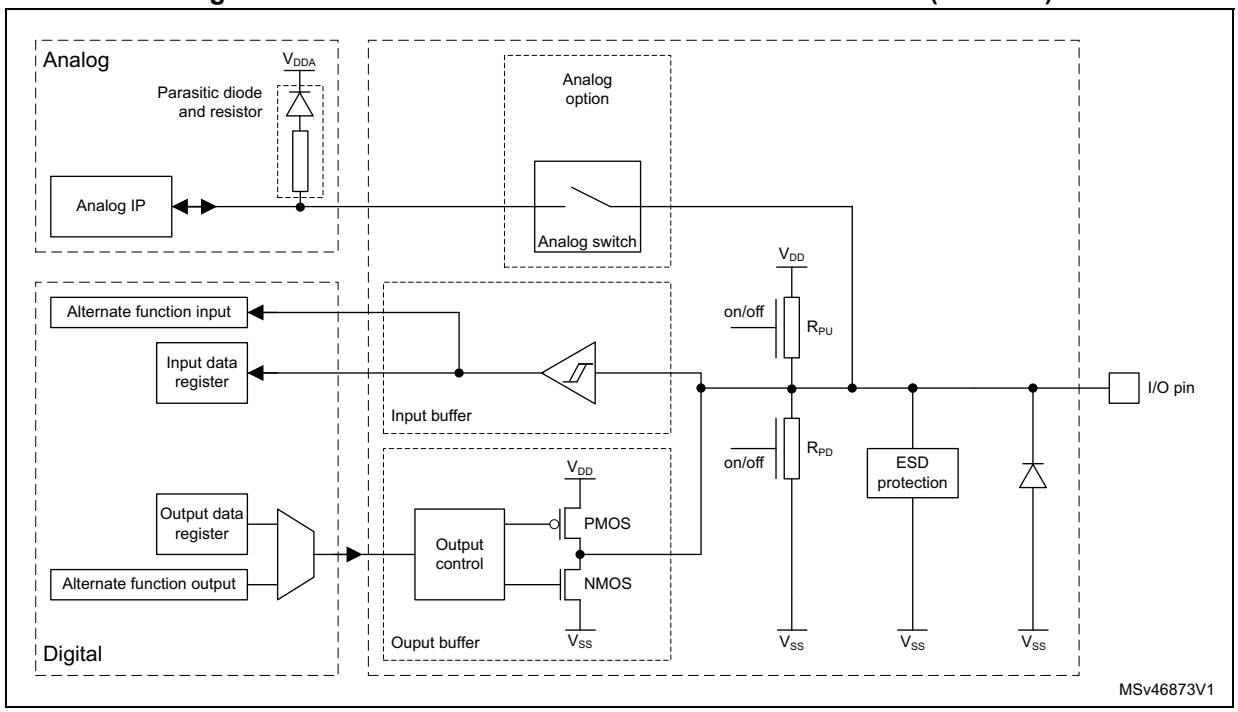
Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The *Table 114* gives the possible port bit configurations.

Figure 40. Structure of three-volt or five-volt tolerant GPIO (TT or FT)



Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

Table 114. Port bit configuration(1)

MODE(i) [1:0]	OTYPE(i)	OSPEED(i) [1:0]	PUPD(i) [1:0]		I/O configuration

11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

13.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

PH3/BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see *Section 13.3.15: Using PH3 as GPIO*).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.

13.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions:**
  - For the ADC, DAC, OPAMP and COMP, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC, OPAMP and COMP registers.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

13.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

13.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (*GPIO port input data register (GPIOx_IDR) (x = A to I)* and *GPIO port output data register (GPIOx_ODR) (x = A to I)*).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

13.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

13.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH and GPIOx_HSLVR.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

13.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can

thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

13.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode). Refer to *Section 21: Extended interrupts and event controller (EXTI)*.

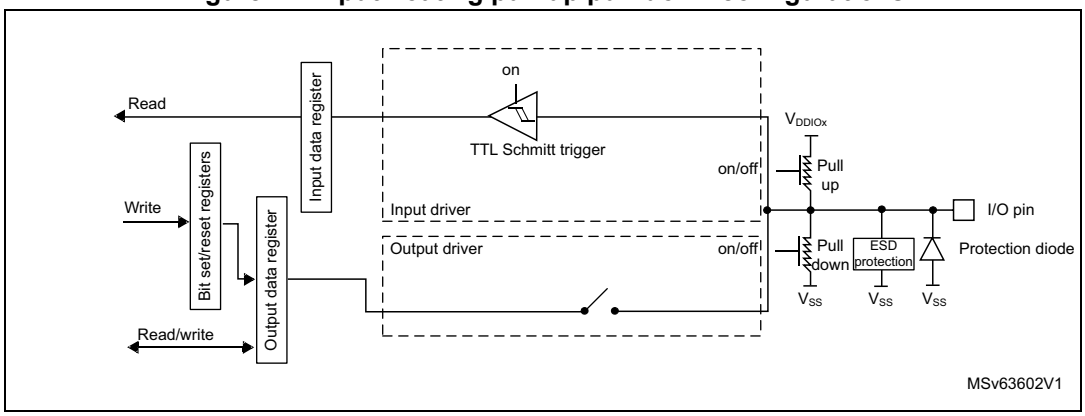
13.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

Figure 41. Input floating/pull-up/pull-down configurations



13.3.10 Output configuration

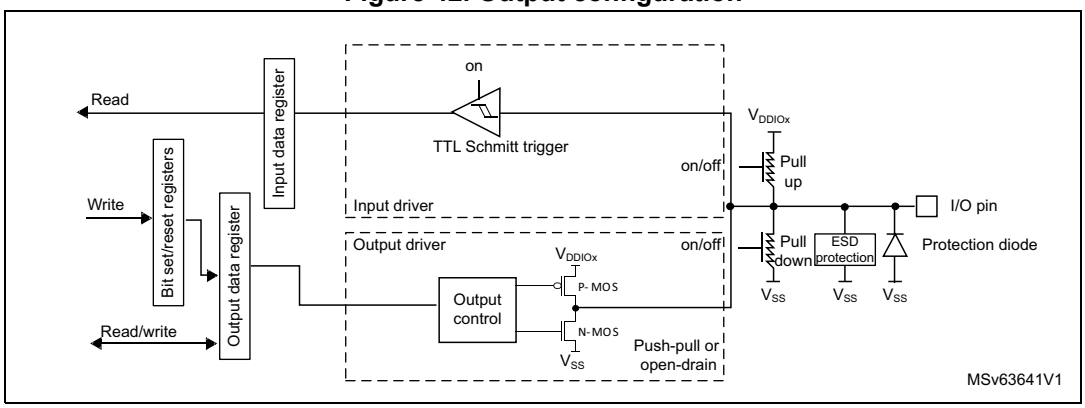
When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.

- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 42. Output configuration



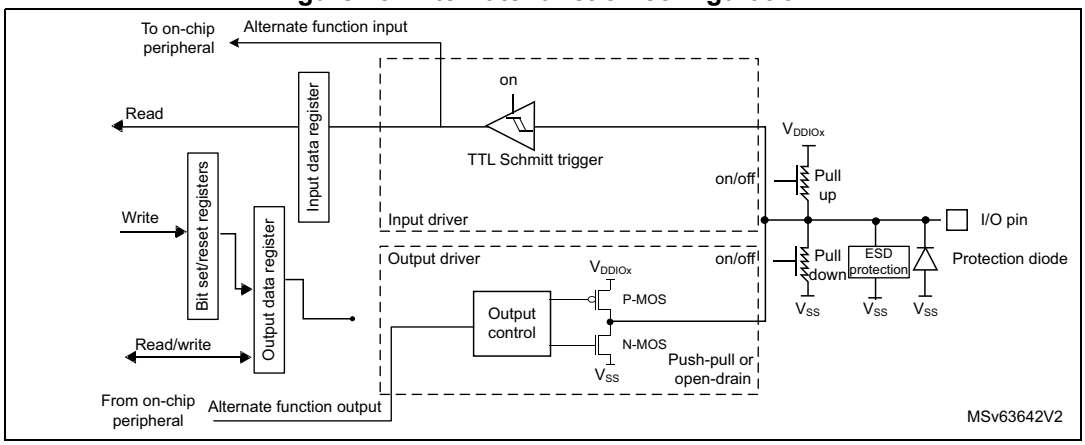
13.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

Figure 43. Alternate function configuration



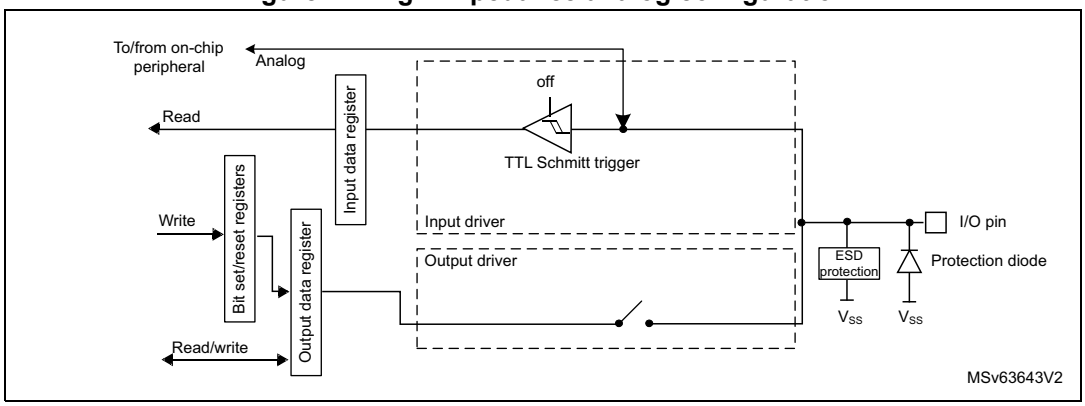
13.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware.
- Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

Figure 44. High-impedance analog configuration



13.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

13.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 54.3: RTC functional description*

13.3.15 Using PH3 as GPIO

PH3 may be used as boot pin (BOOT0) or as a GPIO. Depending on the nSWBOOT0 bit in the user option byte, PH3 switches from the input mode to the analog input mode:

- After the option byte loading phase if nSWBOOT0 = 1.
- After reset if nSWBOOT0 = 0.

13.3.16 OPAMPx_VINM dedicated pins

The OPAMPx_VINM dedicated pins are three-volt tolerant and are supplied by V_{DDA}. These pins do not feature a complete TT structure as shown in *Figure 40*, but a direct connection to OPAMPx. The OPAMPx_VINM dedicated pins are available on specific packages only (refer to the device datasheet for availability of these pins).

13.3.17 TrustZone security

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR. When the TrustZone is active (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a non-secure access. In case of non-secure access, these bits are RAZ/WI. The GPIO clock and reset control bits in the RCC are automatically configured as secure as soon as at least one I/O in the GPIO is secure.

The I/Os with peripherals functions are also conditioned by the peripheral security configuration (see *Section 5: Global TrustZone controller (GTZC)* for more details):

- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a non-secure I/O pin. If this is not respected, the input data to the secure peripheral is forced to 0 (I/O input pin value is ignored) and the output pin value is forced to 0, thus avoiding any secure information leak through non-secure I/Os.
- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a non-secure peripheral. If this is not respected, the switch remains open. This prevent the redirection of secure data to a non-secure peripheral or I/O through analog path. Refer to *Section 3: System security* for more details.
- Some of the paths between I/Os “additional functions” and peripherals are not blocked if the I/O is secure and the peripheral is non-secure. Therefore it is recommended to configure those peripherals as secure even when not used by the application. Refer to *Section 3: System security* for the list of concerned peripherals. When the path has a security control, it follows the same rule as I/O selection through alternate functions.

Refer to the device pins definition table in datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

Table 115 gives a summary of the I/O port secured bits following the security configuration bit in the GPIO_SECCFGR register. When the I/O bit port is configured as secure:

- Secured bits: read and write operations are only allowed by a secure access. Non secure-read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers bits are non-secure. The GPIOx_SECCFGR register is RAZ/WI.

Table 115. GPIO secured bits

Secure configuration bit	Secured bit	Register name	Non-secure access on secure bits
SECy = 1 in GPIOx_SECCFGR(1)	MODEy[1:0]	GPIOx_MODER	RAZ/WI
	OTy	GPIOx_OTYPER	
	OSPEEDy[1:0]	GPIOx_OSPEEDR	
	PUPDy[1:0]	GPIOx_PUPDR	
	IDy	GPIOx_IDR	
	ODy	GPIOx_ODR	
	BSy and BRy	GPIOx_BSRR	
	LCKy	GPIOx_LCKR	
	BRy	GPIOx_BRR	
	AFSELy[3:0]	GPIOx_AFRH	
		GPIOx_AFRL	
	HSLVy	GPIOx_HSLVR	

1. GPIOx, x = A to I. For x = A to H, y = 0 to 15. For x = I, y = 0 to 7.

13.3.18 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

13.3.19 High-speed low-voltage mode (HSLV)

Some I/Os have the capability to increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1).

Caution: The I/O HSLV configuration bit must not be set if the I/O supply (V_{DD} or V_{DDIO2}) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device. The I/O HSLV bit can be set only when the corresponding option bit is activated (IO_VDD_HSLV or IO_VDDIO2_HSLV depending on the I/O supply, refer to *Section 7.4: FLASH option bytes*). There is no hardware protection associated to this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

13.3.20 I/O compensation cell

The I/O commutation slew rate (t_{fall}/t_{rise}) can be adapted by software depending on Process, Voltage and Temperatures conditions, in order to reduce the I/O noise on power supply. Refer to *Section 15: System configuration controller (SYSCFG)* for more details.

13.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half word or byte mode.

13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I)

Address offset:0x00

Reset value: 0xABFF FFFF (for port A)

Reset value: 0xFFFF FEBF (for port B)

Reset value: 0xFFFF FFFF (for ports C..H)

Reset value: 0x0000 FFFF (for port I)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODEy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O mode.
00: Input mode
01: General purpose output mode
10: Alternate function mode
11: Analog mode (reset state)

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to I)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OT15	OT14	OT13	OT12	OT11	OT10	OT9	OT8	OT7	OT6	OT5	OT4	OT3	OT2	OT1	OT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to I)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEED15[1:0]		OSPEED14[1:0]		OSPEED13[1:0]		OSPEED12[1:0]		OSPEED11[1:0]		OSPEED10[1:0]		OSPEED9[1:0]		OSPEED8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OSPEED7[1:0]		OSPEED6[1:0]		OSPEED5[1:0]		OSPEED4[1:0]		OSPEED3[1:0]		OSPEED2[1:0]		OSPEED1[1:0]		OSPEED0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications and the power supply and load conditions for each speed.

The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to I)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPD15[1:0]		PUPD14[1:0]		PUPD13[1:0]		PUPD12[1:0]		PUPD11[1:0]		PUPD10[1:0]		PUPD9[1:0]		PUPD8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

PUPD7[1:0]		PUPD6[1:0]		PUPD5[1:0]		PUPD4[1:0]		PUPD3[1:0]		PUPD2[1:0]		PUPD1[1:0]		PUPD0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.5 GPIO port input data register (GPIOx_IDR) (x = A to I)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.6 GPIO port output data register (GPIOx_ODR) (x = A to I)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OD15	OD14	OD13	OD12	OD11	OD10	OD9	OD8	OD7	OD6	OD5	OD4	OD3	OD2	OD1	OD0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to I).

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to I)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to I)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

- LOCK key read

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked

1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to I)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy:** Port x reset IO pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Reset the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.12 GPIO high-speed low-voltage register (GPIOx_HSLVR) (x = A to I)

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HSLVy:** Port x high-speed low-voltage configuration (y = 15 to 0)

These bits are written by software to optimize the I/O speed when the I/O supply is low.

Each bit is active only if the corresponding IO_VDD_HSLV/IO_VDDIO2_HSLV user option bit is set. It must be used only if the I/O supply voltage is below 2.7 V.

Setting these bits when the I/O supply (V_{DD} or V_{DDIO2}) is higher than 2.7 V may be destructive.

0: I/O speed optimization disabled

1: I/O speed optimization enabled

Note: Not all I/Os support the HSLV mode. Refer to the I/O structure in the corresponding datasheet for the list of I/Os supporting this feature. Other I/Os HSLV configuration must be kept at reset value.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.13 GPIO secure configuration register (GPIOx_SECCFGR) (x = A to I)

When the system is secure (TZEN = 1), this register provides write access security and can be written only by a secure access. It is used to configure a selected I/O as secure. A non-secure write access to this register is discarded.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

Address offset: 0x30

Reset value: 0x0000 FFFF (for ports A to H)

Reset value: 0x0000 00FF (for port I)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECy**: I/O pin of Port x secure bit enable y (y = 15 to 0)

These bits are written by software to enable or disable the I/O port pin security.

0: The I/O pin is non-secure

1: The I/O pin is secure. Refer to *Table 115* for all corresponding secured bits.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

14 Low-power general-purpose I/Os (LPGPIO)

14.1 Introduction

The low-power general-purpose input/output (LPGPIO) allows the I/O control in Stop mode (down to Stop 2 mode), using DMA in memory-to-memory transfer mode. LPGPIO is designed to be used in conjunction with the GPIO.

14.2 LPGPIO main features

- 16 I/Os control in low-power modes down to Stop 2 mode.
- Secure clock and reset management
- Output data from output data register (LPGPIO_ODR)
- Input data to input data register (LPGPIO_IDR)
- Bit set and reset register (LPGPIO_BSRR) for bitwise write access to LPGPIO_ODR
- TrustZone security support

14.3 LPGPIO functional description

14.3.1 LPGPIO and GPIO configuration

The LPGPIO can control in input or output up to 16 I/Os thanks to LPGPIO_Py (y = 0 to 15) pins alternate functions. This control is still functional in Stop 2 mode, thanks to DMA transfers. The I/Os with a LPGPIO function must be configured as LPGPIO alternate function in the *GPIO port mode register (GPIOx_MODER) (x = A to I)*. Then the I/O value can be read in the LPGPIO input data register, and the I/O can be driven by the LPGPIO output data register or thanks to LPGPIO_BSRR/LPGPIO_BRR registers.

14.3.2 LPGPIO control registers

Each of the 16 I/Os controlled by the LPGPIO can be configured as input or output thanks to the *LPGPIO port mode register (LPGPIO_MODER)*.

14.3.3 LPGPIO I/O data registers

The LPGPIO includes the following 16-bit data registers:

- *LPGPIO port output data register (LPGPIO_ODR)* that stores the data to be output (read/write accessible)
- *LPGPIO port input data register (LPGPIO_IDR)*: the data input through the I/O is stored into this input data register (read only)

14.3.4 LPGPIO I/O data bitwise handling

The 32-bit *LPGPIO port bit set/reset register (LPGPIO_BSRR)* is implemented to allow bitwise set and reset in the output data register (LPGPIO_ODR).

Each LPGPIO_ODR bit has the following control bits in LPGPIO_BSRR:

- LPGPIO_BSRR(i): when writing 1 to it, this bit sets the LPGPIO_ODR(i) bit.
- LPGPIO_BSRR(i + 16): when writing 1 to it, this bit resets the LPGPIO_ODR(i) bit.

Note: Writing 0 to these bits has no effect on LPGPIO_ODR corresponding bits.

If there is an attempt to set and reset bits of the same index, the set action takes the priority.

Writing LPGPIO_BSRR register does not lock the LPGPIO_ODR bits, that can be anyway accessed directly. LPGPIO_BSRR provides a way to perform atomic bitwise handling.

The 16-bit *LPGPIO port bit reset register (LPGPIO_BRR)* allows individual bit reset. It is the same as LPGPIO_BSRR but with minimal pattern preparation:

- LPGPIO_BRR(i): when writing 1 to it, this bit resets the LPGPIO_ODR(i) bit.

14.3.5 Security protection

The LPGPIO includes a security mechanism, that allows or locks the access to the I/O configuration and data registers. This system is used to protect the I/O against the data corruption or observation.

The security mechanism within the LPGPIO is directly issued from the *GPIO secure configuration register (GPIOx_SECCFGR) (x = A to I)*. Therefore, no additional configuration is required.

The LPGPIO security means the following:

- When the executed code is secure, all bits can be accessed.
- When the executed code is non-secure, only the bits concerning the non-secure I/Os can be accessed.

A non-secure access to a secure I/O register bit is silent fail:

- A non-secure write to a secure I/O register bit is ignored (WI).
- A non-secure read to a secure I/O register bit returns 0 (RAZ).
- No bus error is generated.

14.3.6 Secure clock and reset management

The LPGPIO clock and reset control bits in the RCC are automatically configured as secured as soon as at least one I/O with LPGPIO alternate function is secure (refer to the corresponding I/Os in GPIO_SECCFGR registers)

14.4 LPGPIO registers

This section gives a detailed description of the LPGPIO registers.

The peripheral registers can be written in word, half-word or byte mode.

14.4.1 LPGPIO port mode register (LPGPIO_MODER)

Address offset:0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE15	MODE14	MODE13	MODE12	MODE11	MODE10	MODE9	MODE8	MODE7	MODE6	MODE5	MODE4	MODE3	MODE2	MODE1	MODE0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MODEy:** Configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O mode.

0: Input mode

1: Output mode

14.4.2 LPGPIO port input data register (LPGPIO_IDR)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID15	ID14	ID13	ID12	ID11	ID10	ID9	ID8	ID7	ID6	ID5	ID4	ID3	ID2	ID1	ID0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

14.4.3 LPGPIO port output data register (LPGPIO_ODR)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OD15	OD14	OD13	OD12	OD11	OD10	OD9	OD8	OD7	OD6	OD5	OD4	OD3	OD2	OD1	OD0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the LPGPIO_BSRR or LPGPIO_BRR registers.

14.4.4 LPGPIO port bit set/reset register (LPGPIO_BSRR)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns 0.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns 0.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

14.4.5 LPGPIO port bit reset register (LPGPIO_BRR)

Address offset: 0x28

Reset value: 0x0000 0000

Refer to *Section 2.3* for the register boundary addresses.

15 System configuration controller (SYSCFG)

15.1 SYSCFG main features

The STM32U575/585 devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Managing robustness feature
- Configuring FPU interrupts
- Enabling/disabling the FMP high-drive mode of some I/Os and voltage booster for I/Os analog switches
- Managing the I/O compensation cell
- Configuring register security access

15.2 SYSCFG functional description

15.2.1 I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the current slew-rate and output impedance in the I/O buffer. Two compensation cells are embedded, one for the I/Os supplied by V_{DD} and one for the I/Os supplied by V_{DDIO2}.

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os. The HSI is used by the compensation cells and must be enabled before enabling the compensation cells in the *SYSCFG compensation cell control/status register (SYSCFG_CCCSR)*.

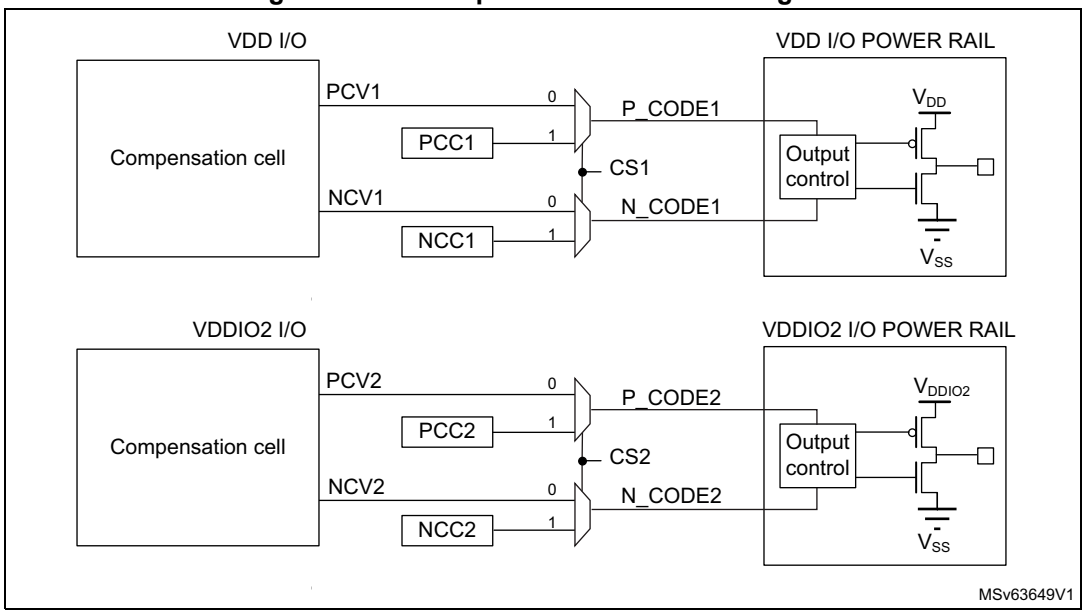
When enabled, the compensation cell tracks the PVT, and the 8-bit code PCVx and NCVx (x = 1 for I/Os supplied by V_{DD}, x = 2 for I/Os supplied by V_{DDIO2}) are available in SYSCFG_CCVR once the RDYx is set. If the CSx bit is cleared, the I/Ox receives the code from SYSCFG_CCVR, resulting from the compensation cell.

To optimize the trimming, the code can be adjusted through SYSCFG_CCCR. Two sets of bits are available: PCC1/NCC1 for the V_{DD} power rail and PCC2/NCC2 for the V_{DDIO2} power rail. They can be selected independently through CS1 and CS2 bits in SYSCFG_CCCSR (see *Figure 45*).

To reduce the power consumption, it is recommended to copy the code from SYSCFG_CCVR to SYSCFG_CCCR. After the result is ready, set the CSx bit and disable the compensation cell.

Note: The compensation cell can be used only when 1.6 V ≤ V_{DDIOx} ≤ 3.6 V.

Figure 45. I/O compensation cell block diagram



15.2.2 SYSCFG TrustZone security and privilege

SYSCFG TrustZone security

When the TrustZone security is activated, the SYSCFG is able to secure registers from being modified by non-secure accesses.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

A non-secure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SYSCFG illegal access event is enabled in the GTZC.

Privileged/unprivileged mode

The SYSCFG registers can be read and written by privileged and unprivileged accesses except the SYSCFG registers for CPU configuration: SYSCFG_CSLCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR registers, and the FPUSEC bit in the SYSCFG_SECCFGR.

An unprivileged access to a privileged register is RAZ/WI.

The table below shows the register security overview.

Table 118. TrustZone security and privilege register accesses

SYSCFG register name	Read/write access		Privileged /unprivileged access
TrustZone configuration(1)	**TZEN = 1**	**TZEN = 0**	**Not applicable**
SYSCFG_SECCFGR	Read: no restriction Write: secure access only Non-secure write is WI and generates an illegal access event.	RAZ/WI	Read: no restriction FPUSEC privileged write only Other bits write: no restriction
SYSCFG_CSLCKR	Read/Write: secure access only Non-secure access is RAZ/WI and generates and an illegal access event.	RAZ/WI	Privileged only Unprivileged: RAZ/WI
SYSCFG_FPUIMR	– If FPUSEC = 1: Read/Write: secure access only Non-secure access is RAZ/WI and generates an illegal access event. – If FPUSEC = 0: Read/Write: no restriction	No restriction	Privileged only Unprivileged: RAZ/WI
SYSCFG_CNSLCKR	Read/write: no restriction	No restriction	Privileged only Unprivileged: RAZ/WI
SYSCFG_CFGR1	Read/Write: secure access only for secure bits depending on peripheral security bits in GTZC Non-secure access only for non-secure bits, otherwise RAZ/WI	No restriction	No restriction
SYSCFG_CFGR2	– If CLASSBSEC = 1: Read/Write: secure access only Non-secure access is RAZ/WI and generates an illegal access event. – If CLASSBSEC = 0:Read/Write: no restriction	No restriction	No restriction
SYSCFG_MESR	– If SYSCFGSEC = 1: Read/Write: secure access only Non-secure access is RAZ/WI and generates an illegal access event. – If SYSCFGSEC = 0:Read/Write: no restriction	No restriction	No restriction
SYSCFG_CCCSR SYSCFG_CCVR SYSCFG_CCCR	– If SYSCFGSEC = 1: Read/Write: secure access only Non-secure access is RAZ/WI and generates an illegal access event – If SYSCFGSEC = 0:Read/Write: no restriction	No restriction	No restriction
SYSCFG_RSSCMDR	RAZ/WI if register access is not allowed(2)	RAZ/WI	No restriction

1. TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.
2. Refer to register description for register access.

15.3 SYSCFG registers

15.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR)

When the system is secure (TZEN =1), this register provides write access security and can be written only when the access is secure. It can be globally write-protected, or each bit of this register can be individually write-protected. A non-secure write access is WI and generates an illegal access event. There are no read restrictions.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access, except for FPUSEC that can be written only with privileged access.

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPUSEC	Res.	CLASSBSEC	SYSCFGSEC
												rw		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **FPUSEC**: FPU security
0: SYSCFG_FPUIMR register can be read and written by secure and non-secure access.
1: SYSCFG_FPUIMR register can be read and written by secure access only.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CLASSBSEC**: Class B security
0: SYSCFG_CFGR2 register can be read and written by secure and non-secure access.
1: SYSCFG_CFGR2 register can be read and written by secure access only.

Bit 0 **SYSCFGSEC**: SYSCFG clock control, memory erase status and compensation cell registers security
0: SYSCFG configuration clock in RCC registers, SYSCFG_MESR and SYSCFG_CCCSR, SYSCFG_CCVR and SYSCFG_CCCR can be read and written by secure and non-secure access.
1: SYSCFG configuration clock in RCC registers, SYSCFG_MESR and SYSCFG_CCCSR, SYSCFG_CCVR and SYSCFG_CCCR can be read and written by secure access only.

15.3.2 SYSCFG configuration register 1 (SYSCFG_CFGR1)

When the system is secure (TZEN =1), this register can be a mix of secure and non-secure bits depending on ADC security configuration bit in GTZC peripheral and GPIO security bits. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	ANASWVDD	BOOSTEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **PB9_FMP**: Fast-mode Plus driving capability activation on PB9

This bit can be read and written only with secure access if PB9 is secure in GPIOB. This bit enables the Fm+ driving mode for PB9 when PB9 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB9 pin operates in standard mode.

1: Fm+ mode is enabled on PB9 pin and the speed control is bypassed.

Bit 18 **PB8_FMP**: Fast-mode Plus driving capability activation on PB8

This bit can be read and written only with secure access if PB8 is secure in GPIOB. This bit enables the Fm+ driving mode for PB8 when PB8 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB8 pin operates in standard mode.

1: Fm+ mode is enabled on PB8 pin and the speed control is bypassed.

Bit 17 **PB7_FMP**: Fast-mode Plus driving capability activation on PB7

This bit can be read and written only with secure access if PB7 is secure in GPIOB. This bit enables the Fm+ driving mode for PB7 when PB7 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB7 pin operates in standard mode.

1: Fm+ mode is enabled on PB7 pin and the speed control is bypassed.

Bit 16 **PB6_FMP**: Fast-mode Plus driving capability activation on PB6

This bit can be read and written only with secure access if PB6 is secure in GPIOB. This bit enables the Fm+ driving mode for PB6 when PB6 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB6 pin operates in standard mode.

1: Fm+ mode is enabled on PB6 pin, and the speed control is bypassed.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **ANASWVDD**: GPIO analog switch control voltage selection
This bit can be read and written only with secure access if ADC1 or ADC4 is secure in GTZC.
0: I/O analog switches are supplied by V_{DDA} or booster when booster is ON.
1: I/O analog switches are supplied by V_{DD}.
Note: Refer to Table 119: BOOSTEN and ANASWVDD set/reset for bit 9 setting.

Bit 8 **BOOSTEN**: I/O analog switch voltage booster enable
This bit can be read and written only with secure access if ADC1 or ADC4 is secure in GTZC.
0: I/O analog switches are supplied by V_{DDA} voltage.
1: I/O analog switches are supplied by a dedicated voltage booster (supplied by V_{DD}).
Note: Refer to Table 119: BOOSTEN and ANASWVDD set/reset for bit 8 setting.

Bits 7:0 Reserved, must be kept at reset value.

the table below describes when the bit 8 (BOOSTEN) and the bit 9 (ANASWVDD) must be set or reset depending on the voltage settings.

Table 119. BOOSTEN and ANASWVDD set/reset

V_{DD}	V_{DDA}	BOOSTEN	ANASWVDD
-	> 2.4 V	0	0
> 2.4 V	< 2.4 V		1
< 2.4 V		1	0

15.3.3 SYSCFG FPU interrupt mask register (SYSCFG_FPUIMR)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the FPUSEC bit in the SYSCFG_SECCFGR register: a non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN =0), there is no access restriction.

This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Address offset: 0x08

Reset value: 0x0000 001F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: Floating point unit interrupts enable bits
FPU_IE[5]: Inexact interrupt enable (interrupt disable at reset)
FPU_IE[4]: Input abnormal interrupt enable
FPU_IE[3]: Overflow interrupt enable
FPU_IE[2]: Underflow interrupt enable
FPU_IE[1]: Divide-by-zero interrupt enable
FPU_IE[0]: Invalid operation Interrupt enable

15.3.4 SYSCFG CPU non-secure lock register (SYSCFG_CNSLCKR)

This register is used to lock the configuration of non-secure MPU and VTOR_NS registers. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKNSMPU	LOCKNSVTOR
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LOCKNSMPU**: Non-secure MPU registers lock
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to non-secure MPU_CTRL_NS, MPU_RNR_NS and MPU_RBAR_NS registers.
0: Non-secure MPU registers write enabled
1: Non-secure MPU registers write disabled

Bit 0 **LOCKNSVTOR**: VTOR_NS register lock
This bit is set by software and cleared only by a system reset.
0: VTOR_NS register write enabled
1: VTOR_NS register write disabled

15.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLOCKR)

This register is used to lock the configuration of PRIS and BFHFNMINS bits in the AIRCR register, SAU, secure MPU and VTOR_S registers.

When the system is secure (TZEN =1), this register can be written only when the access is secure. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), this register is RAZ/WI

This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKSAU	LOCKSMPU	LOCKSVTAIRCR
													rs	rs	rs

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKSAU**: SAU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers.

0: SAU registers write enabled

1: SAU registers write disabled

Bit 1 **LOCKSMPU**: Secure MPU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to secure MPU_CTRL, MPU_RNR and MPU_RBAR registers.

0: Secure MPU registers writes enabled

1: Secure MPU registers writes disabled

Bit 0 **LOCKSVTAIRCR**: VTOR_S register and AIRCR register bits lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to VTOR_S register, PRIS and BFHFNMINS bits in the AIRCR register.

0: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write enabled

1: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write disabled

15.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the CLASSBSEC bit in the SYSCFG_SECCFGR register. When CLASSBSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN =0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x14

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCL	PVDL	SPL	CLL
												rs	rs	rs	rs

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCL**: ECC lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Flash ECC double error signal connection to TIM1/8/15/16/17 break input.

0: ECC double error disconnected from TIM1/8/15/16/17 break input

1: ECC double error connected to TIM1/8/15/16/17 break input

Bit 2 **PVDL**: PVD lock enable bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17 break input, as well as the PVDE and PVDLS[2:0] in the PWR register.

0: PVD interrupt disconnected from TIM1/8/15/16/17 break input. PVDE and PVDLS[2:0] bits can be programmed by the application.

1: PVD interrupt connected to TIM1/8/15/16/17 break input. PVDE and PVDLS[2:0] bits are read only.

Bit 1 **SPL**: SRAM ECC lock bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM ECC double error signal connection to TIM1/8/15/16/17 break inputs.

0: SRAM double error disconnected from TIM1/8/15/16/17 break inputs

1: SRAM double error connected to TIM1/8/15/16/17 break inputs

Bit 0 **CLL**: Cortex-M33 LOCKUP (hardfault) output enable

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the connection of Cortex-M33 LOCKUP (hardfault) output to TIM1/8/15/16/17 break input.

0: Cortex-M33 LOCKUP output disconnected from TIM1/8/15/16/17 break inputs

1: Cortex-M33 LOCKUP output connected to TIM1/8/15/16/17 break inputs

15.3.7 SYSCFG memory erase status register (SYSCFG_MESR)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x18

Power-on reset value: 0x0000 0000

System reset value: 0x0000 000X (bit 0 not affected by system reset)

															rc_w1

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IPMEE**: ICACHE and PKA SRAM erase status

This bit is set by hardware when ICACHE and PKA SRAM erase is completed after potential tamper detection (refer to *Section 55: Tamper and backup registers (TAMP)* for more details). This bit is cleared by software by writing 1 to it.

0: ICACHE and PKA SRAM erase on going if not yet cleared by software

1: ICACHE and PKA SRAM erase done

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MCLR**: Device memories erase status

This bit is set by hardware when SRAM2, BKPSRAM, ICACHE, DCACHE1, PKA SRAM erase is completed after power-on reset or tamper detection (refer to *Section 55: Tamper and backup registers (TAMP)* for more details). This bit is not reset by system reset and is cleared by software by writing 1 to it.

0: memory erase on going if not yet cleared by software

1: Memory erase done

15.3.8 SYSCFG compensation cell control/status register (SYSCFG_CCCSR)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x1C

Reset value: 0x0000 000A

						r	r					rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **RDY2:** VDDIO2 I/Os compensation cell ready flag

This bit provides the compensation cell status of the I/Os supplied by V_{DDIO2}.

0: VDDIO2 I/O compensation cell not ready

1: VDDIO2 I/O compensation cell ready

*Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (*RDY2*) is not set if the HSI clock is not enabled.*

Bit 8 **RDY1:** VDD I/Os compensation cell ready flag

This bit provides the compensation cell status of the I/Os supplied by V_{DD}.

0: VDD I/O compensation cell not ready

1: VDD I/O compensation cell ready

*Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (*RDY1*) is not set if the HSI clock is not enabled.*

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CS2:** VDDIO2 I/Os code selection

This bit selects the code to be applied for the compensation cell of the I/Os supplied by V_{DDIO2}.

0: VDDIO2 I/Os code from the cell (available in the SYSCFG_CCVR)

1: VDDIO2 I/Os code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

Bit 2 **EN2:** VDDIO2 I/Os compensation cell enable
This bit enables the compensation cell of the I/Os supplied by V_{DDIO2}.
0: VDDIO2 I/Os compensation cell disabled
1: VDDIO2 I/Os compensation cell enabled

Bit 1 **CS1:** VDD I/Os code selection
This bit selects the code to be applied for the compensation cell of the I/Os supplied by V_{DD}.
0: VDD I/Os code from the cell (available in the SYSCFG_CCVR)
1: VDD I/Os code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

Bit 0 **EN1:** VDD I/Os compensation cell enable
This bit enables the compensation cell of the I/Os supplied by V_{DD}.
0: VDD I/Os compensation cell disabled
1: VDD I/Os compensation cell enabled

15.3.9 SYSCFG compensation cell value register (SYSCFG_CCVR)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PCV2[3:0]:** PMOS compensation value of the I/Os supplied by V_{DDIO2}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS2 bit of the SYSCFG_CCCSR is reset.

Bits 11:8 **NCV2[3:0]:** NMOS compensation value of the I/Os supplied by V_{DDIO2}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS2 bit of the SYSCFG_CCCSR is reset.

Bits 7:4 **PCV1[3:0]:** PMOS compensation value of the I/Os supplied by V_{DD}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS1 bit of the SYSCFG_CCCSR is reset.

Bits 3:0 **NCV1[3:0]:** NMOS compensation value of the I/Os supplied by V_{DD}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS1 bit of the SYSCFG_CCCSR is reset.

15.3.10 SYSCFG compensation cell code register (SYSCFG_CCCR)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x24

Reset value: 0x0000 7878

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PCC2[3:0]:** PMOS compensation code of the I/Os supplied by V_{DDIO2}
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS2 bit of the SYSCFG_CCCSR is set.

Bits 11:8 **NCC2[3:0]:** NMOS compensation code of the I/Os supplied by V_{DDIO2}
These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS2 bit of the SYSCFG_CCCSR is set.

Bits 7:4 **PCC1[3:0]:** PMOS compensation code of the I/Os supplied by V_{DD}
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS1 bit of the SYSCFG_CCCSR is set.

Bits 3:0 **NCC1[3:0]:** NMOS compensation code of the I/Os supplied by V_{DD}

These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS1 bit of the SYSCFG_CCCSR is set.

15.3.11 SYSCFG RSS command register (SYSCFG_RSSCMDR)

When the system is secure (TZEN =1), this register can be read and written only when the APB access is secure. Otherwise it is RAZ/WI.

When the system is not secure (TZEN =0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x2C

Power-on reset value: 0x0000 0000

Refer to *Section 2.3* for the register boundary addresses.

16 Peripherals interconnect matrix

16.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep, Stop 0, Stop 1 and Stop 2 modes.

16.2 Connection summary

1. Numbers in this table are links to corresponding subsections of *Section 16.3*.
2. "-" means no interconnect.

16.3 Interconnection details

16.3.1 Master to slave interconnection for timers

From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15)

Purpose

Some of the TIMx timers are linked together internally for timer synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop or clock the counter of another timer configured in slave mode.

A description of the feature is provided in *Section 47.4.23: Timer synchronization*.

The synchronization modes are detailed in:

- *Section 46.3.30* for advanced-control timers TIM1/TIM8
- *Section 47.4.22* for general-purpose timers TIM2/TIM3/TIM4/TIM5
- *Section 48.4.23* for the general-purpose timer TIM15

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/TIM8) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/TIM17. The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3.

The possible master/slave connections are given in:

- *Table 430* for advanced-control timers TIM1/TIM8
- *Table 454* for general-purpose timers TIM2/TIM3/TIM4/TIM5
- *Table 470* for the general-purpose timers TIM15

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 443: Effect of low-power modes on TIM1/TIM8*
- *Table 462: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 477: Effect of low-power modes on TIM15/TIM16/TIM17*

16.3.2 Triggers to ADCs

From EXTI, timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) and LP timers (LPTIM1/ LPTIM2/LPTIM3/LPTIM4) to ADC1

From EXTI, timers (TIM1/TIM2/TIM6/TIM15) and LP timers (LPTIM1/LPTIM3) to ADC4

Purpose

A conversion, or a sequence of conversions, can be triggered either by software or by an external event (such as timer capture or input pins). For ADC1, if the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events can trigger a conversion with the selected polarity.

More details in:

- *Section 29.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])*
- EXTEN[1:0] defined in *ADC configuration register (ADC_CFGR1)*
- JEXTEN[1:0] defined in *ADC injected sequence register (ADC_JSQR)*

General-purpose timers (TIM2/TIM3/TIM4/TIM5), basic timer (TIM6), advanced-control timers (TIM1/TIM8) and general-purpose timer (TIM15/TIM16/TIM17) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/ LPTIM2/LPTIM3/LPTIM4) can be used to generate the ADC triggering event through the LPTIM channels (TIMx synchronization described in *Section 46.3.31: ADC triggers* for TIM1/TIM8) in addition to the EXTI on channels 11 and 15.

The ADC4 do not have injected channels. The general-purpose timers (TIM2 and TIM15), basic timers (TIM6), and advanced-control timers (TIM1) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo. Low-power timers (LPTIM1/LPTIM3) can be used to generate the ADC triggering event through the LPTIM channels in addition to EXTI on channel 11 and 15.

Triggering signals

For ADC1, the input triggering signals and the description of the interconnection between ADC1, and timers, are given in:

- adc_ext_trgy: *Table 233: External triggers for regular channels*
- adc_jext_trgy: *Table 234: External triggers for injected channels*
- *Section 29.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])*
- *Section 29.4.25: Timing diagrams example (single/continuous modes, hardware/software triggers)*

For ADC4, the input triggering signals list and the description of the interconnection between ADC4 and timers, are given in:

- *Table 253: ADC interconnection*
- *Section 30.4.16: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)*
- *Section 30.4.21: Example timing diagrams (single/continuous modes hardware/software triggers)*

Active power mode

This interconnection is active in Run and Sleep modes for all ADCs, and under Stop 0, Stop 1 and Stop 2 for ADC4 assuming that its trigger event line is active as well (such as LPTIM). The timers are active in Run and Sleep mode only. The effects of low-power modes are given in:

- *Table 443: Effect of low-power modes on TIM1/TIM8*
- *Table 462: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 477: Effect of low-power modes on TIM15/TIM16/TIM17*
- *Section 30.5: ADC low-power modes* for ADC4
- *Table 489: STM32U575/585 LPTIM features*
- *Table 504: Effect of low-power modes on the LPTIM*

16.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC4 to TIM1/TIM3/TIM8

Purpose

The internal analog watchdog output signals coming from ADC1/ADC4, are connected to on-chip timers. ADC1/ADC4 can provide trigger event through analog watchdog signals to advanced-control timers (TIM1/TIM3/TIM8) in order to reset, start, stop or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- *Section 46.3.6: External trigger input* for TIM1/TIM8
- *Table 431* for the internal ADC1/ADC4 sources connected to TIM1/TIM8 (tim_etr) input multiplexer
- *Table 455* for the internal ADC1 sources connected to TIM3 (tim_etr) input multiplexer
- *Section 29.4.30* for the ADC1/ADC_AWDy_OUT signal output generation
- *Section 30.4.25* for the ADC4/ADC_AWDy_OUT signal output generation

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

Active power mode

ADC1 and ADC4 are active in Run and Sleep modes.

The ADC4 conversion is functional and autonomous in Stop 0, Stop 1 and Stop 2 modes. This conversion can generate a wakeup interrupt and desired trigger action on timers.

16.3.4 Triggers to DAC

From timer (TIM1/TIM2/TIM4/TIM5/TIM6/TIM7/TIM8/TIM15), Low-power timers (LPTIM1/LPTIM3) and EXTI to DAC (DAC1/DAC2)

Purpose

General-purpose timers (TIM2/TIM4/TIM5/TIM15), basic timers (TIM6/TIM7), advanced-control timers (TIM1/TIM8), LP timers (LPTIM1/LPTIM3) outputs channels (lptim1_ch1 and lptim3_ch1) and EXTI can be used as triggering event to start a DAC conversion.

Triggering signals

The output (from timer) on the TIMx_TRGO signal and from LP timers are directly connected to corresponding DAC inputs.

The selection of input triggers on DAC is provided in:

- *Table 266: DAC interconnection*
- *Section 31.4.8: DAC trigger selection*

Active power mode

This interconnect is active in Run, Sleep, Stop 0, Stop 1 and Stop 2 modes.

16.3.5 Triggers on MDF1 or ADF1

From EXTI, ADF1, timers (TIM1/TIM3/TIM4/TIM6/TIM7/TIM8/TIM16) and LP timer (LPTIM1), to MDF1

From EXTI and MDF1 to ADF1

Purpose

General-purpose timers (TIM3/TIM4/TIM16), basic timers (TIM6/TIM7), advanced-control timers (TIM1/TIM8), low-power timer (LPTIM1), EXTI (EXTI11/EXTI15) and ADF1 can be used to generate a triggering event on MDF1 module and start an A/C conversion. In addition, EXTI15 and MDF1 can trigger ADF1.

A description is given in:

- *Section 35.4.2: MDF pins and internal signals*
- *Section 35.4.11: Start-up sequence examples*

Triggering signals

The mdf_trgi[13:0] trigger inputs are the triggering input signals. The MDF and ADF trigger inputs connections are detailed in:

- *Table 293: MDF trigger connections*
- *Table 314: ADF trigger connections*

Active power mode

This interconnection remains active down to Stop 0 and Stop 1 for MDF1, and Stop 0, Stop 1 and Stop 2 for ADF1, assuming the trigger source remains active.

16.3.6 Timer break from MDF1

From MDF1 to advanced-control timer (TIM1/TIM8)

Purpose

The MDF features an out-off limit detectors (OLD) and a short circuit detector (SCD) functions. When a short-circuit or open-circuit errors (such as over current or over voltage) is detected an interrupt event or/and a break signal can be generated to TIM1 and TIM8. This behavior is described in:

- *Section 35.4.7: Short-circuit detectors (SCD)*
- *Section 35.4.9: Out-of-limit detector (OLD)*
- *Section 46.3.18: Using the break function*
- *Section 46.3.19: Bidirectional break inputs*

Triggering signals

The mdf1_break[0:3] output signals are connected to break1 and break2 inputs signals of TIM1/TIM8. The tables below gives the assignment of break signals:

- *Table 294: MDF break connections*
- *Table 432: Timer break interconnect*
- *Table 433: Timer break2 interconnect*

Active power mode

This interconnection is active under Run and Sleep modes. Refer to:

- *Section 35.4.14: Autonomous mode*
- *Table 305: Effect of low-power modes on MDF*

16.3.7 Clock sources to timers

From HSE, LSE, LSI, MSIK, HSI and MCO to timers (TIM1/TIM8/TIM2/TIM3/TIM4/TIM5/TIM15/TIM16/TIM17) and LP timers (LPTIM1/LPTIM2/LPTIM3)

Purpose

A timer input or timer counter can receive different clock sources and can be used to calibrate internal oscillator on a reference clock for example.

External clocks (HSE, LSE), internal clocks (LSI, MSI, HSI) and microcontroller output clock (MCO) can be used as input to timers:

- MSIK/HSI are assigned to advanced-control timers TIM1 and TIM8 as external trigger signals inputs (tim_etr3/ tim_etr4). MSIK/HSI can be selected as counter clock provided by an external clock source in mode2: external trigger input (tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 46.3.7: Clock selection* for TIM1/TIM8
  - *Table 431: Interconnect to the tim_etr input multiplexer* for TIM1/TIM8
- MSIK, HSI and LSI are assigned to general purpose timers TIM2/TIM3/TIM4/TIM5 as external inputs signals. MSIK/HSI/LSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 47.4.5: Clock selection* for TIM2/TIM3/TIM4/TIM5
  - External clock mode1: *Table 450: Interconnect to the tim_ti1 input multiplexer* for TIM5, tim_ti1_in1 (LSI) and tim_ti1_in2 (LSE)
  - External clock mode2: *Table 455: Interconnect to the tim_etr input multiplexer*, tim_etr3 (MSIK), tim_etr4 (HSI) and tim_etr5 (MSIS) for TIM2/TIM3/TIM4/TIM5
- LSE, LSI, MSI and HSI are assigned to general purpose timers TIM15/TIM16/TIM17 as external inputs signals. LSE/LSI/MSI/HSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1 or tim_ti2 signals). Inputs assignment and clock selection description are detailed in:
  - *Table 48.4.6: Clock selection* for TIM15/TIM16/TIM17. External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
  - *Table 468: Interconnect to the tim_ti1 input multiplexer*, tim_ti1_in1 (LSE-TIM15), tim_ti1_in5(LSE-TIM16/TIM17), tim_ti1_in6 (LSI- TIM16/TIM17), tim_ti1_in7/_8 (MSI-TIM16/TIM17) and tim_ti1_in9 (HSI-TIM16/TIM17)
- Microcontroller output clock (MCO) is connected as external input to general-purpose timers TIM16/TIM17. This allows the calibration of the HSI16/MSI system clocks (with TIM15/TIM16 and LSE) or LSI (with TIM16 and HSE). This is also used to precisely measure LSI (with TIM16 and HSI16) or MSI (with TIM17 and HSI16) oscillator frequency. When the low-speed external (LSE) oscillator is used, no additional hardware connections are required. This feature is given in:
  - *Section 11.4.19: Internal/external clock measurement with TIM15/TIM16/TIM17*

  - *Table 468: Interconnect to the tim_ti1 input multiplexer* for TIM15/TIM16/TIM17
- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in *Table 498: LPTIM1 input capture 2 connection*.
- HSI/256 can be selected as input capture 2 to LPTIM2 as described in *Table 499: LPTIM2 input capture 2 connection*.
- MSI/1024 and MSI/4 can be selected as input capture 2 to LPTIM3 as described in *Table 500: LPTIM3 input capture 2 connection*.

Triggering signals

lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration register 2 (LPTIM_CFGR2). For timers, the internal clock signal can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in).

Active power mode

This feature is available under Run and Sleep modes.

16.3.8 Triggers to low-power timers

From comparators (COMP1/COMP2), EXTI, TAMP and RTC alarm to LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4)

Purpose

LPTIM1/LPTIM2/LPTIM3/LPTIM4 counters may be started either by software or after the detection of an active edge on one of the eight trigger inputs (see *Section 50.4.7: Trigger multiplexer*).

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection, according to the LPTIM configuration register 2 (LPTIM_CFGR2).

Triggering signals

This trigger feature is described in *Section 50.4.7: Trigger multiplexer* and the following sections. The input selection is described in *Table 494: LPTIM1/2/3/4 external trigger connection*.

Active power mode

This interconnection remains active down to Stop 2 mode.

16.3.9 Blanking sources to comparators

From timers (TIM1/TIM8/TIM2/TIM3/TIM4/TIM5/TIM15/TIM16/TIM17) to comparators (COMP1/COMP2)

Purpose

Advanced-control timers (TIM1/TIM8) and general-purpose timers (TIM2/TIM3/TIM4/TIM5/TIM15/TIM16/TIM17) can be used as blanking window input to COMP1/COMP2.

The blanking function is described in *Section 33.3.6: Comparator output-blanking function*.

The blanking sources are given in:

- *COMP1 control and status register (COMP1_CSR)*, BLANKSEL[4:0]
- *COMP2 control and status register (COMP2_CSR)*, BLANKSEL[4:0]

Triggering signals

Timer output signal TIMx_Ocx are the inputs to blanking source of COMP1/COMP2.

Active power mode

This feature is available under Run and Sleep modes.

16.3.10 RTC wakeup as inputs to timers

From RTC to timers (TIM5/TIM16/TIM17)

Purpose

RTC wakeup interrupt can be used as input to general-purpose timers (TIM5/TIM16/TIM17) channel 1.

Triggering signals

RTC wakeup signal is connected to tim_ti1_in3 signal as described in *Table 450: Interconnect to the tim_ti1 input multiplexer* for TIM5.

RTC wakeup signal is connected to tim_ti1_in4 signal as described in *Table 468: Interconnect to the tim_ti1 input multiplexer* for TIM16/TIM17.

Active power mode

This interconnection is active down to Stop 3. Timers are not active but the count is performed at wakeup.

16.3.11 USB OTG SOF as trigger to timers

From USB OTG SOF to TIM2

Purpose

USB OTG SOF (start-of-frame) can generate a trigger to the general-purpose timer TIM2. The USB connection to TIM2 is described in *Table 454: TIMx internal trigger connection*.

Triggering signals

The tim_itr11 internal signal is generated by USB SOF.

Active power mode

This interconnection is active in Run and Sleep modes.

16.3.12 Comparators as inputs, trigger or break signals to timers

From comparators to timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17)

Purpose

The comparators (COMP1/COMP2) output values can be connected to timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) input captures, TIMx_ETR or timer break signals. The connection to ETR is described in *Section 46.3.6: External trigger input*.

Comparators (COMP1/COMP2) output values can also generate break input signals for timers (such as TIM1 or TIM8). The sources for break (tim_brk) channel are one of the following:

- external: connected to one of the TIMx_BKIN pin (as per selection done in the AFIO controller) with polarity selection and optional digital filtering
- internal: coming from comparators, tim_brk_cmpx input (refer to *Section 46.3.2: TIM1/TIM8 pins and internal signals* for product specific implementation).

Triggering signals

The tim_etr and tim_brk signals connected TIM1 and TIM8 (coming from COMP1 and COMP2) are given in:

- tim_etr (*Table 431: Interconnect to the tim_etr input multiplexer*): external trigger internal input bus

  These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulse width control.
- tim_brk (*Table 432: Timer break interconnect* and *Table 433: Timer break2 interconnect*)
- *Section 46.3.6: External trigger input*
- *Section 46.3.18: Using the break function*

For TIM2/TIM3/TIM4/TIM5, the sources connected to the tim_ti[1..4] input multiplexers coming from comparators and some other peripherals, are given in:

- *Table 450: Interconnect to the tim_ti1 input multiplexer*
- *Table 451: Interconnect to the tim_ti2 input multiplexer*
- *Table 453: Interconnect to the tim_ti4 input multiplexer*
- *Table 431: Interconnect to the tim_etr input multiplexer*
- *Table 456: Interconnect to the tim_ocref_clr input multiplexer*
- *Section 47.4.22: Timers and external trigger synchronization*
- *TIMx timer input selection register (TIMx_TISEL)(x = 2 to 5)*

For TIM15/TIM16/TIM17, the sources connected to timers coming from comparators and other peripherals are given in:

- *Table 469: Interconnect to the tim_ti2 input multiplexer*
- *Table 471: Timer break interconnect*
- *Table 473: Interconnect to the ocref_clr input multiplexer*
- *Section 48.4.15: Using the break function*
- *Section 48.4.23: External trigger synchronization (TIM15 only)*

Active power mode

Run, Sleep and wakeup capability in Stop 0, Stop 1 and Stop 2 modes for trigger sources. Input and break remain active in same low-power modes as timers activity, on Run and Sleep modes.

16.3.13 System errors as break signals to timers

From system errors to timers (TIM1/TIM8/TIM15/TIM16/TIM17)

Purpose

CSS, CPU lockup, SRAM2/SRAM3 ECC double errors, FLASH ECC double-error detection and PVD can generate system errors in the form of timer break toward timers (TIM1/TIM8/TIM15/TIM16/TIM17).

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

Triggering signals

The possible sources of break are described in:

- *Section 46.3.18: Using the break function* for TIM1/TIM8
- *Section 48.4.15: Using the break function* for TIM15/TIM16/TIM17
- *Table 434: System break interconnect* for TIM1/TIM8
- *Table 472: System break interconnect* for TIM15/TIM16/TIM17

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 443: Effect of low-power modes on TIM1/TIM8*
- *Table 462: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 477: Effect of low-power modes on TIM15/TIM16/TIM17*

16.3.14 Timers generating IRTIM signal

From timers (TIM16/TIM17) to IRTIM

The general-purpose timer (TIM16/TIM17) output channels TIMx_OC1, are used to generate the waveform of the infrared signal output.

This functionality is described in *Section 51: Infrared interface (IRTIM)*.

16.3.15 Triggers for communication peripherals

From LP timers (LPTIM1/LPTIM2/LPTIM3), comparators (COMP1/2), GPDMA1 transfer complete, LPDMA1 transfer complete, EXTI, RTC alarm and RTC wakeup to USART1/2/3, UART4/UART5, LPUART1, I2C1/2/3/4, and SPI1/2/3

Purpose

LP timer (LPTIM1/LPTIM2/LPTIM3) output channels (lptim1_ch1, lptim1_ch2 and lptim3_ch1), comparator (COMP1/COMP2) output channels (comp1_out and comp2_out),

EXTI, RTC alarm and RTC wakeup, can be used as trigger to start a communication on the selected USART, UART, LPUART, I2C or SPI peripheral.

A GPDMA1 transfer complete can trigger both the GPDMA1 regular or linked-list new transfers and communication on selected communication peripheral.

A LPDMA1 transfer complete can trigger both the LPDMA1 new transfers and the communication on selected peripheral.

Triggering signals

The outputs from triggers are directly connected to peripheral trigger inputs.

The selection of input triggers is detailed in:

- *Table 559: USART interconnection (USART1/2/3 and UART4/5)*
- *Table 571: LPUART interconnections (LPUART1)*
- *Table 539: I2C1, I2C2, I2C4 interconnection* and *Table 540: I2C3 interconnection*

The outputs (from timer) are directly connected to SPI1/SPI2/SPI3 inputs on signals spi_itrx (x = 6, 7). The selection of input triggers on SPI is provided in:

- *Table 582: SPI interconnection (SPI1 and SPI2)*
- *Table 583: SPI interconnection (SPI3)*

Active power mode

These interconnections remain active in Run, Sleep and Stop modes if both source and communication line are autonomous under the mode. Refer to:

- *Section 57.6: USART in low-power modes*
- *Section 56.5: I2C low-power modes*
- *Section 59.6: SPI low-power modes*

16.3.16 Triggers to GPDMA/LPDMA

From EXTI, RTC (alarm/wakeup), TAMP (TAMP1/TAMP2/TAMP3), timers (TIM2/TIM15), LP timers (LPTIM1/LPTIM3/LPTIM4), comparators (COMP1/COMP2), LP/GPDMA1 transfer complete (gpdma1_chx_tc/lpdma1_chx_tc), ADC1/ADC4, and analog watchdog to LPDMA1 and GPDMA1

Purpose

An LP/GPDMA trigger can be assigned to an LP/GPDMA channel x. A programmed LP/GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- *Section 18.3.5: LPDMA triggers* and *Section 17.3.5: GPDMA triggers*
- *Section 18.4.12: LPDMA triggered transfer* and *Section 17.4.12: GPDMA triggered transfer*
- *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* and *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0].
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

LPDMA trigger mapping is specified in *Table 136: Programmed LPDMA1 trigger*, according to LPDMA_CxTR2.TRIGSEL[5:0].

GPDMA trigger mapping is specified in *Table 126: Programmed GPDMA1 trigger*, according to GPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

Assuming sources are active down to Stop modes, this interconnection remains functional in Stop 0 and Stop 1 for GPDMA, and Stop 0, Stop 1 and Stop 2 for LPDMA.

Refer to:

- *Section 18.6: LPDMA in low-power modes*
- *Section 17.6: GPDMA in low-power modes*

16.3.17 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1/ADC4), comparators (COMP1/COMP2) and OPAMP (OPAMP1/OPAM2)

Purpose

The internal reference voltage (VREFINT), the internal temperature sensor (VTS) and VBAT monitoring channel are connected to ADC (ADC1/ADC4) input channels. In addition, the internal digital core voltage (VCORE) is connected /to ADC1/ADC4 input channels.

DAC channels (DAC1_OUT/DAC2_OUT) and VREFINT are connected to comparators (COMP1/COMP2).

OPAMP1 and OPAMP2 outputs can be connected to ADC1 or ADC4 input channels through the GPIO. DAC1_OUT1 can be connected to OPAMP1_VINP. DAC1_OUT2 can be connected to OPAMP2_VINP.

Refer to *Table 265: DAC internal input/output signals* for:

- dac_out1 analog output DAC channel1, output, for on-chip peripherals
- dac_out2 analog output DAC channel2, output, for on-chip peripherals

This is according:

- *Section 29.2* and *Section 30.2: ADC main features*
- *Section 29.4.11: Channel selection (SQRx, JSQRx)*
- *Table 286: Operational amplifier possible connections*
- *Section 33.3.2: COMP pins and internal signals*

Active power mode

These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to:

- *Section 30.5: ADC low-power modes*
- *Section 33.4: COMP low-power modes*
- *Section 34.4: OPAMP low-power modes*

16.3.18 ADC data filtering by the MDF1

From ADC1 to MDF1

Purpose

The MDF1 allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] field in the MDF digital filter configuration register x (MDF_DFLTxCICR) is used to select either data from the ADCs in:

- *Section 29.4.4: ADC connectivity*
- *Table 295: MDF ADC data connections*
  - mdf_adcitf1_dat[15:0] to adc1_dat
- *Table 232: Interconnection*
  - adcx_dat[15:0] (x = 1) to mdf1_adcx_dat[15:0]
- *Section 35.5: MDF low-power modes*
  - Stop0 and Stop1 modes

Active power mode

This feature remains available down to Sleep mode.

16.3.19 Clock source for the DAC sample and hold mode

LSI/LSE to DAC1/DAC2

Purpose

DAC1/DAC2 can run in Stop mode. The sample and hold block and its associated registers use the LSI or LSE clock source (dac_hold_ck) in Stop mode.

Table 265: DAC internal input/output signals:

dac_hold_ck, Input, DAC low-power clock used in sample and hold mode

Active power mode

This feature remains available down to Stop 2 mode.

16.3.20 Internal tamper sources

From internal peripherals, clocks or monitoring to tamper.

Purpose

In order to detect any abnormal activity or tentative to corrupt the device, tampers are introduced and alert the system of such undesired event. Different actions can be taken in consequences.

List of tamper sources can be found in *Table 528: TAMP interconnection*.

Active power mode

This interconnection is active in all power modes if the tamper source is activated.

16.3.21 Output from tamper to RTC

From TAMP to RTC

Purpose

The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.

Refer to section *Section 54.3.3: GPIOs controlled by the RTC and TAMP* for more details.

Active power mode

This interconnection remains active in all power modes.

16.3.22 Encryption keys to AES/SAES

From TAMP backup registers, system Flash memory to and in between SAES and AES

Purpose

The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented in order to load them in a non-readable way. Tamper backup registers or system Flash can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to *Section 42.4.9: SAES operation with wrapped keys* for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to *Section 41.4.13: AES operation with shared keys* for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.

17 General purpose direct memory access controller (GPDMA)

17.1 Introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

17.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during low-power modes (see *Section 17.3.2*)

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 17.3.1*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level

  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 17.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and non-secure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and non-secure interrupts reporting, resulting from any of the respectively secure and non-secure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a non-secure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

17.3 GPDMA implementation

17.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 122. GPDMA1 channels implementation

Channel x	Hardware parameters		Features
	dma_fifo_ size[x]	dma_ addressing[x]	
x = 0 to 11	2	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and SRAM.
x = 12 to 15	4	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be also used for GPDMA transfers, between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

17.3.2 GPDMA autonomous mode in low-power modes

The GPDMA autonomous mode and wakeup feature are implemented in the device low-power modes as per the table below.

Table 123. GPDMA1 autonomous mode and wakeup in low-power modes

Feature	Low-power modes
Autonomous mode and wakeup	GPDMA1 in Sleep, Stop 0 and Stop 1 modes

17.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via the REQSEL[6:0] field in *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

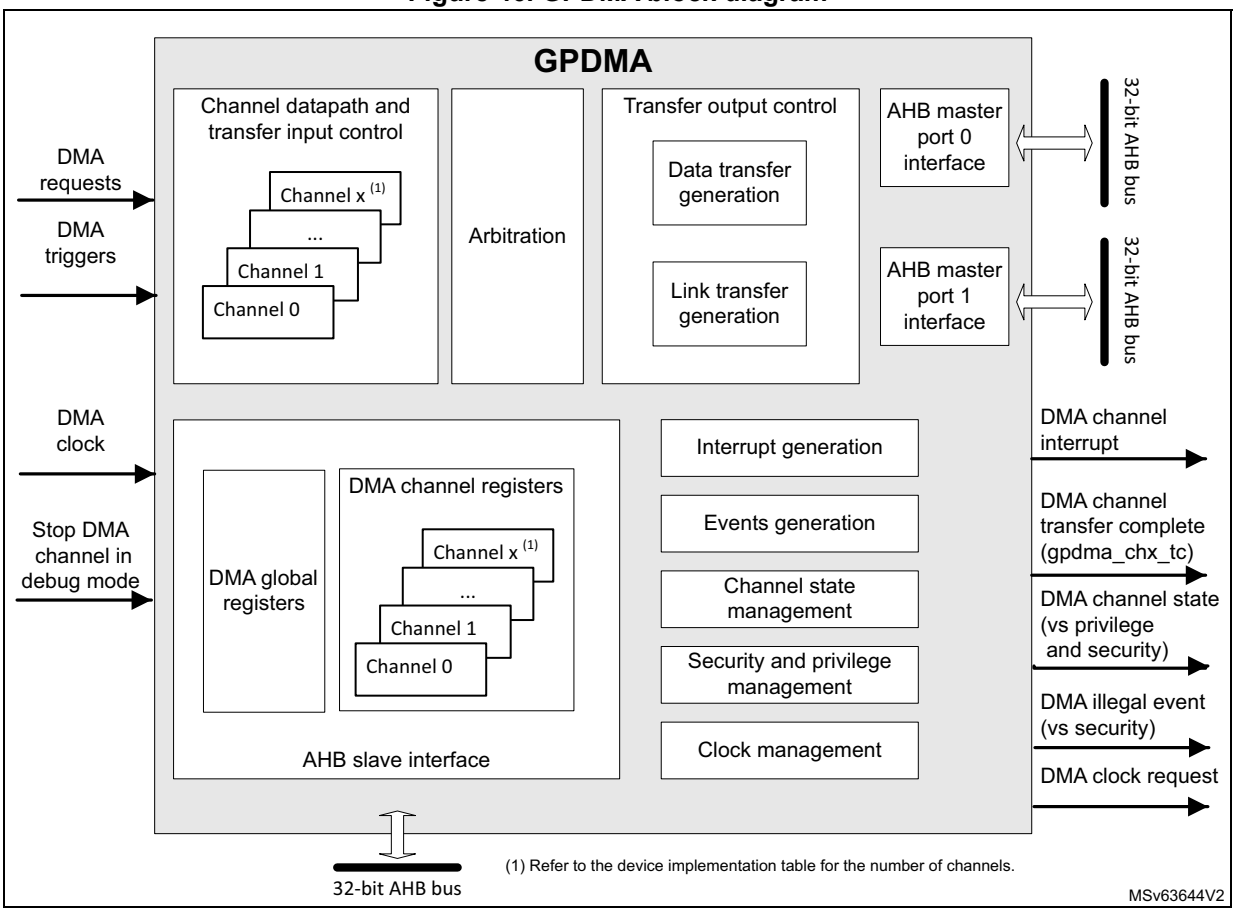
17.4 GPDMA functional description

17.4.1 GPDMA block diagram

Figure 46. GPDMA block diagram



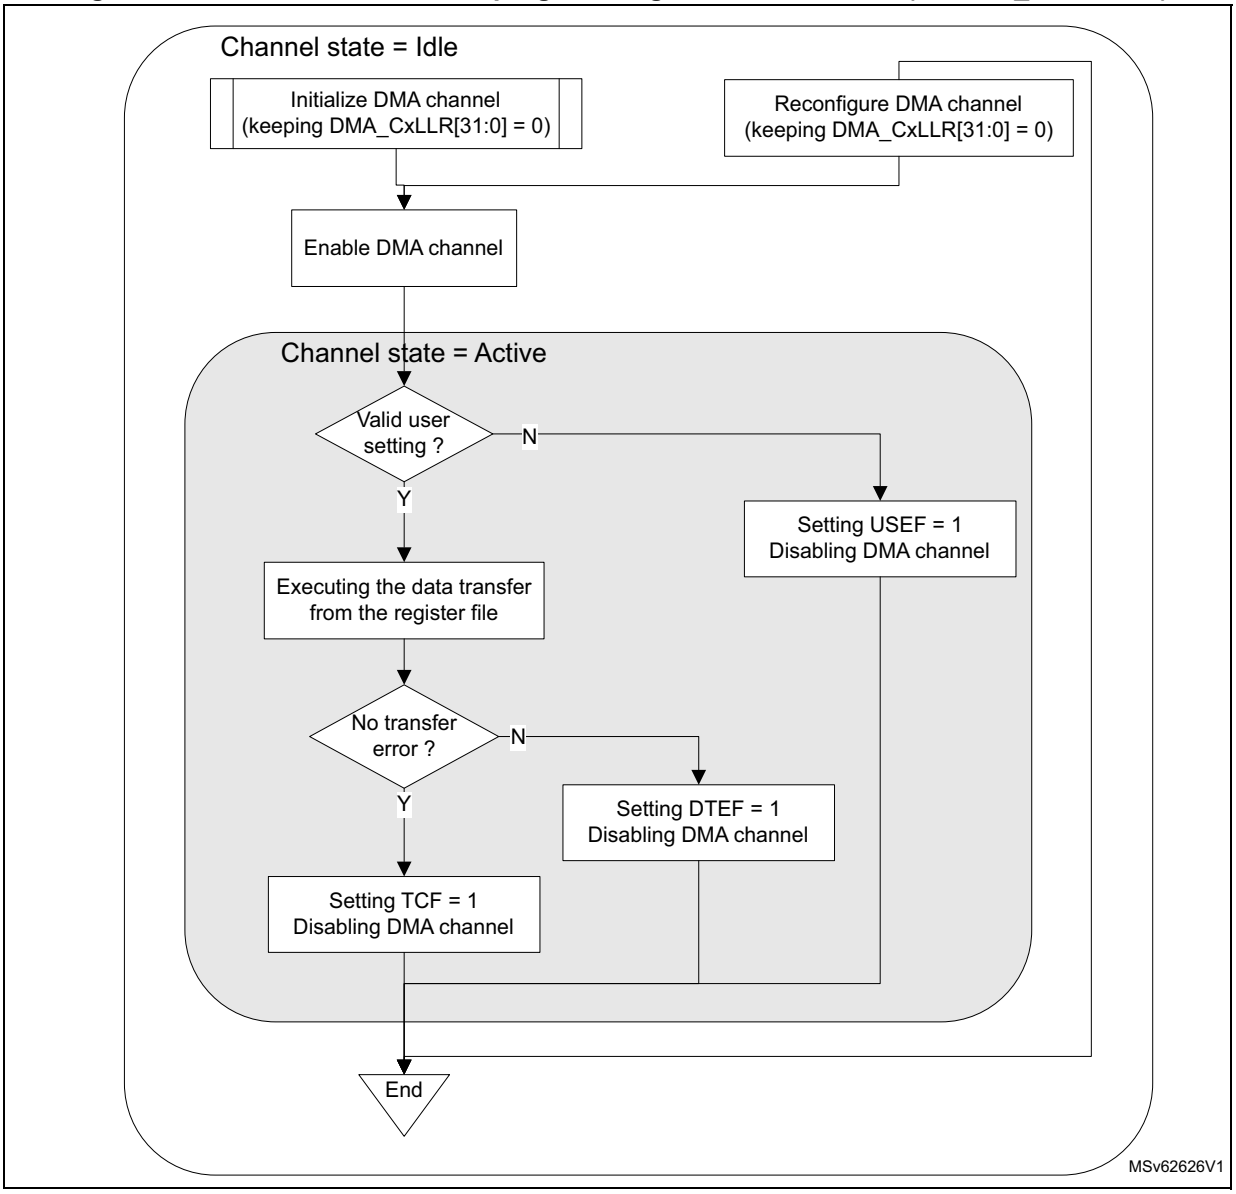
17.4.2 GPDMA channel state and direct programming without any linked-list

After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 into the GPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 into the GPDMA_CxCR.EN bit, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 47. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)



17.4.3 GPDMA channel suspend and resume

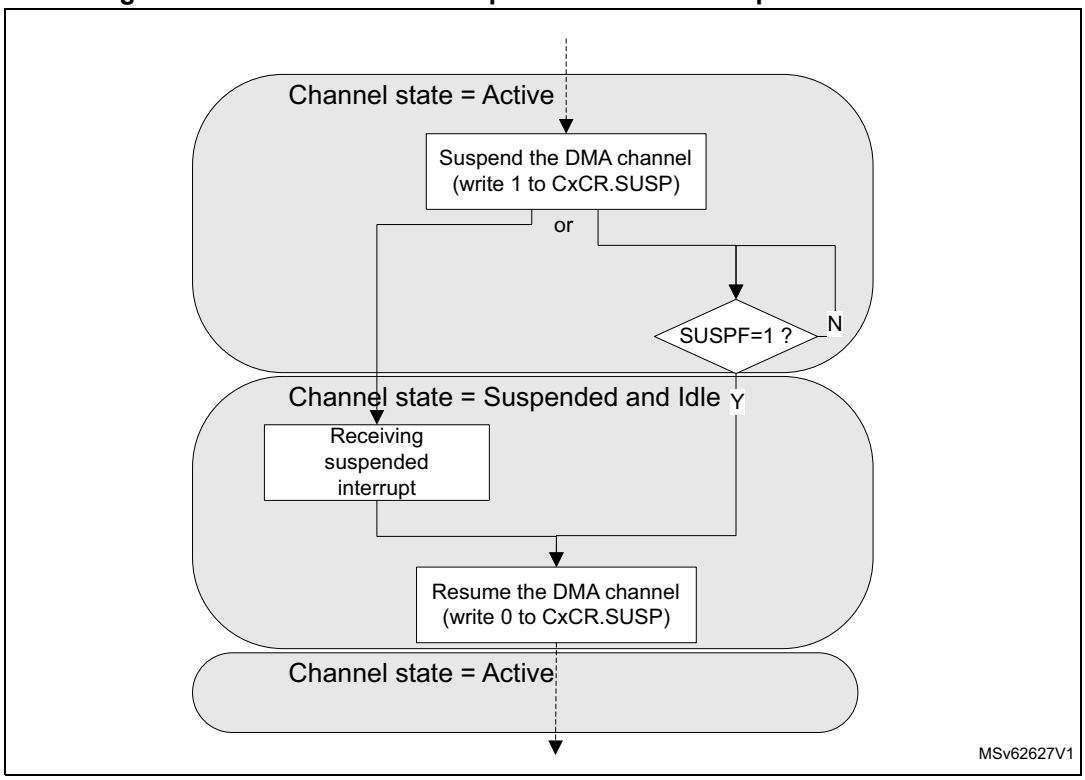
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note that an ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 48. GPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

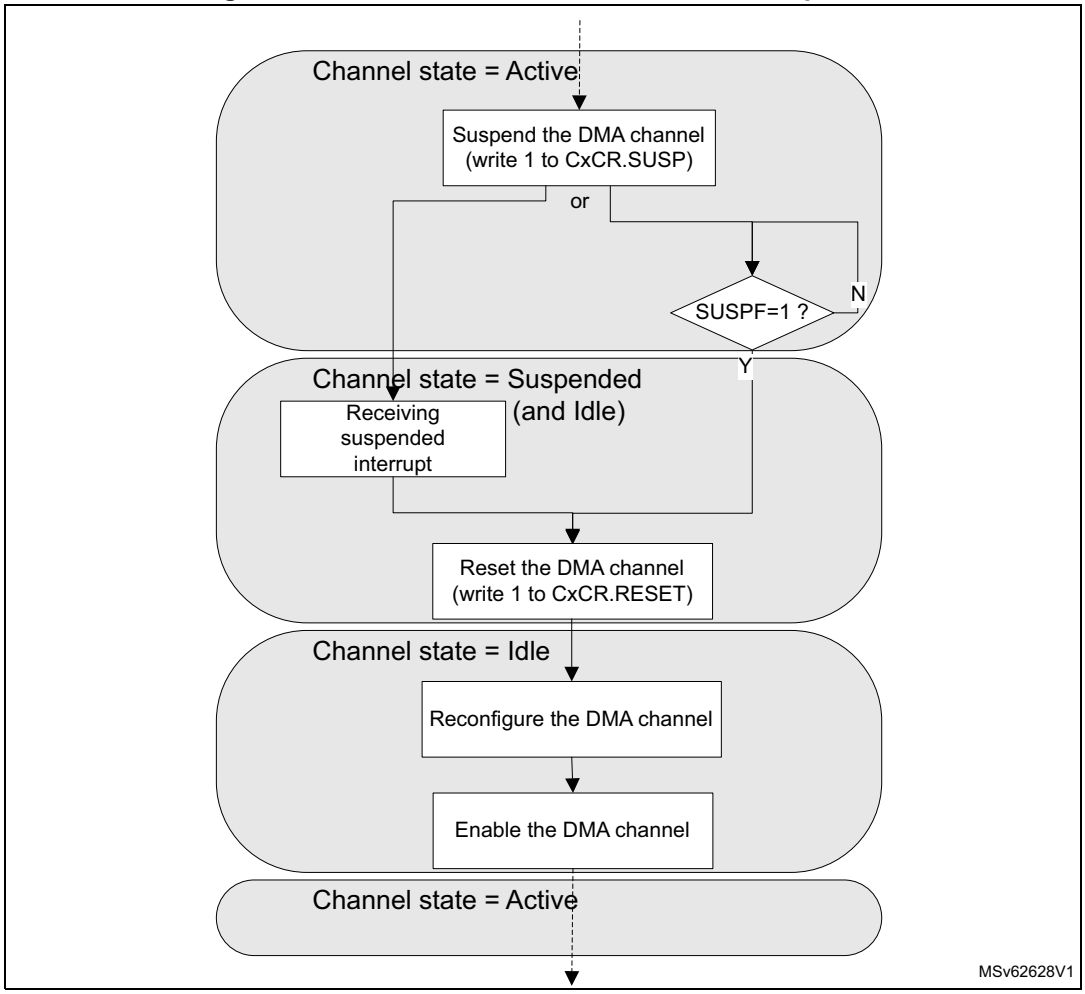
17.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.

5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 49. GPDMA channel abort and restart sequence



17.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 11) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 50*) and including the first linked-list register file (LLI_0) and the next LLIs (LLI_1, LLI_2,...) in the memory
- channel x (x = 12 to 15) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see *Figure 51*), and including the first linked-list register file (LLI_0) and the next LLIs (LLI_1, LLI_2,...) in the memory

Figure 50. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x

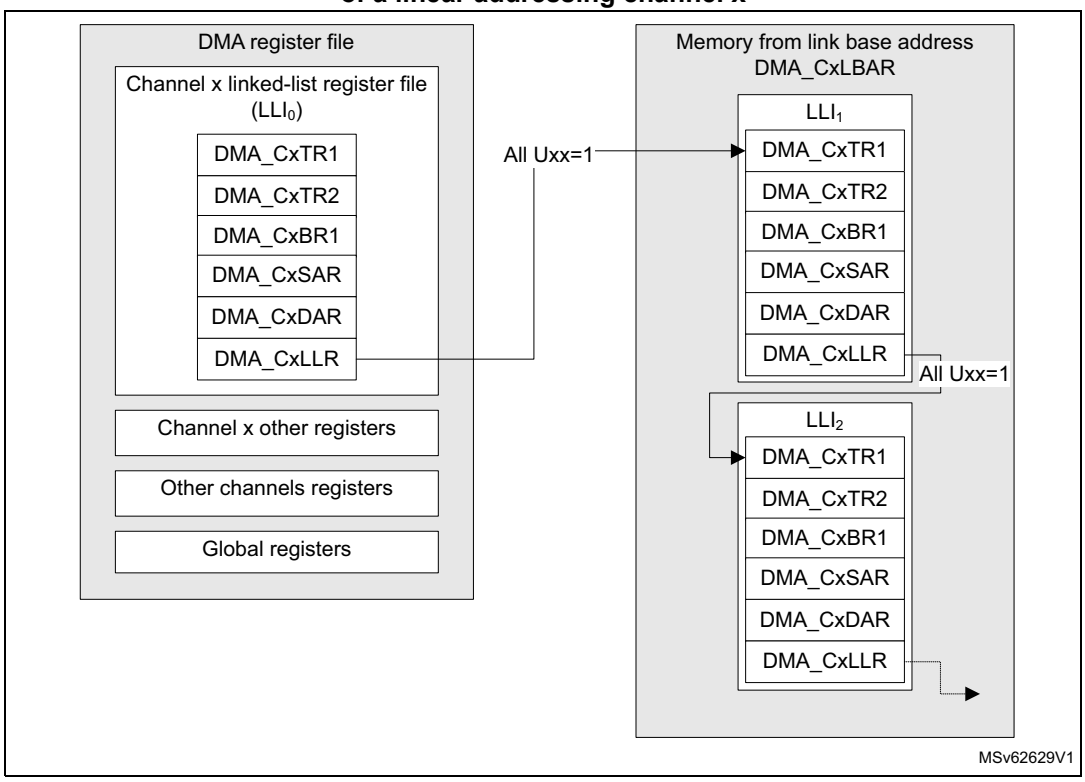


Figure 51. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

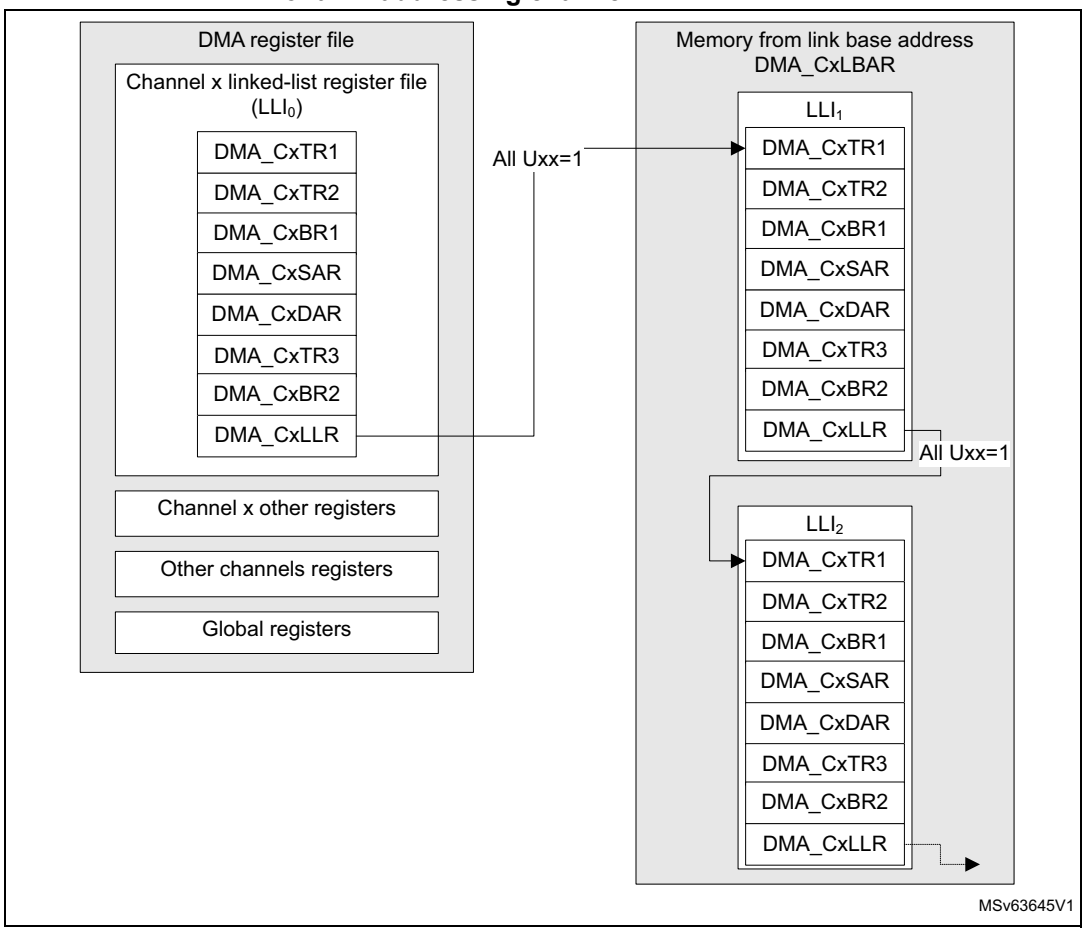

Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 52*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 53*.

Figure 52. GPDMA dynamic linked-list data structure of a linear addressing channel x

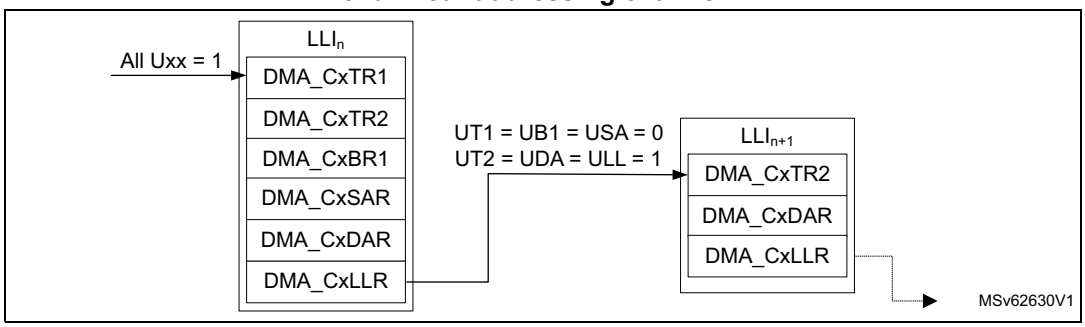

Figure 53. GPDMA dynamic linked-list data structure of a 2D addressing channel x

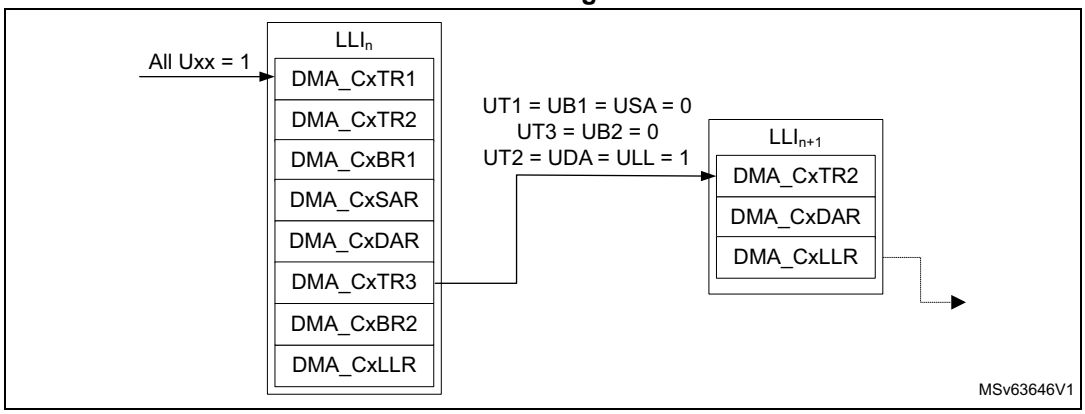


The user must program GPDMA_CxLLR for each LLI$_n$ to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

17.4.6 Linked-list item transfer execution

A LLI$_n$ transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI$_0$)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI$_{n+1}$, as defined by the GPDMA_CxLLR value of the LLI$_n$.

Note: The initial data transfer as defined by the internal register file (LLI$_0$) can be null (GPDMA_CxBR1.BNDT[15:0] = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI$_1$ in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

17.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

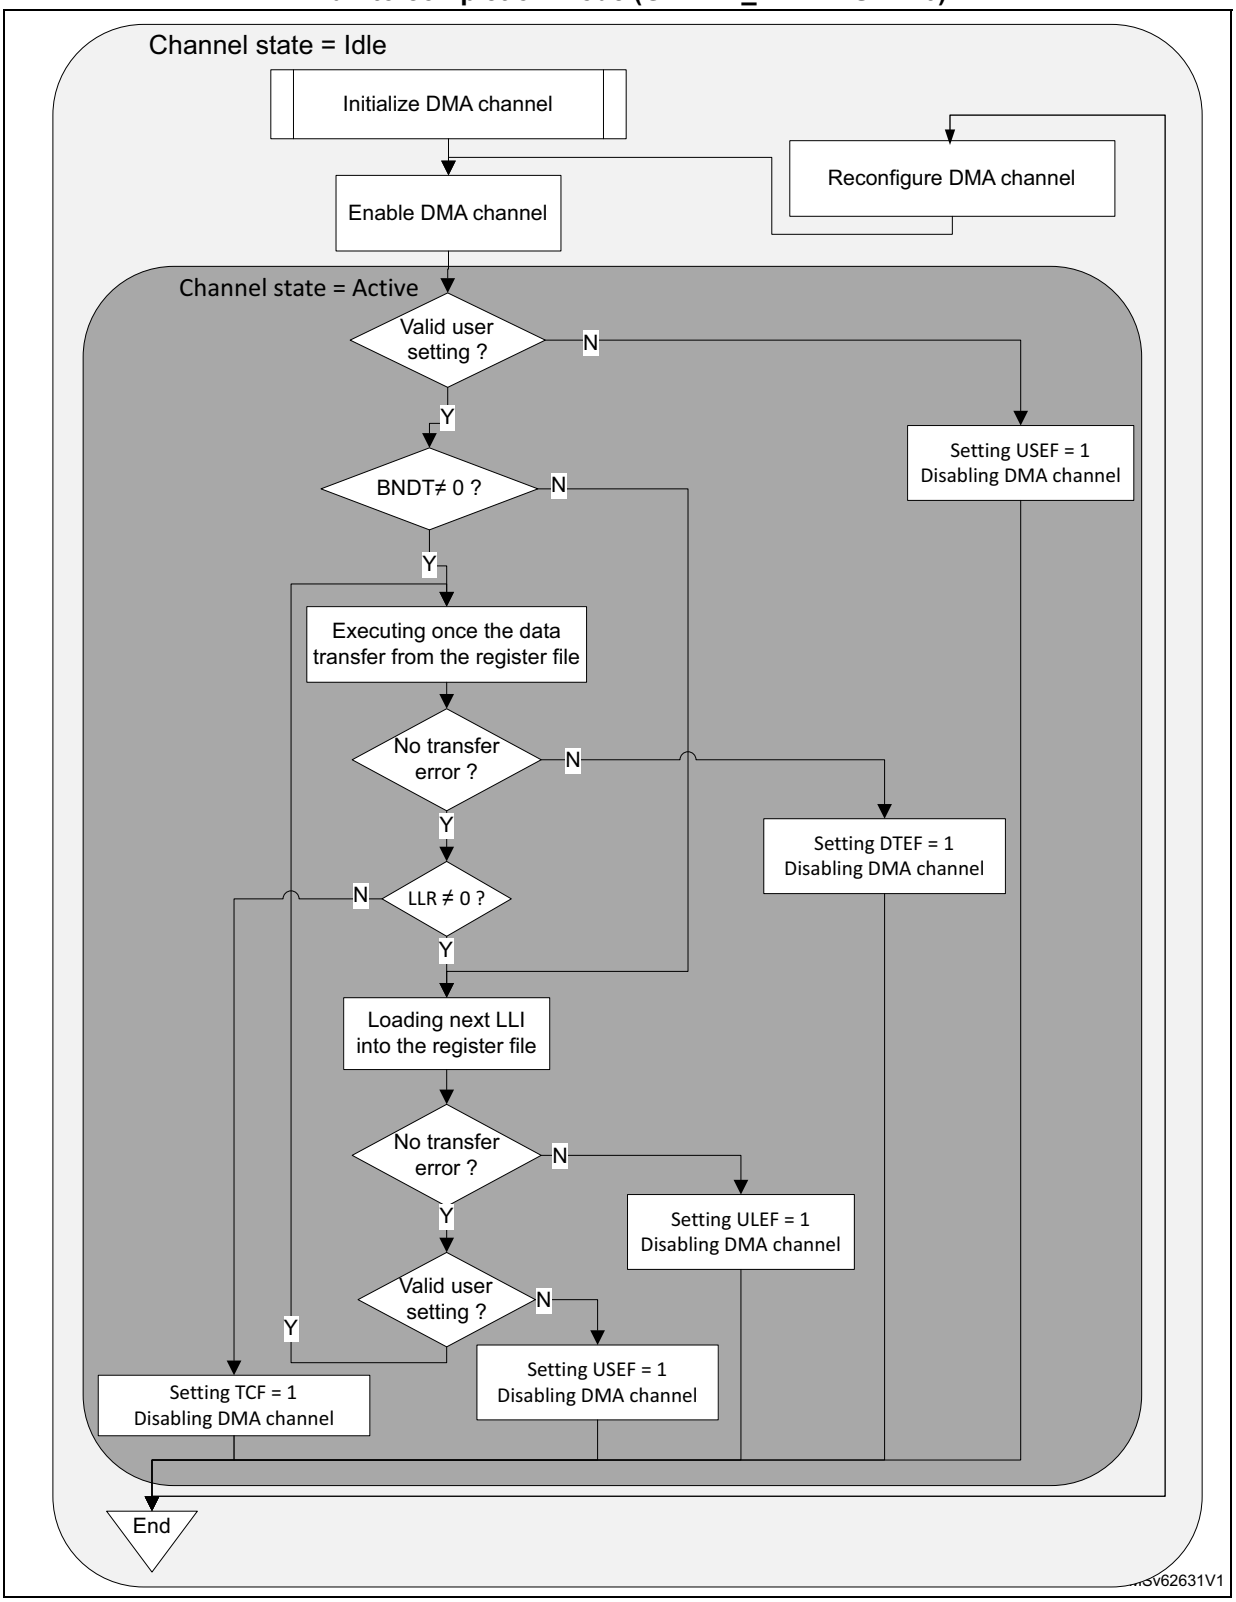
The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- if LLI_N is pointing to a previous LLI

In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

The figure below depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

Figure 54. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)



Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:

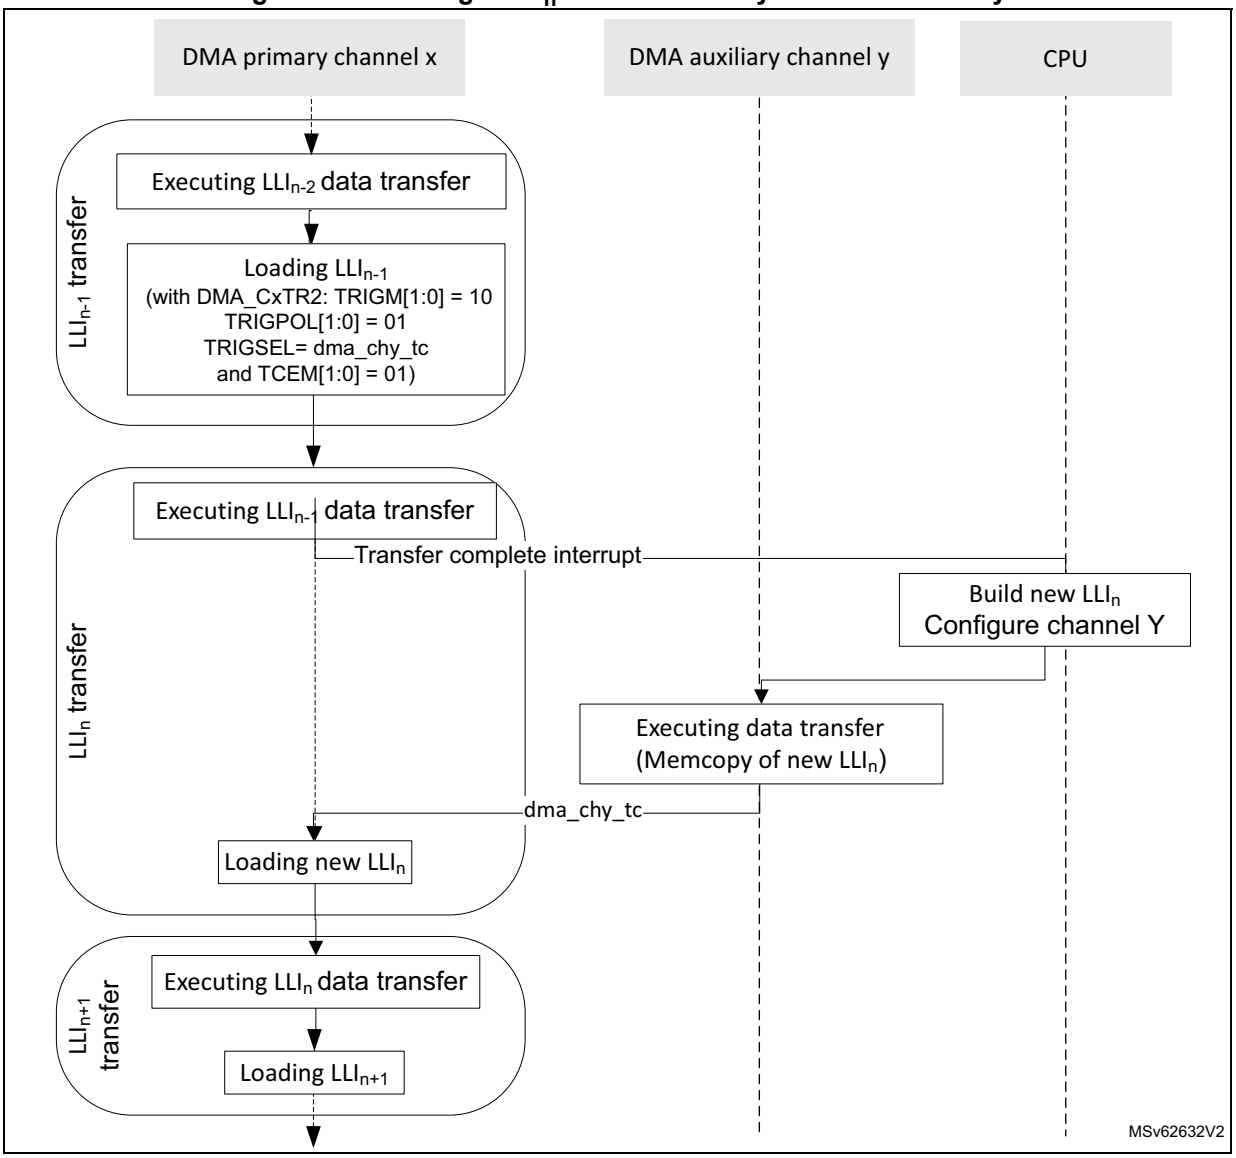
- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 17.3.5* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

The figure below depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 55. Inserting a LLI_n with an auxiliary GPDMA channel y



17.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 12 to 15), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

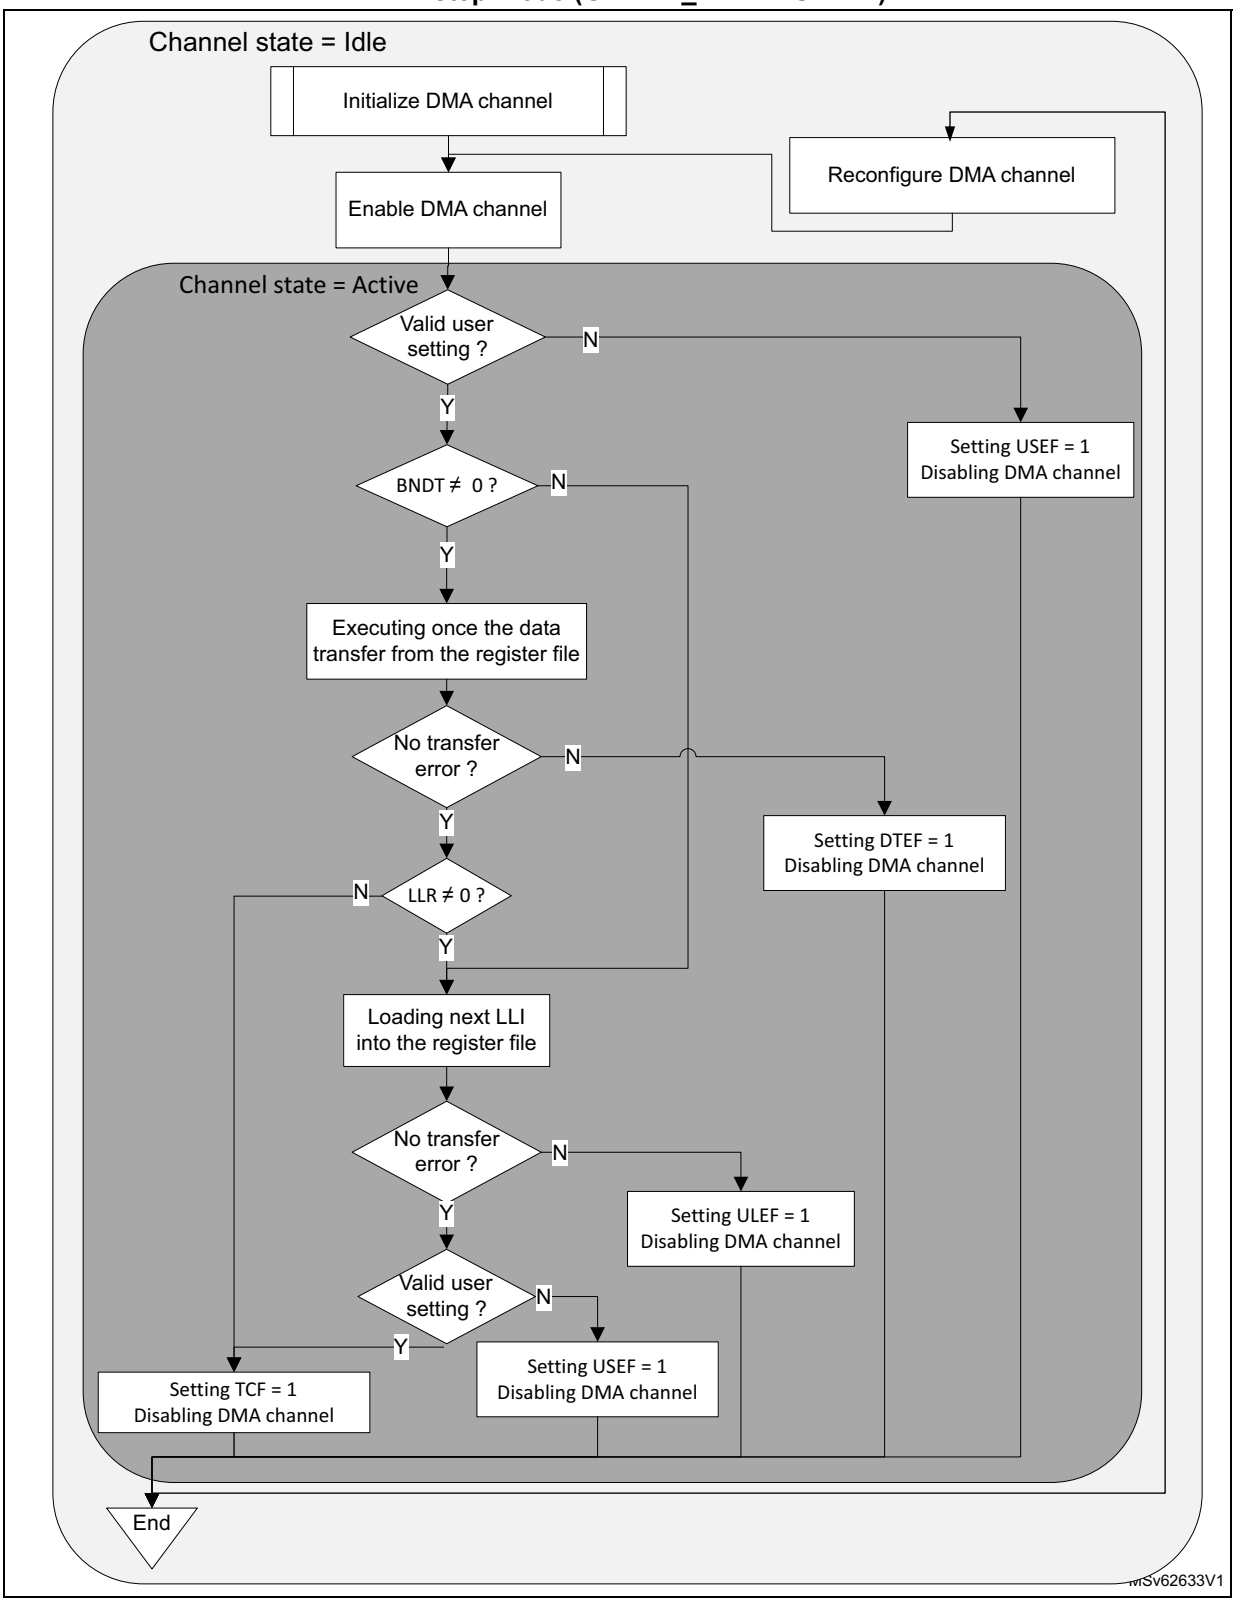
  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 12 to 15) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

The figure below depicts the GPDMA channel execution mode, and its programming in link step mode.

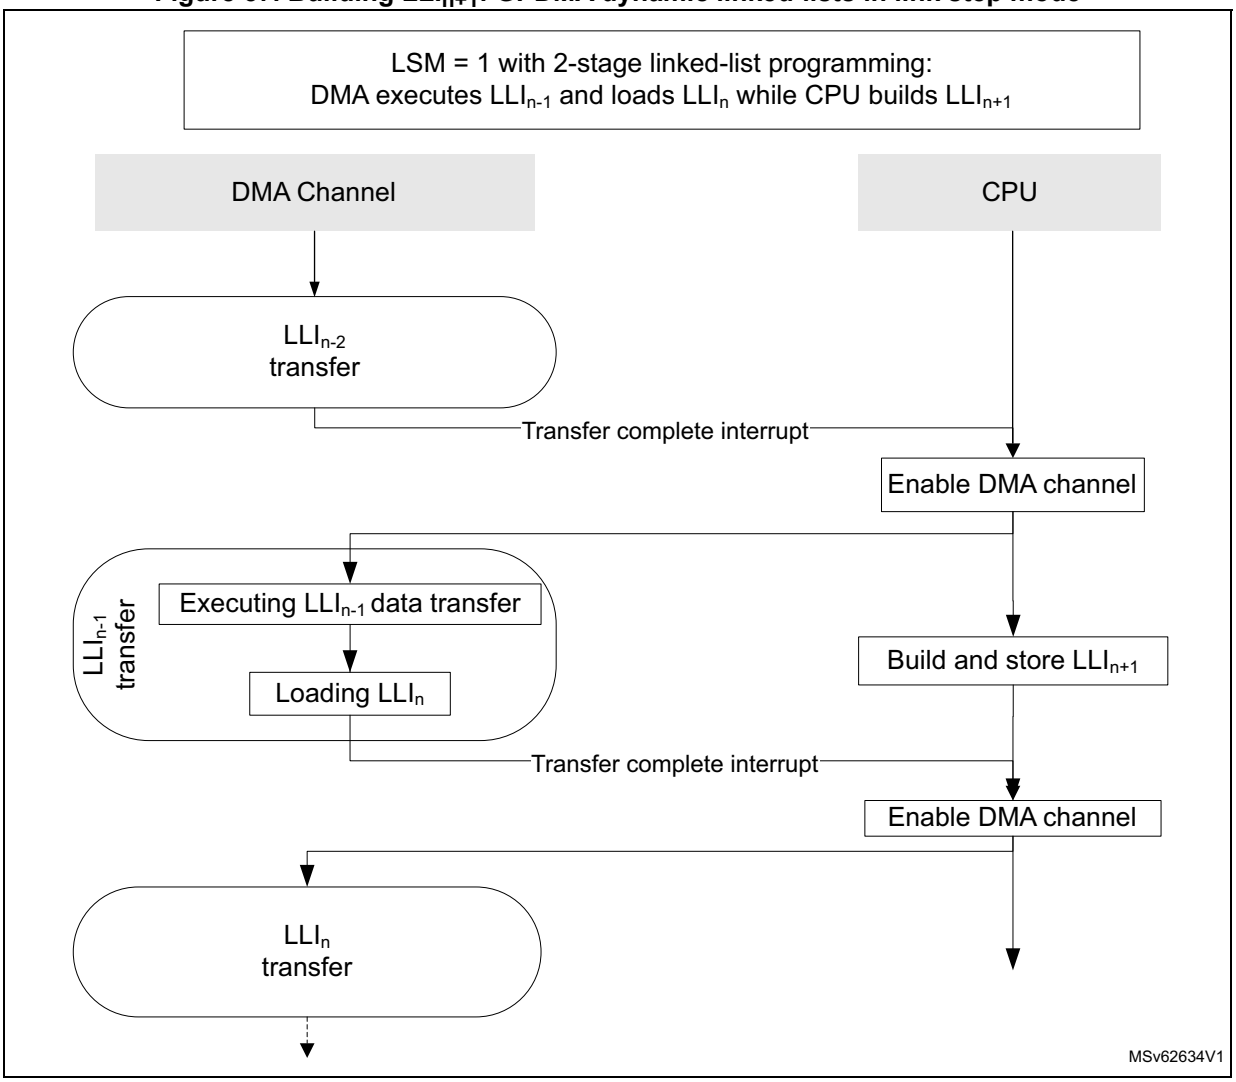
Figure 56. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)



Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

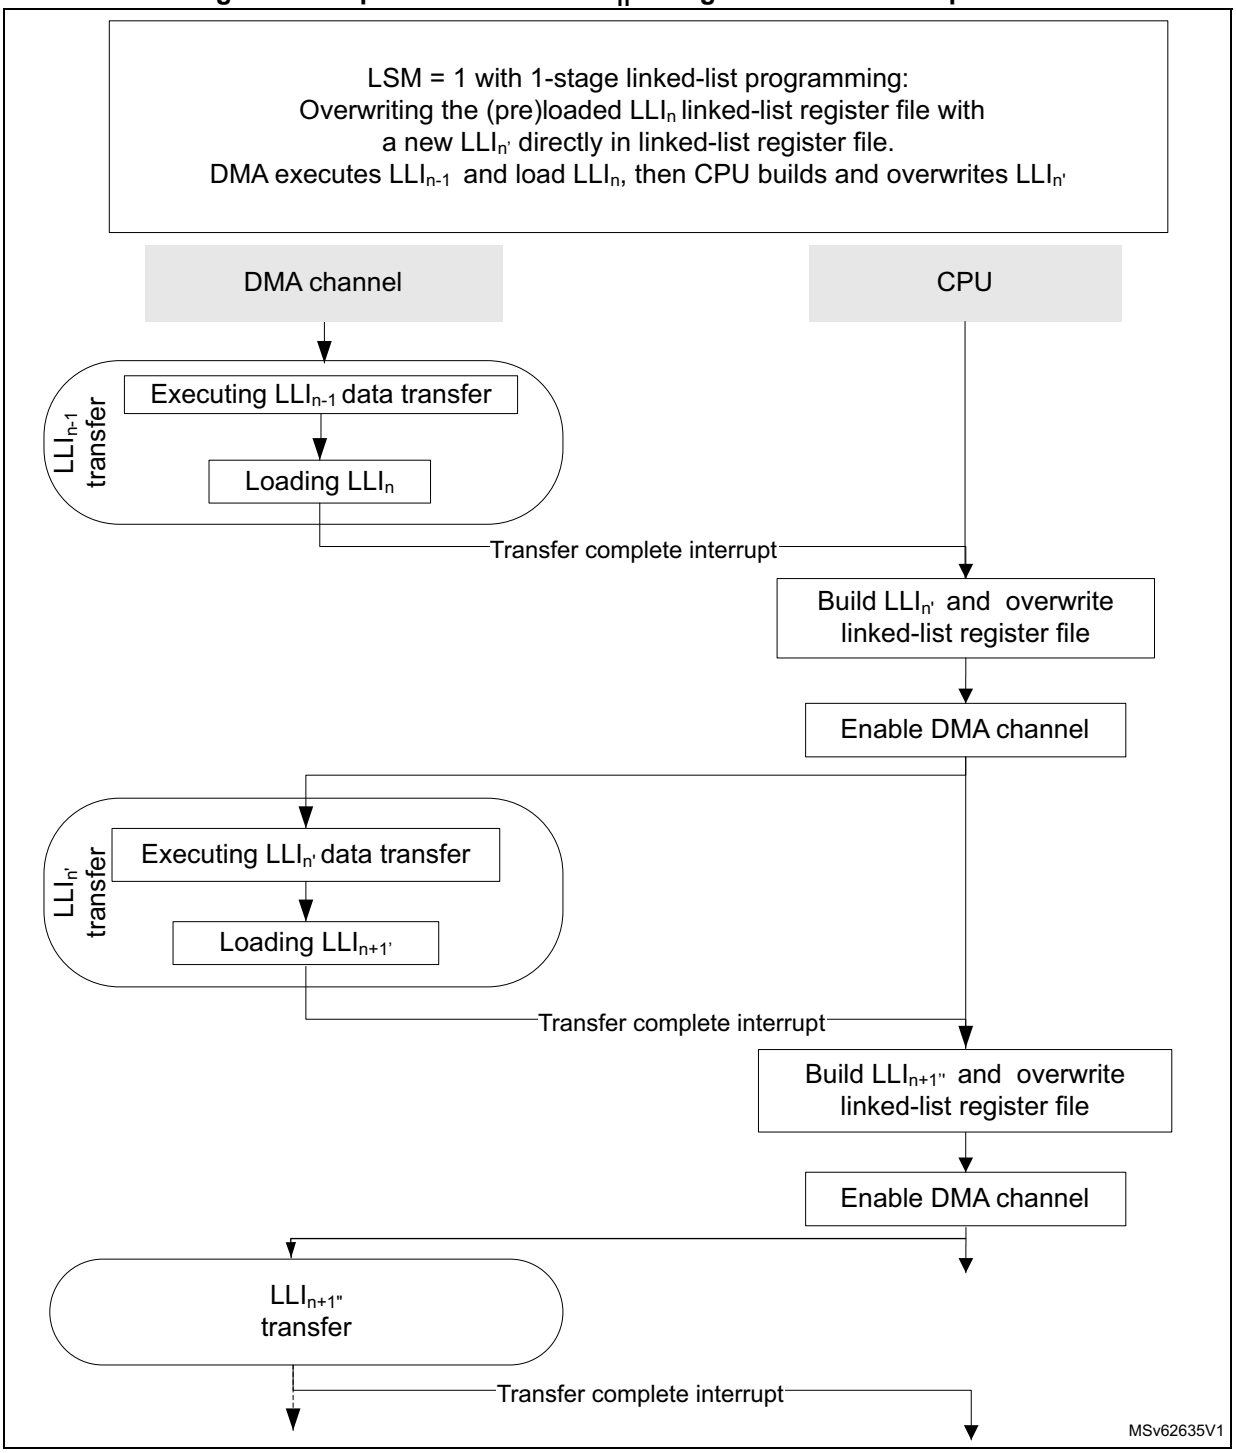
Figure 57. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode



Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in the figure below.

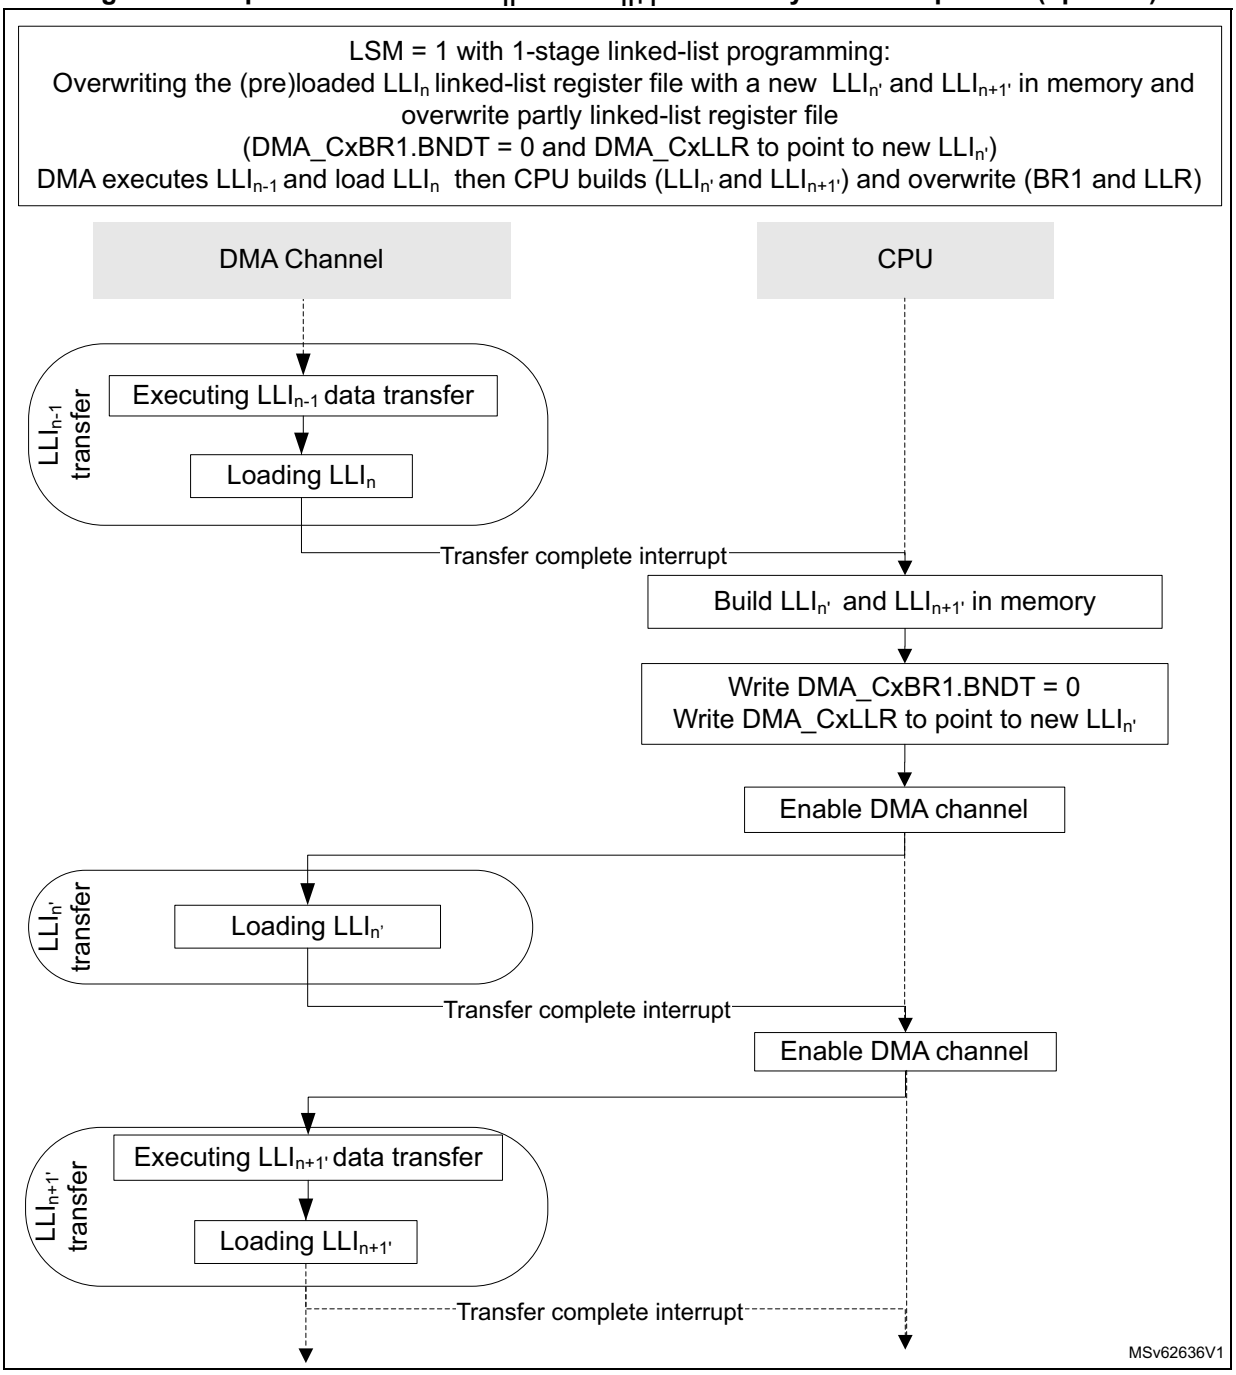
Figure 58. Replace with a new $LLI_{n'}$ in register file in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in the figure below.

Figure 59. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



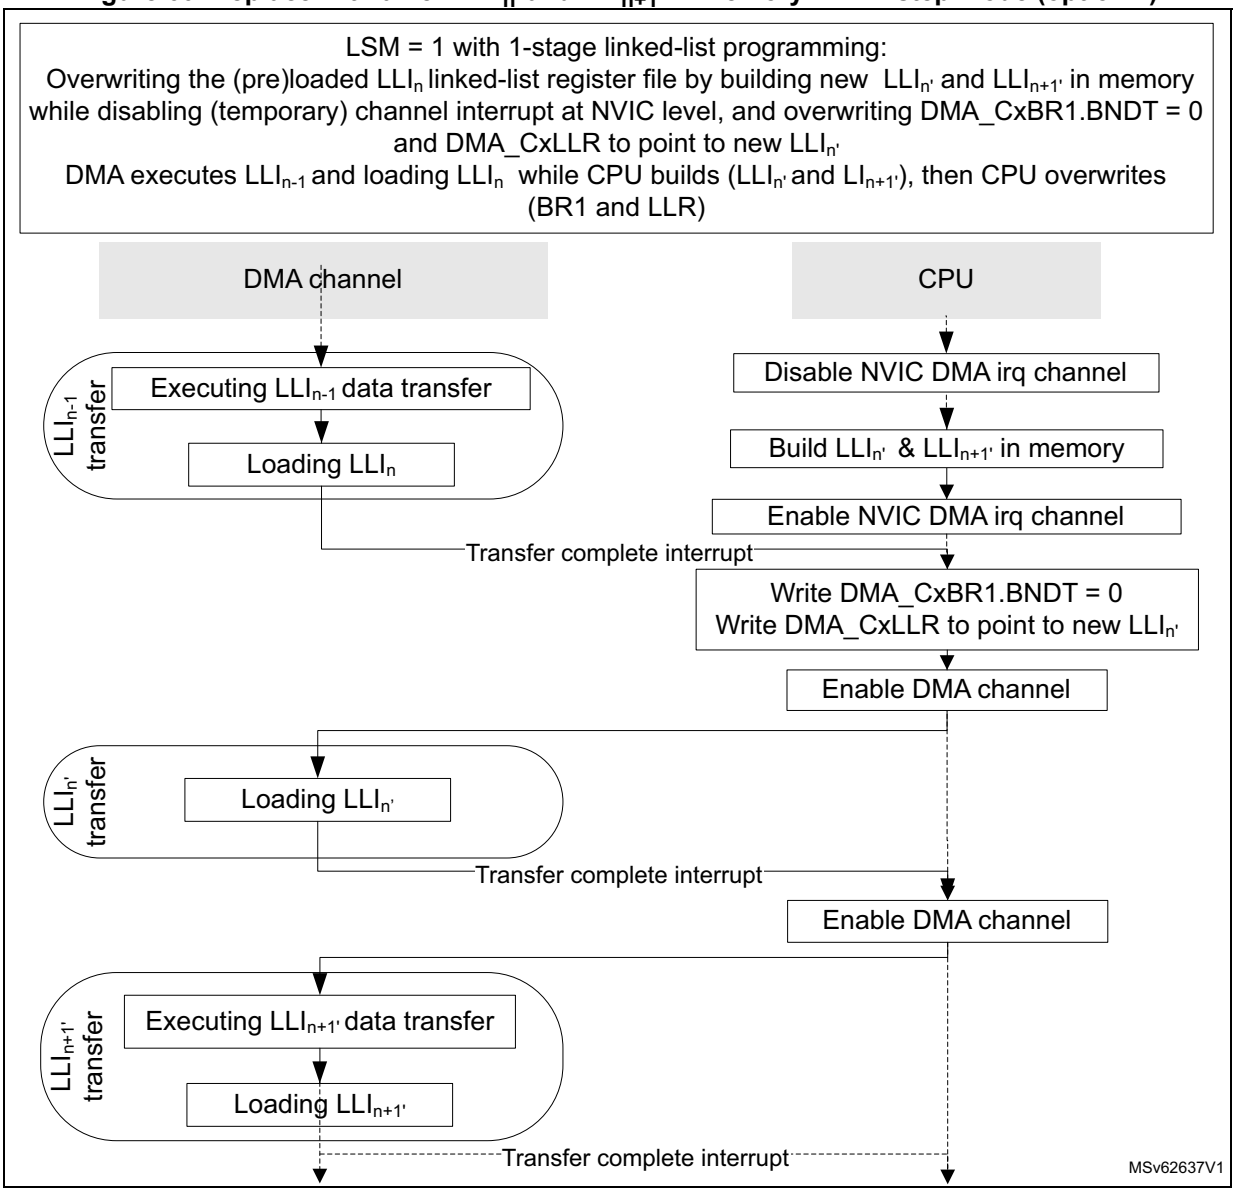
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in the figure below.

Figure 60. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)



17.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

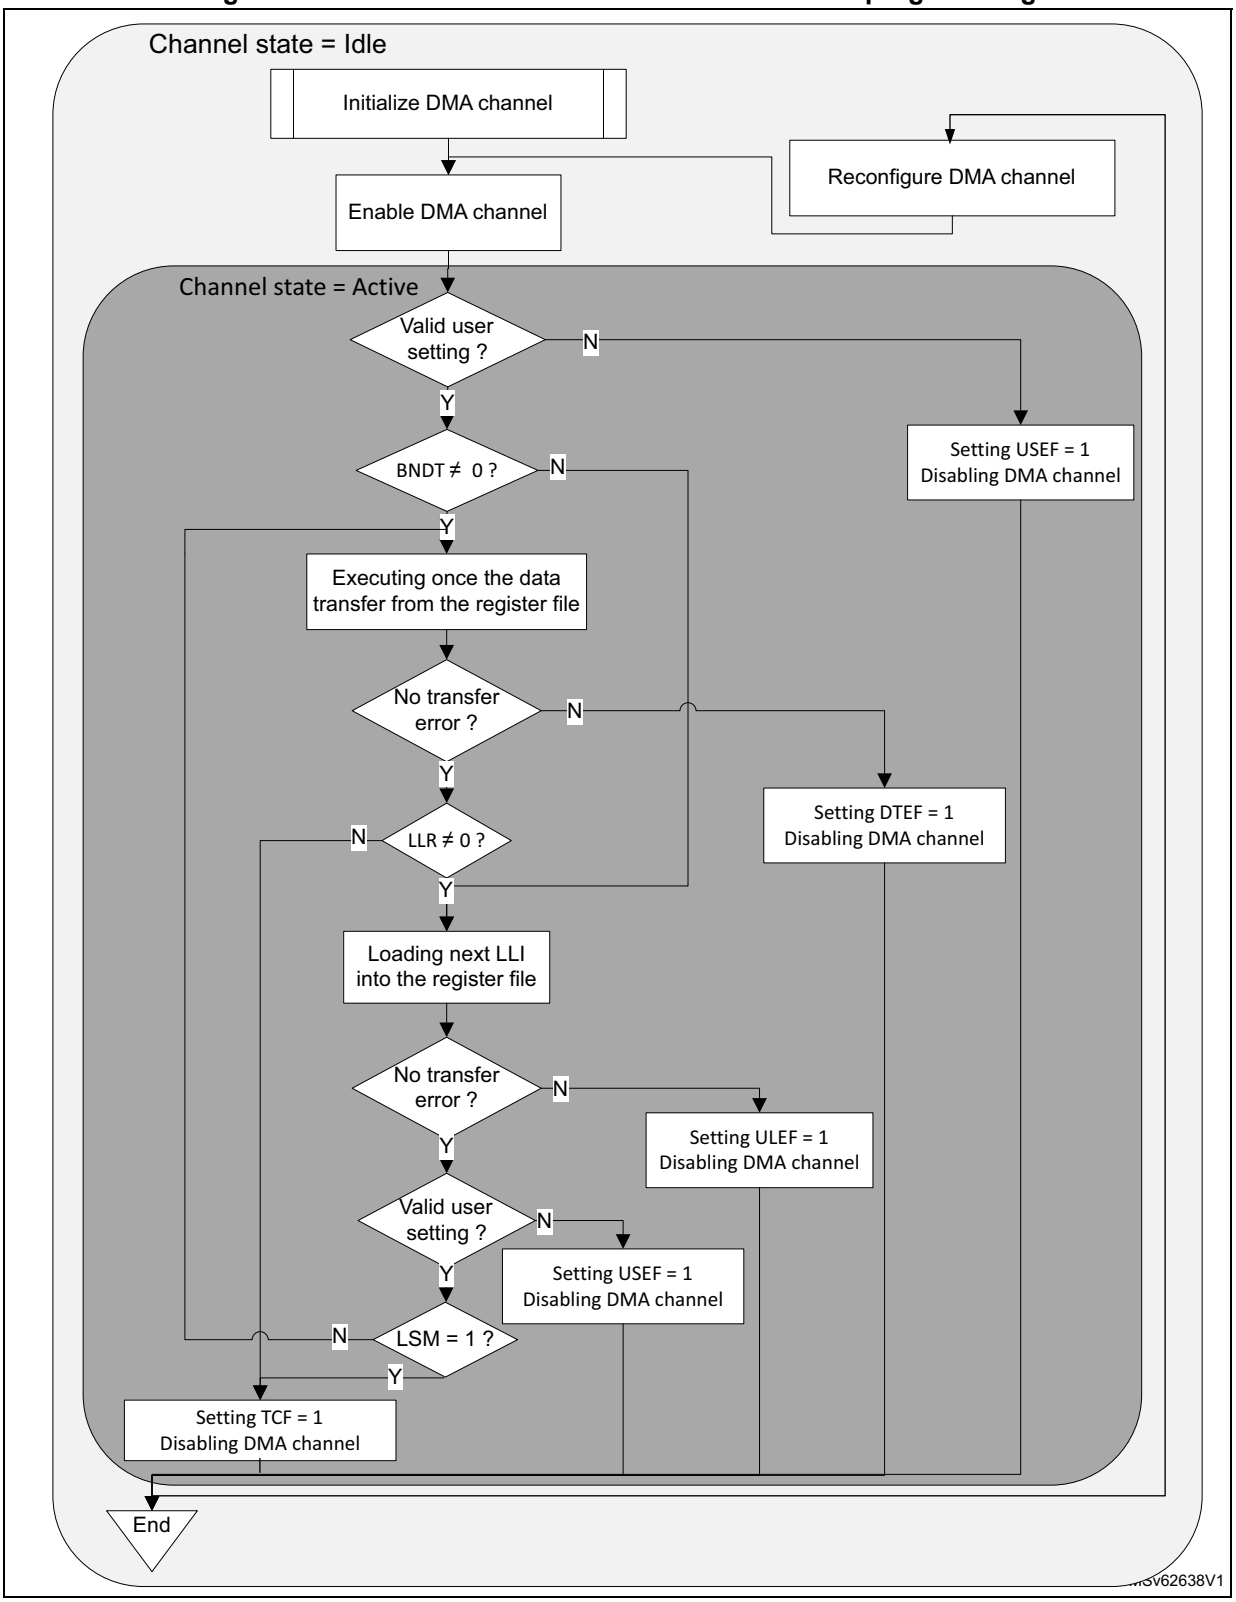
In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 17.4.4*.)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

The figure below shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Figure 61. GPDMA channel execution and linked-list programming



17.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 17.3.1* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a GPDMA burst.

Table 127. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.

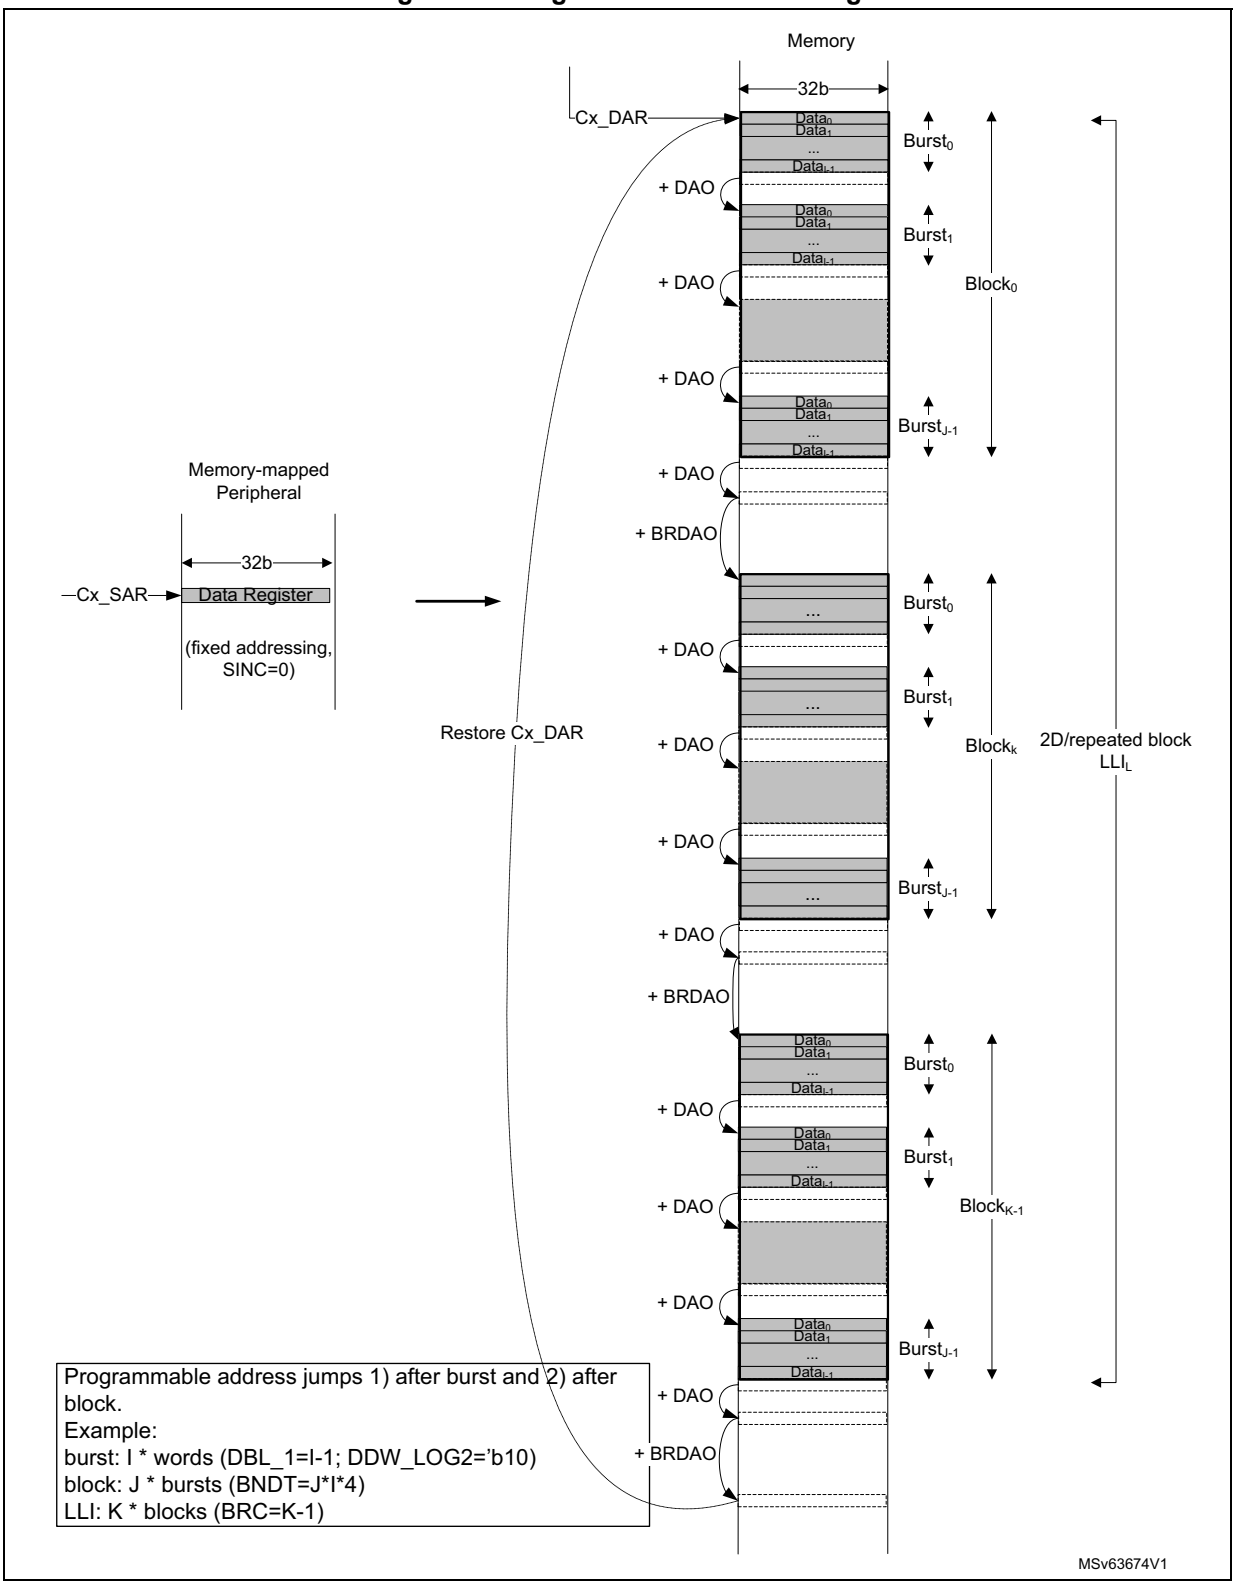
GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by the figure below with a 2D destination buffer.

Figure 62. Programmed 2D addressing



GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma\_fifo\_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW\_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma\_fifo\_size[x]}$ is the half of the FIFO size of the channel x, in bytes (see *Section 17.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW\_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW\_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW\_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[21:0] and DDW_LOG2[1:0] fields (see *Table 128*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 128. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

17.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see *Section 17.3.3*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[6:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 63*, is defined by:

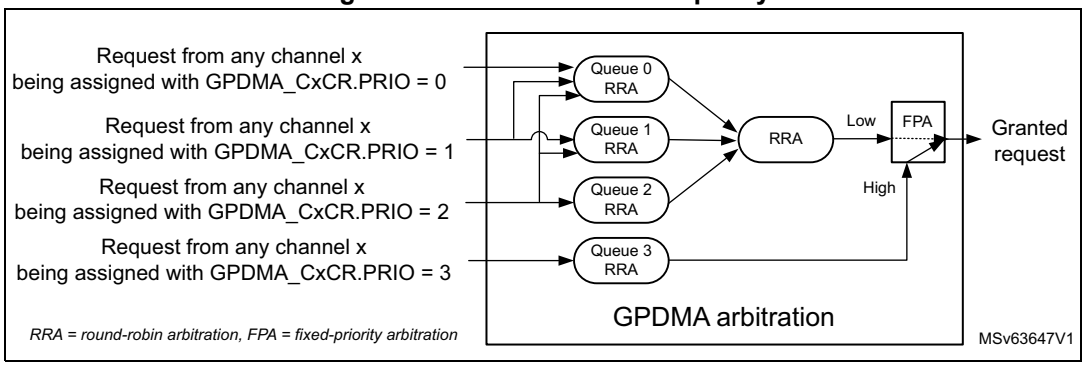
- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

- Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
- Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
- Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 63. GPDMA arbitration policy



GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).

    $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).

    $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$

    $B_{req1} = B_{P1} = (1/2 + 1) * 1/3 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).

    $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$

    $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$

  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

17.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 17.3.5* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 12 to 15), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see the TRIGM[1:0] description in *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

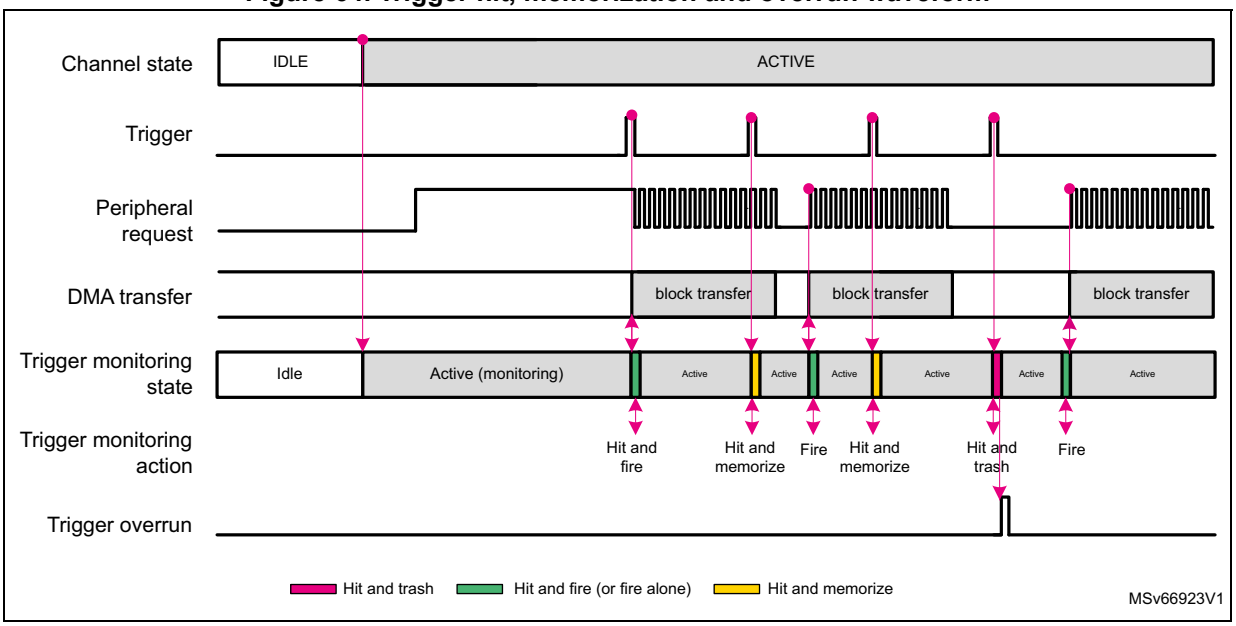
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 64. Trigger hit, memorization and overrun waveform



Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

17.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

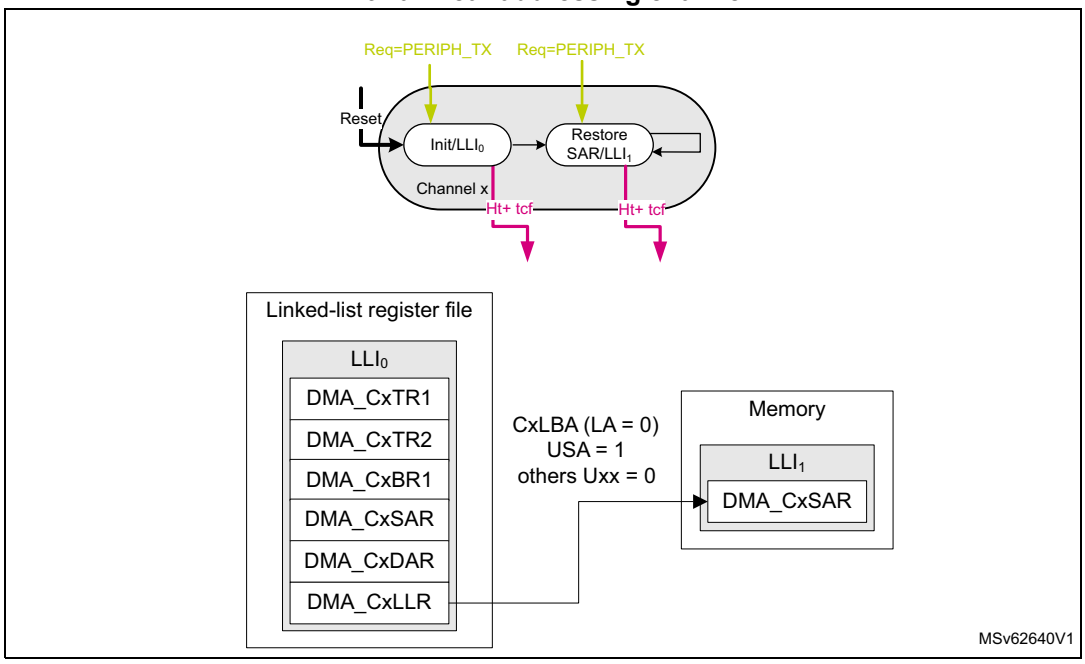
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 65. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel

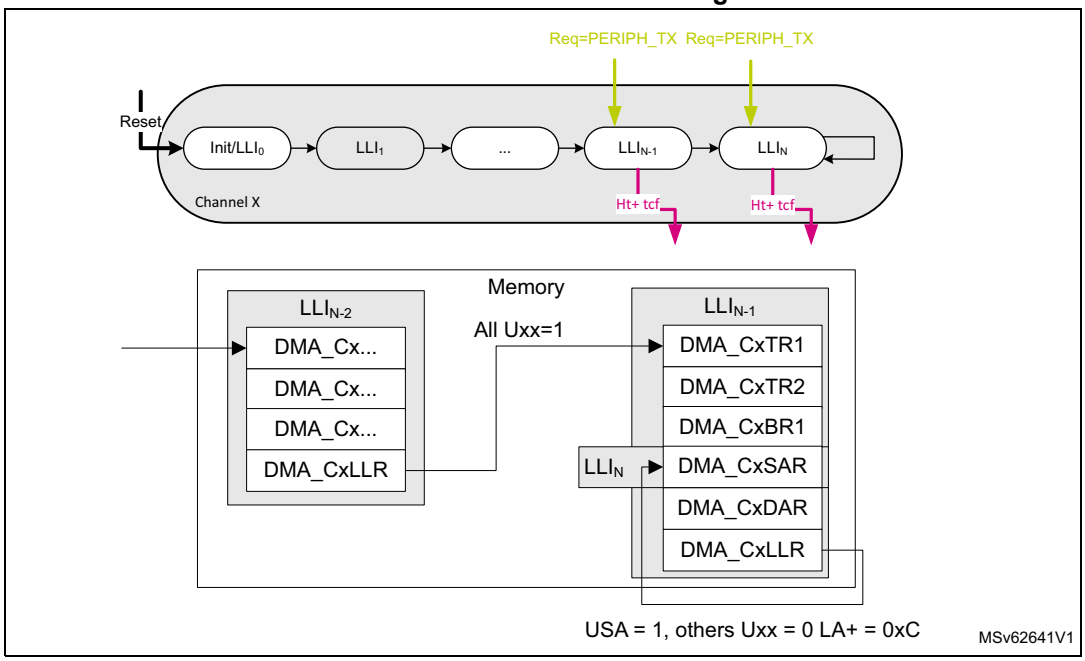


Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

The figure below illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 66. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel



17.4.14 GPDMA secure/non-secure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and non-secure worlds at any given time.

Any channel x is a secure or a non-secure hardware resource, as securely configured by GPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A non-secure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by a non-secure agent.
- A non-secure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or non-secure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/non-secure state of each GPDMA channel x.

The GPDMA also generates a security illegal access pulse signal on an illegal non-secure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a non-secure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next non-secure transfer as a non-secure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the non-secure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

17.4.15 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

17.4.16 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

on a bus access (as a AHB single or a burst) to the source or the destination

- The source or destination target reports an AHB error.

- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

on a tentative update of a GPDMA channel register from the programmed LLI in the memory

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

on a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1]=1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])

- for channel x (x = 12 to 15): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
- for channel x (x = 12 to 15): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
- a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x (x = 12 to 15): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x (x = 12 to 15): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
- a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
- a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

17.4.17 GPDMA autonomous mode

To save dynamic power consumption while the GPDMA executes the programmed linked-list transfers, the GPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run or low-power modes, provided that the RCC is programmed with the corresponding GPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the GPDMA autonomous feature vs the device low-power modes, refer to *Section 17.3.2*.

The user can program and schedule the execution of a given GPDMA transfer at a LLI_n level of a GPDMA channel x, with GPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[5:0], SWREQ and REQSEL[6:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

When used in low-power modes, this functionality enables a CPU wakeup on a specific transfer completion by the enabled GPDMA transfer complete interrupt (GPDMA_CxCR.TCIE = 1) or/and enables to continue with the autonomous GPDMA for operating another LLI_{n+1} transfer over the same channel.

The output channel x transfer complete event, gpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the GPDMA level (see *Section 17.3.5*), allowing autonomous and fine GPDMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given GPDMA channel x asserts its clock request in one of the following conditions:

- if the next transfer to be executed is programmed as conditioned by a trigger (GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if GPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  - if GPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled

The GPDMA channel x releases its clock request as soon as all the following conditions are met:

- The transfer to be executed is completed.
- The GPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the GPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the GPDMA releases its clock request to the RCC.

17.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

17.6 GPDMA in low-power modes

Table 129. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode. The content of the GPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. GPDMA interrupts can cause the device to exit Stop mode(1).
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 17.3.2* to know if any Stop mode is supported.

17.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 130. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 17.4.16*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

17.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

17.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

A write access to this register must be secure. A read access is secure or non-secure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register can mix privileged and unprivileged information. If a channel x is configured as privileged (GPDMA_PRIVCFGR.PRIVx = 1), the SECx bit can be written only by a privileged (and secure) agent.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or non-secure world.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECx**: secure state of channel x (x = 15 to 0)
0: non-secure
1: secure

17.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or non-secure.

This register can mix secure and non-secure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

Bits 15:0 **PRIVx**: privileged state of channel x (x = 15 to 0)
0: unprivileged
1: privileged

17.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock at boot time the secure privileged attributes of any GPDMA

channel/resource (to lock the setting of GPDMA_CxSECCFGR and GPDMA_CxPRIVCFGR for any channel x at boot time).

A read access may be privileged or unprivileged, secure or non-secure.

Note: If TZEN = 0, this register cannot be written.

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: lock the configuration of GPDMA_SECCFGR.SECx and GPDMA_PRIVCFGR.PRIVx, until a global GPDMA reset (x = 15 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

17.8.4 GPDMA non-secure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is a read register.

This is a non-secure register, containing the masked interrupt status bit MISx for each non-secure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full non-secure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and non-secure) channels, other privileged bit fields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: masked interrupt status of channel x (x = 15 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

17.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a non-secure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: masked interrupt status of the secure channel x (x = 15 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

17.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register is either secure or non-secure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

17.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register, secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

17.8.8 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or non-secure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]

	r	r	r	r	r	r	r								r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag

0: no trigger overrun event

1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag

0: no completed suspension event

1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag

0: no user setting error event

1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag

0: no update link transfer error event

1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag

0: no data transfer error event

1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag

0: no half transfer event

1: a half transfer event occurred

A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.

A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0]+1)/2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag

0: no transfer complete event

1: a transfer complete event occurred

A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag

0: channel not in idle state

1: channel in idle state

This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).

This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

17.8.9 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	Res.	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN=0. This bit is read-only when EN=1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 48*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 49*).
0: no channel reset
1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

17.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer non-secure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as non-secure), and the GPDMA transfer to the destination is non-secure.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] =0 , the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer non-secure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx =1 . A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as non-secure), and the GPDMA transfer from the source is non-secure.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word:

0:no byte-based exchange within the unaligned half-word of each source word

1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher that source data width, and the condition PAM_2 is when destination data width is higher than source data width.

Condition: PAM_1

00: source data is transferred as right aligned, padded with 0s up to the destination data width

01: source data is transferred as right aligned, sign extended up to the destination data width

10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: source data is transferred as right aligned, left-truncated down to the destination data width

01: source data is transferred as left-aligned, right-truncated down to the destination data width

Note: 10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] =0 , the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst

0: fixed burst

1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

17.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LGPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1 .

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	Res.	BREQ	DREQ	SWREQ	Res.	Res.	REQSEL[6:0]						
rw	rw			rw	rw	rw			rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (0 to 11), same as 00, channel x (x =12 to 15), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x =12 to 15), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (i.e. directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 17.3.5*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x = 0 to 11, same as 00; channel x (x =12 to 15), at 2D/repeated block level. The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized.memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF =1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ =1 or (SWREQ = 0 and DREQ =0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 17.3.3*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note:

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[6:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **REQSEL[6:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 17.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[6:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

17.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

17.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is

automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.

– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.

- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1]=1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

17.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[21:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

17.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[21:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

17.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

17.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

17.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LA[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer. If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0: no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

17.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer. If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed. GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3* for the register boundary addresses.

18 Low-power direct memory access controller (LPDMA)

18.1 Introduction

The low-power direct memory access (LPDMA) controller is a bus master and system peripheral.

The LPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

18.2 LPDMA main features

- Single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during Sleep and Stop modes
- Transfers arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 4 concurrent LPDMA channels:
  - Intra-channel LPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel LPDMA transfers chaining via programmable LPDMA input triggers connection to LPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive single transfers
  - Programmable LPDMA request and trigger selection
  - Programmable LPDMA half-transfer and transfer-complete events generation

  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the LPDMA linked-list control registers
- Debug:
  - Channel suspend and resume support
  - Channel status reporting and event flags
- TrustZone support
  - Support for secure and non-secure LPDMA transfers, independently at a first channel level, and independently at a source/destination and link sub-levels
  - Secure and non-secure interrupts reporting, resulting from any of the respectively secure and non-secure channels
  - TrustZone-aware AHB slave port, protecting any LPDMA secure resource (register, register field) from a non-secure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged LPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

18.3 LPDMA implementation

18.3.1 LPDMA channels

A given LPDMA channel x is implemented with the hardware parameters as per the table below.

Table 132.LPDMA1 channels implementation

Channel x	Hardware parameters		Features
	dma_fifo_ size[x]	dma_ addressing[x]	
x = 0 to 3	0	0	Channel x (x = 0 to 3) is implemented with: – no FIFO. Only a single source transfer cell is internally registered. – fixed/contiguously incremented addressing

18.3.2 LPDMA autonomous mode in low-power modes

The LPDMA autonomous mode and wakeup feature is implemented in the device low-power modes as per the table below.

Table 133. LPDMA1 autonomous mode and wakeup in low-power modes

Feature	Low-power modes
Autonomous mode and wakeup	LPDMA1 in Sleep, Stop 0, Stop 1and Stop 2 modes

18.3.3 LPDMA requests

A LPDMA request from a peripheral can be assigned to a LPDMA channel x, via the REQSEL[4:0] field in the *LPDMA channel x transfer register 2 (LPDMA_CxTR2)*, provided that SWREQ = 0.

The LPDMA requests mapping is specified in the table below.

Table 134. Programmed LPDMA1 request

LPDMA_CxTR2.REQSEL[4:0]	Selected LPDMA request
0	lpuart1_rx_dma
1	lpuart1_tx_dma
2	spi3_rx_dma
3	spi3_tx_dma
4	i2c3_rx_dma
5	i2c3_tx_dma
6	i2c3_evc_dma
7	adc4_dma
8	dac1_ch1_dma
9	dac1_ch2_dma
10	adf1_flt0_dma

12	lptim1_ic2_dma
13	lptim1_ue_dma
14	lptim3_ic1_dma
15	lptim3_ic2_dma
16	lptim3_ue_dma

18.3.4 LPDMA block requests

Some LPDMA requests must be programmed as a block request, and not as a single request. Then the BREQ bit in *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* must be set for a correct LPDMA execution of the requested peripheral transfer at the hardware level.

The LPDMA block requests are listed in the table below.

Table 135. Programmed LPDMA1 request as a block request

LPDMA block requests
lptim1_ue_dma
lptim3_ue_dma

18.3.5 LPDMA triggers

A LPDMA trigger can be assigned to a LPDMA channel x, via the TRIGSEL[4:0] field in the *LPDMA channel x transfer register 2 (LPDMA_CxTR2)*, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The LPDMA triggers mapping is specified in the table below.

Table 136.Programmed LPDMA1 trigger

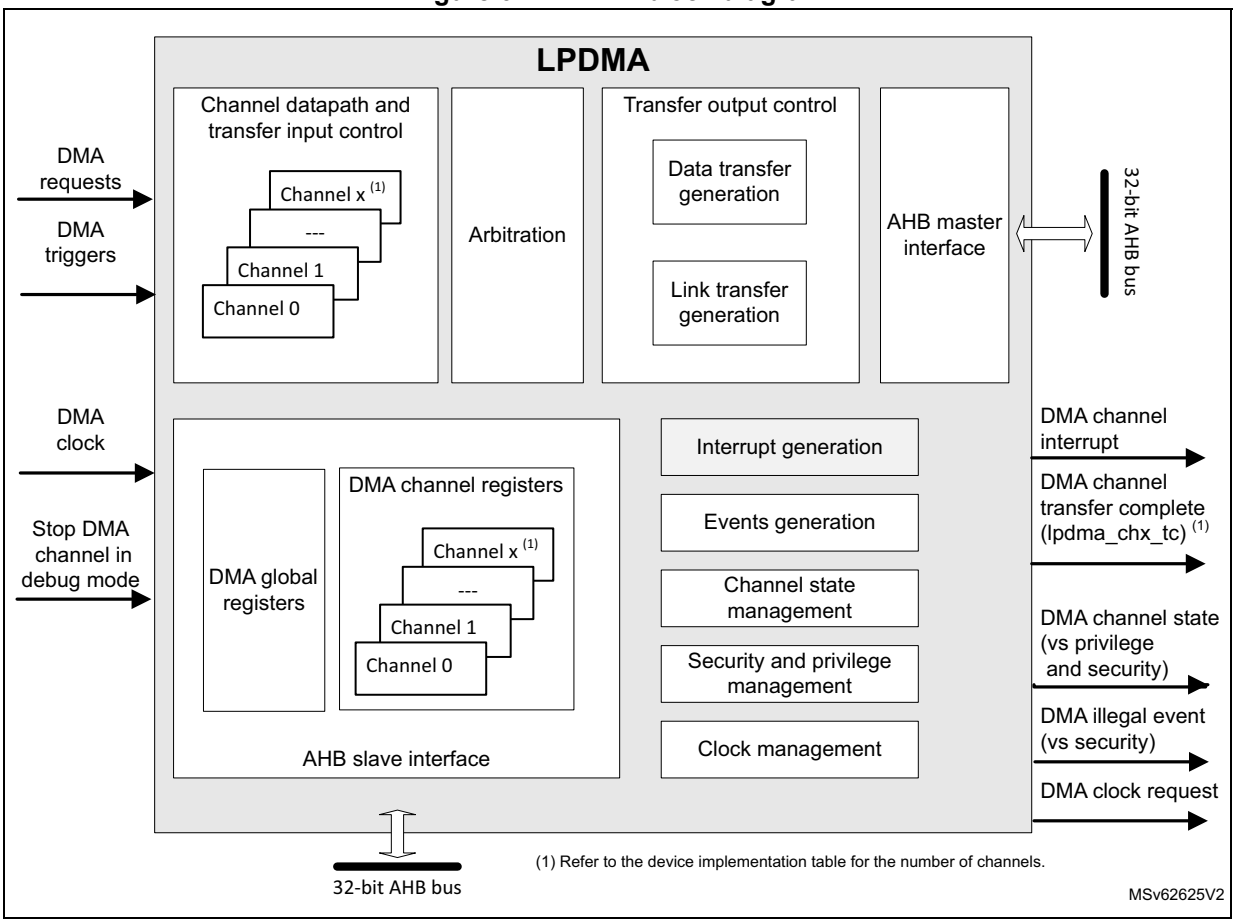
18.4 LPDMA functional description

18.4.1 LPDMA block diagram

The LPDMA block diagram is illustrated in the figure below.

Figure 67. LPDMA block diagram



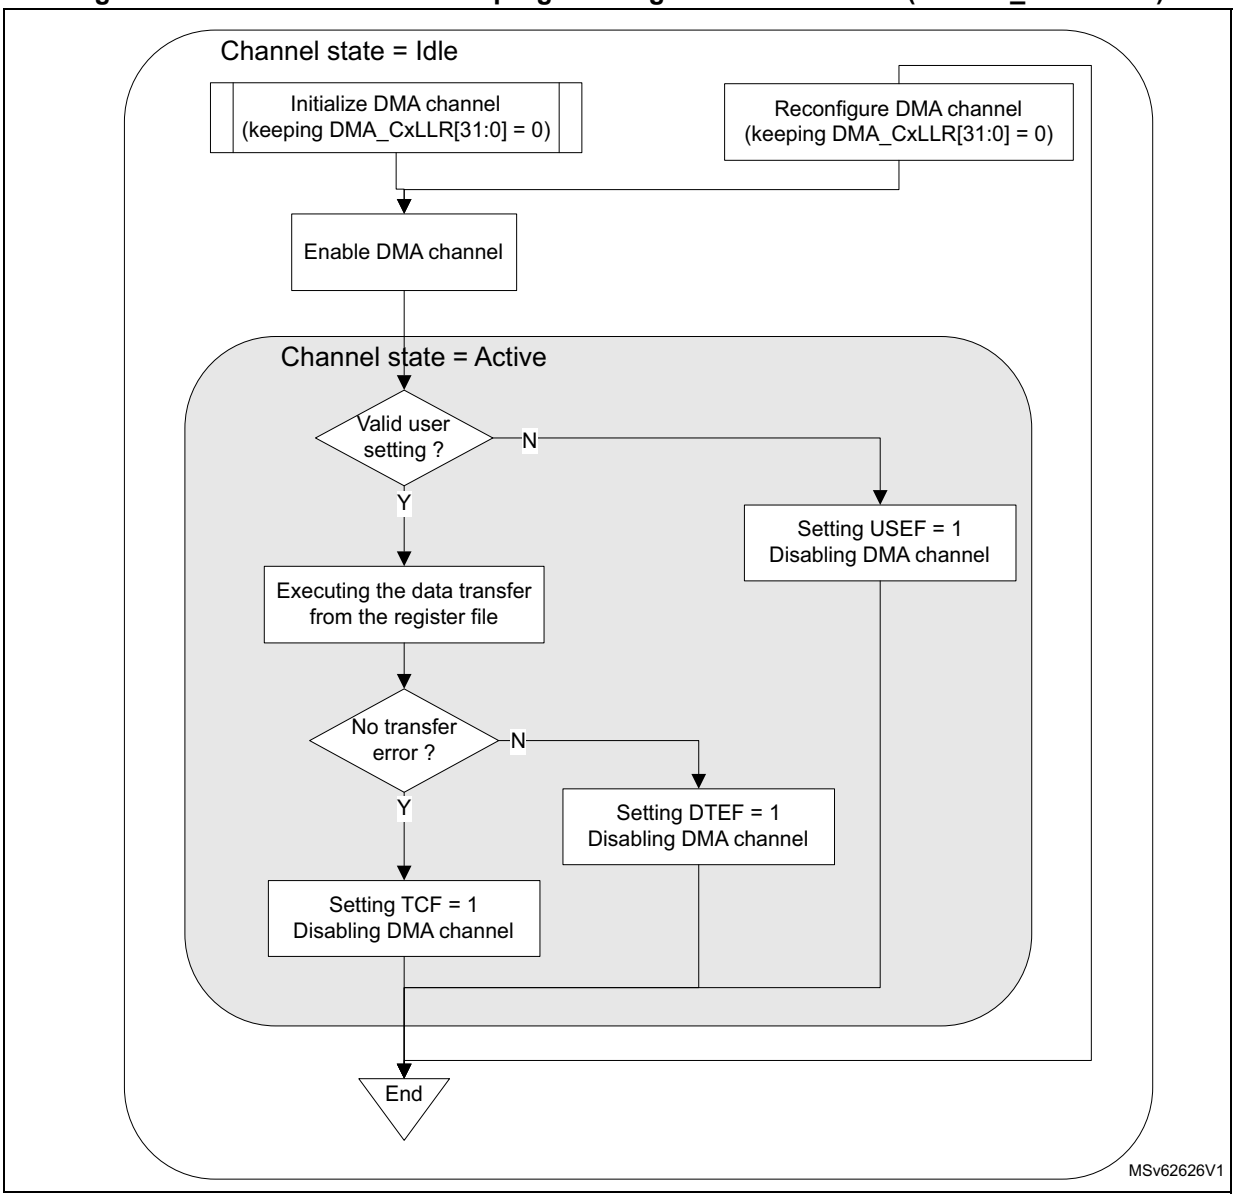
18.4.2 LPDMA channel state and direct programming without any linked-list

After a LPDMA reset, a LPDMA channel x is in idle state. When the software writes 1 into the in LPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (LPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a LPDMA channel transfer by writing 1 into the LPDMA_CxCR.EN bit, a LPDMA channel interrupt on a complete transfer notifies the software that the LPDMA channel is back in idle state (EN is then de-asserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this LPDMA direct programming without any linked-list (LPDMA_CxLLR = 0).

Figure 68. LPDMA channel direct programming without linked-list (LPDMA_CxLLR = 0)



18.4.3 LPDMA channel suspend and resume

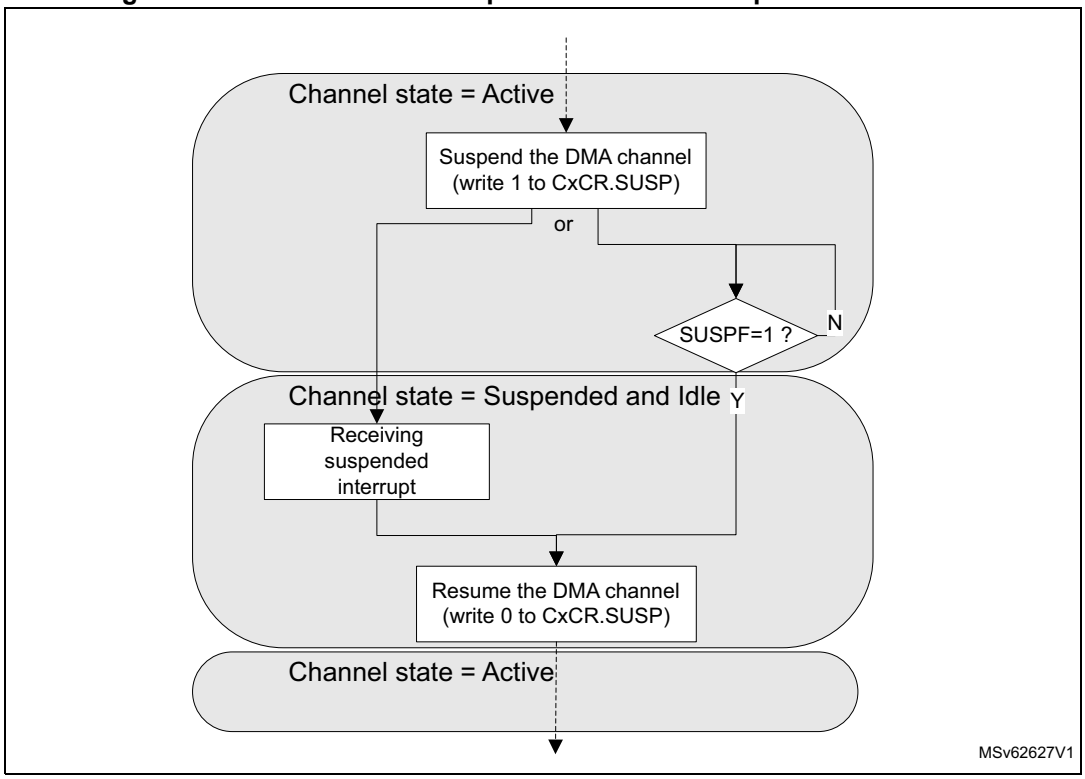
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

   Note that an ongoing LPDMA transfer can be a data transfer (a read-followed-by-write single transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.
3. The software safely resumes the suspended channel by writing 0 to LPDMA_CxCR.SUSP.

The suspend and resume sequence is illustrated in the figure below.

Figure 69. LPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the LPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

18.4.4 LPDMA channel abort and restart

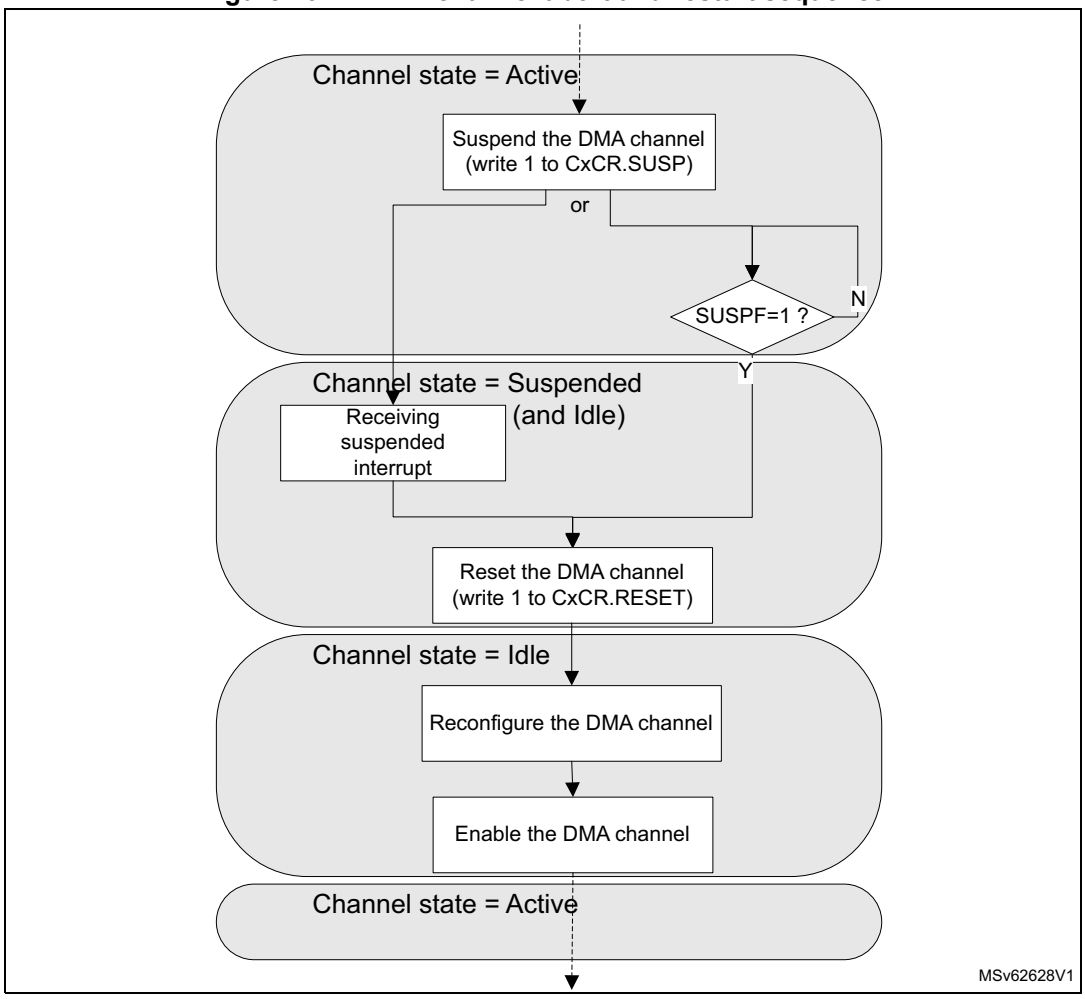
Alternatively, like for aborting a continuous LPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.

2. The software polls suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port.
3. The software resets the channel by writing 1 to LPDMA_CxCR.RESET. This causes the reset of the channel internal state, the reset of the LPDMA_CxCR.EN bit, and the reset of the LPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified LPDMA_CxBR1, LPDMA_CxSAR, and LPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the LPDMA_CxCR.EN bit.

The abort and restart sequence is illustrated in the figure below.

Figure 70. LPDMA channel abort and restart sequence



18.4.5 LPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in LPDMA_CxLBAR)
- the link address offset (LA[15:2] field in LPDMA_CxLLR)

The data structure for each LLI may be specific.

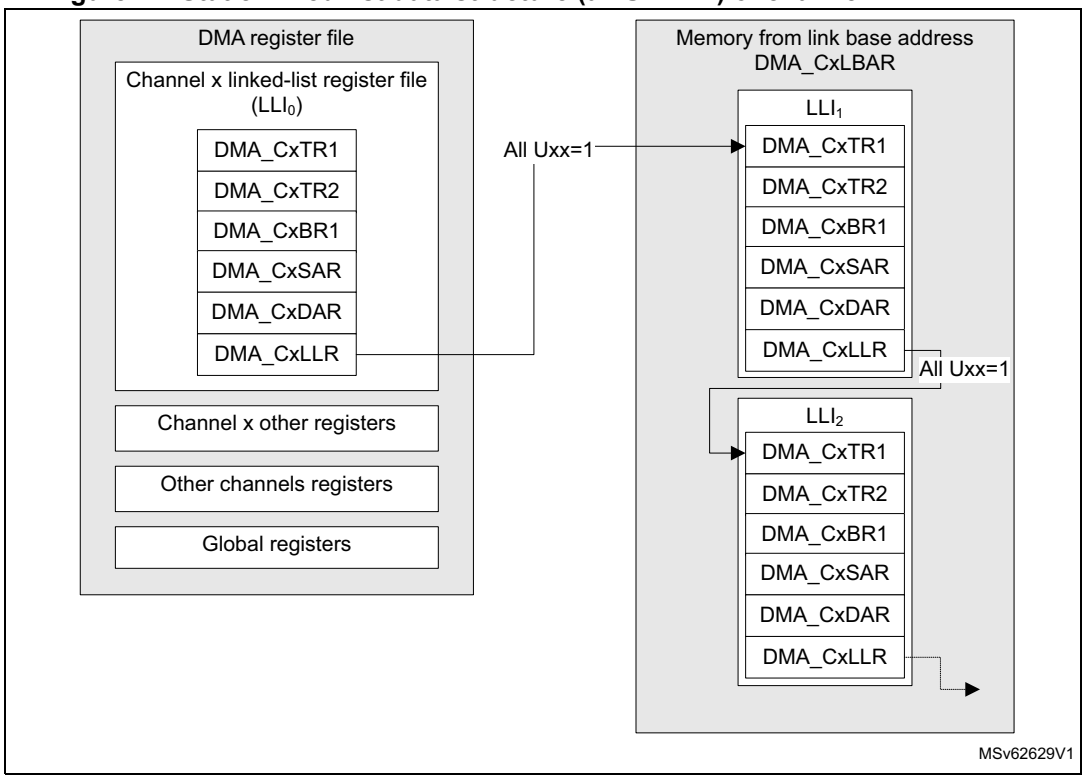
A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits of the LPDMA_CxLLR register.

In linked-list mode, each LPDMA linked-list register (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR or LPDMA_CxLLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the LPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL) of the LPDMA_CxLLR register are all asserted, the linked-list data structure in memory is maximal with six contiguous 32-bit locations, including LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR (see the figure below) and including the first linked-list register file (LLI_0) and the next LLIs (LLI_1, LLI_2,...) in the memory.

Figure 71. Static linked-list data structure (all Uxx = 1) of channel x



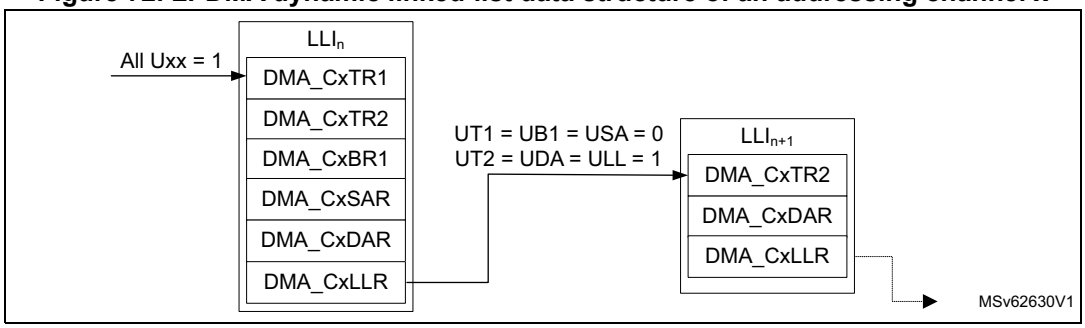
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register LPDMA_CxLLR is pointing to the updated value of the LPDMA_CxTR2 instead of the LPDMA_CxTR1 which is not to be modified.

Example: if UT1 = UB1 = USA = 0, and if UT2 = UDA = ULL = 1, the next LLI does not contain an updated value for LPDMA_CxTR1, nor LPDMA_CxBR1, nor LPDMA_CxSAR. The next LLI contains an updated value for LPDMA_CxTR2, LPDMA_CxDAR, and LPDMA_CxLLR, as shown in the figure below.

Figure 72. LPDMA dynamic linked-list data structure of an addressing channel x



The user must program LPDMA_CxLLR for each LLI_n to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by LPDMA_CxLBAR.

18.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: LPDMA executes the data transfer as described by the LPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: LPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the LPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (LPDMA_CxBR1.BNDT[15:0] = 0) provided that the conditional update bit UB1 in LPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended LPDMA usage, a LPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, LPDMA_CxCR.LSM = 0) or a LPDMA channel x can be programmed for a single execution of a LLI (link step mode, LPDMA_CxCR.LSM = 1), as described in the next paragraphs.

18.4.7 LPDMA channel state and linked-list programming in run-to-completion mode

When LPDMA_CxCR.LSM = 0, a LPDMA channel x is initially programmed, started by writing 1 to LPDMA_CxCR.EN, and after (possibly) completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the LPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when LPDMA_CxLLR[31:0] = 0 and LPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

LPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits LPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits Uxx of LPDMA_CxLLR are null (UT1, UT2, UB1, USA, UDA, ULL).

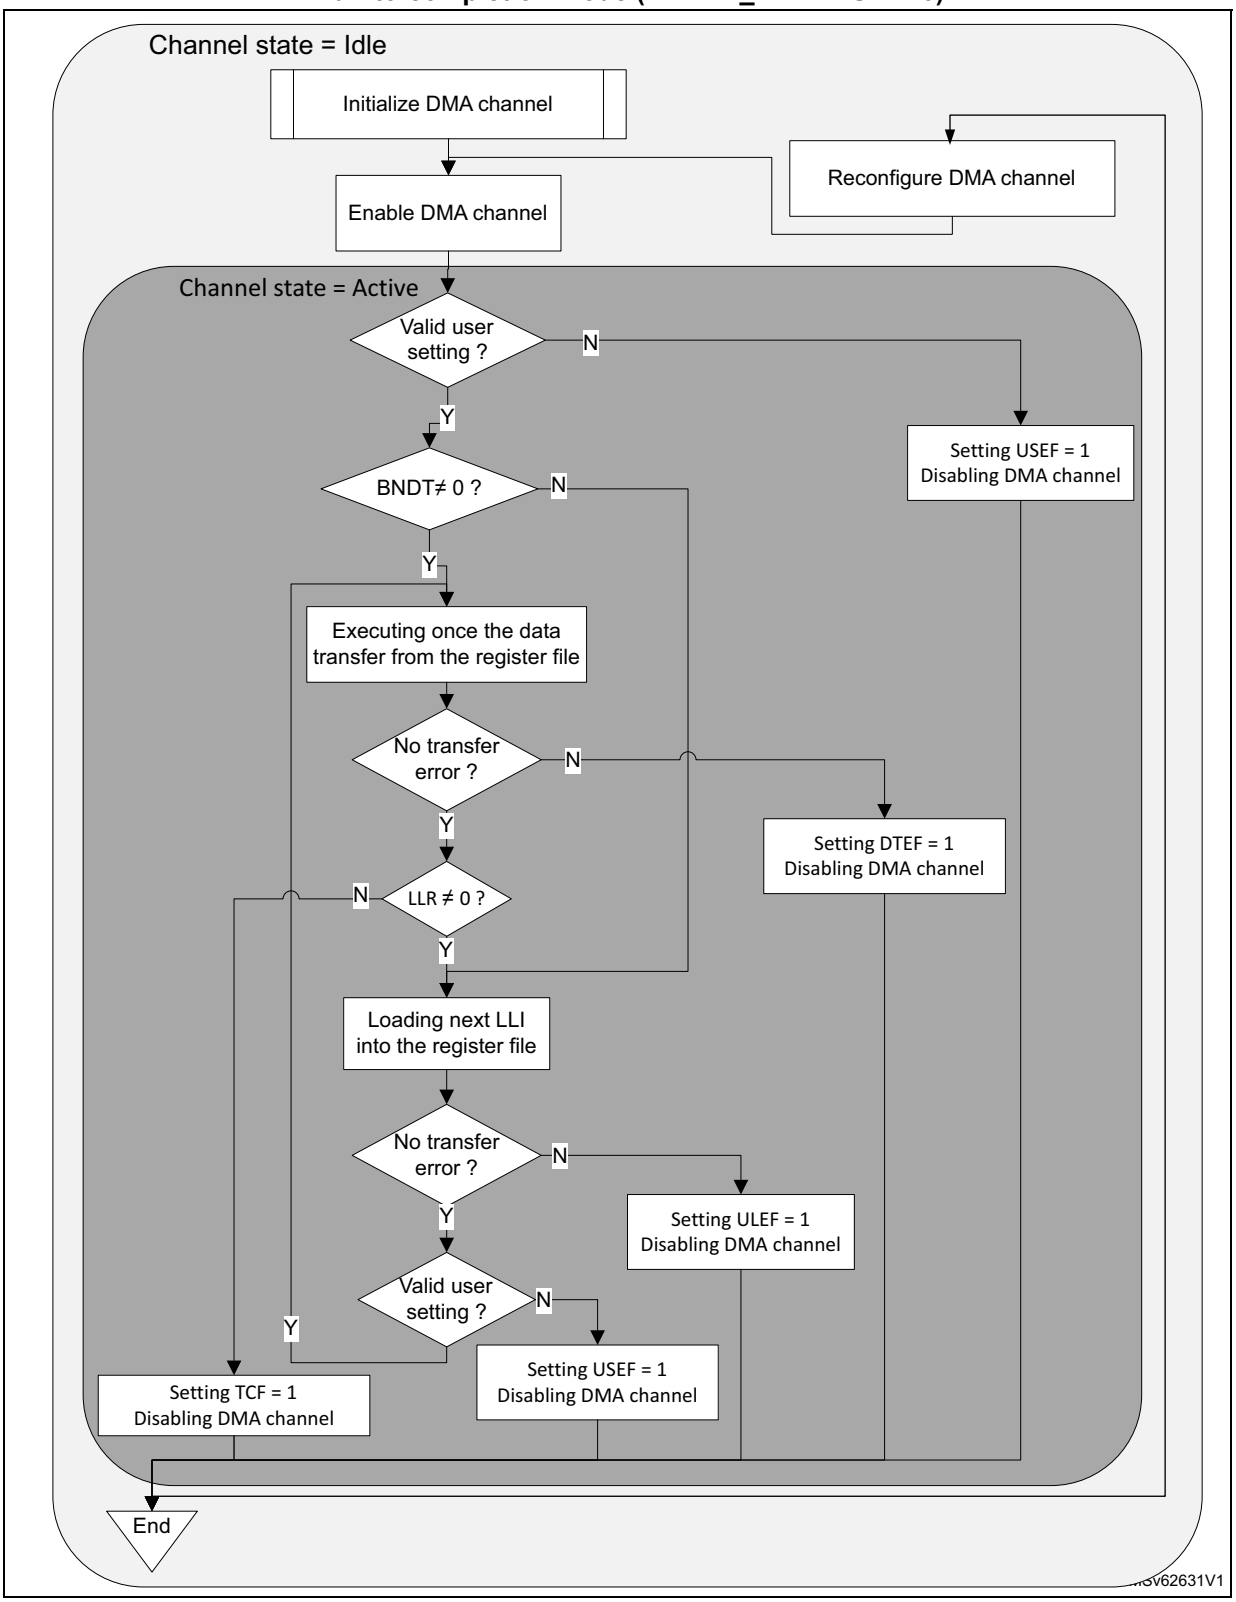
The channel may never be completed when LPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated by the same value
  - or LPDMA_CxLLR.ULL = 0
- if LLI_N is pointing to a previous LLI.

In the typical run-to-completion mode, the allocation of a LPDMA channel, including its fine programming, is done once during the LPDMA initialization. In order to have a reserved data communication link and LPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 73 depicts the LPDMA channel execution and its registers programming in run-to-completion mode.

Figure 73. LPDMA channel execution and linked-list programming in run-to-completion mode (LPDMA_CxCR.LSM = 0)



Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the LPDMA_CxTR2 in the data structure of the LLI_{n-1}:

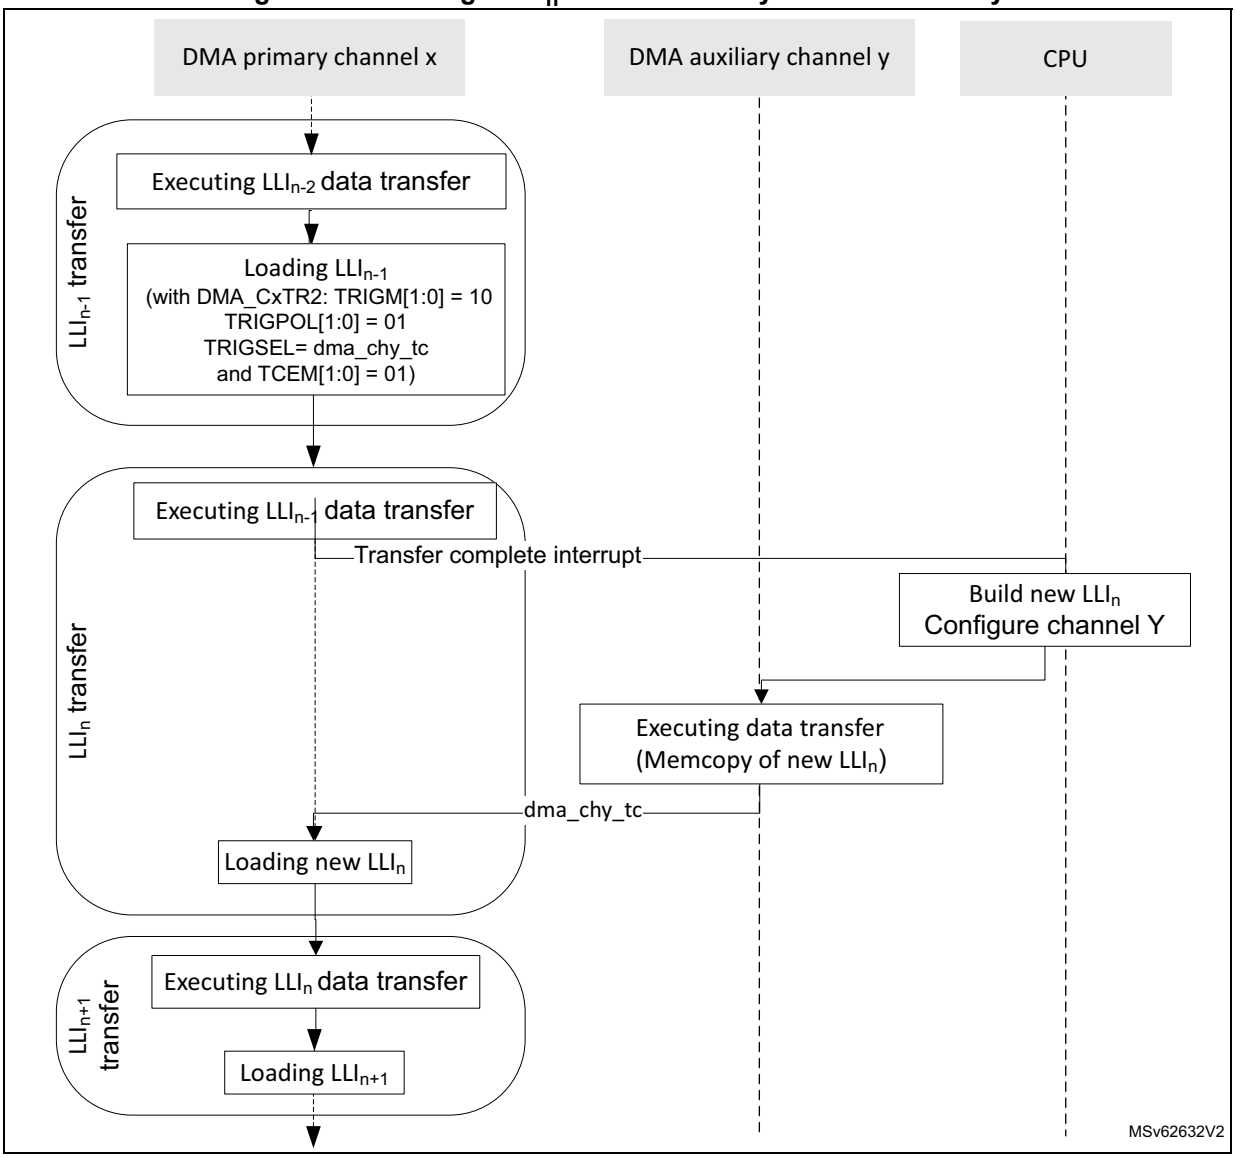
- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[4:0] (see *Section 18.3.5* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event lpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 74 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 74. Inserting a LLI_n with an auxiliary LPDMA channel y



18.4.8 LPDMA channel state and linked-list programming in link step mode

When LPDMA_CxCR.LSM = 1, a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

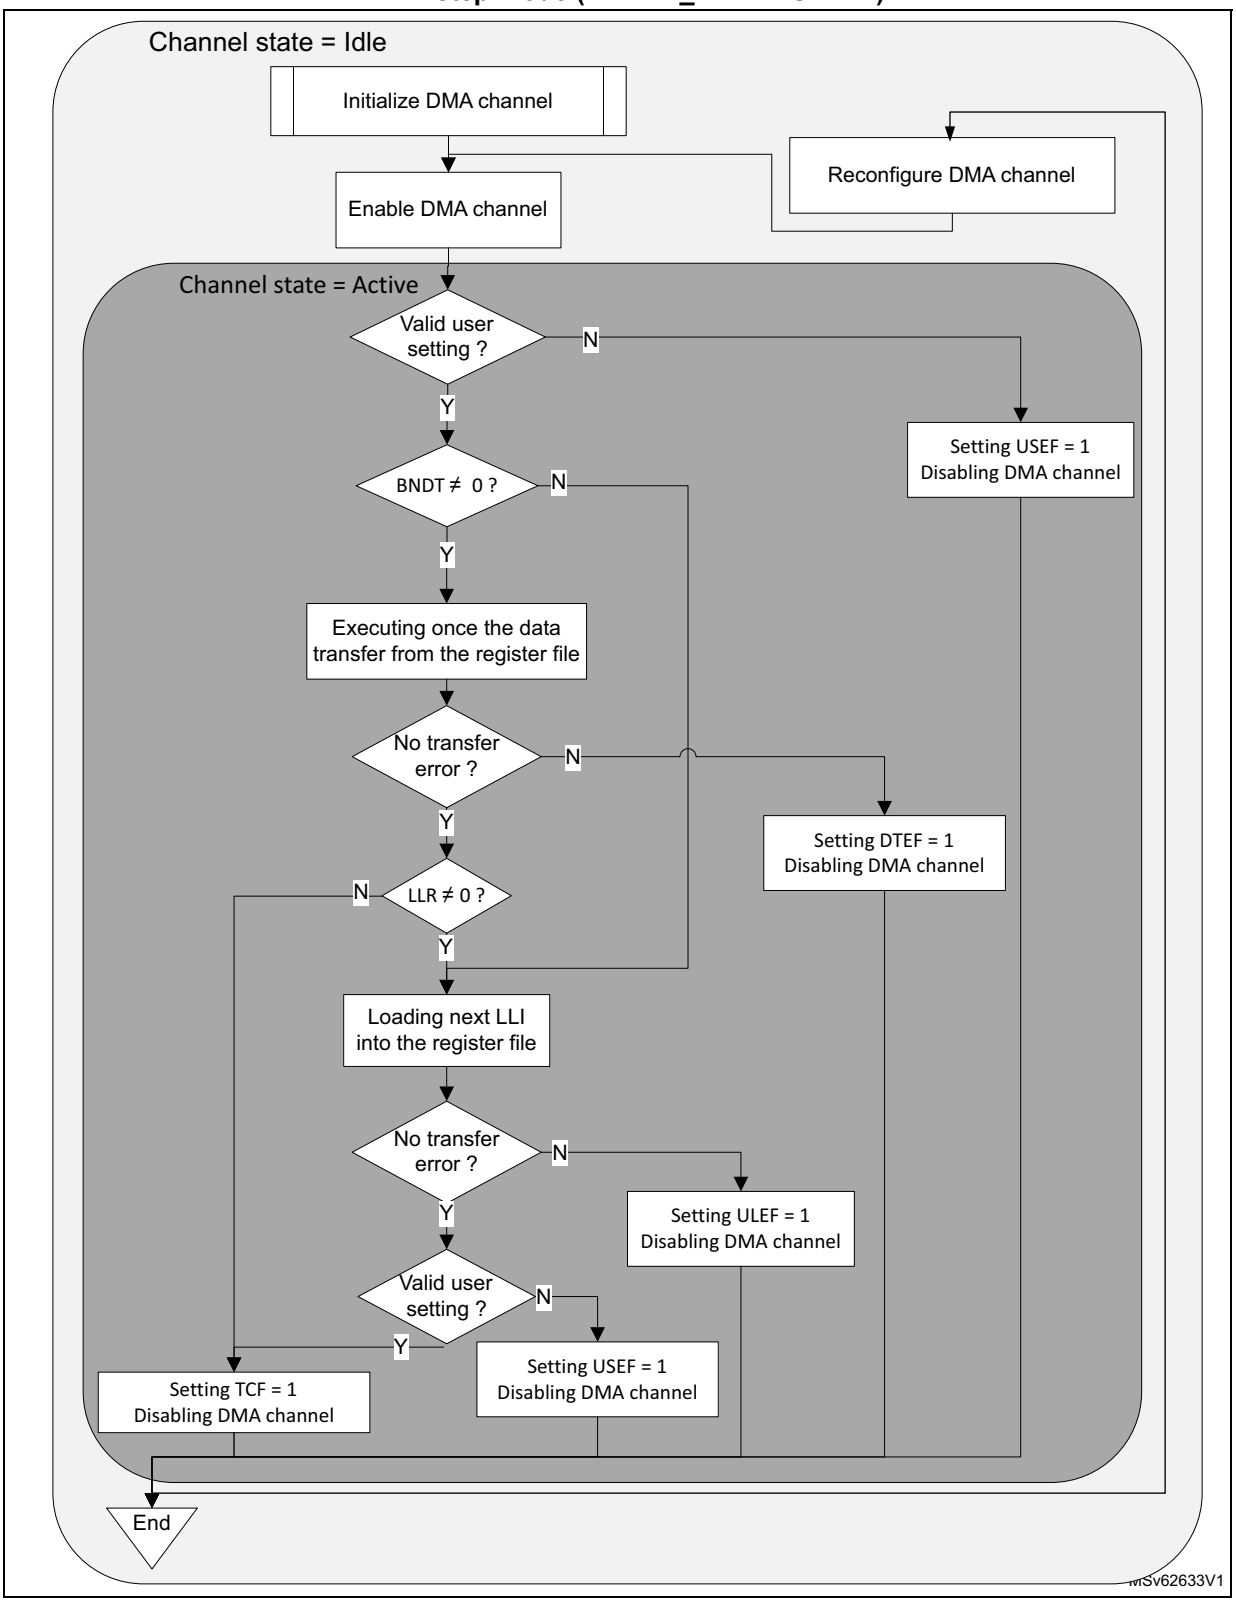
A LPDMA channel transfer can be programmed at LLI level, started by writing 1 into LPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - LPDMA_CxTR1 defines the source/destination elementary single transfers.
  - LPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]).
  - LPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - LPDMA_CxSAR/LPDMA_CxDAR defines the source/destination transfer start address.
  - LPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when LPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the LPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated by the same value, or LPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

Figure 75 depicts the LPDMA channel execution mode, and its programming in link step mode.

Figure 75. LPDMA channel execution and linked-list programming in link step mode (LPDMA_CxCR.LSM = 1)

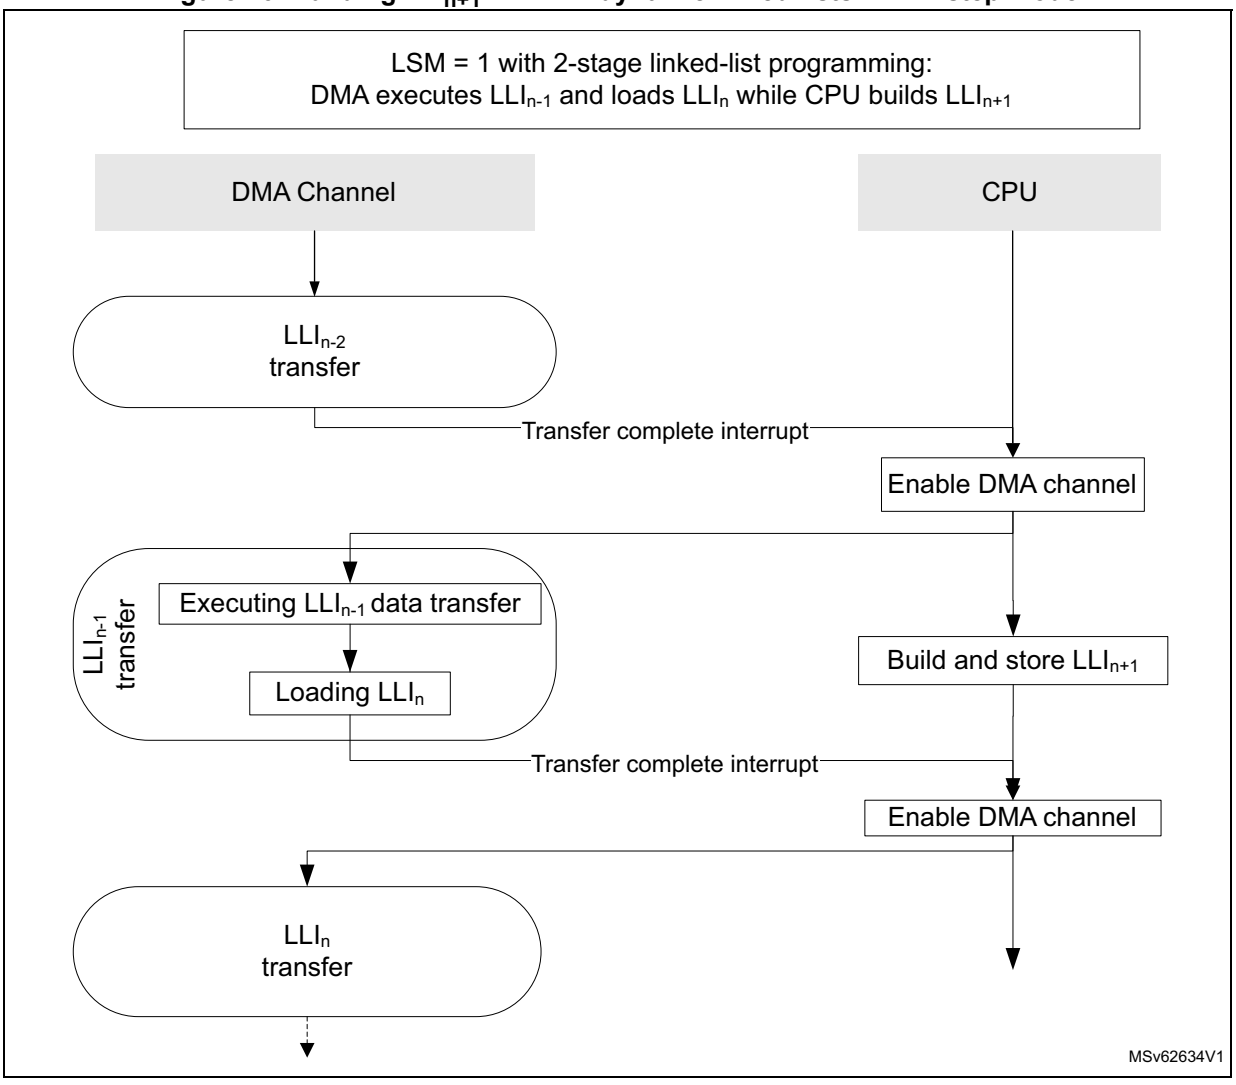


The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of LPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after LPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

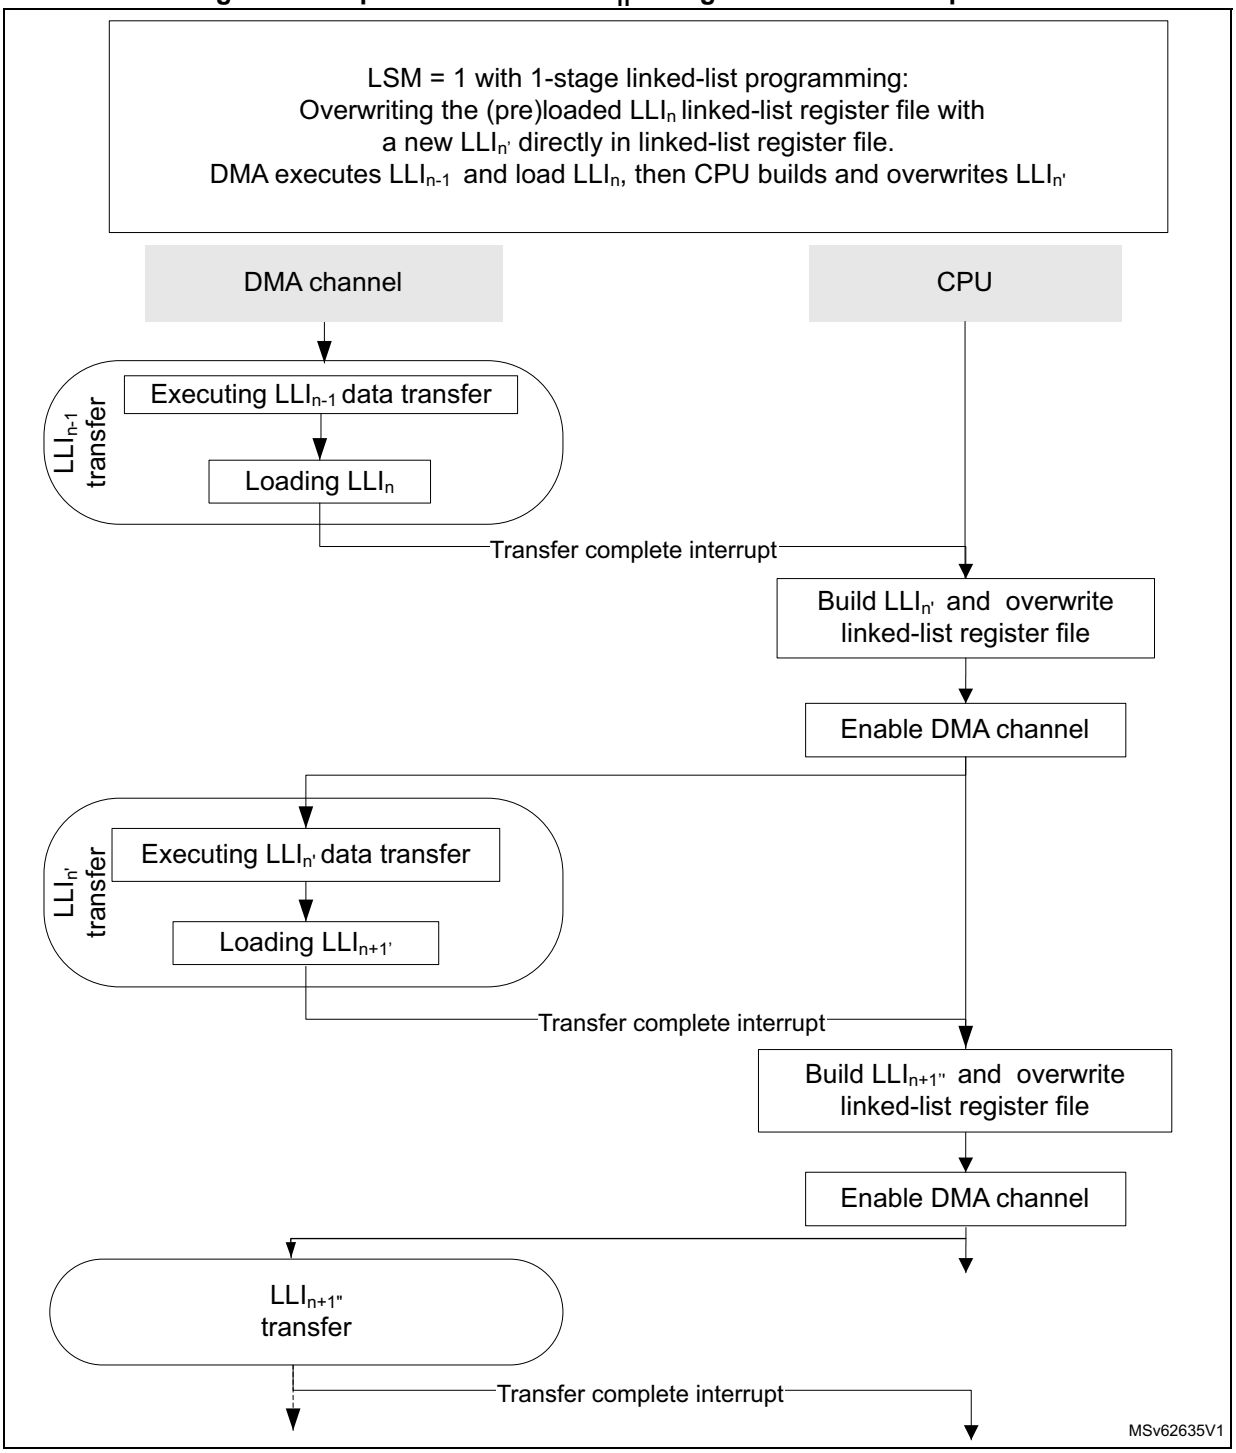
Figure 76. Building LLI_{n+1}: LPDMA dynamic linked-lists in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new $LLI_{n'}$, after LPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new $LLI_{n'}$, as shown in *Figure 77*.

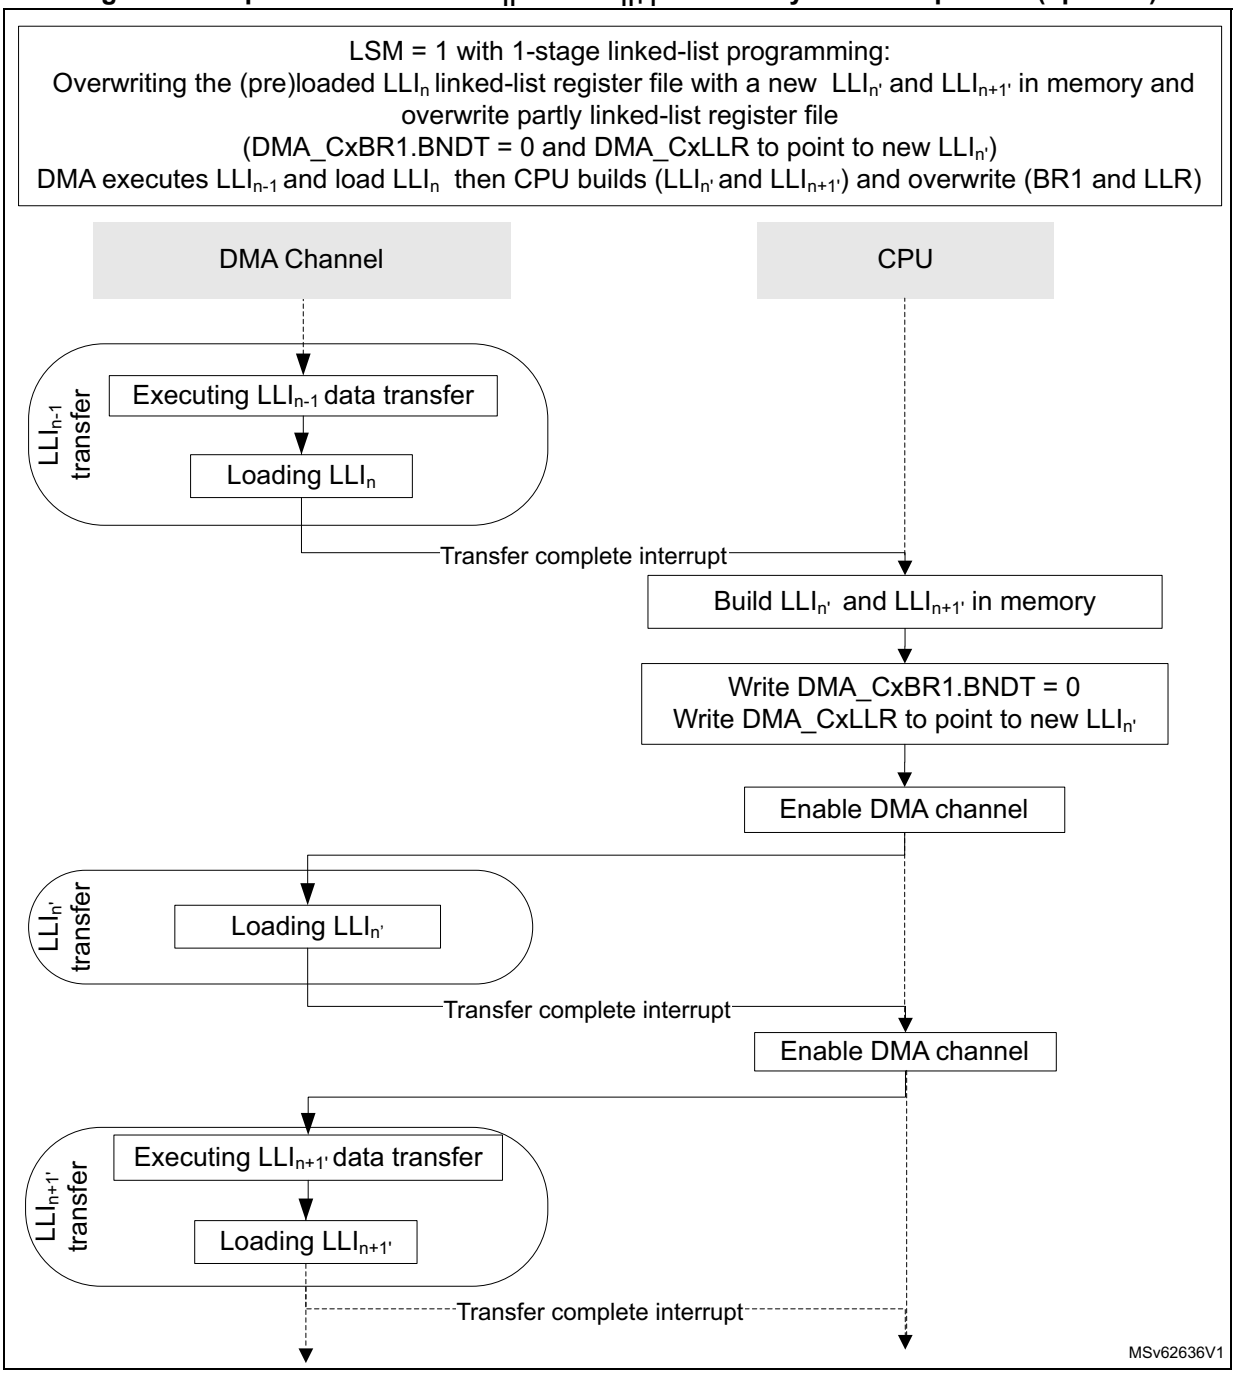
Figure 77. Replace with a new $LLI_{n'}$ in register file in link step mode



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after LPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (LPDMA_CxBR1.BNDT[15:0] to be null and LPDMA_CxLLR to point to new $LLI_{n'}$) as shown in *Figure 78*.

Figure 78. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



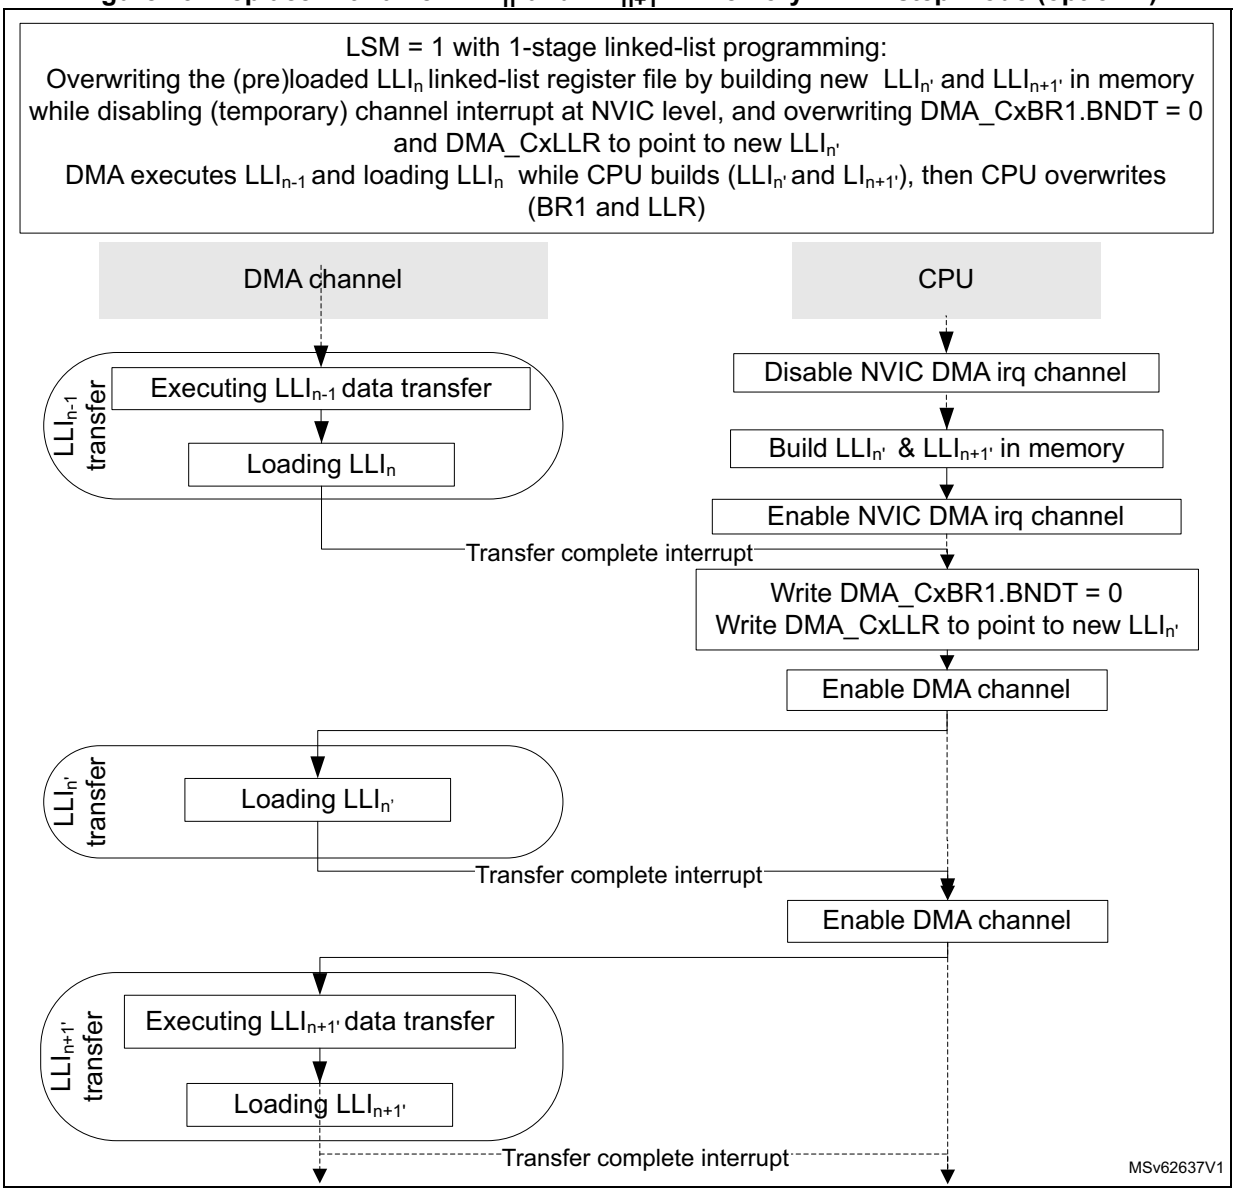
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile LPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite LPDMA_CxBR1.BNDT[15:0] to be null and LPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 79*.

Figure 79. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)



18.4.9 LPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (LPDMA_CxCR.EN = 0) and update the execution mode (LPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

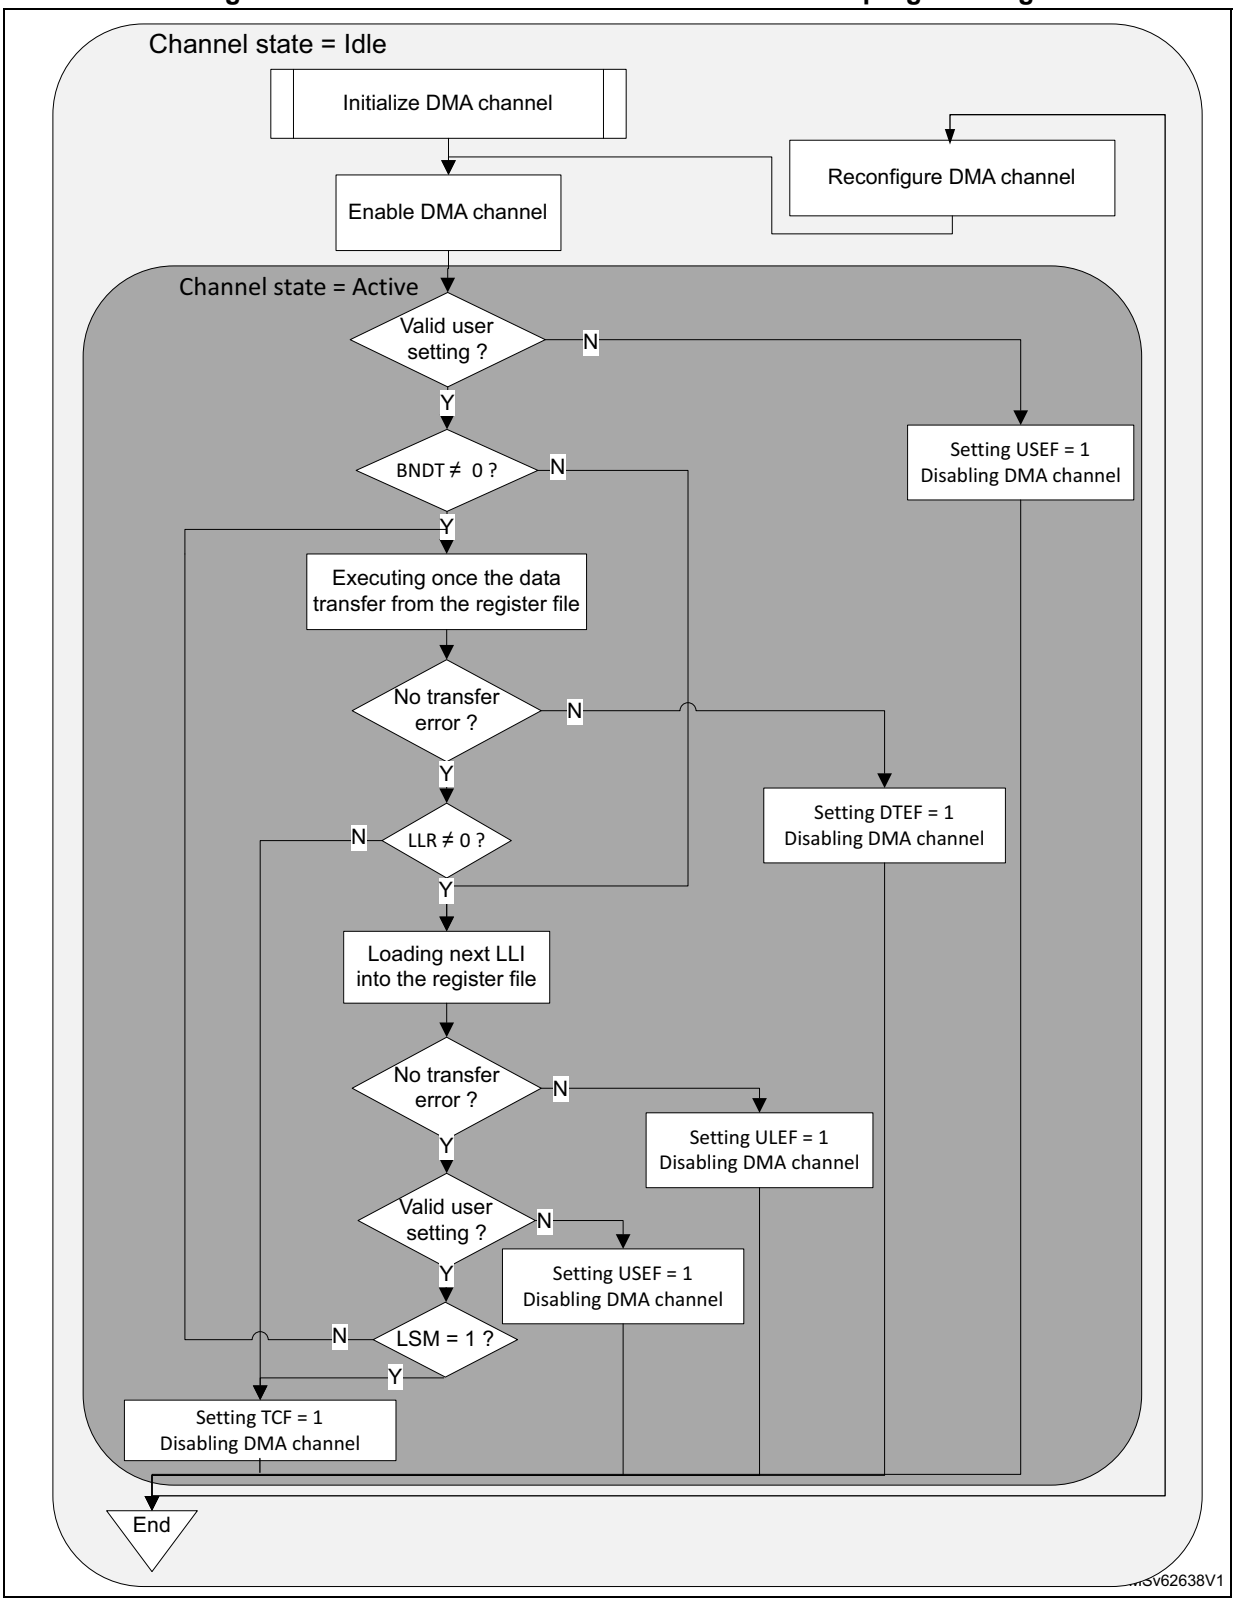
In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the LPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the LPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 18.4.4*)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 80 shows the overall and unified LPDMA linked-list programming, whatever is the execution mode.

Figure 80. LPDMA channel execution and linked-list programming



18.4.10 LPDMA direct transfers

There is a single transfer operation mode called the direct mode. Any LPDMA channel is used in direct mode. Any channel is implemented without any FIFO (for every channel x, dma_fifo_size[x] = 0).

LPDMA single

A programmed transfer at the lowest level is called a LPDMA single.

A LPDMA single data width is 1, 2 or 4 bytes, as defined by the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields of LPDMA_CxTR1(respectively for source and destination).

Note: The user must not assign a 8-byte data width (SDW_LOG2[1:0] = 0b11 or DDW_LOG2[1:0] = 0b11) else a user setting is reported and no transfer is issued.

The addressing mode after each data of a LPDMA single is defined by the SINC and DINC bits of LPDMA_CxTR1(respectively for source and destination): either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a LPDMA source/destination single (defined by LPDMA_CxSAR and LPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a LPDMA single.

The next single address in the table is the next source/destination address, pointed by LPDMA_CxSAR and LPDMA_CxDAR, once the programmed source/destination single is completed.

Table 137. Programmed LPDMA source/destination single

Programmed LPDMA source/destination single	SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/ DINC	Addressing mode	SAR/DAR next single address	Address alignment
Fixed byte single	00	1	0	Fixed	+0	1
Fixed half-word single	01	2				2
Fixed word single	10	4				4
Incremented byte single	00	1	1	Incremented	+1	1
Incremented half-word single	01	2			+2	2
Incremented word single	10	4			+4	4
Forbidden	11	Causes USEF generation and none single to be issued.				

In direct mode, a LPDMA single is an AHB single transfer.

LPDMA data handling: byte-based padding/truncation, sign extension and left/right alignment

The user can configure some data manipulation between a transferred data from the source and its transfer to the destination. Data handling is controlled by the LPDMA_CxTR1 register:

- If destination data width = source data width (DDW_LOG2[1:0] = SDW_LOG2[1:0]), the source data is copied as is and transferred to the destination.
- Else, depending on PAM:
  - If destination data width > source data width, the source data can be either right-aligned and padded with 0 s, or sign extended up to the destination data width.
  - If destination data width < source data width, the source data can be either right-aligned and left-truncated down to the destination data width, or left-aligned and right-truncated down to the destination data width.

There is no data manipulation between two distinct transferred data from the source, before the generation of the destination transfer.

The table below lists possible data handling from the source to the destination.

Table 138. Programmed data handling

SDW_ LOG2[1:0]	Source data	Source data stream(1)	DDW_ LOG2[1:0]	Destination data	PAM[0]	Destination data stream(1)
00	Byte	$B_7,B_6,B_5,B_4,B_3,B_2,B_1,B_0$	00	Byte	x	$B_7,B_6,B_5,B_4,B_3,B_2,B_1,B_0$
			01	Half-word	0 (RA, 0P)(2)(3)	$0B_3,0B_2,0B_1,0B_0$
					1 (RA, SE)(2)(4)	SB_3,SB_2,SB_1,SB_0
			10	Word	0 (RA, 0P)	$000B_1,000B_0$
					1 (RA, SE)	$SSSB_1,SSSB_0$
01	Half-word	$B_7B_6,B_5B_4,B_3B_2,B_1B_0$	00	Byte	0 (RA, LT)(2)	B_6,B_4,B_2,B_0
					1 (LA, RT)(2)	B_7,B_5,B_3,B_1
			01	Half-word	xx	$B_7B_6,B_5B_4,B_3B_2,B_1B_0$
			10	Word	0 (RA, 0P)	$00B_3B_2,00B_1B_0$
					1 (RA, SE)	SSB_3B_2,SSB_1B_0
10	Word	$B_7B_6B_5B_4,B_3B_2B_1B_0$	00	Byte	0 (RA, LT)	B_{12},B_8,B_4,B_0
					1 (LA, RT)	B_{15},B_{11},B_7,B_3
			01	Half-word	0 (RA, LT)	B_5B_4,B_1B_0
				Word	1 (LA, RT)	B_7B_6,B_3B_2
			10		xx	$B_7B_6B_5B_4,B_3B_2B_1B_0$

1. Data stream is timely ordered starting from the byte with the lowest index a.k.a B_0.
2. RA = right aligned. LA = left aligned. RT= right truncated. LT = left truncated.
3. 0P = zero bit padding up to the destination data width.
4. SE = sign bit extended up to the destination data width.

18.4.11 LPDMA transfer request and arbitration

LPDMA transfer request

As defined by LPDMA_CxTR2, a programmed LPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the LPDMA hardware peripheral request is driven by the REQSEL[4:0] field (see *Section 18.3.4*). The selected hardware request can be one of the following:
  - a hardware request from a peripheral configured in LPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - a hardware request from a peripheral for its control registers update from the memory
  - a hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral LPDMA request via LPDMA_CxTR.REQSEL[4:0] to two different channel if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

LPDMA transfer request for arbitration

For a given channel, a LPDMA requested data transfer from the source address to the destination address is arbitrated versus simultaneous requested LPDMA transfers from other channels, in order to be scheduled over the AHB master port. A LPDMA data transfer is atomic to the LPDMA arbitration: it consists of an AHB read single, immediately followed by an AHB write single. It is granted by the arbiter once for both AHB transfers, based on the channel priority defined by LPDMA_CxCR.PRIO[1:0].

An arbitrated LPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR or LPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the master port.

The re arbitration occurs after each granted single transfer:

- whatever how the requested data transfer is programmed:
  - with a software request for a memory-to-memory transfer (LPDMA_CxTR2.SWREQ = 1)
  - with a hardware request (LPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer
- whatever the hardware request type

When the requested data transfer is programmed with a hardware request from a peripheral (LPDMA_CxTR2.SWREQ = 0), the first memory read of a block is gated by the occurrence of the corresponding and selected hardware request, whatever the peripheral is source or destination of the transfer. This first read request to the memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

LPDMA arbitration

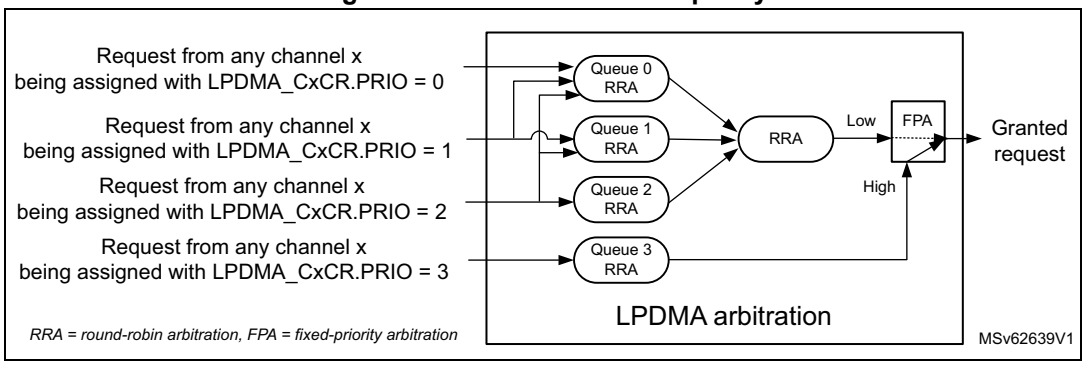
The LPDMA arbitration is directed from the 4-grade assigned channel priority (LPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 81*, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 81. LPDMA arbitration policy



1. RRA: round-robin arbitration
2. FPA: fixed-priority arbitration

LPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive LPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).

    $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).

    $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$

    $B_{req1} = B_{P1} = (1/2 + 1) * 1/3 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).

    $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$

    $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$

  The above computed bandwidth calculation is based on a theoretical input request, always active for any LPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one LPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
- **Example 2**: application where the user distributes a same non-null N number of LPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is

    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is

    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is

    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is

    $B_{n, P0} = 1/N * 1/9 * (1 - B_{Q3})$

    $B_{n, P1} = 1/N * 5/18 * (1 - B_{Q3})$

    $B_{n, P2} = 1/N * 11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for J > 0 (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ (K>0 in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the LPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

18.4.12 LPDMA triggered transfer

A programmed LPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGSEL[4:0] (see *Section 18.3.5* for the trigger selection).

The triggered transfer, as defined by the trigger mode in LPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first single read of a block, or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see the TRIGM[1:0] description in *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* for more details).

Trigger hit memorization and trigger overrun flag generation

The LPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

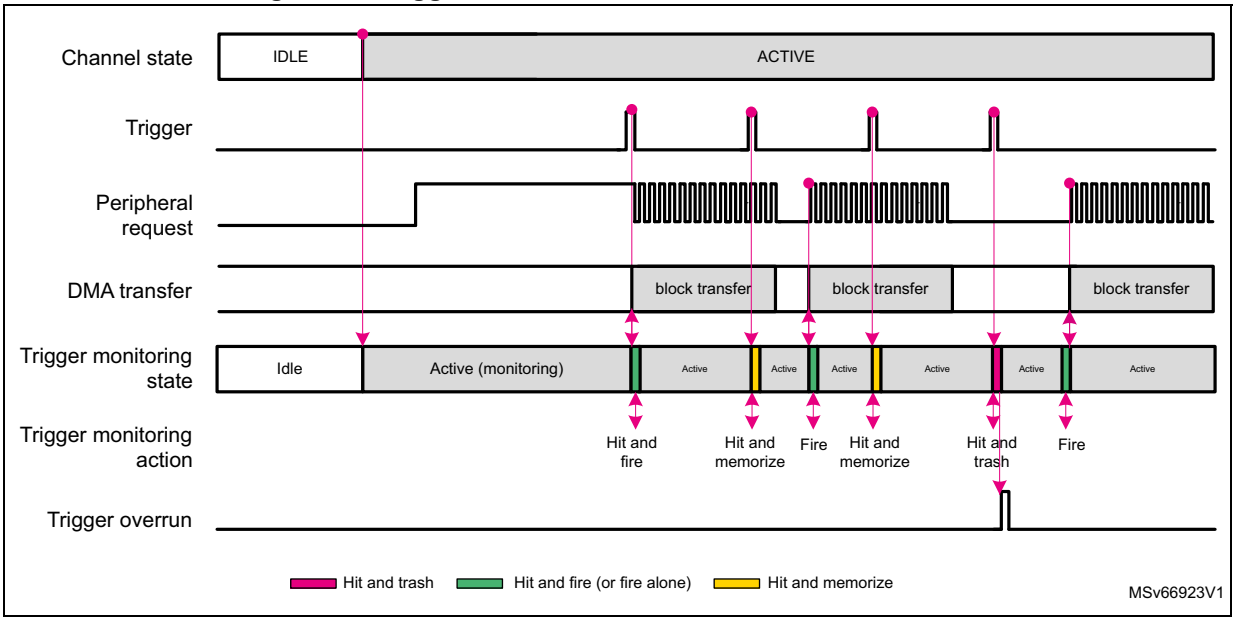
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[4:0] are not modified, and the channel is enabled.

Transferring a next LLI_{n+1}, that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[4:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (LPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 82. Trigger hit, memorization and overrun waveform



Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

18.4.13 LPDMA circular buffering with linked-list programming

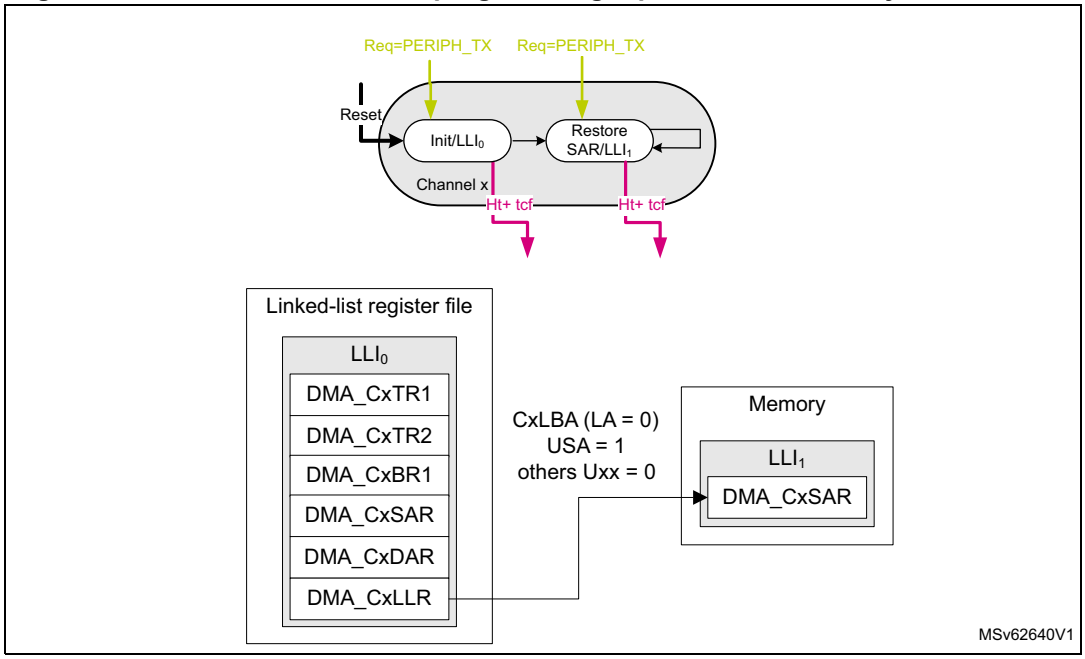
LPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer events/interrupts generation (LPDMA_CxCR.HTIE = 1 and LPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). LPDMA automatically reloads the initially programmed LPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore LPDMA_CxBR1.

The figure below illustrates this programming with a LPDMA channel and a source circular buffer.

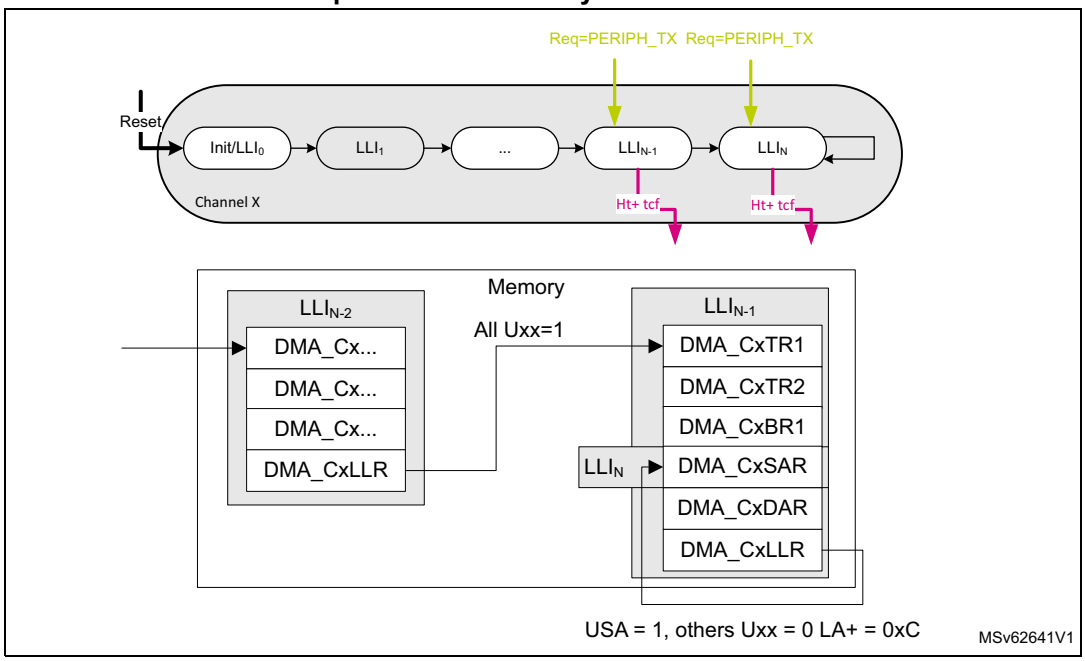
Figure 83. LPDMA circular buffer programming: update of the memory start address



If circular buffering must be executed after some other transfers over the shared LPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

The figure below illustrates this programming with a shared LPDMA channel, and a source circular buffer.

Figure 84. Shared LPDMA channel with circular buffering: update of the memory start address



18.4.14 LPDMA secure/non-secure channel

The LPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and non-secure worlds at any given time.

Any channel x is a secure or a non-secure hardware resource, as configured by LPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure agent, the following access control rules are applied:

- A non-secure read access to a register field of this channel is forced to return 0, except for LPDMA_SECCFGR, LPDMA_PRIVCFGR, LPDMA_RCFGLOCKR that are readable by a non-secure agent.
- A non-secure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or non-secure the LPDMA data transfer from the source (LPDMA_CxTR1.SSEC) and the LPDMA data transfer to the destination (LPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file, is automatically performed with secure transfers via the master port.

LPDMA generates the DMA channel state versus security, reflecting LPDMA_SECCFGR, to keep the other peripherals informed of the secure/non-secure state of each LPDMA channel x.

LPDMA also generates a security illegal access pulse signal on an illegal non-secure access to a secure LPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a non-secure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next non-secure transfer as a non-secure software is not allowed to do so and must have LPDMA_CxCR.EN = 0 before the non-secure software can reprogram the LPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

18.4.15 LPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via LPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for LPDMA_PRIVCFGR, LPDMA_SECCFGR, that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the master port.

LPDMA generates a DMA channel state versus privilege, reflecting LPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each DMA channel x.

Additionally, the LPDMA generates the privileged illegal access pulse signal on an illegal unprivileged access to a privileged LPDMA register. This signal may be used or not, depending on the product (see the system security section for more details).

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have LPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the LPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

18.4.16 LPDMA error management

LPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware). The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the data error (LPDMA_CxSR.DTEF = 1).
- After a LPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a LPDMA data transfer error, the user must issue a channel reset (set LPDMA_CxCR.RESET) to reset the hardware LPDMA channel data path before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a LPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware), the channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the link error (LPDMA_CxSR.ULEF = 1).
- After a LPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (LPDMA_CxLBAR and LPDMA_CxLLR), including the protection attributes.
- After a LPDMA link error, the user must explicitly write the linked-list register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a LPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (LPDMA_CxCR.EN forced and cleared by the LPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and a user setting error (LPDMA_CxSR.USEF = 1).
- After a LPDMA user setting error, the user must perform a debug session, taking care of the LPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (LPDMA_CxBR1.BNDT[15:0] = 0 and LPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source single transfer (LPDMA_CxBR1.BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])

- a programmed unaligned source start address, being not a multiple of the programmed data width of a source single transfer (LPDMA_CxSAR[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
- a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination single transfer (LPDMA_CxDAR[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (LPDMA_CxTR1.SDW_LOG2[1:0] = 0b11)
- a programmed double-word destination data width (LPDMA_CxTR1.DDW_LOG2[1:0] = 0b11
- a programmed linked-list item LLI_{n+1} with a null data transfer (LPDMA_CxLLR.UB1 = 1 and LPDMA_CxBR1. BNDT = 0)

18.4.17 LPDMA autonomous mode

To save dynamic power consumption while LPDMA executes the programmed linked-list transfers, LPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run, Sleep or Stop mode, provided that the RCC is programmed with the corresponding LPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the LPDMA autonomous feature vs the device low-power modes, refer to *Section 18.3.2*.

The user can program and schedule the execution of a given LPDMA transfer at a LLI_n level of a LPDMA channel x, with LPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[4:0], SWREQ and REQSEL[4:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* for more details.

The output channel x transfer complete event, lpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the LPDMA level (see *Section 18.3.5*), allowing autonomous and fine DMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given LPDMA channel x asserts its clock request in one of the following conditions:

- if the next transfer to be executed is programmed as conditioned by a trigger (LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if LPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  - if LPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled

The LPDMA channel x releases its clock request as soon as all the following conditions are met:

- The transfer to be executed is completed.
- The LPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the LPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the LPDMA releases its clock request to the RCC.

18.5 LPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, LPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, LPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

18.6 LPDMA in low-power modes

Table 139. Effect of low-power modes on LPDMA

Mode	Description
Sleep	No effect. LPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the LPDMA registers is kept when entering Stop mode. The content of the LPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. LPDMA interrupts can cause the device to exit Stop mode.
Standby	The LPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 18.3.2* to know which Stop mode is supported.

18.7 LPDMA interrupts

There is one LPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 140. LPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
LPDMA_CHx	Transfer complete	LPDMA_CxCR.TCIE	LPDMA_CxSR.TCF	Write 1 to LPDMA_CxFCR.TCF
	Half transfer	LPDMA_CxCR.HTIE	LPDMA_CxSR.HTF	Write 1 to LPDMA_CxFCR.HTF
	Data transfer error	LPDMA_CxCR.DTEIE	LPDMA_CxSR.DTEF	Write 1 to LPDMA_CxFCR.DTEF
	Update link error	LPDMA_CxCR.ULEIE	LPDMA_CxSR.ULEF	Write 1 to LPDMA_CxFCR.ULEF
	User setting error	LPDMA_CxCR.USEIE	LPDMA_CxSR.USEF	Write 1 to LPDMA_CxFCR.USEF
	Suspended	LPDMA_CxCR.SUSPIE	LPDMA_CxSR.SUSPF	Write 1 to LPDMA_CxFCR.SUSPF
	Trigger overrun	LPDMA_CxCR.TOFIE	LPDMA_CxSR.TOF	Write 1 to LPDMA_CxFCR.TOF

A LPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal lpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (LPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (LPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into LPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by LPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].
- A half transfer event is a half block transfer. A half-block transfer occurs when half of the source block size bytes (rounded-up integer of LPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

See *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single data transfer from the source or to the destination (DTEF)
- during an update of a LPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a LPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the LPDMA channel programming versus the USEF root causes list (see *Section 18.4.16*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

18.8 LPDMA registers

The LPDMA registers must be accessed with an aligned 32-bit word data access.

18.8.1 LPDMA secure configuration register (LPDMA_SECCFGR)

Address offset: 0x000

Reset value: 0x0000 0000

A write access is ignored at bit level if the corresponding channel x is locked (LPDMA_RCFGLOCKR.LOCKx = 1).

A write access to this register must be secure and privileged. A read access is secure or non-secure, privileged or unprivileged.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (when LPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or non-secure world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC3	SEC2	SEC1	SEC0
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **SECx**: secure state of channel x (x = 3 to 0)

0: non-secure

1: secure

18.8.2 LPDMA privileged configuration register (LPDMA_PRIVCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or non-secure.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register can mix secure and non-secure information. If a channel x is configured as secure (LPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (LPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PRIVx**: privileged state of channel x (x = 3 to 0)
0: unprivileged
1: privileged

18.8.3 LPDMA configuration lock register (LPDMA_RCFGLOCKR)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attribute in order to individually lock at boot time the secure privileged attributes of any DMA channel/resource (to lock the setting of LPDMA_SECCFGR, LPDMA_PRIVCFGR for any channel x at boot time).

A read access may be privileged or unprivileged, secure or non-secure.

Note: If TZEN = 0, this register cannot be written.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK3	LOCK2	LOCK1	LOCK0
												rs	rs	rs	rs

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **LOCKx**: lock the configuration of LPDMA_SECCFGR.SECx, LPDMA_PRIVCFGR.PRIVx until a global DMA reset (x = 3 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global DMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

18.8.4 LPDMA non-secure masked interrupt status register (LPDMA_MISR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register is a read register.

This is a non-secure register, containing the masked interrupt status bit MISx for each non-secure channel x (channel x configured with LPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of LPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of LPDMA_CxCR.

Every bit is de-asserted by hardware when writing 1 to the corresponding flag clear bit in LPDMA_CxFCR.

If a channel x is in secure state (LPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFGR.PRIVx. A privileged software can read the full non-secure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and non-secure) channel(s), other privileged bit fields returning zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **MISx**: masked interrupt status of channel x (x = 3 to 0)
0: no interrupt occurred on non-secure channel x
1: an interrupt occurred on non-secure channel x

18.8.5 LPDMA secure masked interrupt status register (LPDMA_SMISR)

Address offset: 0x010

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (LPDMA_SECCFGR.SECx = 1). It is a logical OR of all the LPDMA_CxSR flags, each source flag being enabled by the corresponding LPDMA_CxCR interrupt enable bit.

Every bit is de-asserted by hardware when securely writing 1 to the corresponding LPDMA_CxFCR flag clear bit.

This register does not contain any information about a non-secure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MIS3	MIS2	MIS1	MIS0
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **MISx**: masked interrupt status of the secure channel x (x = 3 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

18.8.6 LPDMA channel x linked-list base address register (LPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x LPDMA_PRIVCFGR.PRIVx.

This register is either secure or non-secure depending on the secure state of the channel x (LPDMA_SECCFGR.SECx).

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the LPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit LPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of LPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

18.8.7 LPDMA channel x flag clear register (LPDMA_CxFCR)

Address offset: 0x05C+ 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This is a write register, secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx) and privileged or non-privileged, depending on the privileged state of the channel x (LPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: clears the corresponding TOF flag

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

18.8.8 LPDMA channel x status register (LPDMA_CxSR)

Address offset: 0x060 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or non-secure, depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (LPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

	r	r	r	r	r	r	r								r

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: clears the corresponding TOF flag

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag
0: no half transfer event
1: a half transfer event occurred
A half transfer event is a half block transfer that occurs when half of the bytes of the source block size (rounded-up integer of LPDMA_CxBR1.BNDT[15:0] / 2) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is de-asserted by hardware when the channel is enabled (LPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

18.8.9 LPDMA channel x control register (LPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel x (LPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	Res.	LSM

	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x LPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (LPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0). Then LPDMA_CxBR1.BNDT[15:0] = 0.
1: channel executed **once** for the current LLI
First the block transfer is executed as defined by the current internal register file until LPDMA_CxBR1.BNDT[15:0] = 0). Secondly the next linked-list data structure is conditionally uploaded from memory as defined by LPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (with an ongoing DMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 69*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (LPDMA_CxSR.SUSPF = 1 and LPDMA_CxSR.IDLEF = LPDMA_CxCR.EN = 1)
- channel in disabled state (LPDMA_CxSR.IDLEF = 1 and LPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (LPDMA_CxBR1, LPDMA_CxSAR and LPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 70*).
0: no channel reset
1: channel reset

Bit 0 **EN:** enable
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
this bit is de-asserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, e.g. if LSM = 1 at the end of a single execution of the LLI).
Else, this bit can be asserted by software.
Writing 0 into this EN bit is ignored.
0: write: ignored, read: channel disabled
1: write: enable channel, read: channel enabled

18.8.10 LPDMA channel x transfer register 1 (LPDMA_CxTR1)

Address offset: 0x090 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in LPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DINC	Res.	DDW_LOG2[1:0]	
rw												rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	Res.	Res.	Res.	PAM	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SINC	Res.	SDW_LOG2[1:0]	
rw				rw								rw		rw	rw

Bit 31 **DSEC**: security attribute of the LPDMA transfer to the destination

If LPDMA_SECCFGR.SECx = 1 and the access is secure:

0: LPDMA transfer non-secure

1: LPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when LPDMA_SECCFGR.SECx = 1. A secure write is ignored when LPDMA_SECCFGR.SECx = 0.

When LPDMA_SECCFGR.SECx is de-asserted, this DSEC bit is also de-asserted by hardware (on a secure reconfiguration of the channel as non-secure), and the LPDMA transfer to the destination is non-secure.

Bits 30:20 Reserved, must be kept at reset value.

Bit 19 **DINC**: destination incrementing single

0: fixed single

1: contiguously incremented single

The destination address, pointed by LPDMA_CxDAR, is kept constant after a single transfer, or is incremented by the offset value corresponding to a contiguous data after a single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a single in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.
A destination single transfer must have an aligned address with its data width (start address LPDMA_CxDAR[2:0] versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the LPDMA transfer from the source
If LPDMA_SECCFGR.SECx = 1 and the access is secure:
0: LPDMA transfer non-secure
1: LPDMA transfer secure
This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when LPDMA_SECCFGR.SECx =1 . A secure write is ignored when LPDMA_SECCFGR.SECx = 0.
When LPDMA_SECCFGR.SECx is de-asserted, this SSEC bit is also de-asserted by hardware (on a secure reconfiguration of the channel as non-secure), and the LPDMA transfer from the source is non-secure.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **PAM**: padding/alignment mode
If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a single destination transfer is equal to the data width of a single source transfer, this bit is ignored.
Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher that source data width, and the condition PAM_2 is when destination data width is higher than source data width.
Condition: PAM_1
0: source data is transferred as right aligned, padded with 0s up to the destination data width
1: source data is transferred as right aligned, sign extended up to the destination data width
Condition: PAM_2
0: source data is transferred as right aligned, left-truncated down to the destination data width
1: source data is transferred as left-aligned, right-truncated down to the destination data width

Bits 10:4 Reserved, must be kept at reset value.

Bit 3 **SINC**: source incrementing single
0: fixed single
1: contiguously incremented single
The source address, pointed by LPDMA_CxSAR, is kept constant after a single transfer or is incremented by the offset value corresponding to a contiguous data after a single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a single in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.
a source block size must be a multiple of the source data width (LPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.
A source single transfer must have an aligned address with its data width (start address LPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

18.8.11 LPDMA channel x transfer register 2 (LPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN =1 .

This register must be written when the channel is completed (the hardware de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory, if LPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	Res.	TRIGSEL[4:0]				
rw	rw					rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	Res.	BREQ	Res.	SWREQ	Res.	Res.	Res.	Res.	REQSEL[4:0]				
rw	rw			rw		rw					rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when LPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: same as 00

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (i.e. directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address LPDMA_CxLLR.LA[15:2] to zero and clears all the LPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[4:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **TRIGSEL[4:0]**: trigger event input selection

These bits select the trigger event input of the LPDMA transfer (as per *Section 18.3.5*), with an active trigger event if TRIGPOL[1:0] = 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (LPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 0b00 or 0b11, these TRIGM[1:0] bits are ignored.

Else, a DMA transfer is conditioned by at least one trigger hit:

00: at block level: the first single read of each block transfer is conditioned by one hit trigger.

01: same as 00

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed single level: each programmed single read is conditioned by one hit trigger.

The LPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 0b01 or respectively TRIGPOL[1:0] = 0b10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[4:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[4:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized, and a trigger overrun flag is reported (LPDMA_CxSR.TOF = 1), an interrupt is generated if enabled (LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BREQ**: block hardware request

If the channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a single level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 18.3.4*).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when LPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[4:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[4:0] is ignored.

Bits 8:5 Reserved, must be kept at reset value.

Bits 4:0 **REQSEL[4:0]**: DMA hardware request selection

These bits are ignored if channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 18.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[4:0] value) to different active DMA channels (LPDMA_CxCR.EN = 1 and LPDMA_CxTR2.SWREQ = 0 for these channels). DMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

18.8.12 LPDMA channel x block register 1 (LPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if LPDMA_CxLLR.UB1 = 1, this register is automatically updated by DMA from the next LLI in memory.
- If LPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed values for the field BNDT[15:0].
- If all the update bits LPDMA_CxLLR.Uxx are null and if LPDMA_CxLLR.LA[15:0] # 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If LPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if LPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if LPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all LPDMA_CxLLR.Uxx = 0 and if LPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if LPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

18.8.13 LPDMA channel x source address register (LPDMA_CxSAR)

Address offset: 0x09C + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer from the source.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (LPDMA_CxTR1.SINC), this field is either kept fixed or incremented by the data width (LPDMA_CxTR1.SDW_LOG2[1:0]) after each single source data, reflecting the next address from which data is read.

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by LPDMA from the memory, provided the LLI is set with LPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source single (SA[32:0] versus LPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

18.8.14 LPDMA channel x destination address register (LPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer to the destination.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UDA = 1.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (LPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (LPDMA_CxTR1.DDW_LOG2[21:0]) after each single destination data, reflecting the next address from which data is written.

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by DMA from the memory, provided the LLI is set with LPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination single (DA[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

18.8.15 LPDMA channel x linked-list address register (LPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.ULL = 1.

LA[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update LPDMA_CxTR1 from memory

This bit controls the update of the LPDMA_CxTR1 register from the memory during the link transfer.

0: no LPDMA_CxTR1 update

1: LPDMA_CxTR1 update

Bit 30 **UT2**: Update LPDMA_CxTR2 from memory

This bit controls the update of the LPDMA_CxTR2 register from the memory during the link transfer.

0: no LPDMA_CxTR2 update

1: LPDMA_CxTR2 update

Bit 29 **UB1**: Update LPDMA_CxBR1 from memory

This bit controls the update of the LPDMA_CxBR1 register from the memory during the link transfer.

0: no LPDMA_CxBR1 update from memory and internally restored to the previous programmed value

1: LPDMA_CxBR1 update

Bit 28 **USA**: update LPDMA_CxSAR from memory

This bit controls the update of the LPDMA_CxSAR register from the memory during the link transfer.

0: no LPDMA_CxSAR update

1: LPDMA_CxSAR update

Bit 27 **UDA**: Update LPDMA_CxDAR register from memory

This bit is used to control the update of the LPDMA_CxDAR register from the memory during the link transfer.

0: no LPDMA_CxDAR update

1: LPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update LPDMA_CxLLR register from memory

This bit is used to control the update of the LPDMA_CxLLR register from the memory during the link transfer.

0: no LPDMA_CxLLR update

1: LPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure

If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list DMA register file.

Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list DMA internal register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3* for the register boundary addresses.

19 Chrom-ART Accelerator controller (DMA2D)

19.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- fill a part or the whole of a destination image with a specific color
- copy a part or the whole of a source image into a part or the whole of a destination image
- copy a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- blend a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

19.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit)
- User programmable working area size
- User programmable offset for sources and destination areas expressed in pixels or bytes
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to memory with pixel format conversion, blending and fixed color foreground, and memory-to memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color
- Copy from an area to another
- Copy with pixel format conversion between source and destination images

- Copy from two sources with independent color format and blending
- Output buffer byte swapping to support refresh of displays through parallel interface
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

19.3 DMA2D functional description

19.3.1 DMA2D block diagram

The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

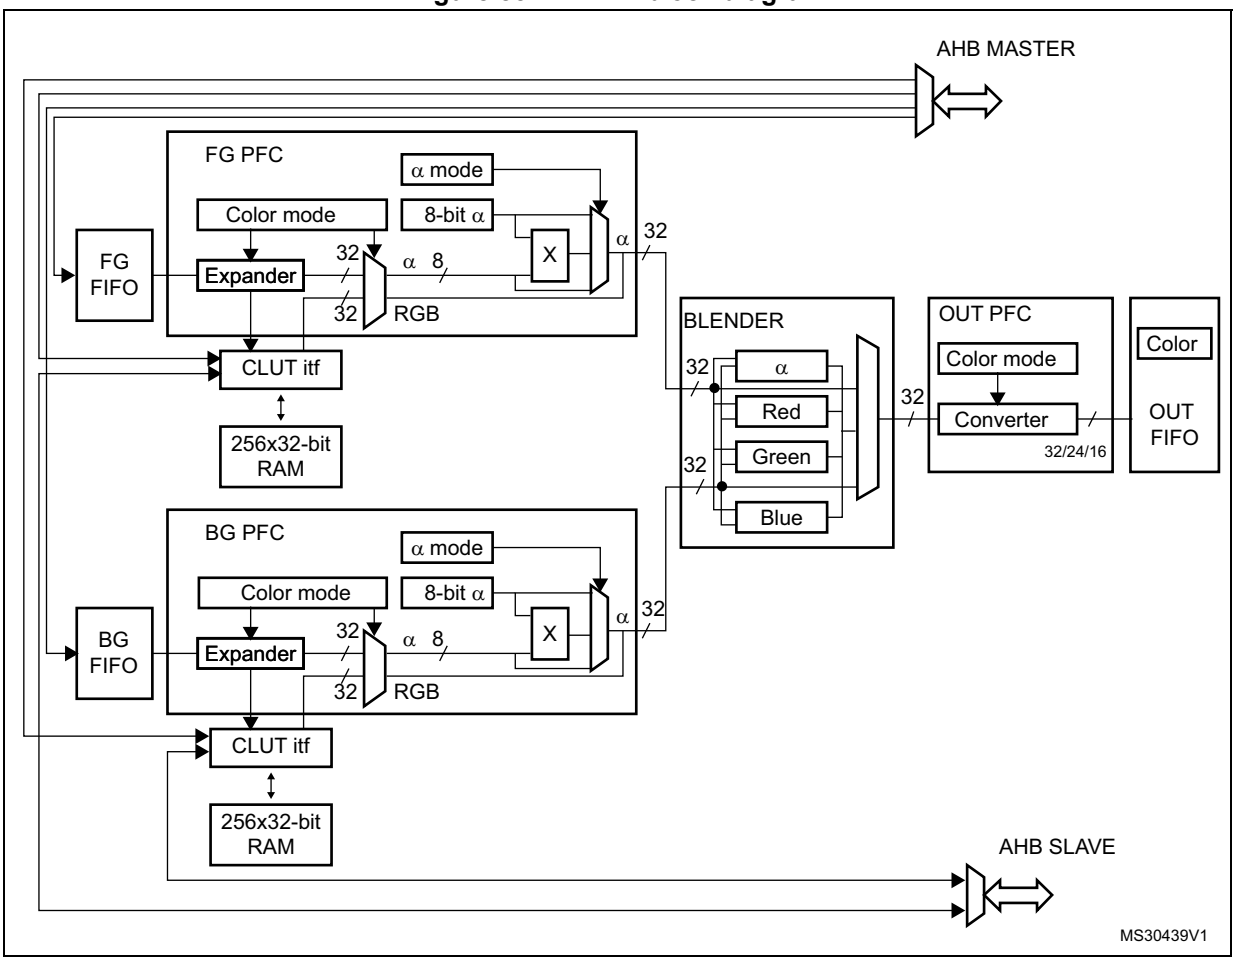
The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with pixel format conversion
- Memory-to-memory with pixel format conversion and blending
- Memory-to memory with pixel format conversion, blending and fixed color foreground
- Memory-to memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in the figure below.

Figure 85. DMA2D block diagram



19.3.2 DMA2D control

The DMA2D controller is configured through the DMA2D control register (DMA2D_CR).

The user application can perform the following operations:

- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

19.3.3 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

These FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC). They are programmed through a set of control registers:

- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)

- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

19.3.4 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in the table below.

Table 142. Supported color mode in input

CM[3:0]	Color mode
0000	ARGB8888
0001	RGB888
0010	RGB565
0011	ARGB1555
0100	ARGB4444
0101	L8
0110	AL44
0111	AL88
1000	L4
1001	A8
1010	A4

The color format is coded as follows:

- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format is direct color mode (ARGB/RGB), the extension to 8 bits per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format is indirect color mode (L/AL), a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D_FGCOLR for foreground pixels and in the DMA2D_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in the table below.

Table 143. Data order in memory

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]
L8	L_3[7:0]	L_2[7:0]	L_1[7:0]	L_0[7:0]
AL44	A_3[3:0]L_3[3:0]	A_2[3:0]L_2[3:0]	A_1[3:0]L_1[3:0]	A_0[3:0]L_0[3:0]
AL88	A_1[7:0]	L_1[7:0]	A_0[7:0]	L_0[7:0]
L4	L_7[3:0]L_6[3:0]	L_5[3:0]L_4[3:0]	L_3[3:0]L_2[3:0]	L_1[3:0]L_0[3:0]
A8	A_3[7:0]	A_2[7:0]	A_1[7:0]	A_0[7:0]
A4	A_7[3:0]A_6[3:0]	A_5[3:0]A_4[3:0]	A_3[3:0]A_2[3:0]	A_1[3:0]A_0[3:0]

The 24-bit RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR/DMA2D_BGPFCCR registers as shown in the table below.

The alpha channel can be:

- kept as it is (no modification)
- replaced by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR
- replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 144. Alpha mode configuration

AM[1:0]	Alpha mode
00	No modification
01	Replaced by value in DMA2D_xxPFCCR
10	Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255
11	Reserved

Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the Alpha value stored in the DMA2D_FGPFCCR/DMA2D_BGPFCCR and in the CLUT.

The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the RGB order used in the CLUT and in the DMA2D_FGCOLR/DMA2D_BGCOLR registers.

19.3.5 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three access types are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading

  The following sequence must be followed to load the CLUT:

  a) Program the CLUT address in DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).

  b) Program the CLUT size with CS[7:0] in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT).

  c) Set the START bit in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- Manual loading

  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped.The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format is 24 or 32 bits. It is configured through the CCM bit in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) as shown in the table below.

Table 145. Supported CLUT color mode

CCM	CLUT color mode
0	32-bit ARGB8888
1	24-bit RGB888

The way the CLUT data are organized in the system memory is specified in the table below.

Table 146. CLUT data order in system memory

CLUT color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]

19.3.6 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by MODE[2:0] in DMA2D_CR.

19.3.7 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by CM[2:0]in DMA2D_OPFCCR.

The supported output formats are given in the table below.

Table 147. Supported color mode in output

CM[2:0]	Color mode
000	ARGB8888
001	RGB888
010	RGB565
011	ARGB1555
100	ARGB4444

Note: To support the alternate format, the calculated alpha value is inverted setting AI bit in DMA2D_OPFCCR. This applies also to the alpha value used in DMA2D_OCOLR.

The R and B fields can also be swapped setting RBS in DMA2D_OPFCCR. This applies also to the RGB order used in DMA2D_OCOLR.

19.3.8 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:

- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR**)**
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR**)**

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

Table 148. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

19.3.9 DMA2D output FIFO byte reordering

The output FIFO bytes are reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:

- RBS bit to swap Red and Blue component
- SB bit to swap byte two-by-two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, the output memory address (MA field in DMA2D_OMAR) must be even, and the output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must be even.
If not, a configuration error is detected.

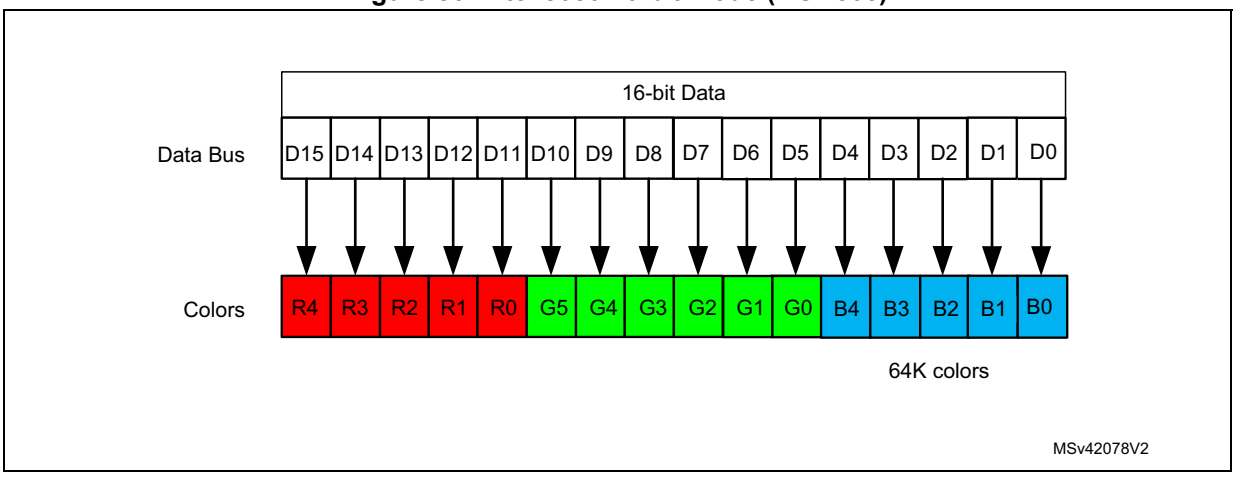
Table 149. Standard data order in memory

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]

16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.

Figure 86. Intel 8080 16-bit mode (RGB565)



18/24-bit mode (RGB888)

This mode needs data reordering.

1. Red and the Blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of a half-word have to be swapped (setting the SB bit).

Figure 87. Intel 8080 18/24-bit mode (RGB888)

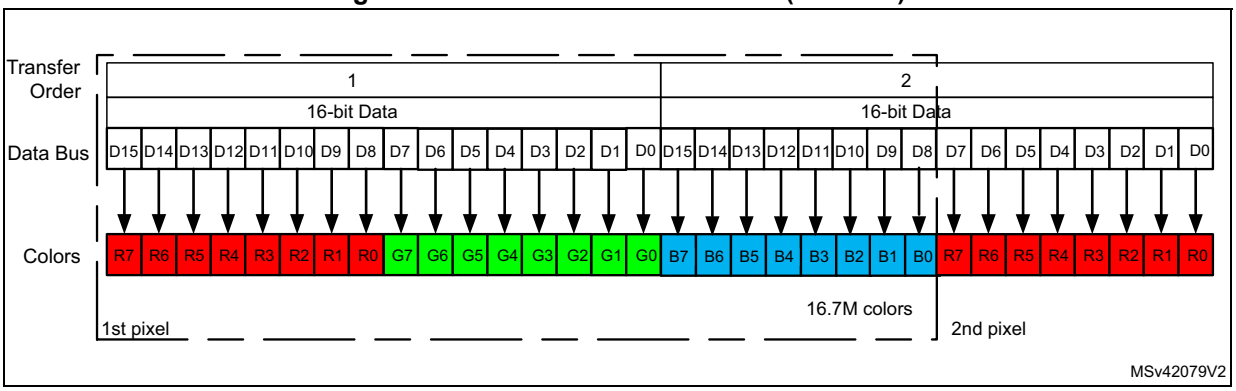


Table 150. Output FIFO byte reordering steps

Steps	@ + 3	@ + 2	@ + 1	@ + 0
Original data ordering	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
Setting the RBS bit				
Data ordering after red and blue swap (RBS set)	R_1[7:0]	B_0[7:0]	G_0[7:0]	R_0[7:0]
	G_2[7:0]	R_2[7:0]	B_1[7:0]	G_1[7:0]
	B_3[7:0]	G_3[7:0]	R_3[7:0]	B_2[7:0]
Setting the SB bit				
Data ordering after byte swapping (SB set)	B_0[7:0]	R_1[7:0]	R_0[7:0]	G_0[7:0]
	R_2[7:0]	G_2[7:0]	G_1[7:0]	B_1[7:0]
	G_3[7:0]	B_3[7:0]	B_2[7:0]	R_3[7:0]

19.3.10 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth availability.

The timer enabling and the dead time value are configured through the AHB master port timer configuration register (DMA2D_AMPTCR).

19.3.11 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers.
The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:

1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR

2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values
4. Pixel format conversion of the resulting pixels according to DMA2D_OCR and programming of the data to the memory location addressed through DMA2D_OMAR

19.3.12 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color.

The color format is set in DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR, and defined in DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D_FGMAR to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed by CM[3:0] in DMA2D_FGPFCCR defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Data are fetched from the location defined in DMA2D_FGMAR and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCCR.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] bits in DMA2D_FGPFCCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCCR.
4. Start the CLUT loading by setting START i nDMA2D_FGPFCCR.

Once the CLUT loading is complete, the CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE = 1 in DMA2D_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the APB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value is added or changed depending on the value programmed in DMA2D_FGPFCCR. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value is modified according to AM[1:0] in DMA2D_FGPFCCR:

- It can be unchanged.
- It can be replaced by the value defined by ALPHA[7:0] in DMA2D_FGPFCCR.
- It can be replaced by the original value multiplied by ALPHA[7:0] divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC and blending

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color FG

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color BG

In this mode, only one source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by DMA2D_BGCOLR and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together, and the resulting 32-bit pixel value is encoded by the output PFC

according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): CM bits in DMA2D_FGPFCCR are invalid
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM in DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_FGPFCCR is A4 or L4, and LOM bit in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode and except in memory-to-memory mode with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with CM in DMA2D_BGPFCCR.
- Memory transfer: (only in blending mode and in blending with fixed color FG mode): CM bits in DMA2D_BGPFCCR are invalid
- Memory transfer (only in blending mode and in blending with fixed color FG mode): PL bits in DMA2D_NLR odd while CM in DMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): LO bits in DMA2D_BGOR are odd while CM in DMA2D_BGPFCCR is A4 or L4, and LOM bit in DMA2D_CR is pixel mode.
- Memory transfer (except in memory-to-memory mode): MA bits in DMA2D_OMAR are not aligned with CM bits in DMA2D_OPFCCR.
- Memory transfer (except in memory to memory mode): CM bits in DMA2D_OPFCCR are invalid.
- Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd or MA bits in DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO bits in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCCR.
- Memory transfer: NL = 0x0 in DMA2D_NLR
- Memory transfer: PL = 0x0 i nDMA2D_NLR
- Memory transfer: MODE bits in DMA2D_CR are invalid.

19.3.13 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting START in DMA2D_CR. Once the transfer is completed, START is automatically reset and TCIF flag in DMA2D_ISR is raised. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR. The transaction can then be aborted by setting ABORT in DMA2D_CR, or can be restarted by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT in DMA2D_CR. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using ABORT or SUSP in DMA2D_CR.

19.3.14 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined by LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, the TWIF flag in DMA2D_ISR is raised, and an interrupt is generated if TWIE is set in DMA2D_CR.

19.3.15 Error management

Two kind of errors can be triggered:

- AHB master port errors signaled by TEIF in DMA2D_ISR
- conflicts caused by a CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by CAEIF in DMA2D_ISR.

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an interrupt if need be (TEIE and CAEIE).

19.3.16 AHB dead time

To limit the AHB bandwidth use, a dead time between two consecutive AHB accesses can be programmed.

This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead time value is stored into DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AHB bus.

The update of the dead time value while the DMA2D runs is taken into account for the next AHB transfer.

19.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Table 151. DMA2D interrupt requests

Interrupt event	Event flag	Enable control bit
Configuration error	CEIF	CEIE
CLUT transfer complete	CTCIF	CTCIE
CLUT access error	CAEIF	CAEIE
Transfer watermark	TWF	TWIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

19.5 DMA2D registers

19.5.1 DMA2D control register (DMA2D_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CEIE	CTCIE	CAEIE	TWIE	TCIE	TEIE	Res.	LOM	Res.	Res.	Res.	ABORT	SUSP	START
		rw	rw	rw	rw	rw	rw		rw				rs	rw	rs

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]**: DMA2D mode
These bits are set and cleared by software. They cannot be modified while a transfer is ongoing.
000: Memory-to-memory (FG fetch only)
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
011: Register-to-memory (no FG nor BG, only output stage active)
100: Memory-to-memory with Blending and fixed color FG (BG fetch only with FG and BG PFC active)
101: Memory-to-memory with Blending and fixed color BG (BG fetch only with FG and BG PFC active)
others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE**: Configuration error interrupt enable
This bit is set and cleared by software.
0: CE interrupt disabled
1: CE interrupt enabled

Bit 12 **CTCIE**: CLUT transfer complete interrupt enable
This bit is set and cleared by software.
0: CTC interrupt disabled
1: CTC interrupt enabled

Bit 11 **CAEIE**: CLUT access error interrupt enable
This bit is set and cleared by software.
0: CAE interrupt disabled
1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark interrupt enable
This bit is set and cleared by software.
0: TW interrupt disabled
1: TW interrupt enabled

Bit 9 **TCIE**: Transfer complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode
This bit configures how is expressed the line offset (pixels or bytes) for the foreground, background and output.
This bit is set and cleared by software. It can not be modified while a transfer is on going.
0: Line offsets expressed in pixels
1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort

This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.

0: No transfer abort requested

1: Transfer abort requested

Bit 1 **SUSP**: Suspend

This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.

0: Transfer not suspended

1: Transfer suspended

Bit 0 **START**: Start

This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:

- at the end of the transfer
- when the data transfer is aborted by the user application (setting ABORT in DMA2D_CR)
- when a data transfer error occurs
- when the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

19.5.2 DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x0004

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CEIF	CTCIF	CAEIF	TWIF	TCIF	TEIF
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CEIF**: Configuration error interrupt flag
This bit is set when START in DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCCR is set and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag
This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag
This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

19.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CCEIF**: Clear configuration error interrupt flag
Programming this bit to 1 clears CEIF in DMA2D_ISR.

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag
Programming this bit to 1 clears CTCIF in DMA2D_ISR.

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag
Programming this bit to 1 clears CAEIF in DMA2D_ISR.

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag
Programming this bit to 1 clears TWIF in DMA2D_ISR.

Bit 1 **CTCIF**: Clear transfer complete interrupt flag
Programming this bit to 1 clears TCIF in DMA2D_ISR.

Bit 0 **CTEIF**: Clear Transfer error interrupt flag
Programming this bit to 1 clears TEIF in DMA2D_ISR.

19.5.4 DMA2D foreground memory address register (DMA2D_FGMAR)

Address offset: 0x000C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

This field contains the address of the data used for the foreground image. This register can only be written when data transfers are disabled. Once the data transfer has started, this register is read-only.

The address alignment must match the image format selected: for example, a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

19.5.5 DMA2D foreground offset register (DMA2D_FGOR)

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

The line offset used for the foreground image, expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

19.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x0014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

This field contains the address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

19.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x0018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field contains the line offset used for the background image, expressed in pixel when the LOM bit is reset, and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

19.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR)

Address offset: 0x001C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	Res.	Res.	AM[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw			rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rs	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied by the original alpha value according to the alpha mode selected through the AM[1:0] bits.

These bits can only be written when data transfers are disabled. Once a transfer has started, they become read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red Blue swap

This bit is used to swap the R and B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha

1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]**: Alpha mode

These bits select the alpha channel value to be used for the foreground image. They can only be written data the transfer are disabled. Once the transfer has started, they become read-only.

00: No modification of the foreground image alpha channel value

01: Replace original foreground image alpha channel value by ALPHA[7:0]

10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

Other: Reserved

Bits 15:8 **CS[7:0]**: CLUT size

These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start

This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode

This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
0: ARGB8888
1: RGB888
Other: Reserved

Bits 3:0 **CM[3:0]**: Color mode

These bits defines the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
Other: Reserved

19.5.9 DMA2D foreground color register (DMA2D_FGCOLR)

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value

These bits define the Red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
These bits can also be used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 15:8 **GREEN[7:0]**: Green value

These bits defines the Green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

These bits can also be used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 7:0 **BLUE[7:0]**: Blue value

These bits defines the Blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

These bits can also be used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

19.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	Res.	Res.	AM[1:0]

CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rs	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red Blue swap

This bit is used to swap the R and B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha

1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]**: Alpha mode

These bits define which alpha channel value to be used for the background image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

00: No modification of the foreground image alpha channel value

01: Replace original background image alpha channel value by ALPHA[7:0]

10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

Other: Reserved

Bits 15:8 **CS[7:0]**: CLUT size

These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic foreground CLUT transfer).

Bit 4 **CCM**: CLUT color mode

These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

Other: Reserved

Bits 3:0 **CM[3:0]**: Color mode

These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

0100: ARGB4444

0101: L8

0110: AL44

0111: AL88

1000: L4

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value

These bits define the Red value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

These bits are also used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 15:8 **GREEN[7:0]**: Green value

These bits define the green value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

These bits are also used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 7:0 **BLUE[7:0]**: Blue value

These bits define the blue value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

These bits are also used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

19.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Address offset: 0x002C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw							rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red Blue swap

This bit is used to swap the R and B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha

1: Inverted alpha

Bits 19:10 Reserved, must be kept at reset value.

Bit 9 **SB**: Swap bytes

When this bit is set, the bytes in the output FIFO are swapped two by two, the number of pixel per line (PL) must be even, and the output memory address (OMAR) must be even.

This register can only be written when the transfer is disabled. Once the transfer has started, this register is read-only.

0: Bytes in regular order in the output FIFO

1: Bytes are swapped two by two in the output FIFO

Bits 8:3 Reserved, must be kept at reset value.

Bits 2:0 **CM[2: 0]**: Color mode

These bits define the color format of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

000: ARGB8888

001: RGB888

010: RGB565

011: ARGB1555

A	RED[4:0]					GREEN[4:0]					BLUE[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **A**: Alpha channel value of the output color in ARGB1555 mode

Bits 14:10 **RED[4:0]**: Red value of the output image in ARGB1555 mode

Bits 9:5 **GREEN[4:0]**: Green value of the output image in ARGB1555 mode

Bits 4:0 **BLUE[4:0]**: Blue value of the output image in ARGB1555 mode

19.5.18 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x0038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB4444 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

ALPHA[3:0]				RED[3:0]				GREEN[3:0]				BLUE[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **ALPHA[3:0]**: Alpha channel of the output color value in ARGB4444

Bits 11:8 **RED[3:0]**: Red value of the output image in ARGB4444 mode

Bits 7:4 **GREEN[3:0]**: Green value of the output image in ARGB4444 mode

Bits 3:0 **BLUE[3:0]**: Blue value of the output image in ARGB4444 mode

19.5.19 DMA2D output memory address register (DMA2D_OMAR)

Address offset: 0x003C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory Address

This field contains the address of the data used for the output FIFO. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only. The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

19.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x0040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field contains the line offset used for the output expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

19.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x0044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PL[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

NL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **PL[13:0]**: Pixel per lines

Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15:0]**: Number of lines

Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

19.5.22 DMA2D line watermark register (DMA2D_LWR)

Address offset: 0x0048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LW[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LW[15:0]**: Line watermark

These bits allow the configuration of the line watermark for interrupt generation.
An interrupt is raised when the last pixel of the watermarked line has been transferred.
These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

19.5.23 DMA2D AHB master timer configuration register (DMA2D_AMTCR)

Address offset: 0x004C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DT[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN
rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DT[7:0]**: Dead time

Dead time value in the AHB clock cycle inserted between two consecutive accesses on the AHB master port. These bits represent the minimum guaranteed number of cycles between two consecutive AHB accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Enable

Enables the dead time functionality.

19.5.24 DMA2D foreground CLUT (DMA2D_FGCLUTx)

Address offset: 0x0400 + 0x4 * x, (x = 0 to 255)

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

20 Nested vectored interrupt controller (NVIC)

20.1 NVIC main features

- 125 maskable interrupt channels (not including the 16 Cortex-M33 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late arriving interrupts.

The NVIC registers are banked across secure and non-secure states.

All interrupts including the core exceptions are managed by the NVIC.

20.2 SysTick calibration value register

The Cortex-M33 with TrustZone mainline security extension embeds two SysTick timers.

When TrustZone is activated, the following SysTick timers are available:

- SysTick, secure instance
- SysTick, non-secure instance

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. In order to match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When SysTick clock source is CPU clock HCLK
  reload value = (HCLK x STCALIB) - 1
- When SysTick clock source is external clock (HCLK/8)
  reload value = ((HCLK/8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms:

SysTick reload value = (100 x STCALIB) - 1 = 0x1869F

20.3 Interrupt and exception vectors

The grey rows in the table below describe the vectors without specific position.

Table 153. STM32U575/585 vector table

Position	Priority	Type of priority	Acronym	Description	Address

21 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wakeup through configurable event inputs. It provides wakeup requests to the power control and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wakeup requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes.

The EXTI also includes the EXTI mux IO port selection.

21.1 EXTI main features

The EXTI main features are the following:

- Up to 24 input events supported
- All event inputs allow the possibility to wake up the system.
- Events that do not have an associated wakeup flag in the peripheral, have a flag in the EXTI and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wakeup event.

The configurable events have the following features:

- Selectable active trigger edge
- Interrupt pending status register bits independent for the rising and falling edge
- Individual interrupt and event generation mask, used for conditioning the CPU wakeup, interrupt and event generation
- Software trigger possibility
- Secure events: The access to control and configuration bits of secure input events can be made secure and or privilege.
- EXTI IO port selection

21.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block and EXTI mux as shown in *Figure 88*.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wakeup, interrupt and event outputs, and their masking.

The EXTI mux provides the IO port selection on to the EXTI event signal.

Figure 88. EXTI block diagram

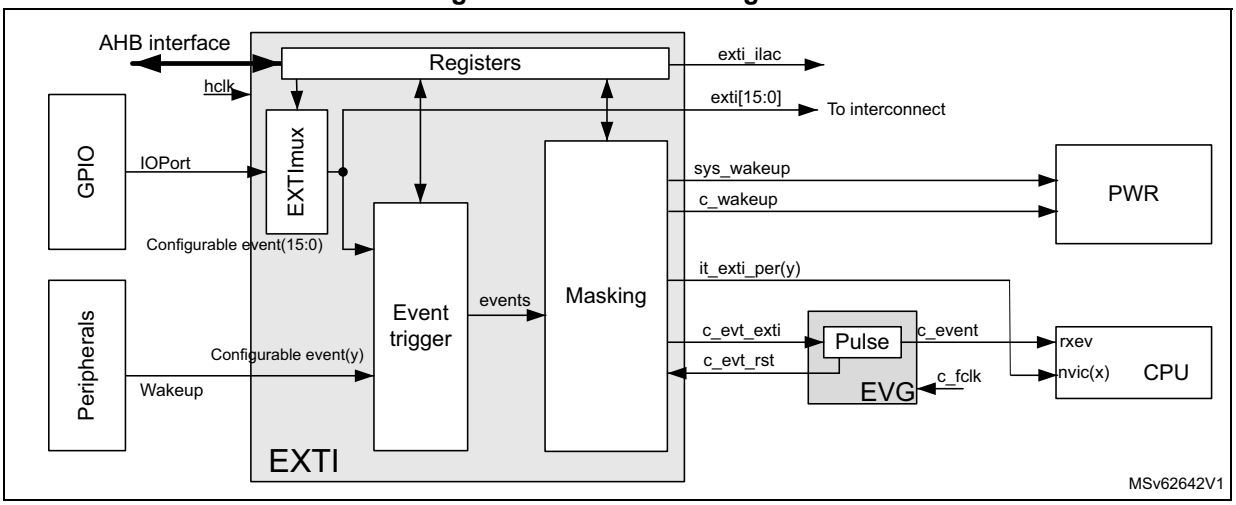

Table 154. EXTI signals

Name	I/O	Description
AHB interface	I/O	EXTI register bus interface. When one event is configured to enable security, the AHB interface supports secure accesses.
hclk	I	AHB bus clock and EXTI system clock
Configurable event(y)	I	Asynchronous wakeup events from peripherals that do not have an associated interrupt and flag in the peripheral
exti_ilac	O	Illegal access event
IOPort(n)	I	GPIOs block IO ports[15:0]
exti[15:0]	O	EXTI GPIO output port to trigger other peripherals
it_exti_per (y)	O	Interrupts to the CPU associated with configurable event (y)
c_evt_exti	O	High-level sensitive event output for CPU, synchronous to hclk
c_evt_rst	I	Asynchronous reset input to clear c_evt_exti
sys_wakeup	O	Asynchronous system wakeup request to PWR for ck_sys and hclk
c_wakeup	O	Wakeup request to PWR for CPU, synchronous to hclk

Table 155. EVG signals

Name	I/O	Description
c_fclk	I	CPU free running clock
c_evt_in	I	High-level sensitive events input from EXTI, asynchronous to CPU clock
c_event	O	Event pulse, synchronous to CPU clock
c_evt_rst	O	Event reset signal, synchronous to CPU clock

21.2.1 EXTI connections between peripherals and CPU

Some peripherals able to generate wakeup or interrupt events when the system is in Stop mode, are connected to the EXTI.

- Peripheral wakeup signals that generate a pulse or do not have an interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit that requires to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wakeup signals are connected to the PWR and are used to wake up the system and the CPU sub-system bus clocks.

21.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in the table below.

Table 156. EXTI line connections

EXTI line	Line source	Line type
0-15	GPIO	Configurable
16	PVD output	Configurable
17	COMP1 output	Configurable
18	COMP2 output	Configurable
19	V_{DDUSB} voltage monitor	Configurable
20	V_{DDIO2} voltage monitor	Configurable
21	V_{DDA} voltage monitor 1	Configurable
22	V_{DDA} voltage monitor 2	Configurable
23(1)	LSECSSD(1) OR MSI_PLL_UNLOCK(1)	Configurable

1. Not available in STM32U575/585 rev. X devices. Available in all other STM32U575/585 revisions.

21.3 EXTI functional description

The events features are controlled from register bits as follows:

- Active trigger edge enable
  - by rising edge selection in the *EXTI rising trigger selection register (EXTI_RTSR1)*
  - by falling edge selection in the *EXTI falling trigger selection register (EXTI_FTSR1)*
- Software trigger in the *EXTI software interrupt event register (EXTI_SWIER1)*
- Interrupt pending flag in the

  EXTI rising edge pending register (EXTI_RPR1)

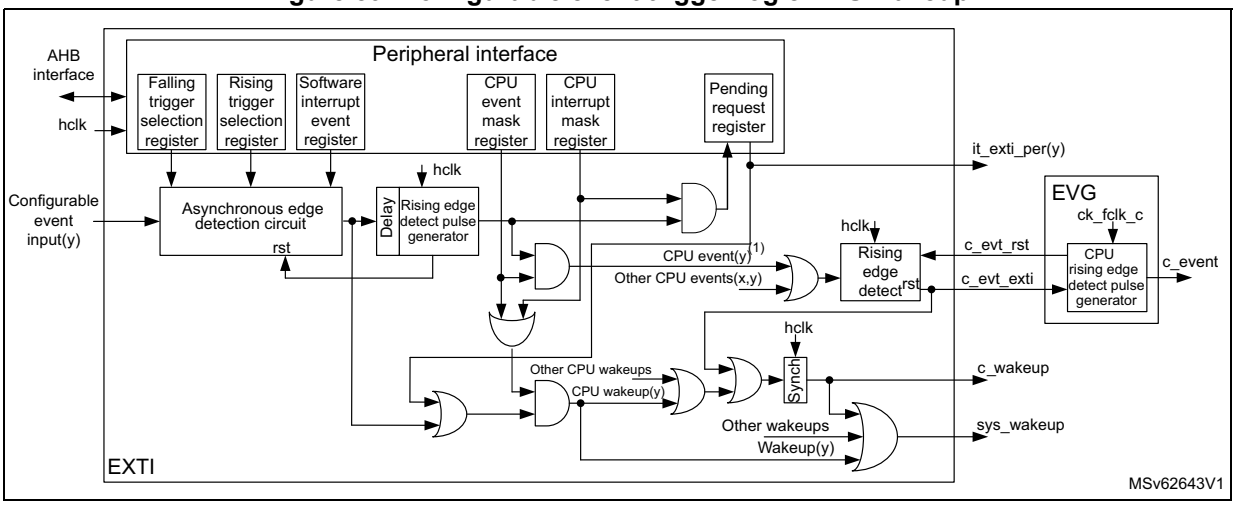
  EXTI falling edge pending register (EXTI_FPR1)

- CPU wakeup and interrupt enable in the
  EXTI CPU wakeup with interrupt mask register (EXTI_IMR1)
- CPU wakeup and event enable
  EXTI CPU wakeup with interrupt mask register (EXTI_IMR1)

21.3.1 EXTI configurable event input wakeup

The figure below is a detailed representation of the logic associated with configurable event inputs that wake up the CPU sub-system bus clocks and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wakeup event.

Figure 89. Configurable event trigger logic CPU wakeup



1. Only for the input events that support CPU rxev generation c_event.

The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wakeup (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.

When a CPU wakeup (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

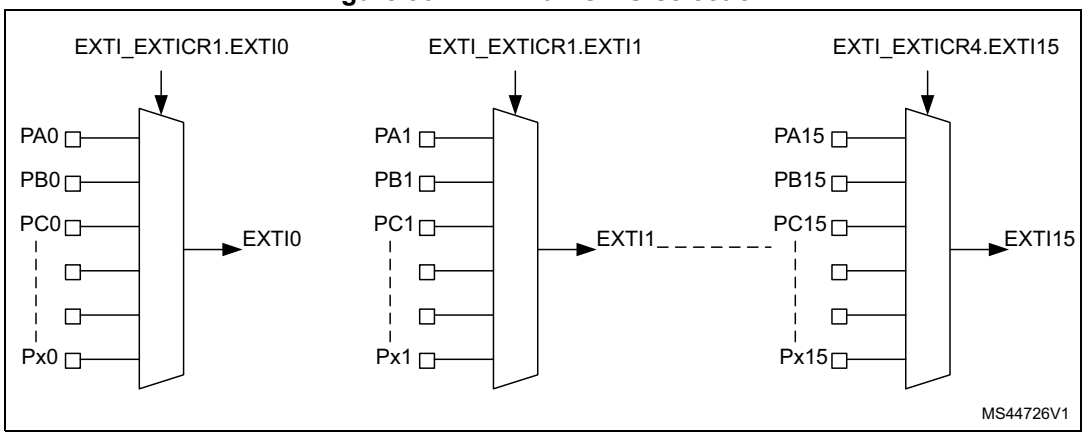
Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

21.3.2 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wakeup. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event.

The selection of GPIO port as EXTI mux output is controlled in the *EXTI external interrupt selection register (EXTI_EXTICRm)*.

Figure 90. EXTI mux GPIO selection



The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR and EXTI_EMR registers.

21.4 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the CPU wakeup generation is conditioned by the CPU interrupt mask and CPU event mask.

Table 157. Masking functionality

CPU interrupt enable (in EXTI_IMR.IMn)	CPU event enable (in EXTI_EMR.EMn)	Configurable event inputs (in EXTI_RPR.RPIFn and EXTI_FPR.FPIFn)	Exti(n) interrupt(1)	CPU event	CPU wakeup
0	0	No	Masked	Masked	Masked
	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes(2)
	1	Status latched	Yes	Yes	Yes

1. The single exti(n) interrupt goes to the CPU. If no interrupt is required for CPU(m), the exti(n) interrupt must be masked in the CPU NVIC.
2. Only if CPU interrupt is enabled in EXTI_IMR.IMn.

For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn is/are set: the CPU sub-system is woken up and the CPU interrupt signal is activated. The EXTI_RPR.RPIFn and/or

EXTI_FPR.FPIFn pending bits must be cleared by software writing it to 1. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

21.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by non-secure and unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_SECCFGR and EXTI_PRIVCFGR. At EXTI level, the protection consists in preventing the following unauthorized write access:

- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

Table 158. Register protection overview

Register name	Access type	Protection(1)(2)
EXTI_RTSR	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_FTSR	RW	
EXTI_SWIER	RW	
EXTI_RPR	RW	
EXTI_FPR	RW	
EXTI_SECCFGR	RW	Always secure. Privilege can be bit-wise enabled in EXTI_PRIVCFGR.
EXTI_PRIVCFGR	RW	Always privilege. Security can be bit-wise enabled in EXTI_SECCFGR.
EXTI_EXTICRn	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_LOCKR	RW	Always secure
EXTI_IM	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_EMR	RW	

1. Security is enabled with the individual input event (EXTI_SECCFGR register).
2. Privilege is enabled with the individual Input event (EXTI_PRIVCFGR register).

21.5.1 EXTI security protection

When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access. A non-secure write access is discarded and a read returns 0.

When input events are non-secure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and non-secure access.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

21.5.2 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

The privileged configuration in registers EXTI_PRIVCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

21.6 EXTI registers

The EXTI register map is divided in the following sections:

Table 159. EXTI register map sections

Address offset	Description
0x000 - 0x01C	General configurable event [22:0] configuration
0x060 - 0x06C	EXTI IO port mux selection
0x070	EXTI protection lock configuration
0x080 - 0x0BC	CPU input event configuration

All the registers can be accessed with word (32-bit), half-word (16-bit) and byte (8-bit) access.

21.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT23	RT22	RT21	RT20	RT19	RT18	RT17	RT16
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RT15	RT14	RT13	RT12	RT11	RT10	RT9	RT8	RT7	RT6	RT5	RT4	RT3	RT2	RT1	RT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **RTx:** Rising trigger event configuration bit of configurable event input x[(1)] (x = 23 to 0)

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

21.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

Contains only register bits for configurable events.

								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FT15	FT14	FT13	FT12	FT11	FT10	FT9	FT8	FT7	FT6	FT5	FT4	FT3	FT2	FT1	FT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **FTx:** Falling trigger event configuration bit of configurable event input x [(1)] (x = 23 to 0)

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and Interrupt) for input line

1: Falling trigger enabled (for event and Interrupt) for input line.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

21.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI23	SWI22	SWI21	SWI20	SWI19	SWI18	SWI17	SWI16
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWI15	SWI14	SWI13	SWI12	SWI11	SWI10	SWI9	SWI8	SWI7	SWI6	SWI5	SWI4	SWI3	SWI2	SWI1	SWI0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **SWIx:** Software interrupt on event x (x = 23 to 0)

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Non-secure write to this SWI x is discarded, non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

21.6.4 EXTI rising edge pending register (EXTI_RPR1)

Address offset: 0x00C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF23	RPIF22	RPIF21	RPIF20	RPIF19	RPIF18	RPIF17	RPIF16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **RPIFx:** configurable event inputs x rising edge pending bit (x = 23 to 0)
When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Non-secure write to this RPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

21.6.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF23	FPIF22	FPIF21	FPIF20	FPIF19	FPIF18	FPIF17	FPIF16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **FPIFx:** configurable event inputs x falling edge pending bit (x = 23 to 0)
When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

21.6.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014

Reset value: 0x0000 0000

This register provides write access security, a non-secure write access is ignored and causes the generation of an illegal access event. A non-secure read returns the register data.

Contains only register bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC23	SEC22	SEC21	SEC20	SEC19	SEC18	SEC17	SEC16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **SECx:** Security enable on event input x (x = 23 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (non-secure)
1: Event security enabled (secure)

21.6.7 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV23	PRIV22	PRIV21	PRIV20	PRIV19	PRIV18	PRIV17	PRIV16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **PRIVx:** Security enable on event input x (x = 23 to 0)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and non-secure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. Non-secure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

21.6.8 EXTI external interrupt selection register (EXTI_EXTICRm)

Address offset: 0x060 + 0x004 * (m - 1) (m = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EXTI{4*(m-1)+3}[7:0]								EXTI{4*(m-1)+2}[7:0]

21.6.9 EXTI lock register (EXTI_LOCKR)

Address offset: 0x070

Reset value: 0x0000 0000

This register provides write access security: a non-secure write access is ignored and a read access returns zero data, and both generates an illegal access event.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LOCK**: Global security and privilege configuration registers (EXTI_SECCFGR and EXTI_PRIVCFGR) lock

This bit is written once after reset.

0: Security and privilege configuration open, can be modified.

1: Security and privilege configuration locked, can no longer be modified.

21.6.10 EXTI CPU wakeup with interrupt mask register (EXTI_IMR1)

Address offset: 0x080

Reset value: 0x0000 0000

Contains register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IM23	IM22	IM21	IM20	IM19	IM18	IM17	IM16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **IMx:** CPU wakeup with interrupt mask on event input x [(1)] (x = 23 to 0)

When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Non-secure write to this bit is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wakeup with interrupt request from input event x is masked.

1: Wakeup with interrupt request from input event x is unmasked.

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

21.6.11 EXTI CPU wakeup with event mask register (EXTI_EMR1)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **EMx:** CPU wakeup with event generation mask on event input x (x = 23 to 0)

When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Non-secure write to this bit x is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wakeup with event generation from Line x is masked.

1: Wakeup with event generation from Line x is unmasked.

22 Cyclic redundancy check calculation unit (CRC)

22.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

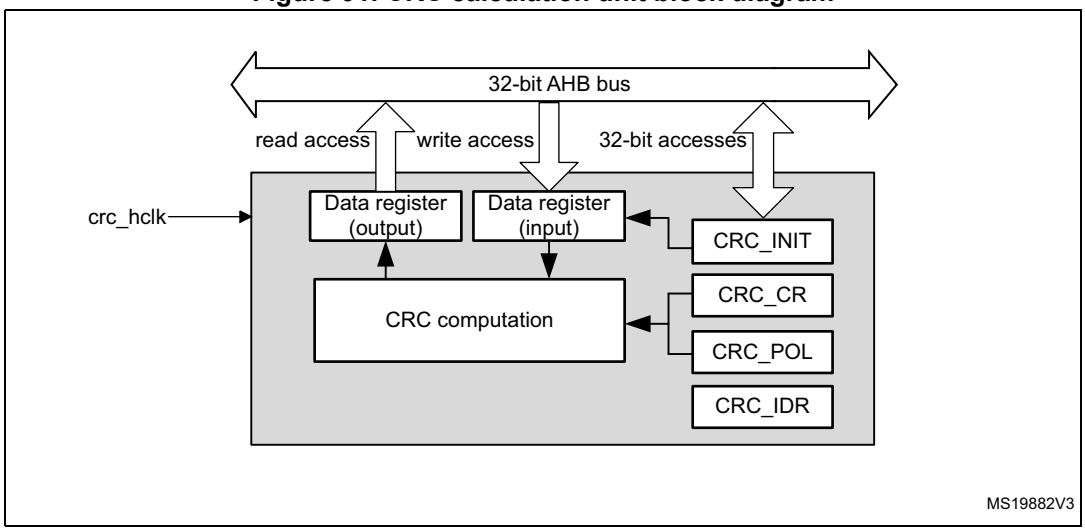
22.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

22.3 CRC functional description

22.3.1 CRC block diagram

Figure 91. CRC calculation unit block diagram



22.3.2 CRC internal signals

Table 161. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

22.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

22.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

22.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

22.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

22.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REV_OUT	REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
								rw	rw	rw	rw	rw			rs

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **REV_OUT**: Reverse output data

This bit controls the reversal of the bit order of the output data.
0: Bit order not affected
1: Bit-reversed output format

Bits 6:5 **REV_IN[1:0]**: Reverse input data

These bits control the reversal of the bit order of the input data
00: Bit order not affected
01: Bit reversal done by byte
10: Bit reversal done by half-word
11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.
00: 32 bit polynomial
01: 16 bit polynomial
10: 8 bit polynomial
11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware

22.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

22.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

22.4.6 CRC register map

Table 162. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 115* for the register boundary addresses.

23 CORDIC co-processor (CORDIC)

23.1 CORDIC introduction

The CORDIC co-processor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making it possible the use of a lower operating frequency, or freeing up processor cycles in order to perform other tasks.

23.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

23.3 CORDIC functional description

23.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle θ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle θ. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of θ. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

23.3.2 CORDIC functions

The first step when using the co-processor is to select the required function, by programming the FUNC field of the CORDIC_CR register accordingly.

Table 163 lists the functions supported by the CORDIC co-processor.

Table 163. CORDIC functions

Function	Primary argument (ARG1)	Secondary argument (ARG2)	Primary result (RES1)	Secondary result (RES2)
Cosine	angle θ	modulus m	$m \cdot \cos\theta$	$m \cdot \sin\theta$
Sine	angle θ	modulus m	$m \cdot \sin\theta$	$m \cdot \cos\theta$
Phase	x	y	atan2(y,x)	$\sqrt{x^2+y^2}$
Modulus	x	y	$\sqrt{x^2+y^2}$	atan2(y,x)
Arctangent	x	none	$\tan^{-1} x$	none
Hyperbolic cosine	x	none	cosh x	sinh x
Hyperbolic sine	x	none	sinh x	cosh x
Hyperbolic arctangent	x	none	$\tanh^{-1} x$	none
Natural logarithm	x	none	ln x	none
Square root	x	none	$\sqrt{x}$	none

Several functions take two input arguments (ARG1 and ARG2) and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: sin θ also generates cos θ, cos θ also generates sin θ. Similarly for rectangular-to-polar conversion (phase(x,y), modulus(x,y)) and for hyperbolic functions (cosh θ, sinh θ).

Note: The exponential function, exp x, can be obtained as the sum of sinh x and cosh x. Furthermore, base N logarithms, $\log_N x$, can be derived by multiplying ln x by a constant K, where K = 1/ln N.

For certain functions (atan, log, sqrt) a scaling factor (see *Section 23.3.4*) can be applied to extend the range of the function beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 164. Cosine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m · cos θ	[-1, 1]

Table 164. Cosine parameters (continued)

Parameter	Description	Range
RES2	m · sin θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the cosine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 165. Sine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m · sin θ	[-1, 1]
RES2	m · cos θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the sine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 166. Phase parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Phase angle θ in radians, divided by π	[-1, 1]

Table 166. Phase parameters (continued)

Parameter	Description	Range
RES2	Modulus m	[0, 1]
SCALE	Not applicable	0

This function calculates the phase angle in the range -π to π of a vector **v** = [x y] (also known as atan2(y,x). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle θ of the vector **v**. RES1 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES2 is saturated to 1.

Modulus

Table 167. Modulus parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Modulus m	[0, 1]
RES2	Phase angle θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the magnitude, or modulus, of a vector **v** = [x y]. It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle θ of the vector **v**. RES2 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

Arctangent

Table 168. Arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-1, 1]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \tan^{-1} x$, in radians, divided by p	[-1, 1]
RES2	Not applicable	-
SCALE	n	[0 7]

This function calculates the arctangent, or inverse tangent, of the input argument x.

The primary argument, ARG1, is the input value, $x = \tan \theta$. If $|x| > 1$, a scaling factor of 2^{-n} must be applied in software such that $-1 < x \cdot 2^{-n} < 1$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the scale factor n must be programmed in the SCALE parameter.

Note that the maximum input value allowed is $\tan \theta = 128$, which corresponds to an angle $\theta = 89.55$ degrees. For $|x| > 128$, a software method must be used to find $\tan^{-1} x$.

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle $\theta = \tan^{-1} x$. RES1 must be multiplied by $2^n \cdot \pi$ to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 169. Hyperbolic cosine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \cosh x$	[0.5 0.846]
RES2	$2^{-n} \cdot \sinh x$	[-0.683 0.683]
SCALE	n	1

This function calculates the hyperbolic cosine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. Since the minimum value of cosh x is 1, which is beyond the range of the q1.31 format, a scaling factor of 2^{-n} must be applied in software. The factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

Table 170. Hyperbolic sine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559, 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \sinh x$	[-0.683, 0.683]
RES2	$2^{-n} \cdot \cosh x$	[0.5, 0.846]
SCALE	n	1

This function calculates the hyperbolic sine of a hyperbolic angle x. It can also be used to calculate the exponential functions e^x = cosh x + sinh x, and e^{-x} = cosh x- sinh x.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. For all input values, a scaling factor of 2^{-n} must be applied in software, where n = 1. The scaled value x · 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

Table 171. Hyperbolic arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.403 0.403]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \text{atanh } x$	[-0.559 0.559]
RES2	Not applicable	-
SCALE	n	1

This function calculates the hyperbolic arctangent of the input argument x.

The primary argument is the input value x. Only values of x in the range -0.806 to +0.806 are supported. The value x must be scaled by a factor 2^{-n}, where n = 1. The scaled value

$x \cdot 0.5$ is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, atanh x. RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

Natural logarithm

Table 172. Natural logarithm parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.054 0.875]
ARG2	Not applicable	-
RES1	$2^{-(n+1)}.\ln x$	[-0.279 0.137]
RES2	Not applicable	-
SCALE	n	[1 4]

This function calculates the natural logarithm of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.107 to 9.35 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < 1-2^{-n}$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 173 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 173. Natural log scaling factors and corresponding ranges

n	x range	ARG1 range
1	$0.107 \leq x < 1$	$0.0535 \leq ARG1 < 0.5$
2	$1 \leq x < 3$	$0.25 \leq ARG1 < 0.75$
3	$3 \leq x < 7$	$0.375 \leq ARG1 < 0.875$
4	$7 \leq x \leq 9.35$	$0.4375 \leq ARG1 < 0.584$

The secondary argument is not used.

The primary result is the natural logarithm, ln x. RES1 must be multiplied by $2^{(n+1)}$ to obtain the correct value.

The secondary result is not used.

Square root

Table 174. Square root parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.027 0.875]
ARG2	Not applicable	-
RES1	$2^{-n}\sqrt{x}$	[0.04 1]
RES2	Not applicable	-
SCALE	n	[0 2]

This function calculates the square root of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.027 to 2.34 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < (1 - 2^{(-n-2)})$.

The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 175 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 175. Square root scaling factors and corresponding ranges

n	x range	ARG1 range
0	$0.027 \leq x < 0.75$	0.027 ≤ ARG1 < 0.75
1	$0.75 \leq x < 1.75$	0.375 ≤ ARG1 < 0.875
2	$1.75 \leq x \leq 2.341$	0.4375 ≤ ARG1 ≤ 0.585

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2^n to obtain the correct value.

The secondary result is not used.

23.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to $1 - 2^{-31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to $1 - 2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

23.3.4 Scaling factor

Several of the functions listed in *Section 23.3.2* specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output or internal registers. If the scaling factor is

required, it has to be calculated in software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

23.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see *Figure 92*.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see *Figure 93*). The square root function converges at roughly twice the speed of the hyperbolic functions (see *Figure 94*).

Figure 92. CORDIC convergence for trigonometric functions

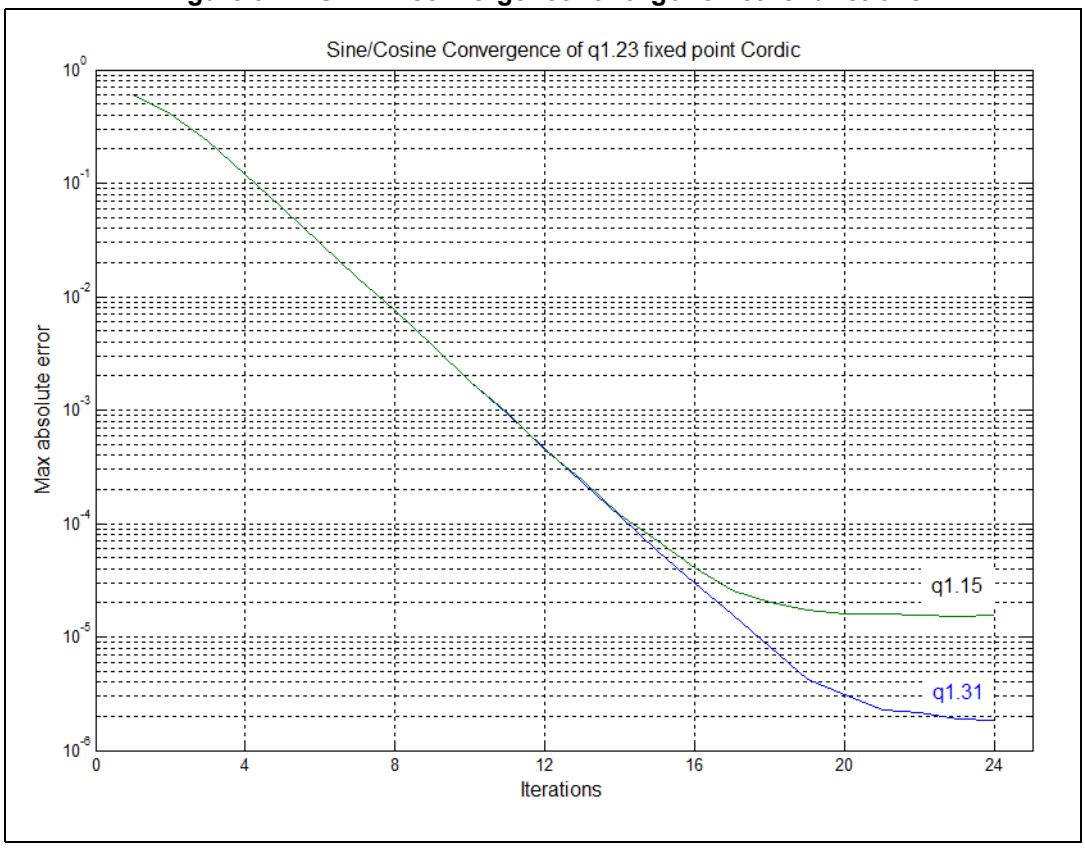

Figure 93. CORDIC convergence for hyperbolic functions

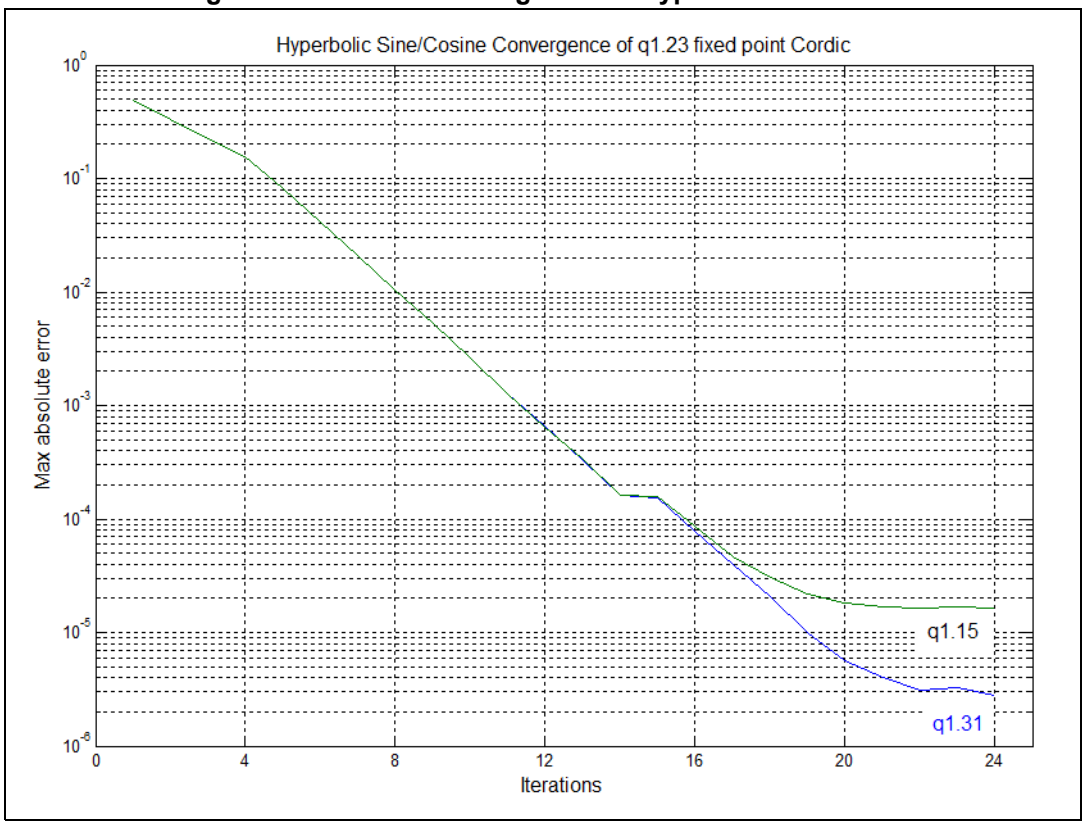

Figure 94. CORDIC convergence for square root

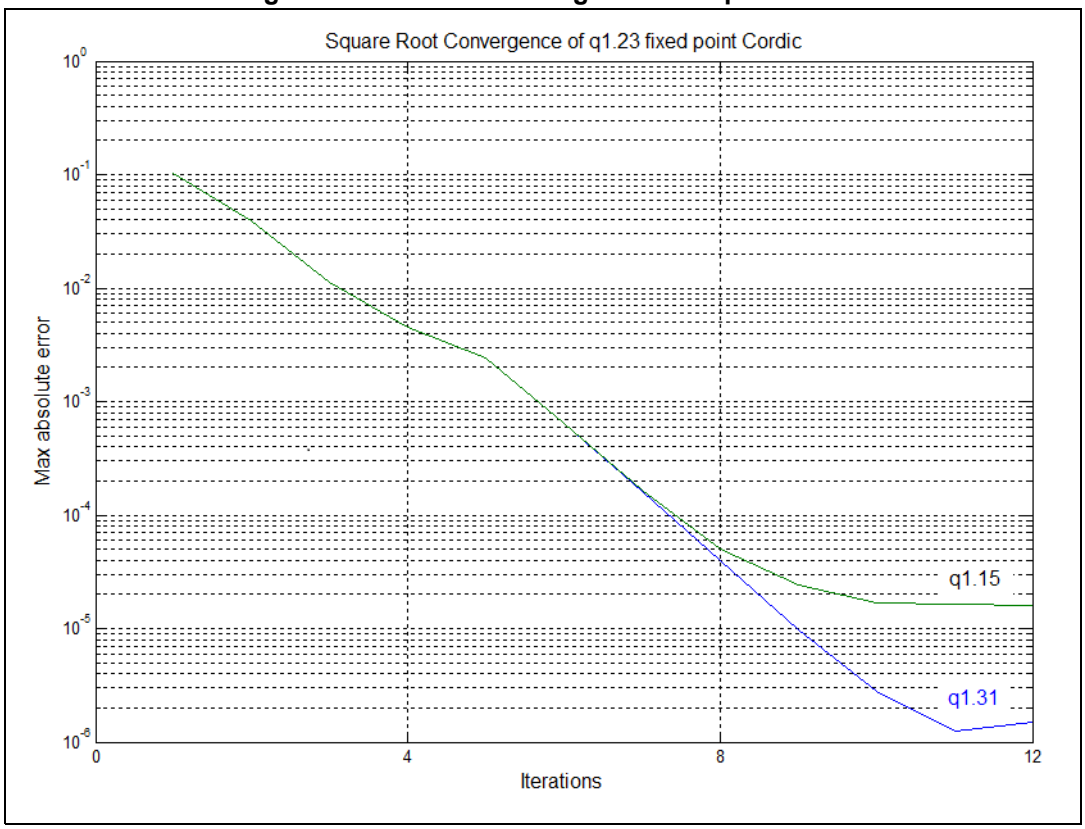

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in *Table 176*, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The co-processor stops as soon as the programmed number of iterations has completed, and the result can be read immediately.

Table 176. Precision vs. number of iterations

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sin, Cos, Phase(2), Mod, Atan(4)	4	1	2^{-3}	2^{-3}
	8	2	2^{-7}	2^{-7}
	12	3	2^{-11}	2^{-11}
	16	4	2^{-15}	2^{-15}
	20	5	2^{-18}	2^{-16}
	24	6	2^{-19}	2^{-16}

Table 176. Precision vs. number of iterations (continued)

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sinh, Cosh, Atanh, Ln(3)	4	1	2^{-2}	2^{-2}
	8	2	2^{-6}	2^{-6}
	12	3	2^{-10}	2^{-10}
	16	4	2^{-13}	2^{-13}
	20	5	2^{-17}	2^{-15}
	24	6	2^{-18}	2^{-15}
Sqrt(4)	4	1	2^{-7}	2^{-7}
	8	2	2^{-14}	2^{-14}
	12	3	2^{-19}	2^{-15}

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.
2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.
3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.
4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.

23.3.6 Zero-overhead mode

The fastest way to use the co-processor is to pre-program the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

Subsequently, a calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished) a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to re-program the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument, ARG1, must be written first, followed by the secondary argument, ARG2. If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait states until the calculation is completed, before returning the result. Hence it is possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation and prepare the next input data, if needed. The CORDIC_CSR register can be re-programmed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous arguments have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed in order to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be one calculation in progress, or waiting for the results to be read, and one operation pending. Any further access to CORDIC_WDATA while an operation is pending, cancels the pending operation and overwrite the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step *3*.

23.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. However the processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (e.g. if low latency interrupts must be serviced).

23.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

23.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention.This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. Note that the sequence is started by the processor setting the DMAWEN flag. Thereafter the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generate a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore only useful when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.

Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and could block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

23.4 CORDIC registers

The CORDIC registers can only be accessed in 32-bit word format

23.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARG SIZE	RES SIZE	NARG S	NRES	DMA WEN	DMA REN	IEN
r									rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SCALE[2:0]			PRECISION[3:0]				FUNC[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **RRDY**: Result ready flag

0: No new data in output register

1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data

0: 32-bit

1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format. The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data

0: 32-bit

1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.

Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register
0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.
Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register
0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.
1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.
Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel
0: Disabled. No DMA write requests are generated.
1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel
0: Disabled. No DMA read requests are generated.
1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt.
0: Disabled. No interrupt requests are generated.
1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor
The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to *Section 23.3.2* for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to *Table 176*.
Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 **FUNC[3:0]**: Function

0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square Root
10 to 15: reserved

23.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARG[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARG[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 23.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG 2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

23.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RES[31:0]**: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed.

A read from this register resets the RRDY flag in the CORDIC_CSR register.

23.4.4 CORDIC register map

Table 177. CORDIC register map and reset value

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

24 Filter math accelerator (FMAC)

24.1 FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

24.2 FMAC main features

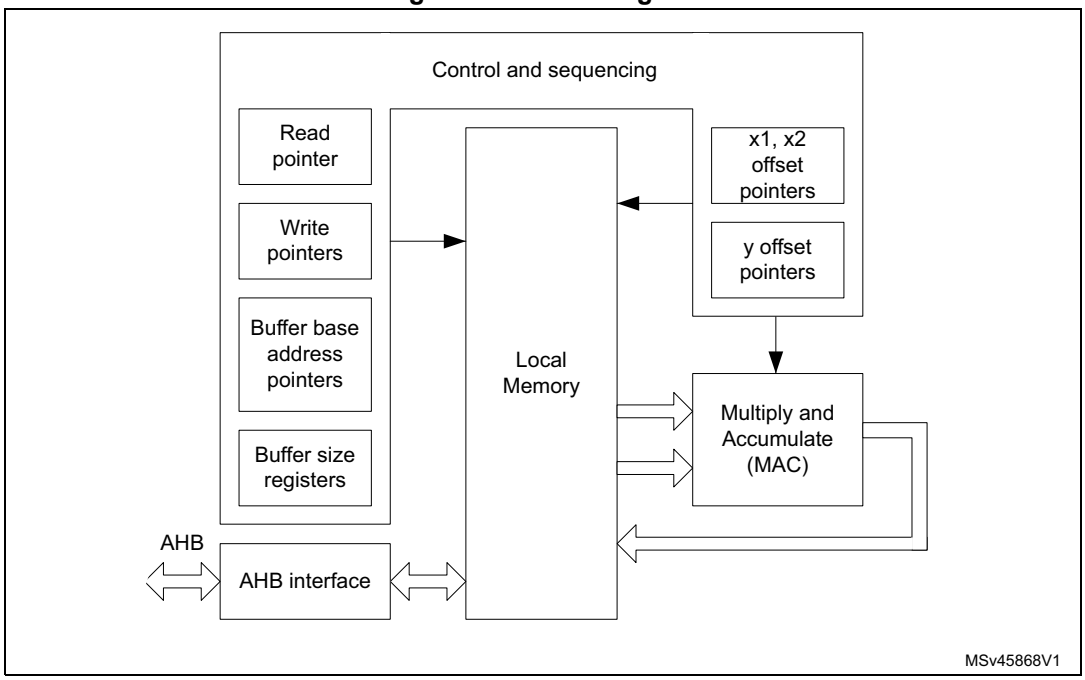
- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels

24.3 FMAC functional description

24.3.1 General description

The FMAC is shown in *Figure 95*.

Figure 95. Block diagram



The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in *Section 24.3.6: Filter functions*.

24.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (*Section 24.3.5: Initialization functions*) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in *Section 24.3.6: Filter functions*. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.

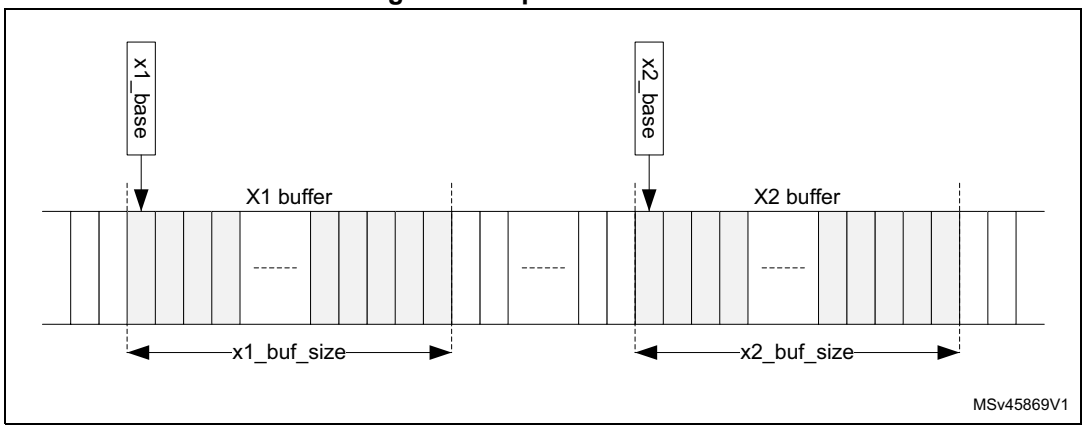
There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level should be chosen according to the application performance requirements. For maximum throughput, the input buffer should never go empty, so d should be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

24.3.3 Input buffers

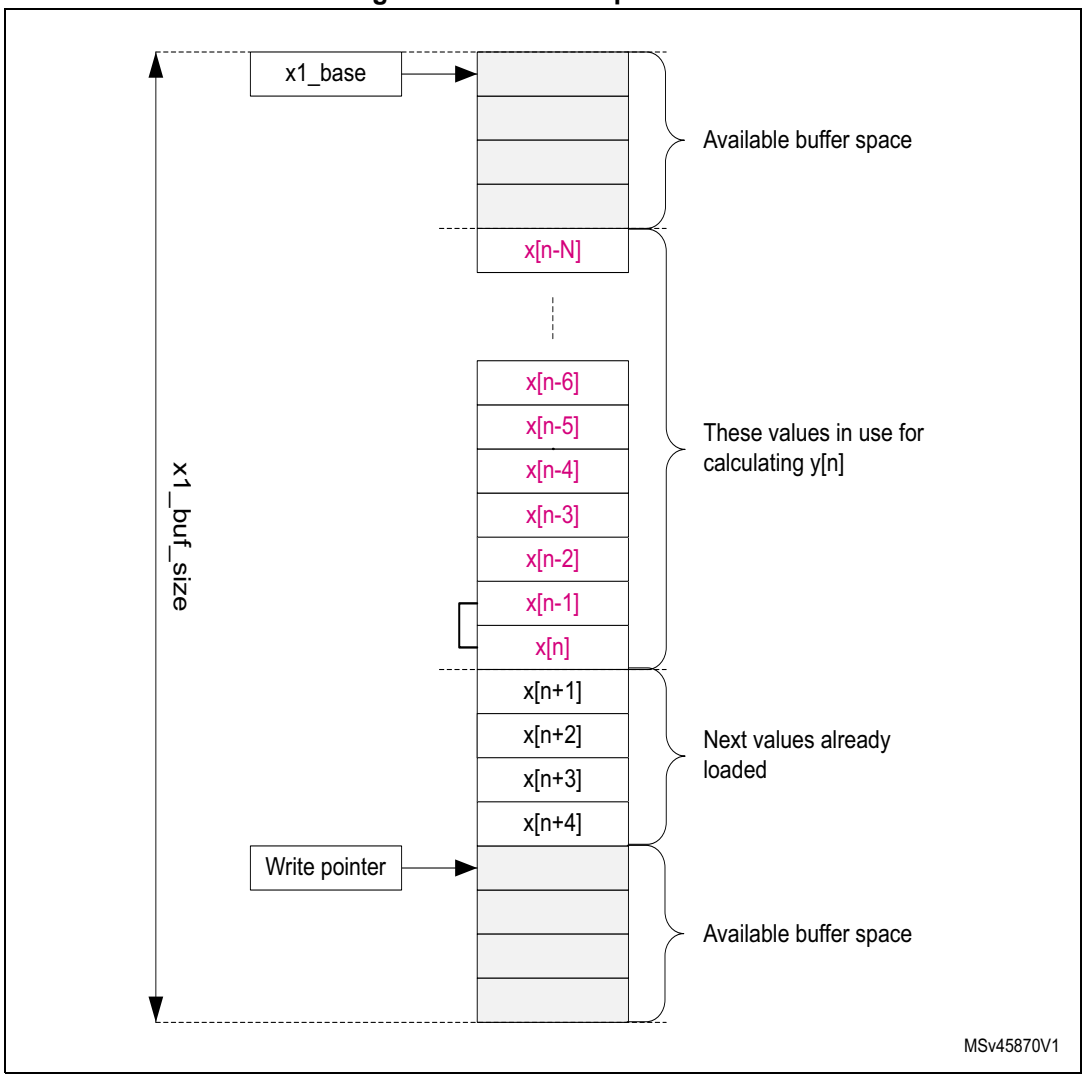
The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.

Figure 96. Input buffer areas



The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.

Figure 97. Circular input buffer



The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) should generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. *Figure 97* illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.

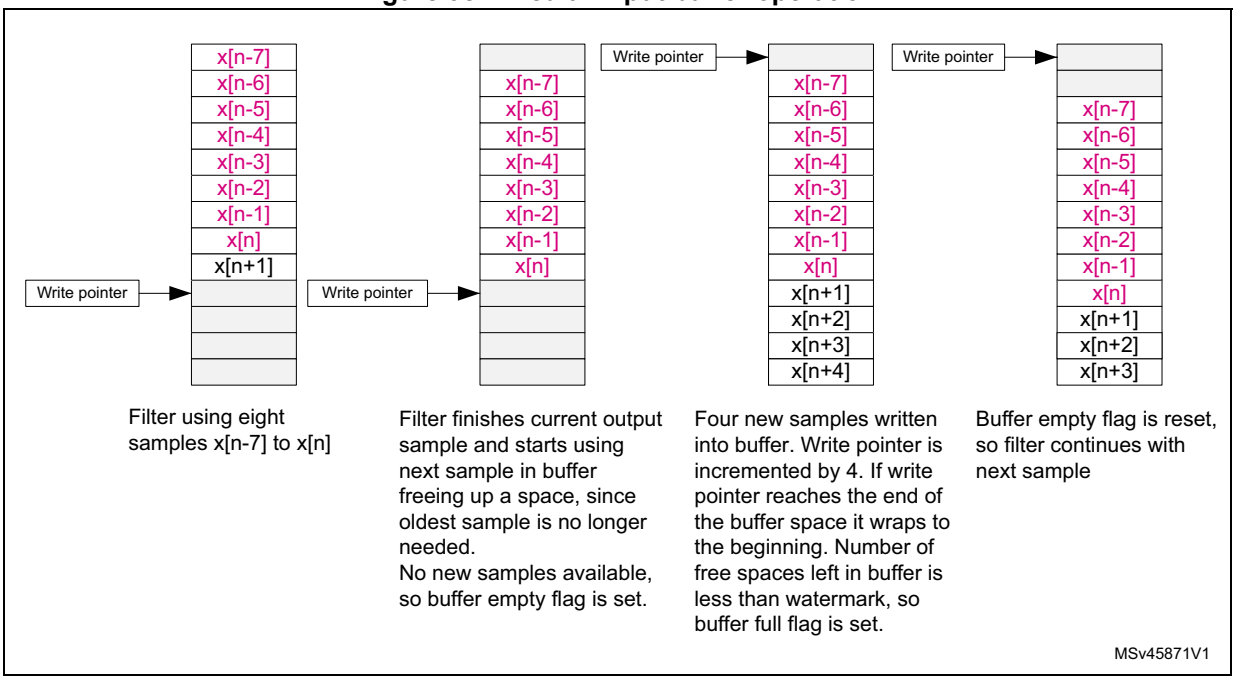
The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.

Note: If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in *Figure 98*. This example shows an 8-tap FIR filter with a watermark set to four.

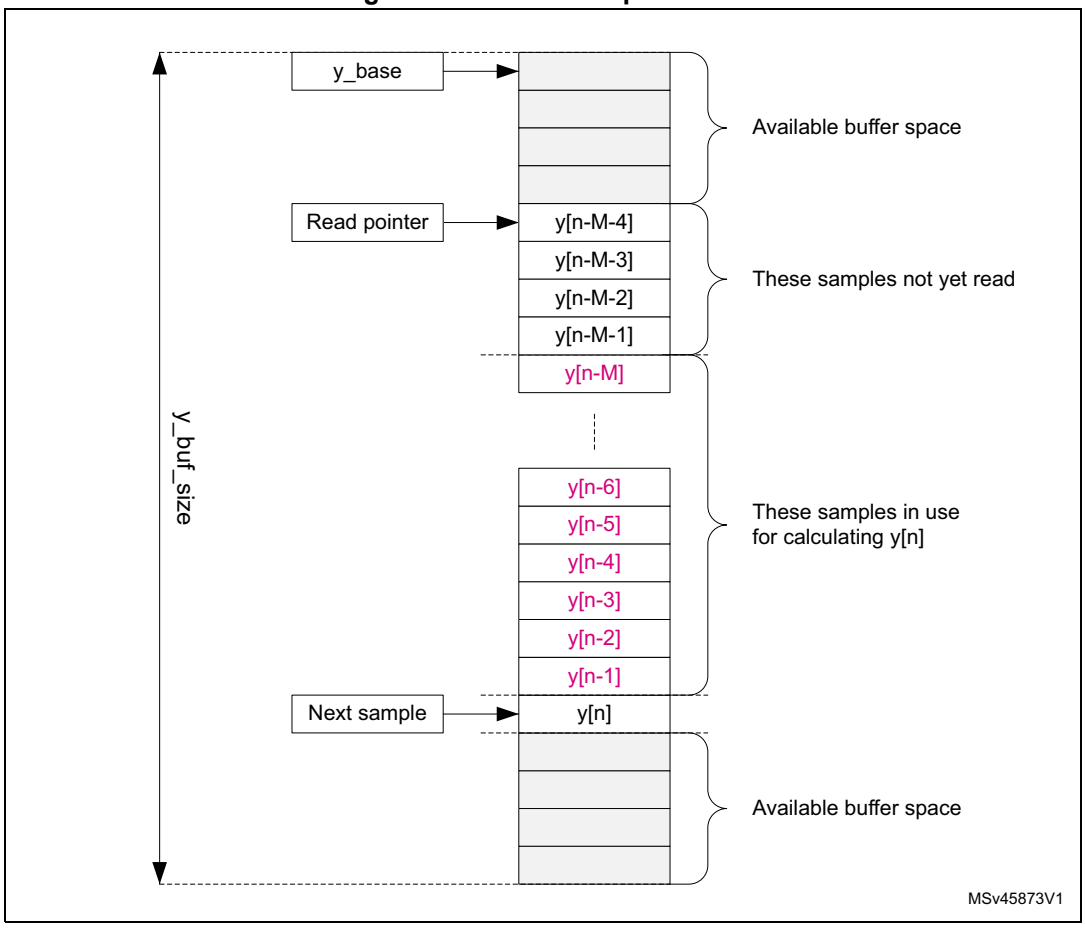
Figure 98. Circular input buffer operation



24.3.4 Output buffer

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.

Figure 99. Circular output buffer



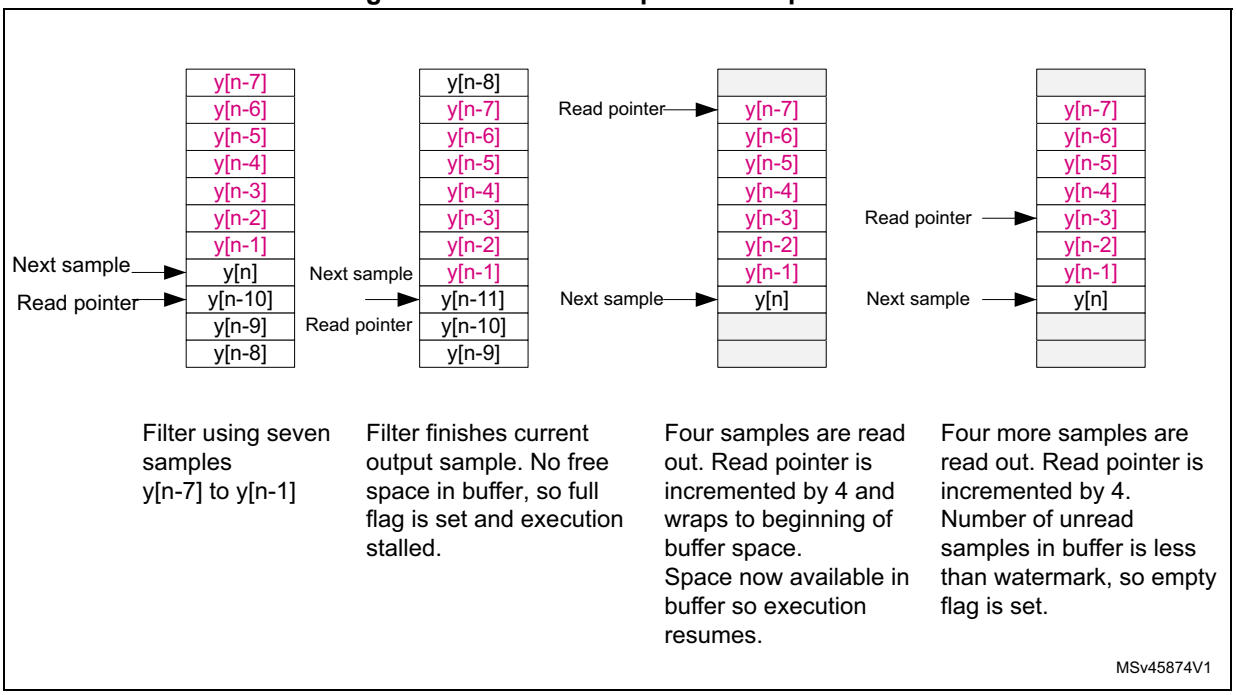
The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of M previous output samples, y[n-M] to y[n-1], used for calculating the next output sample y[n]. Each time a new sample is added to the set, the least recent sample y[n-M] drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in *Figure 100*. This example shows a 7-tap IIR filter with a watermark set to four.

Figure 100. Circular output buffer operation



24.3.5 Initialization functions

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

Load X1 buffer

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

Load X2 buffer

This function pre-loads the X2 buffer with N + M values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the N feed-forward and M feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to N + M. For an FIR, there are no feedback coefficients, so M = 0.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter Q contains the number of values, M, to be loaded into the X2 buffer starting from address X2_BASE + N.
- The parameter R is not used.

The function completes when N + M writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with N values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + N when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

Parameters

- The parameter P contains the number of values to be loaded into the Y buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

24.3.6 Filter functions

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

Convolution (FIR filter)

Y = **B***__X__

$$y_n = 2^R \cdot \sum_{k=0}^{N} b_k x_{n-k}$$

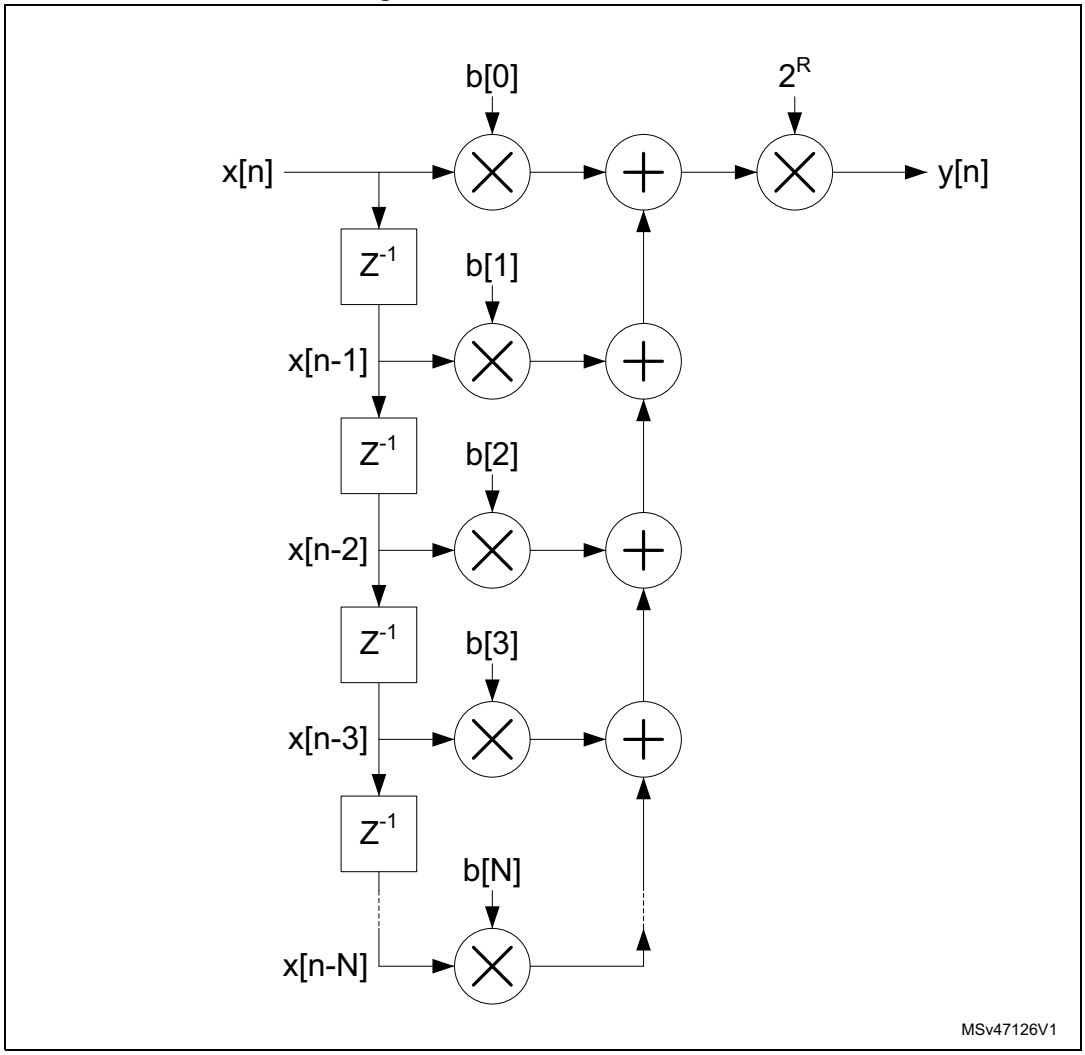
This function performs a convolution of a vector **B** of length N+1 and a vector **X** of indefinite length. The elements of **Y** for incrementing values of n are calculated as the dot product,

$y_n = \underline{\mathbf{B}}.\underline{\mathbf{X}}_{\mathbf{n}}$, where $\underline{\mathbf{X}}_{\mathbf{n}} = [x_{n-N},...,x_n]$ is composed of the N+1 elements of $\underline{\mathbf{X}}$ at indexes n - N to n.

This function corresponds to a finite impulse response (FIR) filter, where vector **B** contains the filter coefficients and vector **X** the sampled data.

The structure of the filter (direct form) is shown in *Figure 101*.

Figure 101. FIR filter structure



Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector **B**.

Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1 + d.
- X2 buffer contains the elements of vector **B**. It is a fixed buffer of length N + 1.

Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length d.

Parameters:

- The parameter P contains the length, N+1, of the coefficient vector **B** in the range [2:127].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7]
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.

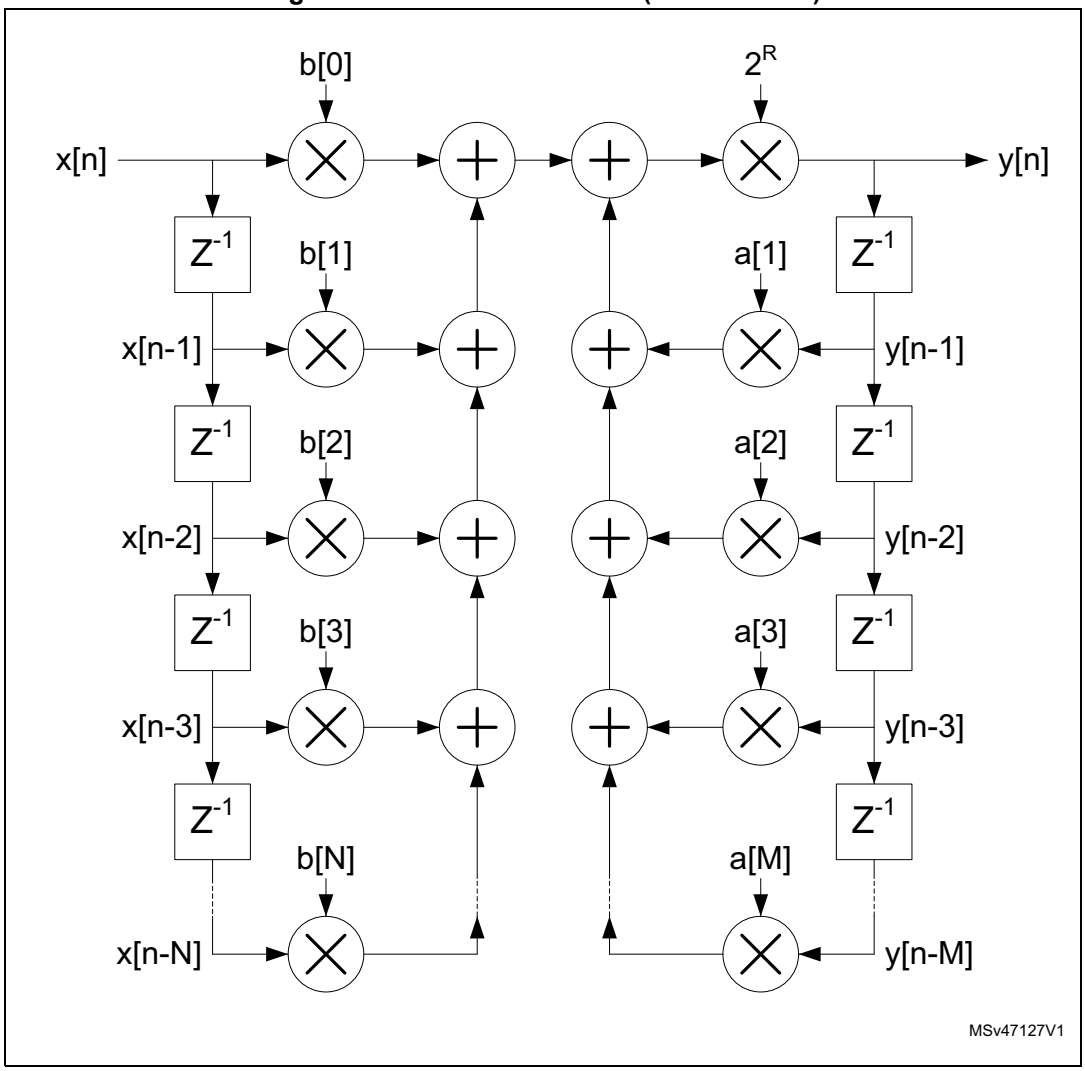
IIR filter

Y = **B*****X**+**A*****Y'**

$$y_n = 2^R \cdot \left(\sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right)$$

This function implements an infinite impulse response (IIR) filter. The filter output vector **Y** is the convolution of a coefficient vector **B** of length N+1 and a vector **X** of indefinite length, plus the convolution of the delayed output vector **Y'** with a second coefficient vector **A**, of length M. The elements of **Y** for incrementing values of n are calculated as y_n = **B**.$\mathbf{X_n}$ + **A**.$\mathbf{Y_{n-1}}$, where $\mathbf{X_n}$ = $[x_{n-N},...,x_n]$ comprises the N+1 elements of **X** at indexes n - N to n, while $\mathbf{Y_{n-1}}$ = $[y_{n-M},...,y_{n-1}]$ comprises the M elements of **Y** at indexes n - M to n - 1. The structure of the filter (direct form 1) is shown in *Figure 102*.

Figure 102. IIR filter structure (direct form 1)



Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1+ d.
- X2 buffer contains the elements of coefficient vectors **B** and **A** concatenated (b_0, b_1, b_2..., b_N, a_1, a_2, ..., a_M). It is a fixed buffer of length M+N+1.

Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length M + d.

Parameters

- The parameter P contains the length, N + 1, of the coefficient vector **B** in the range [2:64].
- The parameter Q contains the length, M, of the coefficient vector **A** in the range [1:63].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7].

The function completes when the START bit in the FMAC_PARAM register is reset by software.

24.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15.

In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2^{-15} (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x2000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2^{-15} or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

24.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

- N coefficients
- N input samples
- 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers should be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N;
- Y_BUF_SIZE = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration could be:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = 2N + d1

However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = N

In this case, Y_BUF_SIZE = X1_BUF_SIZE = N + d1, so that the buffers remain in sync.

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

The filter coefficients **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register should be programmed according to the method used for writing and reading data to and from the FMAC memory.

Three methods are supported:

- Polling: No DMA request or Interrupt request is generated. Software must check that the X1_FULL flag is low before writing to WDATA, or that the Y_EMPTY flag is low before reading from RDATA.
- Interrupt: The interrupt request is asserted while the X1_FULL flag is low, for writes, or when the Y_EMPTY flag is low, for reads.
- DMA: DMA requests are asserted on the DMA write channel while the X1_FULL flag is low, and on the read channel while the Y_EMPTY flag is low.

Different methods can be used for read and for write. However it is not recommended to use both interrupts and DMA requests for the same operation[(a)]. The valid combinations are listed in *Table 178*.

Table 178. Valid combinations for read and write methods

WIEN	RIEN	DMAWEN	DMAREN	Write	Read
0	0	0	0	Polling	Polling
0	1	0	0	Polling	Interrupt
1	0	0	0	Interrupt	Polling
1	1	0	0	Interrupt	Interrupt
0	0	0	1	Polling	DMA
0	0	1	0	DMA	Polling
0	0	1	1	DMA	DMA
0	1	1	0	DMA	Interrupt
1	0	0	1	Interrupt	DMA

a. If both interrupts and DMA requests are enabled then only DMA should perform the transfer.

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 8 (FIR filter);
- P = N (number of coefficients);
- Q = “Don’t care”;
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine should check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples).

When 2^{EMPTY_WM} output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine should check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

24.3.9 Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length N, where N is the number of feed-forward taps or coefficients. The number of feedback coefficients, M, can be any value from 1 to N-1. Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with N feed-forward coefficients and M feed-back coefficients is 2N + 2M:

- N + M coefficients
- N input samples
- M output samples

If M = N-1, then the maximum filter length that can be implemented is N = 64.

As for the FIR, for maximum throughput a small amount of additional space, d1 and d2, should be allowed in the input and output buffer size respectively, making the total memory requirement 2M + 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N + M;
- Y_BUF_SIZE = M + d2;

The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- X2_BASE = 0;
- X1_BASE = N + M;
- Y_BASE = 2N + M + d1;

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

The filter coefficients (N feed-forward followed by M feedback) **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. The Y buffer can optionally be pre-loaded with any number of values up to a maximum of M. This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC_CR register should be programmed in the same way as for the FIR filter (see *Section 24.3.8: Implementing FIR filters with the FMAC*).

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 9 (IIR filter);
- P = N (number of feed-forward coefficients);
- Q = M (number of feed-back coefficients);
- R = Gain;
- START = 1;

If less than $N + d - 2^{FULL\_WM}$ values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine should check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

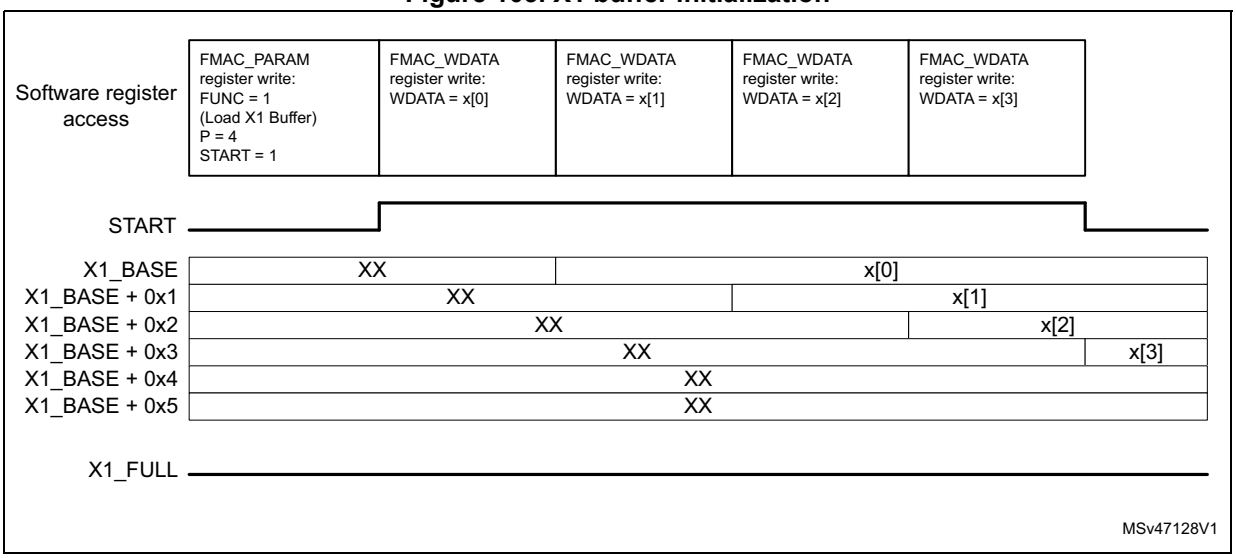
The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first N samples in the X1 buffer, and the first M samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at Y_BASE + M.

When 2^{EMPTY_WM} new output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine should check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

24.3.10 Examples of filter initialization

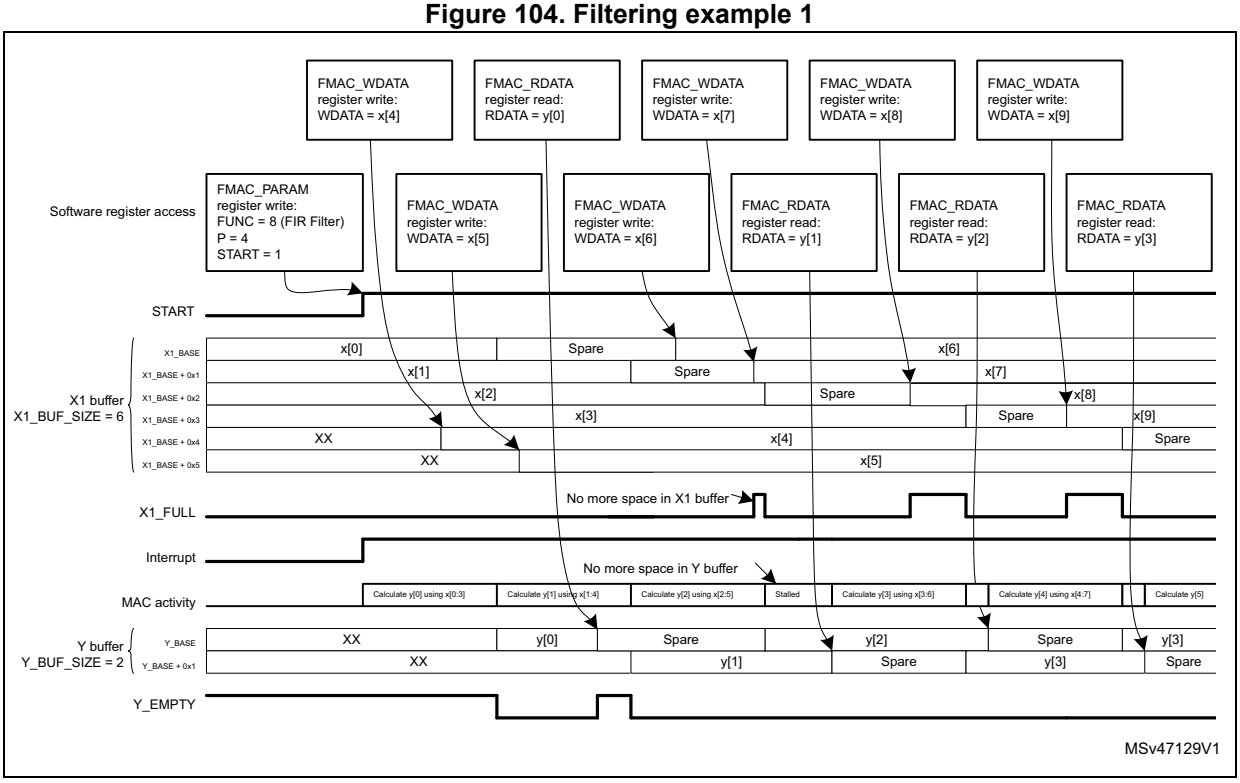
Figure 103. X1 buffer initialization



The example in *Figure 103* illustrates a X1 buffer pre-load with four samples (P = 4). The buffer size is six (X1_BUF_SIZE = 6). The initialization is launched by programming the FMAC_PARAM register with the START bit set. The four samples are then written to FMAC_WDATA, and transferred into local memory from X1_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1_BASE + 0x4.

24.3.11 Examples of filter operation

Figure 104. Filtering example 1



The example in *Figure 104* illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 103*. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.

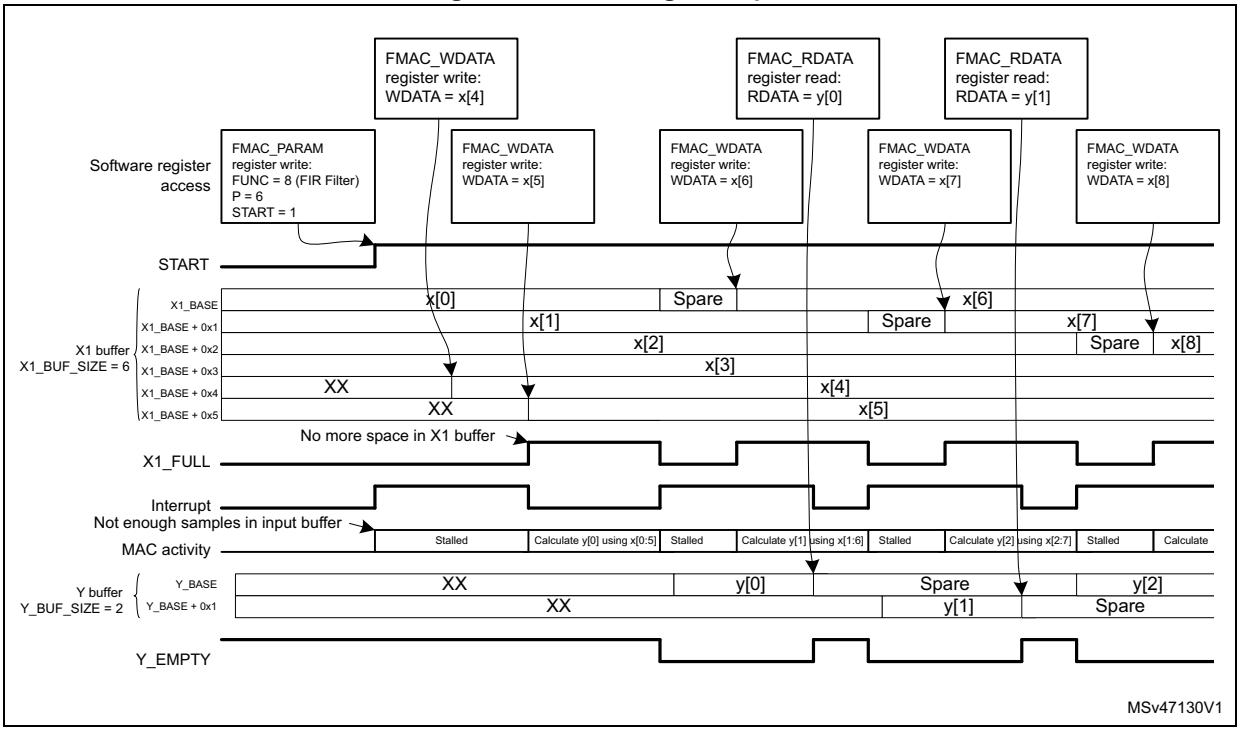
In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

Note: In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the

filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size would not help.

Figure 105. Filtering example 2



The example in *Figure 105* illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 103*. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.

24.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms should be converted to direct form 1.
2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.
3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients' absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is "undone" before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.
4. The IIR filter has feed-forward (numerator) coefficients $[b_0, b_1, ..., b_{N-1}]$, and feed-back (denominator) coefficients $[1, a_1, ..., a_M]$. Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor 2^{-R}, such that $2^{-R}.[1, a_1, ..., a_M]$ are all less than 1, such filters can be implemented. However an inverse gain of 2^R must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.

24.4 FMAC registers

24.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG)

Address offset: 0x00

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FULL_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X1_BUF_SIZE[7:0]								X1_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FULL_WM[1:0]**: Watermark for buffer full flag

Defines the threshold for setting the X1 buffer full flag when operating in circular mode. The flag is set if the number of free spaces in the buffer is less than 2^{FULL_WM}.

0: Threshold = 1

1: Threshold = 2

2: Threshold = 4

3: Threshold = 8

Setting a threshold greater than 1 allows several data to be transferred into the buffer under one interrupt.

Threshold should be set to 1 if DMA write requests are enabled (DMAWEN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **X1_BUF_SIZE[7:0]**: Allocated size of X1 buffer in 16-bit words

The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1).

Bits 7:0 **X1_BASE[7:0]**: Base address of X1 buffer

24.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG)

Address offset: 0x04

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X2_BUF_SIZE[7:0]								X2_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **X2_BUF_SIZE[7:0]**: Size of X2 buffer in 16-bit words
This bitfield can not be modified when a function is ongoing (START = 1).

Bits 7:0 **X2_BASE[7:0]**: Base address of X2 buffer
The X2 buffer base address can be modified while START=1, for example to change coefficient values. The filter should be stalled when doing this, since changing the coefficients while a calculation is ongoing affects the result.

24.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG)

Address offset: 0x08

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	EMPTY_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Y_BUF_SIZE[7:0]								Y_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **EMPTY_WM[1:0]**: Watermark for buffer empty flag
Defines the threshold for setting the Y buffer empty flag when operating in circular mode. The flag is set if the number of unread values in the buffer is less than 2^{EMPTY_WM}.
0: Threshold = 1
1: Threshold = 2
2: Threshold = 4
3: Threshold = 8
Setting a threshold greater than 1 allows several data to be transferred from the buffer under one interrupt.
Threshold should be set to 1 if DMA read requests are enabled (DMAREN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **Y_BUF_SIZE[7:0]**: Size of Y buffer in 16-bit words
For FIR filters, the minimum buffer size is 1 (+ the watermark threshold). For IIR filters the minimum buffer size is the number of feedback taps (+ the watermark threshold).

Bits 7:0 **Y_BASE[7:0]**: Base address of Y buffer

24.4.4 FMAC parameter register (FMAC_PARAM)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
START	FUNC[6:0]							R[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Q[7:0]								P[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **START**: Enable execution
0: Stop execution
1: Start execution
Setting this bit triggers the execution of the function selected in the FUNC bitfield. Resetting it by software stops any ongoing function. For initialization functions, this bit is reset by hardware.

Bits 30:24 **FUNC[6:0]**: Function
0: Reserved
1: Load X1 buffer
2: Load X2 buffer
3: Load Y buffer
4 to 7: Reserved
8: Convolution (FIR filter)
9: IIR filter (direct form 1)
10 to 127: Reserved
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 23:16 **R[7:0]**: Input parameter R.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 15:8 **Q[7:0]**: Input parameter Q.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 7:0 **P[7:0]**: Input parameter P.
The value of this parameter is dependent on the function
This bitfield can not be modified when a function is ongoing (START = 1)

24.4.5 FMAC control register (FMAC_CR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESET
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLIP EN	Res.	Res.	Res.	Res.	Res.	DMA WEN	DMA REN	Res.	Res.	Res.	SAT IEN	UNFL IEN	OVFL IEN	WIEN	RIEN
rw						rw	rw				rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RESET**: Reset FMAC unit

This resets the write and read pointers, the internal control logic, the FMAC_SR register and the FMAC_PARAM register, including the START bit if active. Other register settings are not affected. This bit is reset by hardware.

0: Reset inactive

1: Reset active

Bit 15 **CLIPEN**: Enable clipping

0: Clipping disabled. Values at the output of the accumulator which exceed the q1.15 range, wrap.

1: Clipping enabled. Values at the output of the accumulator which exceed the q1.15 range are saturated to the maximum positive or negative value (+1 or -1) according to the sign.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DMAWEN**: Enable DMA write channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the X1 buffer is not full.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bit 8 **DMAREN**: Enable DMA read channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the Y buffer is not empty.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SATIEN**: Enable saturation error interrupts

0: Disabled. No interrupts are generated upon saturation detection.

1: Enabled. An interrupt request is generated if the SAT flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 3 **UNFLIEN**: Enable underflow error interrupts

0: Disabled. No interrupts are generated upon underflow detection.

1: Enabled. An interrupt request is generated if the UNFL flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 2 **OVFLIEN**: Enable overflow error interrupts
0: Disabled. No interrupts are generated upon overflow detection.
1: Enabled. An interrupt request is generated if the OVFL flag is set
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt
0: Disabled. No write interrupt requests are generated.
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt
0: Disabled. No read interrupt requests are generated.
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

24.4.6 FMAC status register (FMAC_SR)

Address offset: 0x14

Reset value: 0x0000 0001

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SAT	UNFL	OVFL	Res.	Res.	Res.	Res.	Res.	Res.	X1 FULL	Y EMPTY
					r	r	r							r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SAT**: Saturation error flag
Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.
0: No saturation detected
1: Saturation detected. If the SATIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 9 **UNFL**: Underflow error flag
An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.
0: No underflow detected
1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 8 **OVFL**: Overflow error flag
An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.
0: No overflow detected
1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **X1FULL**: X1 buffer full flag

The buffer is flagged as full if the number of available spaces is less than the FULL_WM threshold. The number of available spaces is the difference between the write pointer and the least recent sample currently in use.

0: X1 buffer not full. If the WIEN bit is set, the interrupt request is asserted until the flag is set. If DMAWEN is set, DMA write channel requests are generated until the flag is set.

1: X1 buffer full.

This flag is set and cleared by hardware, or by a reset.

Note: after the last available space in the X1 buffer is filled there is a delay of 3 clock cycles before the X1FULL flag goes high. To avoid any risk of overflow it is recommended to insert a software delay after writing to the X1 buffer before reading the FMAC_SR. Alternatively, a FULL_WM threshold of 2 can be used.

Bit 0 **YEMPTY**: Y buffer empty flag

The buffer is flagged as empty if the number of unread data is less than the EMPTY_WM threshold. The number of unread data is the difference between the read pointer and the current output destination address.

0: Y buffer not empty. If the RIEN bit is set, the interrupt request is asserted until the flag is set. If DMAREN is set, DMA read channel requests are generated until the flag is set.

1: Y buffer empty.

This flag is set and cleared by hardware, or by a reset.

Note: after the last sample is read from the Y buffer there is a delay of 3 clock cycles before the YEMPTY flag goes high. To avoid any risk of underflow it is recommended to insert a software delay after reading from the Y buffer before reading the FMAC_SR. Alternatively, an EMPTY_WM threshold of 2 can be used.

24.4.7 FMAC write data register (FMAC_WDATA)

Address offset: 0x18

Reset value: 0x0000 0000

Access: word and half-word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WDATA[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WDATA[15:0]**: Write data

When a write access to this register occurs, the write data are transferred to the address offset indicated by the write pointer. The pointer address is automatically incremented after each write access.

24.4.8 FMAC read data register (FMAC_RDATA)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: word and half-word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RDATA[15:0]**: Read data

When a read access to this register occurs, the read data are the contents of the Y output buffer at the address offset indicated by the READ pointer. The pointer address is automatically incremented after each read access.

24.4.9 FMAC register map

Table 179.FMAC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

25 Flexible static memory controller (FSMC)

25.1 Introduction

The flexible static memory controller (FSMC) includes two memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller

This memory controller is also named flexible memory controller (FMC).

25.2 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, and NAND Flash memory. Its main purposes are:

- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

The Write FIFO is common to all memory controllers and consists of:

- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM). In this case, the AHB burst is broken into two FIFO entries.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up.

However, only a few bits can be changed on-the-fly:

- MBKEN, FMCEN, WEN bits in FMC_BCRx register
- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register

Follow the below sequence to modify parameters while the FMC is enabled:

1. First disable the FMC controller to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC controller again.

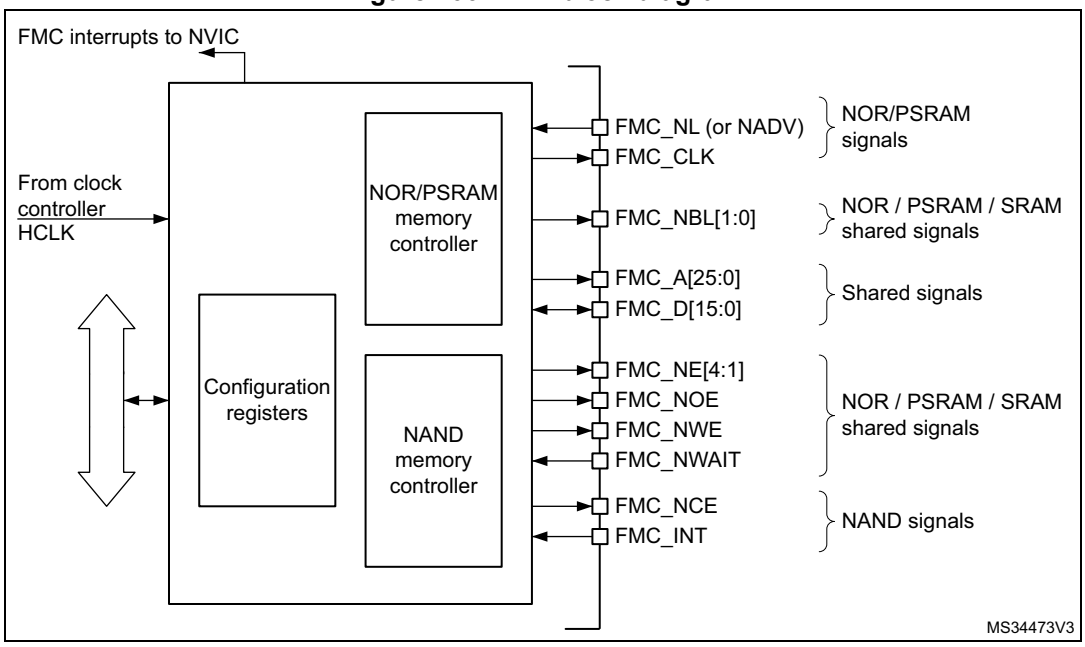
25.3 FMC block diagram

The FMC consists of the following main blocks:

- The AHB interface (including the FMC configuration registers)
- The NOR Flash/PSRAM/SRAM controller

The block diagram is shown in the figure below.

Figure 106. FMC block diagram



25.4 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:

- When reading or writing to a FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC_BCRx register.

The effect of an AHB error depends on the AHB master which has attempted the R/W access:

- If the access has been attempted by the Cortex®-M33 CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

25.4.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal

  There is no issue in this case.
- AHB transaction size is greater than the memory size:

  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.
- AHB transaction size is smaller than the memory size:

  The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM)

    In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes NBL[1:0].

    Bytes to be written are addressed by NBL[1:0].

    All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.

– Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)

This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the Flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

Wrap support for NOR Flash/PSRAM

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

Configuration registers

The FMC can be configured through a set of registers. Refer to *Section 25.6.6*, for a detailed description of the NOR Flash/PSRAM controller registers. Refer to *Section 25.7.7*, for a detailed description of the NAND Flash registers.

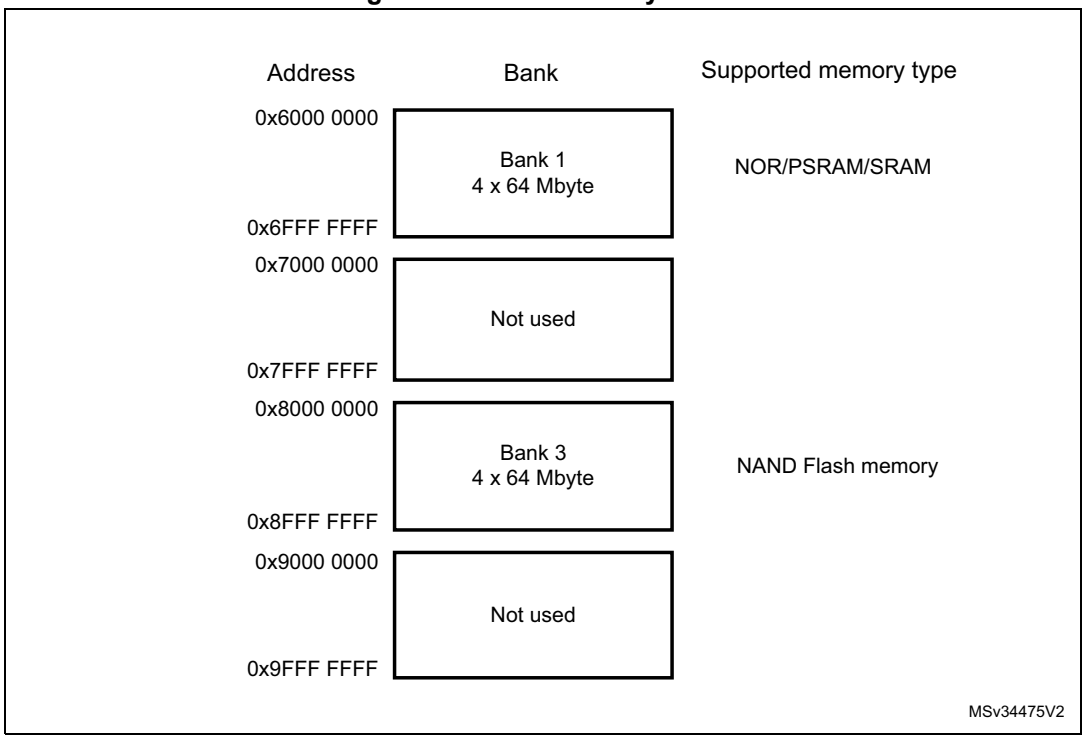
25.5 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see *Figure 107*):

- Bank 1 used to address up to 4 NOR Flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 3 used to address NAND Flash memory devices.The MPU memory attribute for this space must be reconfigured by software to Device.

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 107. FMC memory banks



25.5.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in *Table 180*.

Table 180. NOR/PSRAM bank selection

HADDR[27:26](1)	Selected bank
00	Bank 1 - NOR/PSRAM 1
01	Bank 1 - NOR/PSRAM 2
10	Bank 1 - NOR/PSRAM 3
11	Bank 1 - NOR/PSRAM 4

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 181. NOR/PSRAM External memory address

Memory width(1)	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	HADDR[25:0]	64 Mbytes x 8 = 512 Mbits
16-bit	HADDR[25:1] >> 1	64 Mbytes/2 x 16 = 512 Mbits

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0].
Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].

25.5.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in *Table 182*.

Table 182. NAND memory mapping and timing registers

Start address	End address	FMC bank	Memory space	Timing register
0x8800 0000	0x8BFF FFFF	Bank 3 - NAND Flash	Attribute	FMC_PATT (0x8C)
0x8000 0000	0x83FF FFFF		Common	FMC_PMEM (0x88)

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in *Table 183* below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 183. NAND bank selection

Section name	HADDR[17:16]	Address range
Address section	1X	0x020000-0x03FFFF
Command section	01	0x010000-0x01FFFF
Data section	00	0x000000-0x0FFFF

The application software uses the 3 sections to access the NAND Flash memory:

- **To sending a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data,** the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

25.6 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits

- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see *Section 25.6.6: NOR/PSRAM controller registers*). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to *Section 25.6.5: Synchronous transactions* for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see *Section 25.6.6: NOR/PSRAM controller registers*).

The programmable memory parameters include access times (see *Table 184*) and support for wait management (for PSRAM and NOR Flash accessed in Burst mode).

Table 184. Programmable NOR/PSRAM access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	AHB clock cycle (HCLK)	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	AHB clock cycle (HCLK)	1	15
NBL setup	Duration of the byte lanes setup phase	Asynchronous	AHB clock cycle (HCLK)	0	3

Table 184. Programmable NOR/PSRAM access parameters (continued)

Parameter	Function	Access mode	Unit	Min.	Max.
Data setup	Duration of the data setup phase	Asynchronous	AHB clock cycle (HCLK)	1	256
Data hold	Duration of the data hold phase	Asynchronous	AHB clock cycle (HCLK)	0	3
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read / write	AHB clock cycle (HCLK)	0	15
Clock divide ratio	Number of AHB clock cycles (HCLK) to build one memory clock cycle (CLK)	Synchronous	AHB clock cycle (HCLK)	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle (CLK)	2	17

25.6.1 External memory interface signals

Table 185, *Table 186* and *Table 187* list the signals that are typically used to interface with NOR Flash memory, SRAM and PSRAM.

Note: The prefix “N” identifies the signals that are active low.

NOR Flash memory, non-multiplexed I/Os

Table 185. Non-multiplexed I/O NOR Flash memory

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[15:0]	I/O	Bidirectional data bus
NE[x]	O	Chip select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR Flash devices)
NWAIT	I	NOR Flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

NOR Flash memory, 16-bit multiplexed I/Os

Table 186. 16-bit multiplexed I/O NOR Flash memory

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR Flash devices)
NWAIT	I	NOR Flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

PSRAM/FRAM/SRAM, non-multiplexed I/Os

Table 187. Non-multiplexed I/Os PSRAM/SRAM

FMC signal name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[15:0]	I/O	Data bidirectional bus
NE[x]	O	Chip select, x = 1..4 (called NCE by PSRAM (CellularRAM™ i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits.

PSRAM, 16-bit multiplexed I/Os

Table 188. 16-Bit multiplexed I/O PSRAM

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)

Table 188. 16-Bit multiplexed I/O PSRAM (continued)

FMC signal name	I/O	Function
NE[x]	O	Chip select, x = 1..4 (called NCE by PSRAM (CellularRAM™ i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

25.6.2 Supported memories and transactions

Table 189 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR Flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 189. NOR Flash/PSRAM: example of supported memories and transactions

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
NOR Flash (muxed I/Os and nonmuxed I/Os)	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	-
	Synchronous	R	16	16	Y	-
	Synchronous	R	32	16	Y	-

Table 189. NOR Flash/PSRAM: example of supported memories and transactions (continued)

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	-
	Synchronous	R	16	16	Y	-
	Synchronous	R	32	16	Y	-
	Synchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Synchronous	W	16/32	16	Y	-
SRAM and ROM	Asynchronous	R	8 / 16	16	Y	-
	Asynchronous	W	8 / 16	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses Use of byte lanes NBL[1:0]

25.6.3 General timing rules

Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

25.6.4 NOR Flash/PSRAM controller asynchronous transactions

Asynchronous static memories (NOR Flash, PSRAM, SRAM, FRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory

- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/FRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 108. Mode 1 read access waveforms

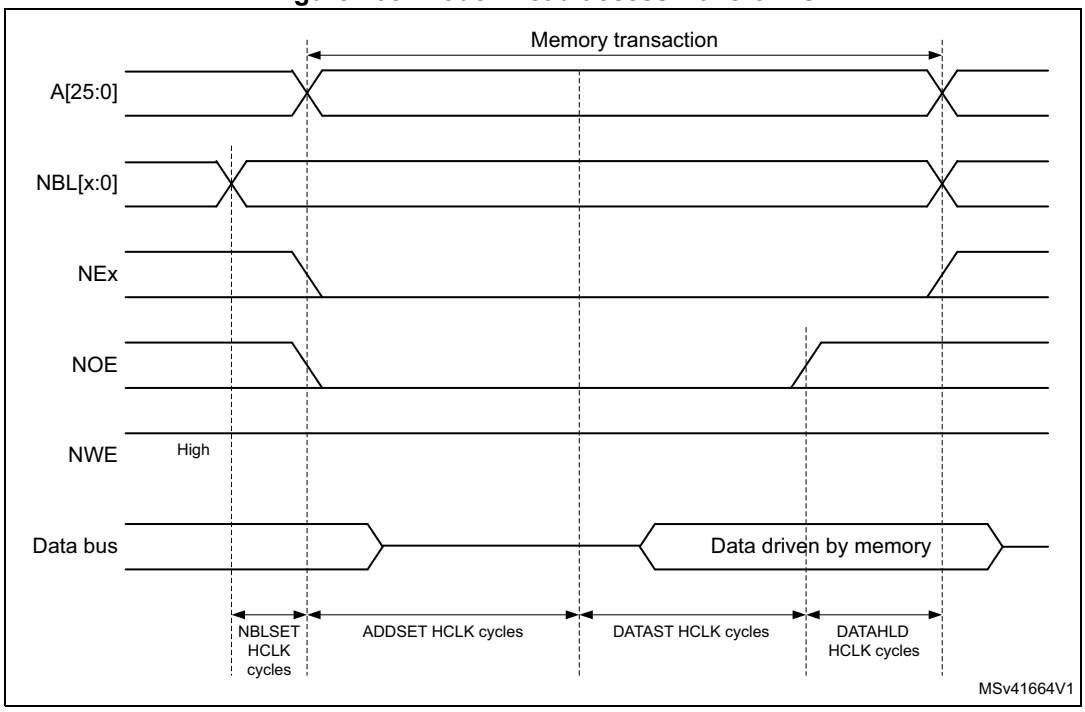


Figure 109. Mode 1 write access waveforms

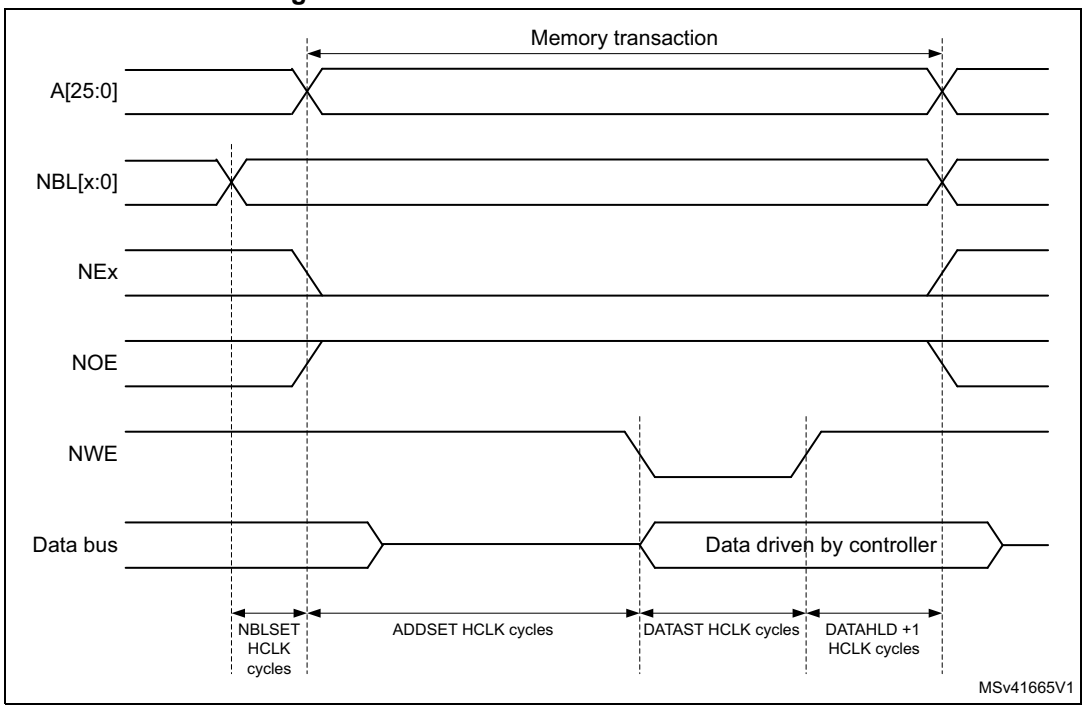


The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

Table 190. FMC_BCRx bitfields (mode 1)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:24	Reserved	0x000
23:22	NBLSET[1:0]	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in Asynchronous mode)
12	WREN	As needed
10	Reserved	0x0
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1
6	FACCEN	Don’t care

Table 190. FMC_BCRx bitfields (mode 1) (continued)

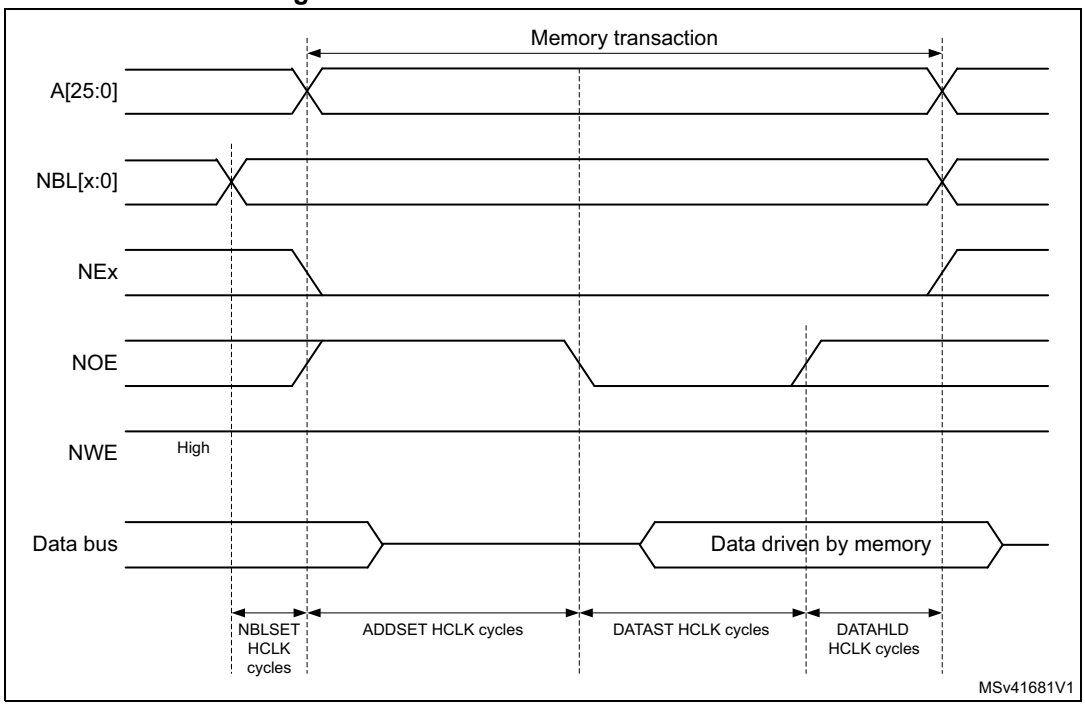
Bit number	Bit name	Value to set
5:4	MWID	As needed
3:2	MTYP	As needed, exclude 0x2 (NOR Flash memory)
1	MUXE	0x0
0	MBKEN	0x1

Table 191. FMC_BTRx bitfields (mode 1)

Bit number	Bit name	Value to set
31:30	DATAHLD	Duration of the data hold phase (DATAHLD HCLK cycles for read accesses, DATAHLD+1 HCLK cycles for write accesses).
29:28	ACCMOD	Don’t care
27:24	DATLAT	Don’t care
23:20	CLKDIV	Don’t care
19:16	BUSTURN	Time between NEx high to NEx low (BUSTURN HCLK).
15:8	DATAST	Duration of the second access phase (DATAST HCLK cycles).
7:4	ADDHLD	Don’t care
3:0	ADDSET	Duration of the first access phase (ADDSET HCLK cycles). Minimum value for ADDSET is 0.

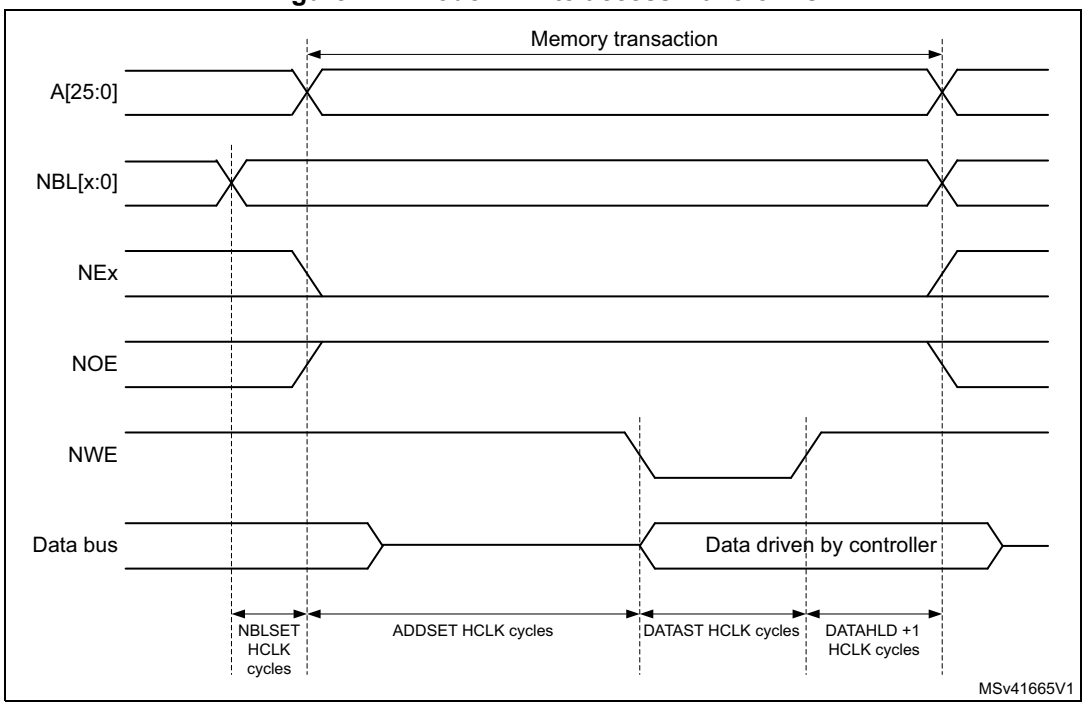
Mode A - SRAM/FRAM/PSRAM (CRAM) OE toggling

Figure 110. Mode A read access waveforms



1. NBL[1:0] are driven low during the read access

Figure 111. Mode A write access waveforms



The differences compared with Mode 1 are the toggling of NOE and the independent read and write timings.

Table 192. FMC_BCRx bitfields (mode A)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:24	Reserved	0x000
23:22	NBLSET[1:0]	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.

7:4	ADDHLD	Duration of the middle phase of the write access (ADDHLD HCLK cycles)
3:0	ADDSET	Duration of the first access phase (ADDSET HCLK cycles) for write accesses. Minimum value for ADDSET is 1.

Muxed mode - multiplexed asynchronous access to NOR Flash memory

Figure 119. Muxed read access waveforms

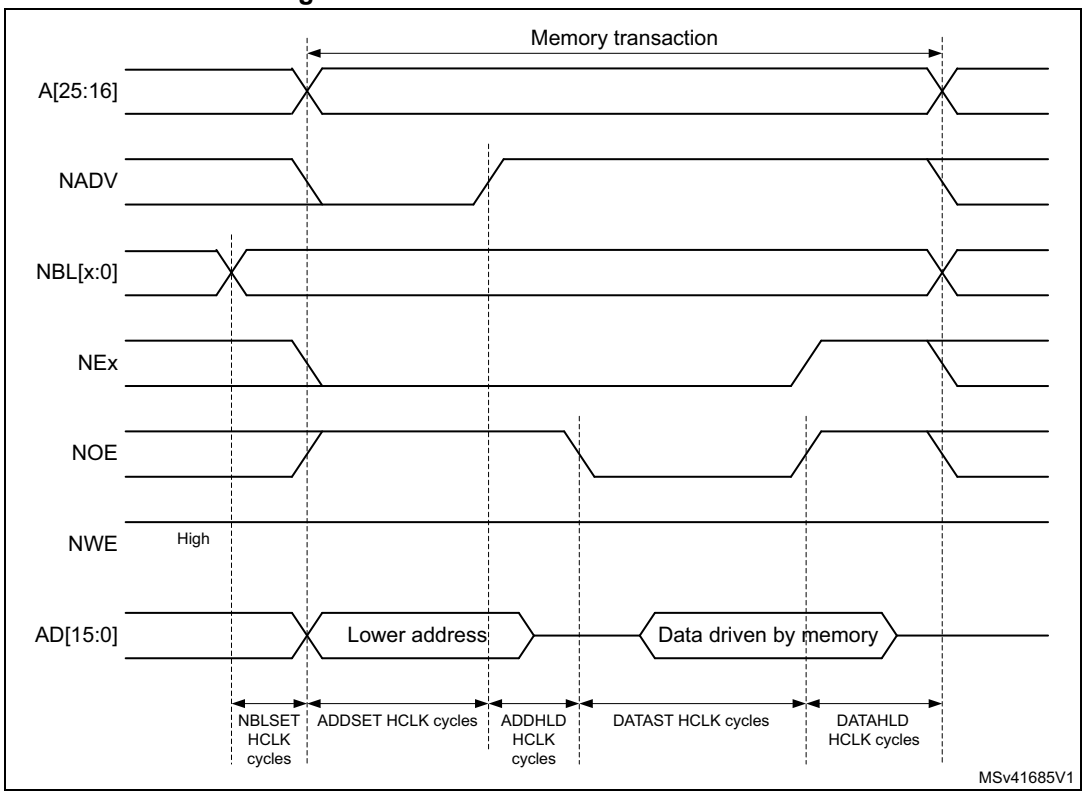

Figure 120. Muxed write access waveforms

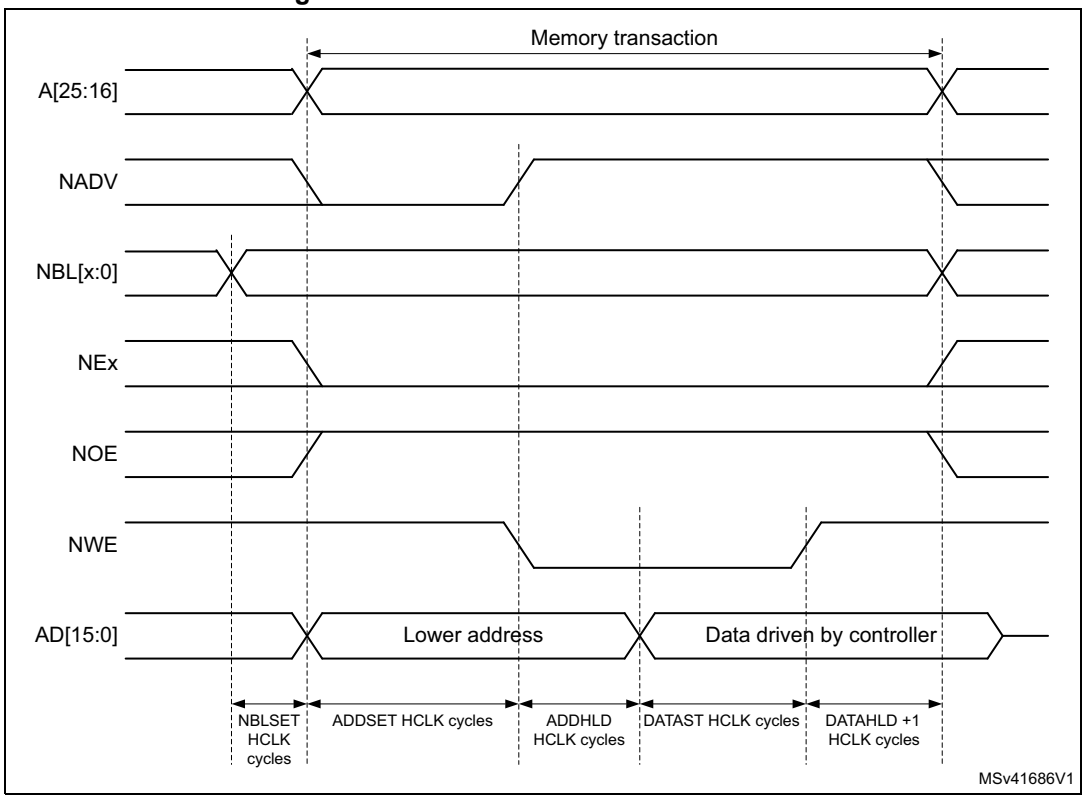


The difference with mode D is the drive of the lower address byte(s) on the data bus.

Table 204. FMC_BCRx bitfields (Muxed mode)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:24	Reserved	0x000
23:22	NBLSET[1:0]	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in Asynchronous mode)
12	WREN	As needed
11	WAITCFG	Don’t care
10	Reserved	0x0
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1

Table 204. FMC_BCRx bitfields (Muxed mode) (continued)

Bit number	Bit name	Value to set
6	FACCEN	0x1
5:4	MWID	As needed
3:2	MTYP	0x2 (NOR Flash memory) or 0x1(PSRAM)
1	MUXEN	0x1
0	MBKEN	0x1

Table 205. FMC_BTRx bitfields (Muxed mode)

Bit number	Bit name	Value to set
31:30	DATAHLD	Duration of the data hold phase (DATAHLD HCLK cycles for read accesses, DATAHLD+1 HCLK cycles for write accesses).
29:28	ACCMOD	0x0
27:24	DATLAT	Don’t care
23:20	CLKDIV	Don’t care
19:16	BUSTURN	Time between NEx high to NEx low (BUSTURN HCLK).
15:8	DATAST	Duration of the second access phase (DATAST HCLK cycles).
7:4	ADDHLD	Duration of the middle phase of the access (ADDHLD HCLK cycles).
3:0	ADDSET	Duration of the first access phase (ADDSET HCLK cycles). Minimum value for ADDSET is 1.

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$DATAST \geq (4 \times HCLK) + max\_wait\_assertion\_time$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if

$$max\_wait\_assertion\_time > address\_phase + hold\_phase$$

   then:

$$DATAST \geq (4 \times HCLK) + (max\_wait\_assertion\_time - address\_phase - hold\_phase)$$

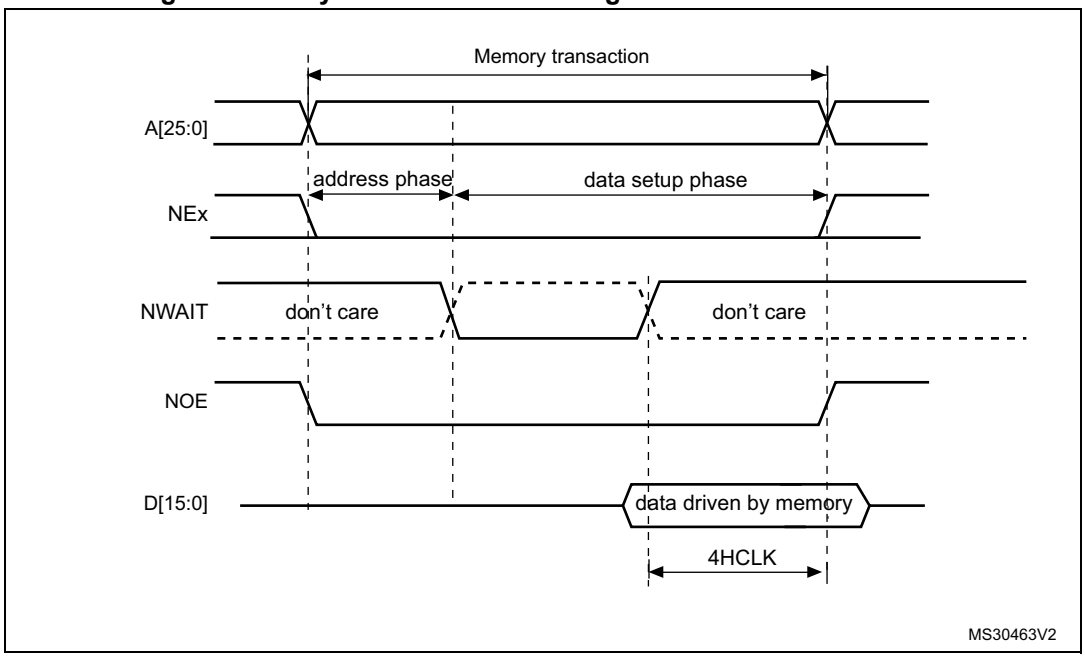
   otherwise

$$DATAST \geq 4 \times HCLK$$

   where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

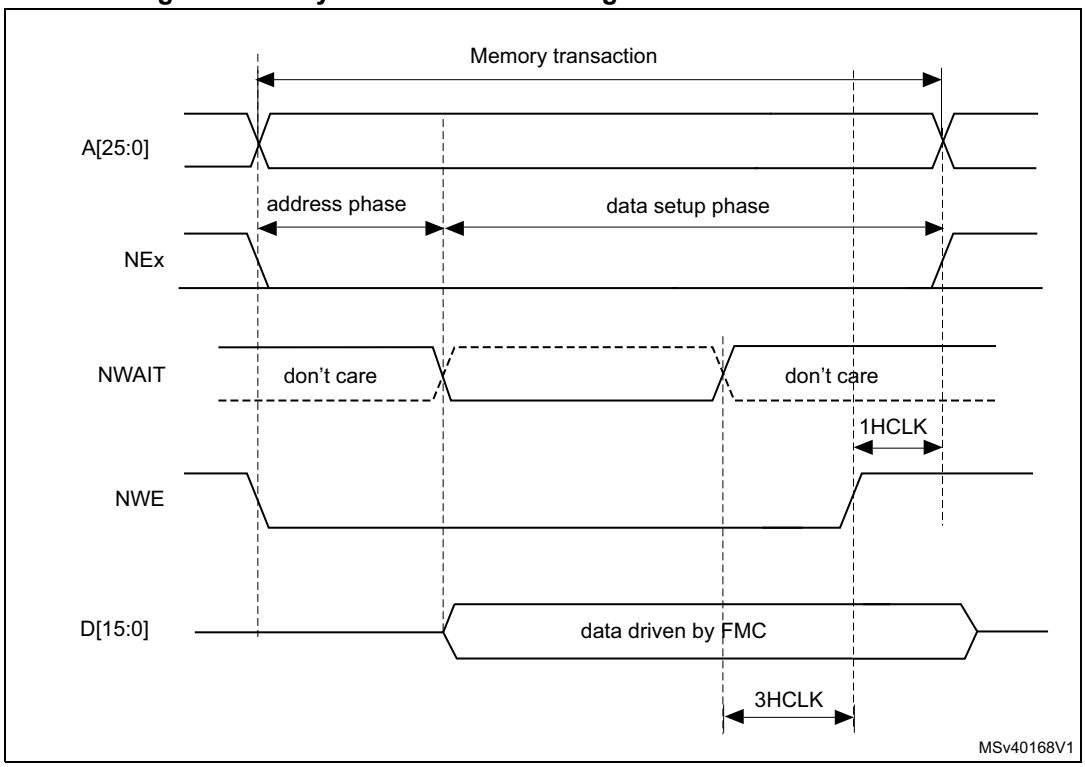
Figure 121 and *Figure 122* show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 121. Asynchronous wait during a read access waveforms



1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 122. Asynchronous wait during a write access waveforms



1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not allow maintaining the chip select signal (NE) low for longer than the t_{CEM} timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses

25.6.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:

- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR Flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration

register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for CellularRAM™ 1.5

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller is used to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR Flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

Figure 123. Wait configuration waveforms

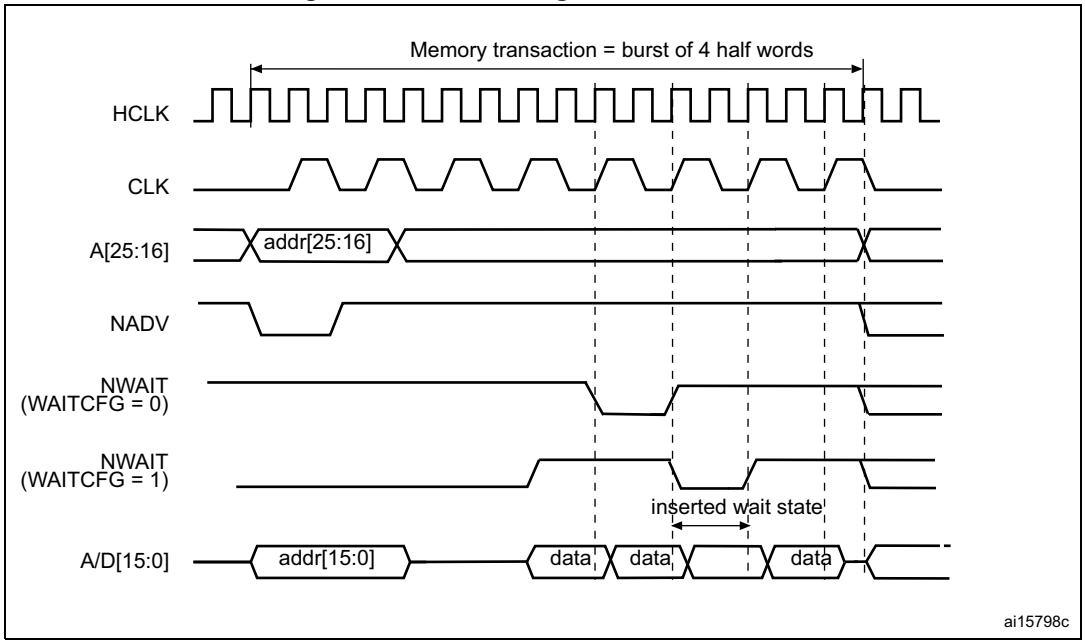


Figure 124. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

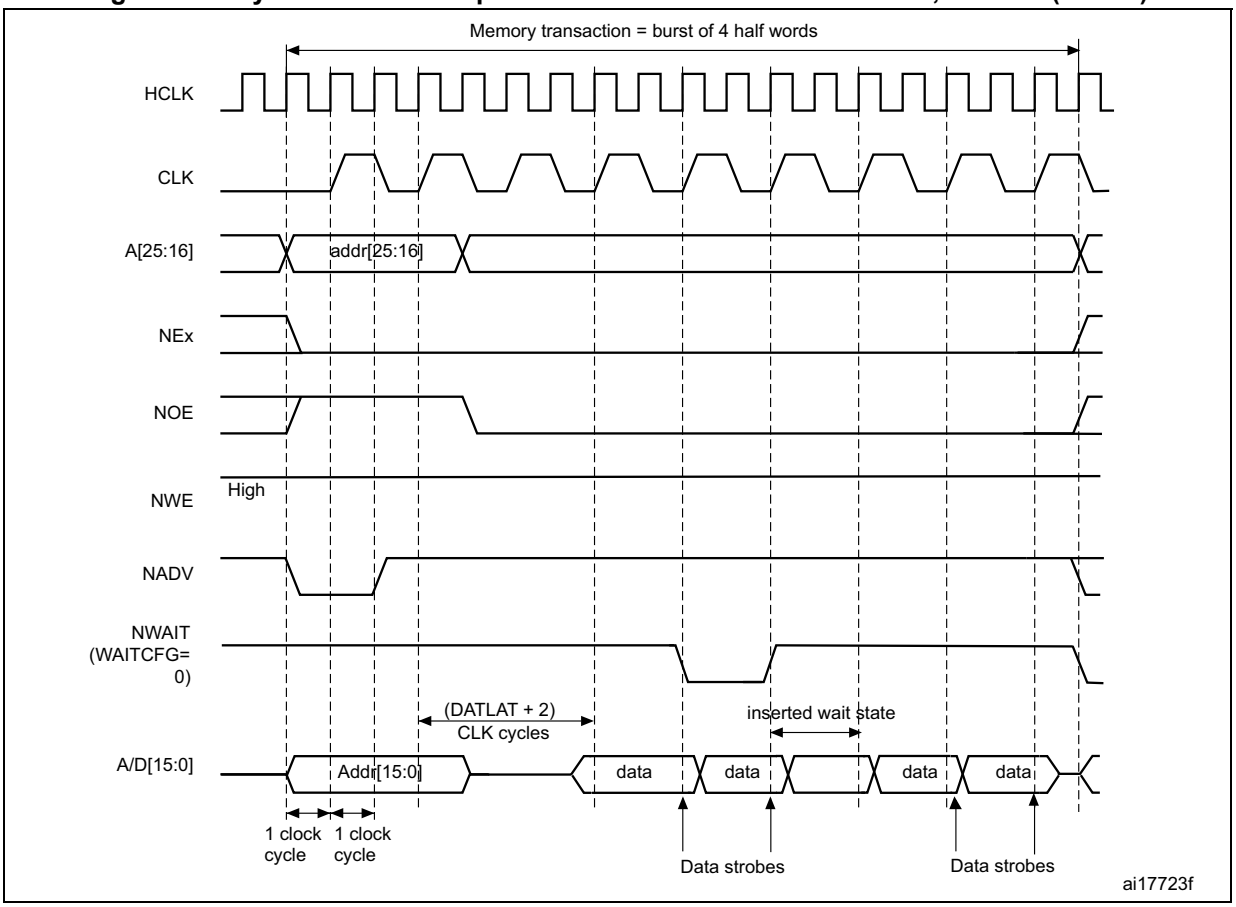

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

Table 206. FMC_BCRx bitfields (Synchronous multiplexed read mode)

Bit number	Bit name	Value to set
31	FMCEN	0x1

25.6.6 NOR/PSRAM controller registers

SRAM/NOR-Flash chip-select control register for bank x (FMC_BCRx) (x = 1 to 4)

Address offset: 8 * (x – 1), (x = 1 to 4)

Reset value: Bank 1: 0x0000 30DB

Reset value: Bank 2: 0x0000 30D2

Reset value: Bank 3: 0x0000 30D2

Reset value: Bank 4: 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR Flash memories.

Bit 31 **FMCEN**: FMC controller enable

This bit enables or disables the FMC controller.

0: Disable the FMC controller

1: Enable the FMC controller

Note: The FMCEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bits 30:24 Reserved, must be kept at reset value.

Bits 23:22 **NBLSET[1:0]:** Byte lane (NBL) setup

These bits configure the NBL setup timing from NBLx low to chip select NEx low.

00: NBL setup time is 0 AHB clock cycle

01: NBL setup time is 1 AHB clock cycle

10: NBL setup time is 2 AHB clock cycles

11: NBL setup time is 3 AHB clock cycles

Bit 21 **WFDIS:** Write FIFO disable

This bit disables the Write FIFO used by the FMC controller.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

Note: The WFDIS bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bit 20 **CCLKEN:** Continuous clock enable

This bit enables the FMC_CLK clock output to external memory devices.

0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).

1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

Note: The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

Note: If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.

Note: If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRW:** Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode.

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size

These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset)

001: 128 bytes

010: 256 bytes

011: 512 bytes

100: 1024 bytes

Others: reserved

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset).

1: NWAIT signal is taken in to account when running an asynchronous protocol.

Bit 14 **EXTMOD:** Extended mode enable

This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)

1: values inside FMC_BWTR register are taken into account

Note: When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).*

Bit 13 **WAITEN:** Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period).

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12 **WREN:** Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC.

0: Write operations are disabled in the bank by the FMC, an AHB error is reported.

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG:** Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset).

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL:** Wait signal polarity bit

Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.

0: NWAIT active low (default after reset)

1: NWAIT active high

Bit 8 **BURSTEN:** Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.

1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN:** Flash access enable

Enables NOR Flash memory access operations.

0: Corresponding NOR Flash memory access is disabled.

1: Corresponding NOR Flash memory access is enabled (default after reset).

Bits 5:4 **MWID[1:0]:** Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: reserved

11: reserved

Bits 3:2 **MTYP[1:0]:** Memory type

Defines the type of external memory attached to the corresponding memory bank.

00: SRAM/FRAM (default after reset for Bank 2...4)

01: PSRAM (CRAM) / FRAM

10: NOR Flash/OneNAND Flash (default after reset for Bank 1)

11: reserved

Bit 1 **MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:

0: Address/data non multiplexed

1: Address/data multiplexed on databus (default after reset)

Bit 0 **MBKEN:** Memory bank enable bit

Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.

0: Corresponding memory bank is disabled.

1: Corresponding memory bank is enabled.

SRAM/NOR-Flash chip-select timing register for bank x (FMC_BTRx)

Address offset: 0x04 + 8 * (x – 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories.If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAHLD[1:0]		ACCMOD[1:0]		DATLAT[3:0]				CLKDIV[3:0]				BUSTURN[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DATAHLD[1:0]:** Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to *Figure 108* to *Figure 120*), used in asynchronous accesses:

For read accesses

00: DATAHLD phase duration = 0 × HCLK clock cycle (default)

01: DATAHLD phase duration = 1 × HCLK clock cycle

10: DATAHLD phase duration = 2 × HCLK clock cycle

11: DATAHLD phase duration = 3 × HCLK clock cycle

For write accesses

00: DATAHLD phase duration = 1 × HCLK clock cycle (default)

01: DATAHLD phase duration = 2 × HCLK clock cycle

10: DATAHLD phase duration = 3 × HCLK clock cycle

11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]:** Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: Access mode A

01: Access mode B

10: Access mode C

11: Access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

0000: Data latency of 2 CLK clock cycles for first burst access

1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:

0000: FMC_CLK period= 1x HCLK period

0001: FMC_CLK period = 2 × HCLK periods

0010: FMC_CLK period = 3 × HCLK periods

1111: FMC_CLK period = 16 × HCLK periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don't care.

Note: Refer to Section 25.6.5: Synchronous transactions for FMC_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank.

This delay is used to match the minimum time between consecutive transactions (t_{EHEL} from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (t_{EHQZ}, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.

(BUSTURN + 1)HCLK period ≥ max(t_{EHEL} min, t_{EHQZ} max)

For FRAM memories, the bus turnaround delay should be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the tPC memory timing. The chip select is toggling between any consecutive accesses.

(BUSTURN + 1)HCLK period ≥ t_{PC} min

0000: BUSTURN phase duration = 1 HCLK clock cycle added

...

1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to *Figure 108* to *Figure 120*), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × HCLK clock cycles

0000 0010: DATAST phase duration = 2 × HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (*Figure 108* to *Figure 120*).

Example: Mode 1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

Note: In synchronous accesses, this value is don't care.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 108* to *Figure 120*), used in mode D or multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration =1 × HCLK clock cycle
0010: ADDHLD phase duration = 2 × HCLK clock cycle
...
1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (*Figure 108* to *Figure 120*).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 108* to *Figure 120*), used in SRAMs, ROMs, asynchronous NOR Flash and PSRAM:
0000: ADDSET phase duration = 0 × HCLK clock cycle
...
1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (*Figure 108* to *Figure 120*).

Note: In synchronous accesses, this value is don't care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.
With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).

SRAM/NOR-Flash write timing registers x (FMC_BWTRx)

Address offset: 0x104 + 8 * (x – 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAHLD[1:0]		ACCMOD[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSTURN[3:0]			
rw	rw	rw	rw									rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DATAHLD[1:0]:** Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to *Figure 108* to *Figure 120*), used in asynchronous write accesses:
00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
01: DATAHLD phase duration = 2 × HCLK clock cycle
10: DATAHLD phase duration = 3 × HCLK clock cycle
11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]:** Access mode.

Specifies the asynchronous access modes as shown in the next timing diagrams.These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
00: Access mode A
01: Access mode B
10: Access mode C
11: Access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of current write transaction to next transaction on the same bank.
For FRAM memories, the bus turnaround delay should be configured to match the minimum t_{PC} (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read). The chip select is toggling between any consecutive accesses.
(BUSTURN + 1)HCLK period ≥ tPC min

0000: BUSTURN phase duration = 1 HCLK clock cycle added
...
1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to *Figure 108* to *Figure 120*), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:
0000 0000: Reserved
0000 0001: DATAST phase duration = 1 × HCLK clock cycles
0000 0010: DATAST phase duration = 2 × HCLK clock cycles
...
1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 117* to *Figure 120*), used in asynchronous multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration = 1 × HCLK clock cycle
0010: ADDHLD phase duration = 2 × HCLK clock cycle
...
1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

Note: In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in HCLK cycles (refer to *Figure 108* to *Figure 120*), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

PSRAM chip select counter register (FMC_PCSCNTR)

Address offset: 0x20

Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width (t_{CEM}) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.

CSCOUNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CNTB4EN:** Counter Bank 4 enable

This bit enables the chip select counter for PSRAM/NOR Bank 4.

0: Counter disabled for Bank 4

1: Counter enabled for Bank 4

Bit 18 **CNTB3EN:** Counter Bank 3 enable

This bit enables the chip select counter for PSRAM/NOR Bank 3.

0: Counter disabled for Bank 3.

1: Counter enabled for Bank 3

Bit 17 **CNTB2EN:** Counter Bank 2 enable

This bit enables the chip select counter for PSRAM/NOR Bank 2.

0: Counter disabled for Bank 2

1: Counter enabled for Bank 2

Bit 16 **CNTB1EN:** Counter Bank 1 enable

This bit enables the chip select counter for PSRAM/NOR Bank 1.

0: Counter disabled for Bank 1

1: Counter enabled for Bank 1

Bits 15:0 **CSCOUNT[15:0]:** Chip select counter.
These bits are written by software to define the maximum chip select low pulse duration. It is expressed in FMC_CLK cycles for synchronous accesses and in HCLK cycles for asynchronous accesses.
The counter is disabled if the programmed value is 0.

25.7 NAND Flash controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND Flash memories

The NAND bank is configured through dedicated registers (*Section 25.7.7*). The programmable memory parameters include access timings (shown in *Table 210*) and ECC configuration.

Table 210. Programmable NAND Flash access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (HCLK) required to set up the address before the command assertion	Read/Write	AHB clock cycle (HCLK)	1	255
Memory wait	Minimum duration (in HCLK clock cycles) of the command assertion	Read/Write	AHB clock cycle (HCLK)	2	255
Memory hold	Number of clock cycles (HCLK) during which the address must be held (as well as the data if a write access is performed) after the command de-assertion	Read/Write	AHB clock cycle (HCLK)	1	254
Memory databus high-Z	Number of clock cycles (HCLK) during which the data bus is kept in high-Z state after a write access has started	Write	AHB clock cycle (HCLK)	1	255

25.7.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND Flash memory.

Note: The prefix “N” identifies the signals which are active low.

8-bit NAND Flash memory

Table 211. 8-bit NAND Flash

FMC signal name	I/O	Function
A[17]	O	NAND Flash address latch enable (ALE) signal
A[16]	O	NAND Flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus
NCE	O	Chip select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)

Table 211. 8-bit NAND Flash (continued)

FMC signal name	I/O	Function
NWE	O	Write enable
NWAIT/INT	I	NAND Flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

16-bit NAND Flash memory

Table 212. 16-bit NAND Flash

FMC signal name	I/O	Function
A[17]	O	NAND Flash address latch enable (ALE) signal
A[16]	O	NAND Flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND Flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

25.7.2 NAND Flash supported memories and transactions

Table 213 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND Flash controller are shown in gray.

Table 213. Supported memories and transactions

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	-
	Asynchronous	W	8	8	Y	-
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses

Table 213. Supported memories and transactions (continued)

Device	Mode	R/W	AHB data size	Memory data size	Allowed/ not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses

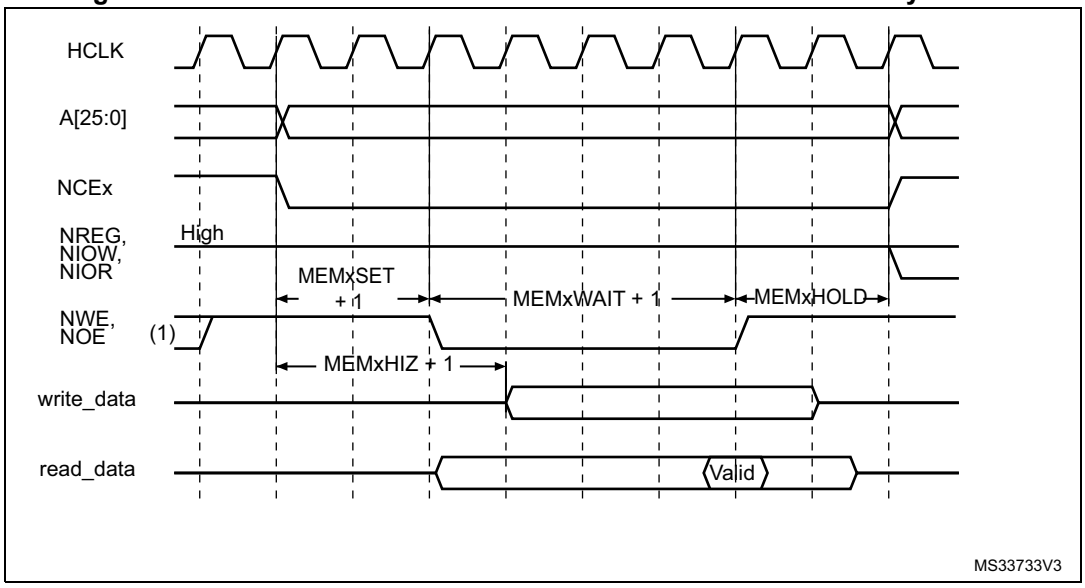
25.7.3 Timing diagrams for NAND Flash memory

The NAND Flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. *Figure 126* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 126. NAND Flash controller waveforms for common memory access



1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write access, the hold phase delay is (MEMHOLD) HCLK cycles and for read access is (MEMHOLD + 2) HCLK cycles.

25.7.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

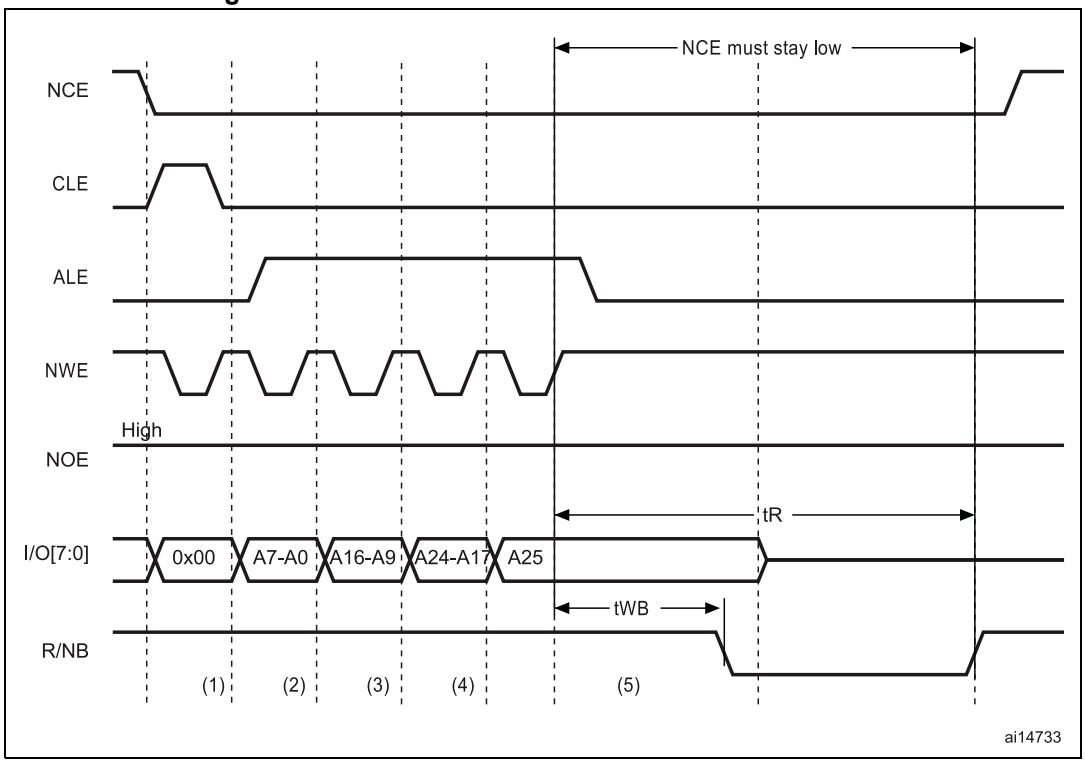
A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see *Section 25.7.5: NAND Flash prewait functionality*) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see *Section 25.5.2: NAND Flash memory address mapping* for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used to implement the prewait functionality needed by some NAND Flash memories (see details in *Section 25.7.5: NAND Flash prewait functionality*).
4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.
6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   - by simply performing the operation described in step 5
   - a new random address can be accessed by restarting the operation at step 3
   - a new command can be sent to the NAND Flash device by restarting at step 2

25.7.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see *Figure 127*).

Figure 127. Access to non 'CE don't care' NAND-Flash



1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × HCLK = 112 ns > t_{WB} max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don't care).

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the t_{WB} timing. However any CPU read access to the NAND Flash memory has a hold delay of (MEMHOLD + 2) HCLK cycles and CPU write access has a hold delay of (MEMHOLD) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the t_{WB} timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

25.7.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

To perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

25.7.7 NAND Flash controller registers

NAND Flash control registers (FMC_PCR)

Address offset: 0x80

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCPS[2:0]			TAR3
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAR[2:0]			TCLR[3:0]				Res.	Res.	ECCEN	PWID[1:0]		PTYP	PBKEN	PWAITEN	Res.
rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]:** ECC page size
Defines the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 **TAR[3:0]:** ALE to RE delay
Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).
Time is: t_ar = (TAR + SET + 2) × THCLK where THCLK is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles
Note: SET is MEMSET or ATTSET according to the addressed space.

Bits 12:9 **TCLR[3:0]:** CLE to RE delay
Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
Time is t_clr = (TCLR + SET + 2) × THCLK where THCLK is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles
Note: SET is MEMSET or ATTSET according to the addressed space.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN:** ECC computation logic enable bit
0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]:** Data bus width
Defines the external memory device width.
00: 8 bits
01: 16 bits (default after reset).
10: reserved.
11: reserved.

Bit 3 **PTYP:** Memory type
Defines the type of device attached to the corresponding memory bank:
0: Reserved, must be kept at reset value
1: NAND Flash (default after reset)

Bit 2 **PBKEN:** NAND Flash memory bank enable bit
Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
0: Corresponding memory bank is disabled (default after reset)
1: Corresponding memory bank is enabled

Bit 1 **PWAITEN:** Wait feature enable bit
Enables the Wait feature for the NAND Flash memory bank:
0: disabled
1: enabled

Bit 0 Reserved, must be kept at reset value.

FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FEMPT	IFEN	ILEN	IREN	IFS	ILS	IRS
									r	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT:** FIFO empty

Read-only bit that provides the status of the FIFO

0: FIFO not empty

1: FIFO empty

Bit 5 **IFEN:** Interrupt falling edge detection enable bit

0: Interrupt falling edge detection request disabled

1: Interrupt falling edge detection request enabled

Bit 4 **ILEN:** Interrupt high-level detection enable bit

0: Interrupt high-level detection request disabled

1: Interrupt high-level detection request enabled

Bit 3 **IREN:** Interrupt rising edge detection enable bit

0: Interrupt rising edge detection request disabled

1: Interrupt rising edge detection request enabled

Bit 2 **IFS:** Interrupt falling edge status

The flag is set by hardware and reset by software.

0: No interrupt falling edge occurred

1: Interrupt falling edge occurred

Note: If this bit is written by software to 1 it is set.

Bit 1 **ILS:** Interrupt high-level status

The flag is set by hardware and reset by software.

0: No Interrupt high-level occurred

1: Interrupt high-level occurred

Bit 0 **IRS:** Interrupt rising edge status

The flag is set by hardware and reset by software.

0: No interrupt rising edge occurred

1: Interrupt rising edge occurred

Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)

Address offset: Address: 0x88

Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEMHIZ[7:0]								MEMHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEMWAIT[7:0]								MEMSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ[7:0]:** Common memory x data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a NAND Flash write access to common memory space on socket. This is only valid for write transactions:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:

0000 0000: reserved.

0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access

1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access

1111 1111: reserved.

Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to common memory space on socket. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **MEMSET[7:0]:** Common memory x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved

Attribute memory space timing register (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 25.7.5: NAND Flash prewait functionality*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ[7:0]								ATTHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATTWAIT[7:0]								ATTSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ATTHIZ[7:0]:** Attribute memory data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND Flash write access to attribute memory space on socket. Only valid for writ transaction:

0000 0000: 0 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:

0000 0000: reserved

0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access

1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access

1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:
0000 0000: 1 HCLK cycle
1111 1110: 255 HCLK cycles
1111 1111: reserved.

ECC result registers (FMC_ECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND Flash memory page at the correct address (refer to *Section 25.7.6: Computation of the error correction code (ECC) in NAND Flash memory*), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set to 1.

Refer to *Section 2.3 on page 115* for the register boundary addresses.

26 Octo-SPI interface (OCTOSPI)

26.1 Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR Flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- Indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data and transfer parameters.
- Automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting.
- Memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the Regular-command frame format with the command, address, alternate byte, dummy cycles and data phase
- the HyperBus™ frame format

26.2 OCTOSPI main features

- Functional modes: Indirect, Automatic status-polling, and Memory-mapped
- Read and write support in Memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad and octal communication
- Dual memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for Indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

26.3 OCTOSPI implementation

Table 216. OCTOSPI implementation

OCTOSPI feature	OCTOSPI1/2
HyperBus standard compliant	X
Xcella standard compliant	X
XSPI (JEDEC251ES) standard compliant	X

8-, 16-, and 32-bit data accesses	X
Interrupt on FIFO threshold, timeout, operation complete, and access error	X
Compliant with dual-OCTOSPI arbiter (communication regulation)	X
Extended CSHT timeout	X
Memory-mapped write	X
Refresh counter	X
GPDMA interface	X

26.4 OCTOSPI functional description

26.4.1 OCTOSPI block diagram

Figure 128. OCTOSPI block diagram in octal configuration

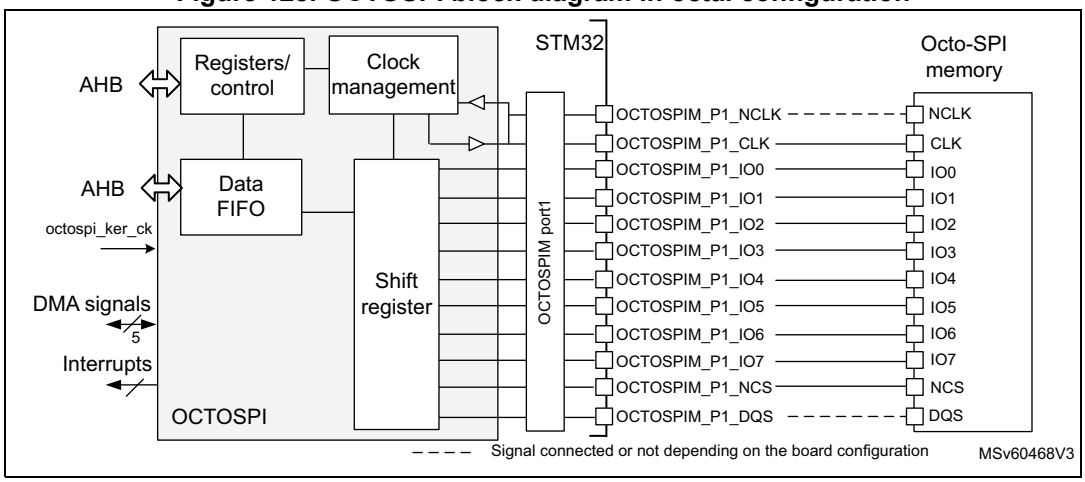

Figure 129. OCTOSPI block diagram in quad configuration

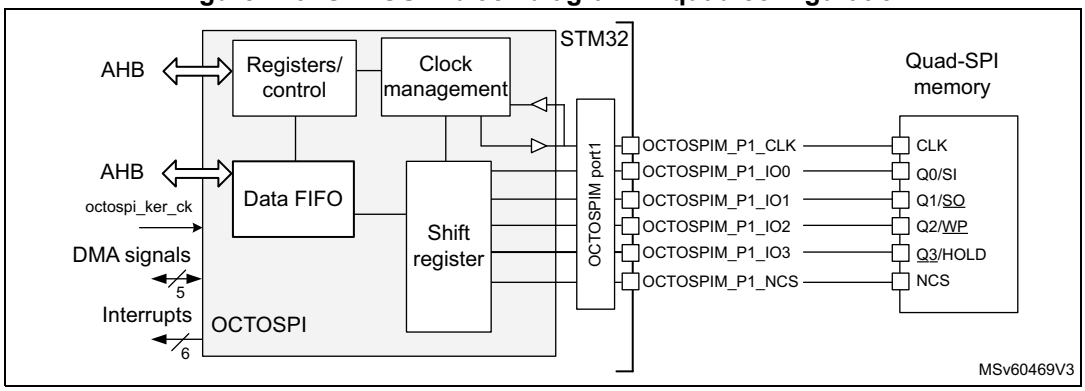

Figure 130. OCTOSPI block diagram in dual-quad configuration

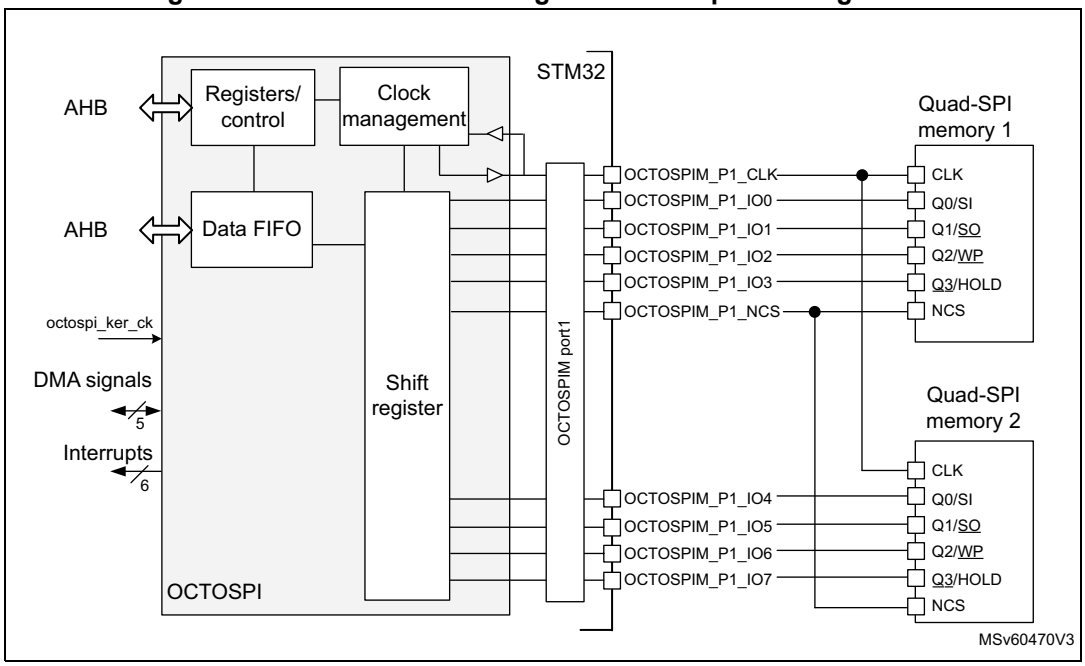


26.4.2 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:

- Regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in Regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

26.4.3 OCTOSPI Regular-command protocol

When in Regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:

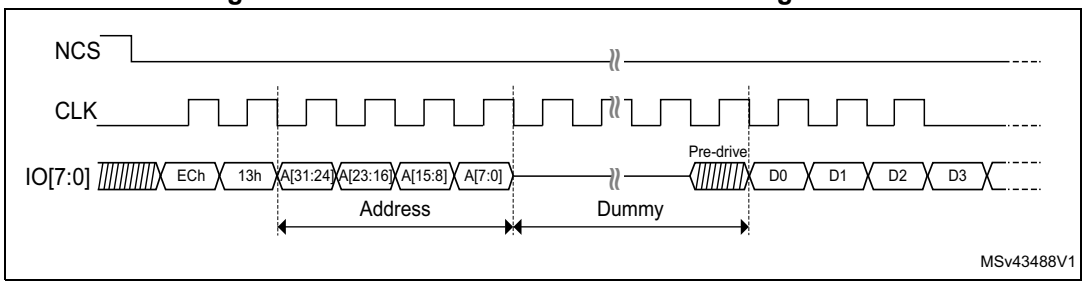
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In Memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 131. SDR read command in octal configuration



The specific Regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In Memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of OCTOSPI_CCR.

In Indirect and Automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of OCTOSPI_AR. In Memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] of OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR of OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In Memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

Alternate-bytes phase

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] of OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In Memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR and the alternate byte format is specified in OCTOSPI_WCCR. The

alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.

Dummy-cycle phase

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-SPI, the quad-SPI or the octal-SPI mode, to receive data from the external device.

In Memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In Indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in Indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In Automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR and the data received from the external device can be obtained by reading OCTOSPI_DR.

In Memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] of OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in Indirect-write mode.

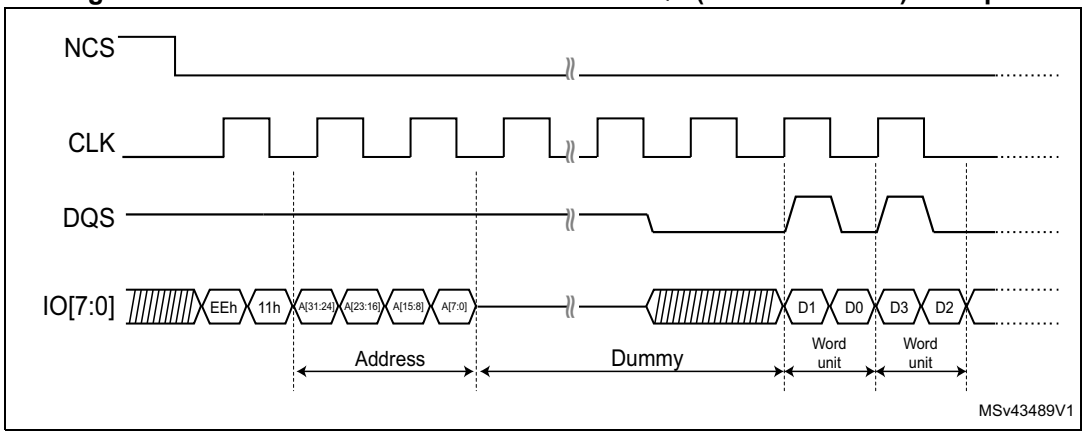
In Memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

DQS usage

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE of OCTOSPI_CCR.

Figure 132. DTR read in octal-SPI mode with DQS (Macronix mode) example



26.4.4 OCTOSPI Regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

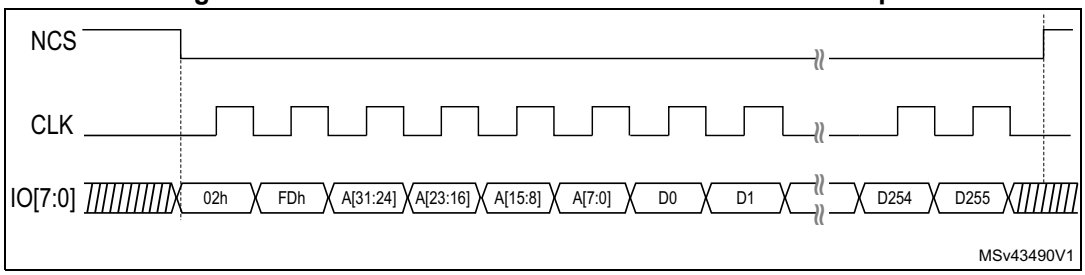
Single-data rate (SDR) mode

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

Figure 133. SDR write command in octo-SPI mode example



Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In Memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

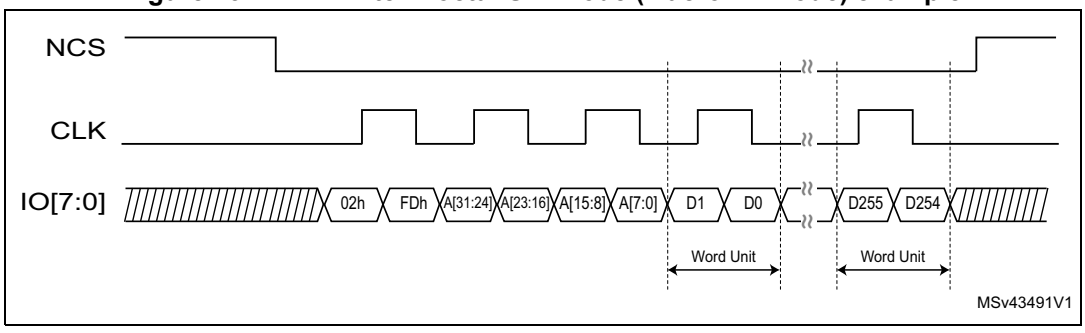
In DTR mode, when the OCTOSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid to hold issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 134. DTR write in octal-SPI mode (Macronix mode) example



Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 011, two external Quad-SPI devices (device A and device B) are used in order to

send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of OCTOSPI_DCR1, must reflect the total external device capacity, that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in Regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

26.4.5 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

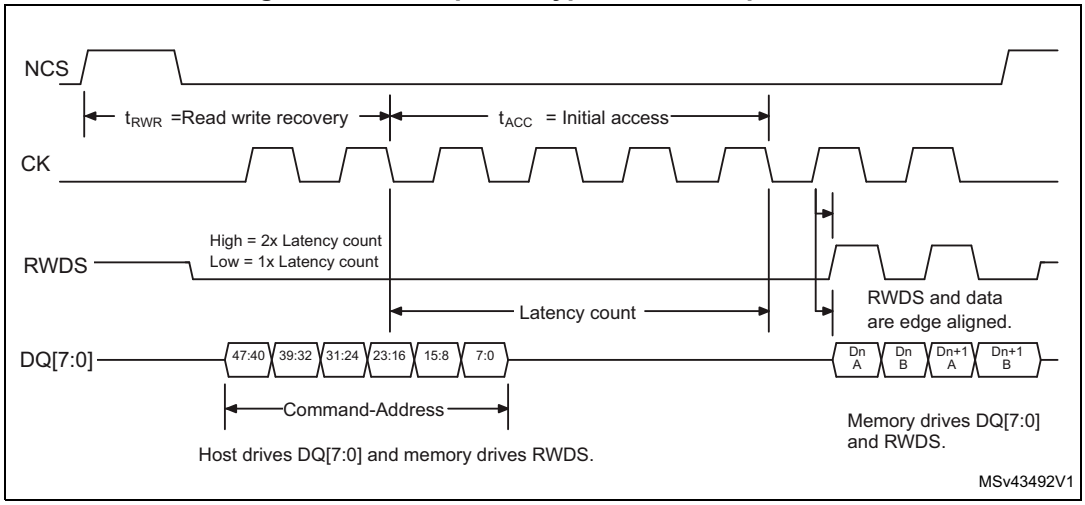
The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 135. Example of HyperBus read operation



Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 217. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

The address space is configured through the memory type MTYP[2:0] of OCTOSPI_DCR1.

The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined in TRWR[7:0] of OCTOSPI_HLCR)
- t_{ACC}: access time for the device (defined in TAC[7:0] of OCTOSPI_HLCR)

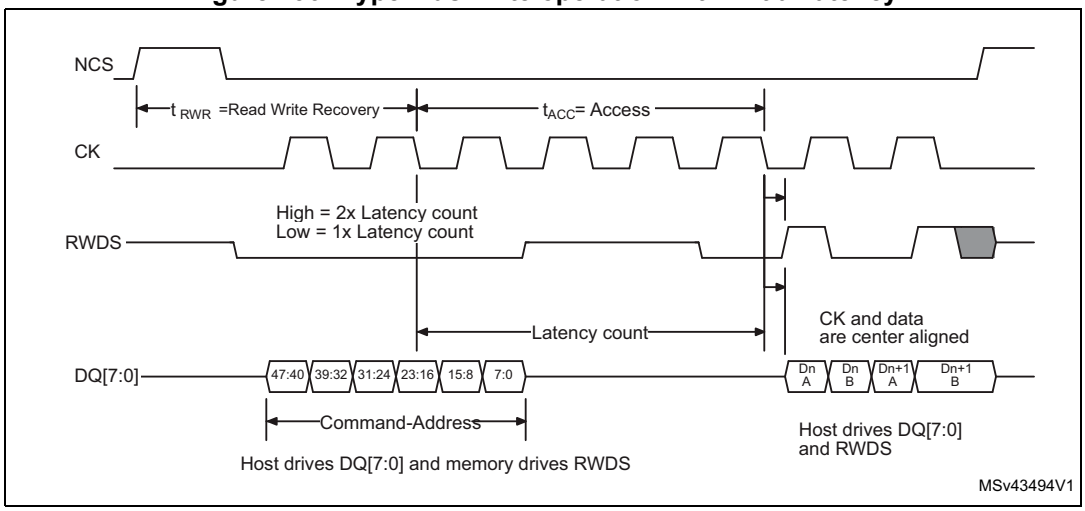
During the read operation, the RWDS is used by the device, in two ways (see *Figure 135*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation the RWDS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

Figure 136. HyperBus write operation with initial latency



Read/write operation with additional latency

If the device needs an additional latency (during refresh period of a SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional t_{ACC} duration is added by the OCTOSPI to meet the device request.

Figure 137. HyperBus read operation with additional latency

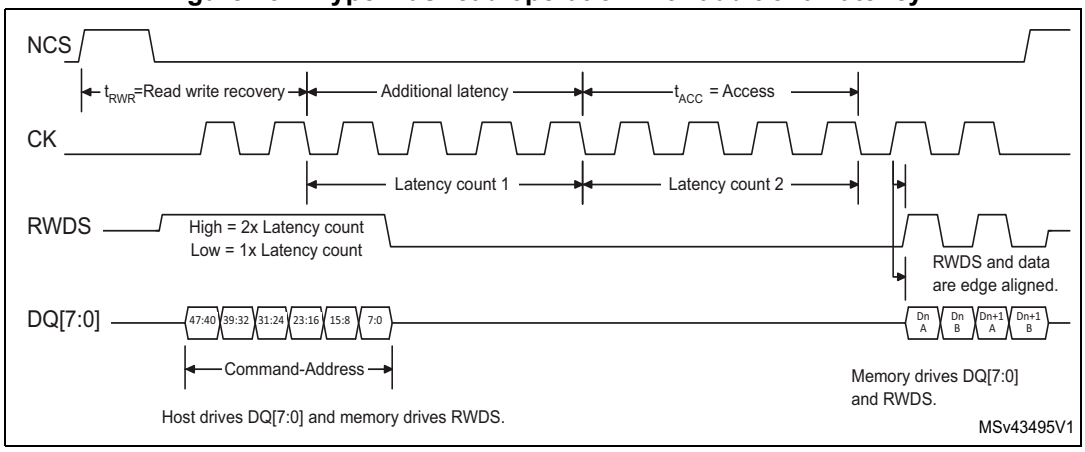


Figure 138. HyperBus write operation with additional latency

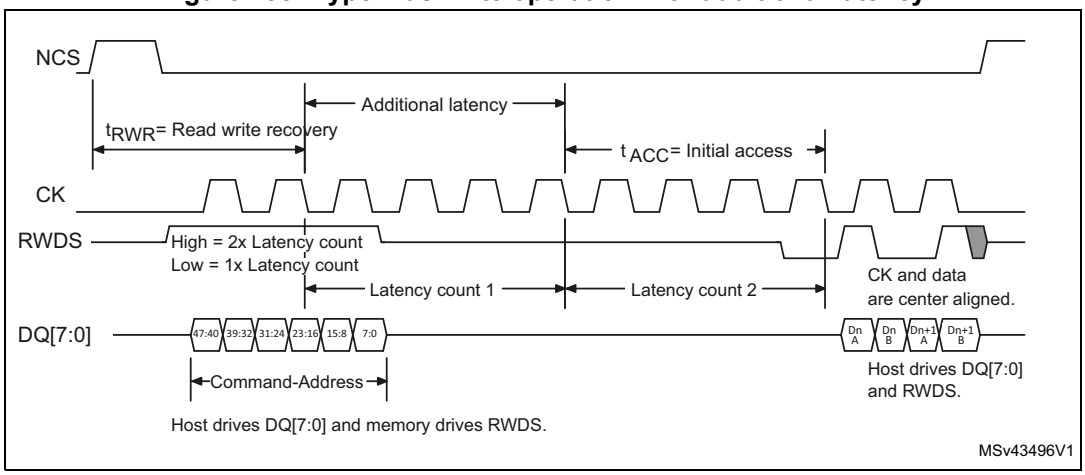


Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

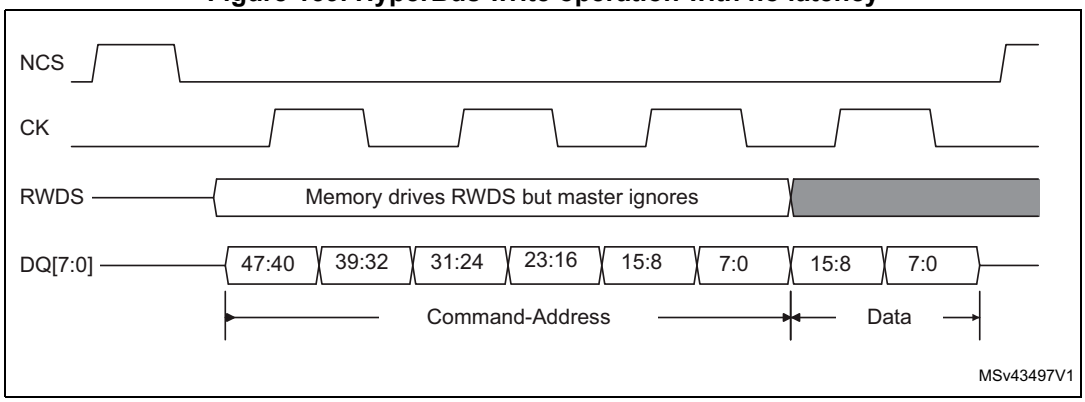
The latency can be forced to 2 x t_{ACC} by setting LM of OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

Figure 139. HyperBus write operation with no latency

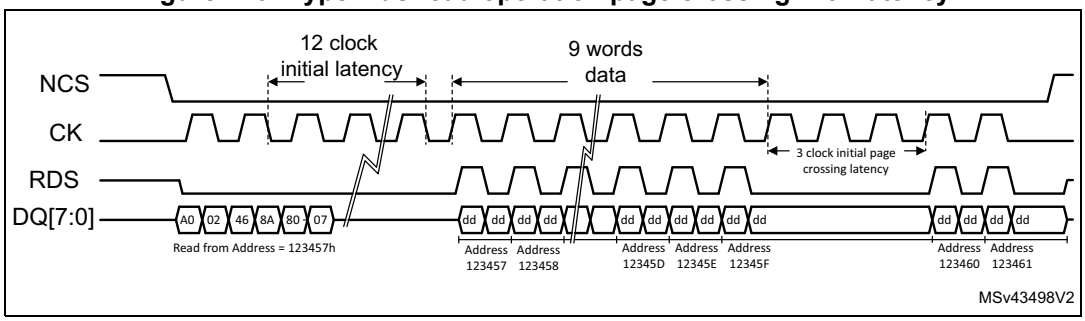


Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 140. HyperBus read operation page crossing with latency



26.4.6 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh
- Communication regulation

Wrap support

The OCTOSPI supports an hybrid wrap as defined by the HyperBus protocol. An hybrid wrap is also supported in the Regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and Regular-command protocols. To enable wrapped-read accesses, the dedicated registers OCTOSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated OCTOSPI_WPxxx registers apply for both HyperBus and Regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured in CSBOUND[4:0] of OCTOSPI_DCR3 and it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of 3 is recommended.

The NCS boundary feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of OCTOSPI_DCR3.

If the number of clock cycles reach the MAXTRAN + 1 value, and if the second OCTOSPI requests an access, the NCS is released and a new transaction is issued to address the next data. If the second OCTOSPI does not request an access, the transaction is not stopped and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

Note: The communication regulation feature cannot be used in write mode for the Flash memory devices that require extra command to re-enable the write operation after the NCS is active again.

If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Re-starting after an interrupted transfer

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

26.4.7 OCTOSPI operating modes introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either Regular-command or HyperBus):

- Indirect mode (read or write)
- Automatic status-polling mode
- Memory-mapped mode

26.4.8 OCTOSPI Indirect mode

In Indirect mode, the commands are started by writing to the OCTOSPI registers and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in OCTOSPI_CR, the OCTOSPI is in Indirect-write mode: bytes are sent to the external device during the data phase. Data is provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in Indirect-read mode: bytes are received from the external device during the data phase. Data is recovered by reading OCTOSPI_DR.

In Indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in OCTOSPI_SR and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

Triggering the start of a transfer in Regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in Indirect mode when using Regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in Indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in Indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in Indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) in Indirect-read mode (when FMODE = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in Indirect-write mode (when FMODE = 00).
- when a write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for both Indirect read and write modes

Note: In case of HyperBus, a (dummy) write to OCTOSPI_IR is required to trigger the transfer, as for Regular-command protocol.

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in Indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR and immediately transferred in the internal FIFO.

In Indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In Indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In Indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

26.4.9 OCTOSPI Automatic status-polling mode

In Automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The access to the device begins in the same manner as in Indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in Automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In Automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

26.4.10 OCTOSPI Memory-mapped mode

When configured in Memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations ends up quickly since their results were pre-fetched.

By default, the OCTOSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

26.4.11 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

26.4.12 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- Functional mode with FMODE[1:0]
- Automatic status-polling mode behavior if needed with PMM and APMS
- FIFO level with FTHRES
- DMA usage with DMAEN
- Timeout counter usage with TCEN
- Dual-memory configuration, if needed, with DMM

In case of an interrupt usage, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

26.4.13 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2.The user must program:

- Device size with DEVSIZE[4:0]
- Chip-select minimum high time with CSHT[5:0]
- Clock mode with FRCK and CKMODE
- Device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:

- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- HyperBus memory mode: the protocol follows the HyperBus specification, and an 8-data-bit DTR mode must be selected.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be non-cacheable, or the Indirect read/write modes must be used.

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the Latency mode must be configured in OCTOSPI_HLCR.

26.4.14 OCTOSPI Regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected and data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in Indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The Automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read.The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled; The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the Flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

When the OCTOSPI is used in Memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for read operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 have no effect and is not signaled with an error response. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

OCTOSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

OCTOSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

Sending the instruction only once (SIOO)

A Flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for Memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

SIOO mode is not supported when any of the communication regulation, NCS boundary or refresh features are used.

26.4.15 OCTOSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Make a write operation in OCTOSPI_IR and enable the DMA channel if needed.
3. Specify the targeted address in OCTOSPI_AR.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In Indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In Indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration (HyperBus)

The Automatic status-polling mode is enabled setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, it can be internally processed to:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set.

In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the targeted address in OCTOSPI_AR.

The command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration (HyperBus)

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

The Memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

All the configuration operation must be completed prior to the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

26.4.16 OCTOSPI error management

A error can be generated in the following cases:

- in Indirect or Automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]). This sets TEF and an interrupt is generated if enabled.
- in Indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.
- in Memory-mapped mode when an out-of-range access is done by an AHB master. This generates an AHB error as a response to the faulty AHB request.
- when the Memory-mapped mode is disabled. An access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The OCTOSPI generates an AHB slave error in the following situations:

- Memory-mapped mode is disabled and an AHB read request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing.
- OCTOSPI is disabled while a read or write burst is ongoing.
- Write wrap burst is received.
- Write request is received while DQSE = 0 in OCTOSPI_WCCR in octal DTR mode or in dual-memory configuration.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means the HSIZE is different from 4 bytes (only for Memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 4 bytes (only for Memory-mapped mode).

26.4.17 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In Indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In Automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in Memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers.

Note: Some devices may misbehave if a write operation to a status register is aborted.

26.4.18 OCTOSPI reconfiguration or deactivation

Prior to any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

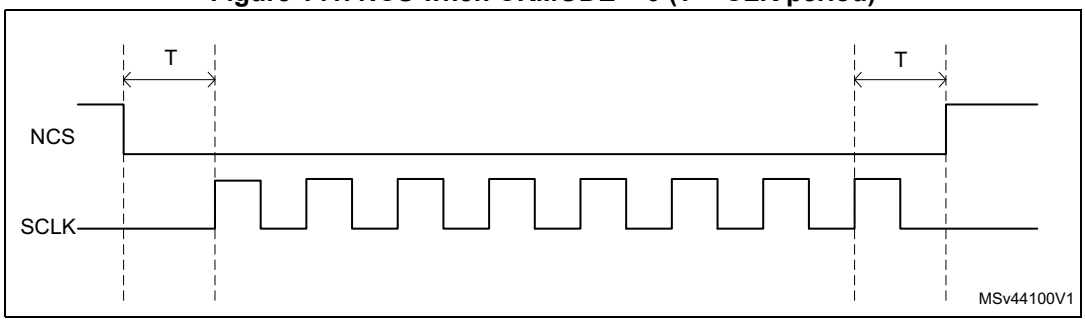
- After a Memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a Memory-mapped read, the software must perform a synchronization barrier then an abort.

26.4.19 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

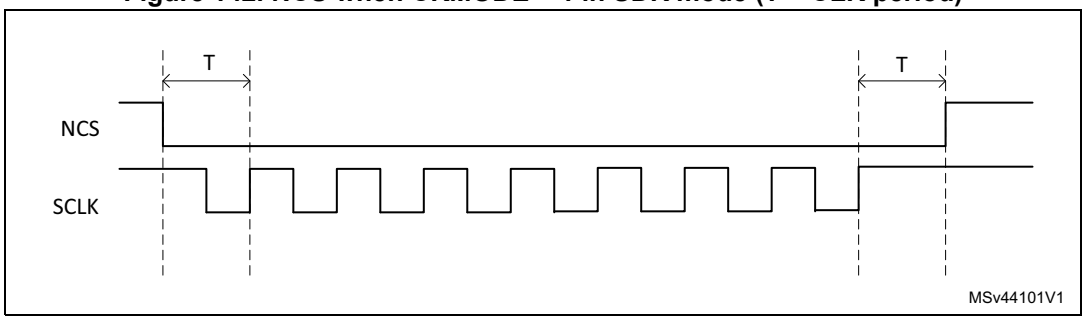
When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 141. NCS when CKMODE = 0 (T = CLK period)



When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

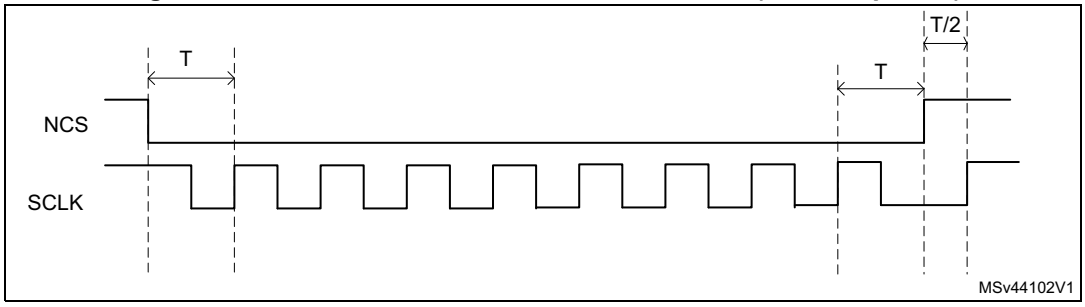
Figure 142. NCS when CKMODE = 1 in SDR mode (T = CLK period)



When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations

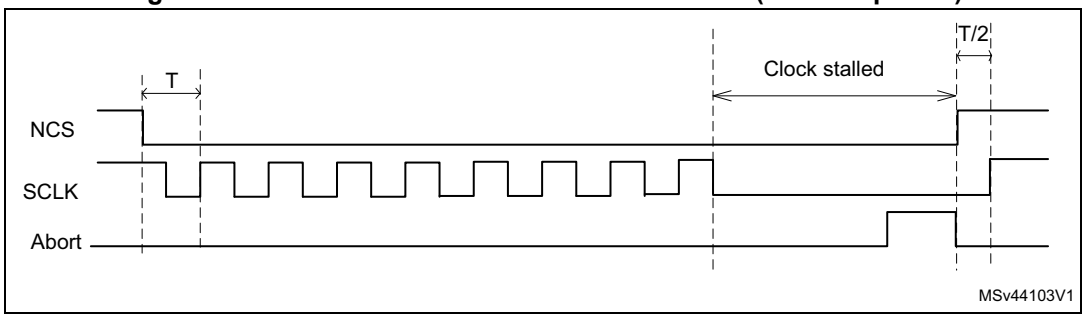
must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 143. NCS when CKMODE = 1 in DTR mode (T = CLK period)



When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 144. NCS when CKMODE = 1 with an abort (T = CLK period)



26.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 218. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad Flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				

Table 218. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad Flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal Flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal Flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write				
	MM write				

1. To be respected by the software.
2. IND = Indirect mode.
3. MM = Memory-mapped mode
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.

26.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 219. OCTOSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

26.7 OCTOSPI registers

26.7.1 OCTOSPI control register (OCTOSPI_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	FMODE[1:0]		Res.	Res.	Res.	Res.	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
		rw	rw					rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					MSEL	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **FMODE[1:0]**: Functional mode

This field defines the OCTOSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

Note: This field can be modified only when BUSY = 0.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the Automatic status-polling mode.

0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.

1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the Automatic status-polling mode is stopped after a match.
0: automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
1: automatic status-polling mode stops as soon as there is a match.
Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: interrupt disabled
1: interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
0: interrupt disabled
1: interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: interrupt disabled
1: interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: interrupt disabled
1: interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: interrupt disabled
1: interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level
This field defines, in Indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI_SR, to be set.
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in Indirect-read mode.
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in Indirect-read mode.
...
11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in Indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in Indirect-read mode.
Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 **MSEL**: External memory select
This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).
0: external memory 1 selected (data exchanged over IO[3:0])
1: external memory 2 selected (data exchanged over IO[7:4])
This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: dual-memory configuration disabled

1: dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the Memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in Memory-mapped mode.

1: timeout counter is enabled, and thus the chip-select is released in the Memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In Indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for Indirect mode

1: DMA enabled for Indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: no abort requested

1: abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the OCTOSPI.

0: OCTOSPI disabled

1: OCTOSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

26.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	Res.	DEVSIZE[4:0]				
					rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	DLY BYP	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw					rw		rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bit indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad- and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad- and octal-SPI modes with dedicated address mapping.

100: HyperBus memory mode, the protocol follows the HyperBus specification. 8-data-bit DTR mode must be selected.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or Indirect read/write modes must be used.

Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]**: Device size

This field defines the size of the external device using the following formula:

Number of bytes in device = $2^{[DEVSIZE+1]}$.

DEVSIZE+1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

In Regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the capacity of one of the two external devices.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...

0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: the internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).

1: the delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set.

Bit 0 **CKMODE**: Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).

0: CLK must stay low while NCS is high (chip-select released). This is referred to as clock mode 0.

1: CLK must stay high while NCS is high (chip-select released). This is referred to as clock mode 3.

26.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This field indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this field indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

000: Wrapped reads are not supported by the memory.

010: external memory supports wrap size of 16 bytes.

011: external memory supports wrap size of 32 bytes.

100: external memory supports wrap size of 64 bytes.

101: external memory supports wrap size of 128 bytes.

Others: reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This field defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

26.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAXTRAN[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This field enables the transaction boundary feature. When active, a minimum value of 3 is recommended.

The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer

This field enables the communication regulation feature.

The NCS is released every MAXTRAN+1 clock cycles when the other OCTOSPI request the access to the bus.

0: maximum communication disabled

Others: maximum communication is set to MAXTRAN + 1 bytes.

26.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This field enables the refresh rate feature.

The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads.

Note: These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: refresh disabled

Others: maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the divided clock period: if OCTOSPI_DCR2 PRESCALER field is changed, the REFRESH field must be updated accordingly.

26.7.6 OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This field gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In Automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in Automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR).
It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In Indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.
It is cleared automatically as soon as the threshold condition is no longer true.
In Automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in Indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in Indirect mode when an invalid address is being accessed in Indirect mode.
It is cleared by writing 1 to CTEF.

26.7.7 OCTOSPI flag clear register (OCTOSPI_FCR)

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the OCTOSPI_SR register.

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the OCTOSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the OCTOSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the OCTOSPI_SR register.

26.7.8 OCTOSPI data length register (OCTOSPI_DLR)

Address offset: 0x0040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31: 0]**: Data length

Number of data to be retrieved (value+1) in Indirect and Automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for Automatic status-polling mode.

All 1’s in Indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This field has no effect in Memory-mapped mode.

26.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.
Writes to this field are ignored when BUSY = 1 or when FMODE = 11 (Memory-mapped mode).

26.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31: 0]**: Data

Data to be sent/received to/from the external SPI device
In Indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
In Indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
In Automatic status-polling mode, this register contains the last data read from the external device (without masking).
Word, half-word, and byte accesses to this register are supported. In Indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.
Similarly, in Indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in Indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

26.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in Automatic status-polling mode

For bit n:

0: bit n of the data received in Automatic status-polling mode is masked and its value is not considered in the matching logic.

1: bit n of the data received in Automatic status-polling mode is unmasked and its value is considered in the matching logic.

26.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31: 0]**: Status match

Value to be compared with the masked status register to get a match

26.7.13 OCTOSPI polling interval register (OCTOSPI_PIR)

Address offset: 0x0090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15: 0]**: Polling interval

Number of CLK cycle between a read during the Automatic status-polling phases

26.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR)

Address offset: 0x0100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SIOO	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]

Res.	Res.	ADSIZE[1:0]		AD DTR	ADMODE[2:0]			Res.	Res.	ISIZE[1:0]		IDTR	IMODE[2:0]		
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **SIOO**: Send instruction only once mode
This bit has no effect when IMODE = 00 (see *Sending the instruction only once (SIOO)*).
0: send instruction on every transaction
1: send instruction only for the first command

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: no data
001: data on a single line
010: data on two lines
011: data on four lines
100: data on eight lines
Others: reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate bytes phase.
0: DTR mode disabled for alternate bytes phase
1: DTR mode enabled for alternate bytes phase
This field can be written only when BUSY = 0.

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
000: no address
001: address on a single line
010: address on two lines
011: address on four lines
100: address on eight lines
Others: reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bit defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This field defines the instruction phase mode of operation.
000: no instruction
001: instruction on a single line
010: instruction on two lines
011: instruction on four lines
100: instruction on eight lines
Others: reserved

26.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: no shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
0: no delay hold
1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
It is recommended to have at least six dummy cycles when using memories with DQS activated.

26.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

26.7.17 OCTOSPI alternate bytes register (OCTOSPI_ABR)

Address offset: 0x0120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31: 0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address.

26.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR)

Address offset: 0x00130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15: 0]**: Timeout period

After each access in Memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.

This field indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

26.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for data phase

1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: no data
001: data on a single line
010: data on two lines
011: data on four lines
100: data on eight lines
Others: reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate bytes size
This bit defines alternate bytes size.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
000: no address
001: address on a single line
010: address on two lines
011: address on four lines
100: address on eight lines
Others: reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This field defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This field defines the instruction phase mode of operation.
000: no instruction
001: instruction on a single line
010: instruction on two lines
011: instruction on four lines
100: instruction on eight lines

Bit 30 **SSHIFT**: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: no shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: no quarter cycle delay
1: quarter cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

26.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: no data
001: data on a single line
010: data on two lines
011: data on four lines
100: data on eight lines
Others: reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate bytes size
This field defines alternate bytes size:
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate-bytes phase.
0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
000: no address
001: address on a single line
010: address on two lines
011: address on four lines
100: address on eight lines
Others: reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bit defines instruction size:
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This field defines the instruction phase mode of operation.
000: no instruction
001: instruction on a single line
010: instruction on two lines
011: instruction on four lines
100: instruction on eight lines
Others: reserved

26.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR)

Address offset: 0x0188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

26.7.25 OCTOSPI write instruction register (OCTOSPI_WIR)

Address offset: 0x0190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31: 0]**: Alternate bytes

Optional data to be sent to the external SPI device right after the address

26.7.27 OCTOSPI HyperBus latency configuration register (OCTOSPI_HLCR)

Address offset: 0x0200

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read write recovery time

Device read write recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7: 0]**: Access time

Device access time expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.
0: latency on write accesses
1: no latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the Latency mode.
0: variable initial latency
1: fixed latency

27 OCTOSPI I/O manager (OCTOSPIM)

27.1 Introduction

The OCTOSPI I/O manager is a low-level interface that enables an efficient OCTOSPI pin assignment with a full I/O matrix (before alternate function map) and multiplex of single/dual/quad/octal SPI interfaces over the same bus.

27.2 OCTOSPIM main features

- Supports up to two single/dual/quad/octal SPI interfaces
- Supports up to two ports for pin assignment
- Fully programmable I/O matrix for pin assignment by function (data/control/clock)

27.3 OCTOSPIM implementation

The table below describes the OCTOSPIM implementation.

Table 221. OCTOSPIM implementation

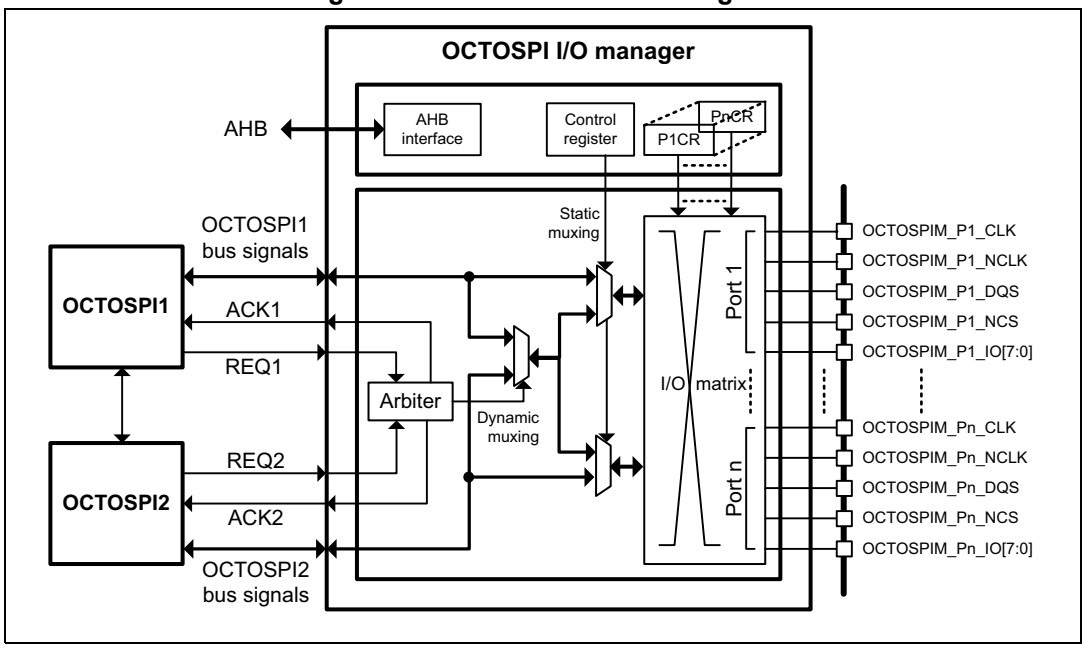
OCTOSPI feature	Available on the devices
Supports up to two single/dual/quad interfaces	X
Fully I/O multiplexing capability	X
Supports time-multiplexed mode	X
Supports high-speed interface	-
Chip select selection if OCTOSPI provides dual chip select	-
Supports 16-bit data interface and dual-octal mode	-

27.4 OCTOSPIM functional description

27.4.1 OCTOSPIM block diagram

The block diagram of the OCTOSPI I/O manager is shown in *Figure 145*.

Figure 145. OCTOSPIM block diagram



1. The number of ports (n) is 2.
2. Arbitration is possible for both I/O matrix input ports.

27.4.2 OCTOSPIM matrix

The OCTOSPI I/O manager matrix allows the user to set a fully programmable pre-mapping of functions:

- Any OCTOSPIM_Pn_CLK / OCTOSPIM_Pn_NCLK pair can be mapped independently to OCTOSPI1_CLK/OCTOSPI1_NCLK or OCTOSPI2_CLK/OCTOSPI2_NCLK
- Any OCTOSPIM_Pn_DQS can be mapped independently to OCTOSPI1_DQS or OCTOSPI2_DQS
- Any OCTOSPIM_Pn_NCS can be mapped independently to OCTOSPI1_NCS or OCTOSPI2_NCS
- Any OCTOSPIM_Pn_IO[3:0] and OCTOSPIM_Pn_IO[7:4] can be mapped independently to OCTOSPI1_IO[3:0], OCTOSPI1_IO[7:4], OCTOSPI2_IO1[3:0] or OCTOSPI2_IO[7:4]

For each OCTOSPI I/O manager port, individual signal enables and mapping are configured through the corresponding OCTOSPI I/O manager Port n configuration register (OCTOSPIM_PnCR).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the OCTOSPI1 and OCTOSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The OCTOSPIM configuration can be changed only when all OCTOSPIs are disabled.

27.4.3 OCTOSPIM multiplexed mode

When this mode is set the OCTOSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit of the configuration register OCTOSPIM_CR.

The fairness counter (MAXTRAN) of each OCTOSPI can be used to accurately manage the maximum duration for which a given OCTOSPI takes the bus: this feature ensures a maximum bus access latency for the other OCTOSPI(s). When the bus is released by one OCTOSPI, an arbitration phase occurs, which is round-robin: when another OCTOSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both OCTOSPI interfaces must be activated.

OCTOSPIn_NCS are not part of the multiplexing.Only OCTOSPIn_IOs, OCTOSPIn_DQS and OCTOSPIn_CLK / OCTOSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the OCTOSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the OCTOSPI, when used, may be increased.

Minimum switching duration

The minimum number of cycles needed to switch from an OCTOSPI to another can be configured.

This internal timer guarantees a latency between the falling edge of the REQ signal of the active OCTOSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting OCTOSPI (the bus is granted to the requesting one).

The duration is defined by the REQ2ACK_TIME field of the configuration register OCTOSPIM_CR.

Pin mapping in Multiplexed mode

In Multiplexed mode, the mapping of the bus is done as described below:

- OCTOSPI1_NCS and OCTOSPI2_NCS work in the same way, then in Non-multiplexed mode they have to be assigned to their respective OCTOSPIM_Pn_NCS.
- All the other signals are seen by the I/O matrix as if they were seen from OCTOSPI1.

27.5 OCTOSPIM registers

27.5.1 OCTOSPIM control register (OCTOSPIM_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REQ2ACK_TIME[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MUXEN
															rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **REQ2ACK_TIME[7:0]**: REQ to ACK time

In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions. The value is the number of OCTOSPI clock cycles - 1

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MUXEN**: Multiplexed mode enable

This bit enables the multiplexing of the two OCTOSPIs.

0: No multiplexing, hence no arbitration

1: OCTOSPI1 and OCTOSPI2 are multiplexed over the same bus.

27.5.2 OCTOSPIM Port n configuration register (OCTOSPIM_PnCR)

Address offset: 0x0000 + 0x04*n (n=1 to 2)

Reset value: 0x0301 0111, 0x0705 0333

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	IOHSRC[1:0]		IOHEN	Res.	Res.	Res.	Res.	Res.	IOLSRC[1:0]		IOLEN
					rw	rw	rw						rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	NCSSRC	NCSEN	Res.	Res.	DQSSRC	DQSEN	Res.	Res.	CLKSRC	CLKEN
						rw	rw			rw	rw			rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:25 **IOHSRC[1:0]**: IO[7:4] source for Port n

This bits select the source of Port n IO[7:4].

00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode

01: OCTOSPI1_IO[7:4] in non multiplexed mode / multiplexed_IO[7:4] in multiplexed mode

10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode

11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 24 **IOHEN**: IO[7:4] enable for Port n
This bit enables the Port n IO[7:4].
0: IO[7:4] for Port n disabled
1: IO[7:4] for Port n enabled

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:17 **IOLSRC[1:0]**: IO[3:0] source for Port n
This bits select the source of Port n IO[3:0].
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
01: OCTOSPI1_IO[7:4] in non multiplexed mode / multiplexed_IO[7:4] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 16 **IOLEN**: IO[3:0] enable for Port n
This bit enables the Port n IO[3:0].
0: IO[3:0] for Port n disabled
1: IO[3:0] for Port n enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **NCSSRC**: NCS source for Port n
This bit selects the source of Port n NCS.
0: OCTOSPI1_NCS
1: OCTOSPI2_NCS

Bit 8 **NCSEN**: NCS enable for Port n
This bit enables the Port n NCS.
0: NCS for Port n is disabled
1: NCS for Port n is enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **DQSSRC**: DQS source for Port n
This bit selects the source of Port n DQS.
0: OCTOSPI1_DQS in non multiplexed mode / multiplexed_DQS in multiplexed mode
1: OCTOSPI2_DQS in non multiplexed mode / unused port in multiplexed mode

Bit 4 **DQSEN**: DQS enable for Port n
This bit enables the Port n DQS.
0: DQS for Port n is disabled
1: DQS for Port n is enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **CLKSRC**: CLK/NCLK source for Port n
This bit selects the source of Port n CLK/NCLK.
0: OCTOSPI1_CLK/NCLK in non multiplexed mode / multiplexed_CLK/CLKn in multiplexed mode
1: OCTOSPI2_CLK/NCLK in non multiplexed mode / unused port in multiplexed mode

Bit 0 **CLKEN**: CLK/NCLK enable for Port n
This bit enables the Port n CLK/NCLK.
0: CLK/NCLK for Port n is disabled
1: CLK/NCLK for Port n is enabled

27.5.3 OCTOSPIM register map

Table 222. OCTOSPIM register map and reset values

Refer to *Section 2.3 on page 115* for the register boundary addresses.

28 Delay block (DLYB)

28.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

28.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

28.3 DLYB implementation

Table 223. STM32U575/585 features

DLYB associated peripheral	DLYBOS1	DLYBOS2	DLYBSD1	DLYBSD2
OCTOSPI1	X	-	-	-
OCTOSPI2	-	X	-	-
SDMMC1	-	-	X	
SDMMC2	-	-	-	X

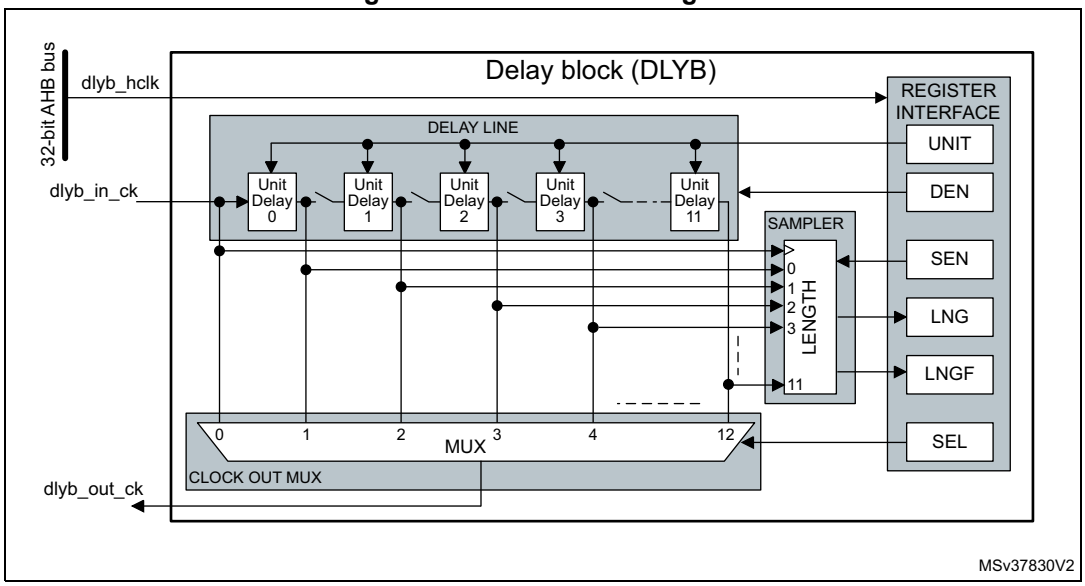
28.4 DLYB functional description

28.4.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 146. DLYB block diagram



28.4.2 DLYB pins and internal signals

Table 224 lists the DLYB internal signals.

Table 224. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

28.4.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 225. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don't care	Don't care	Don't care	Don't care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don't care	Don't care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

28.4.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

28.4.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

28.5 DLYB registers

All registers can be accessed in word, half-word and byte access.

28.5.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

28.5.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.

These bits can only be written when SEN = 1.

Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.

These bits can only be written when SEN = 1.

Output clock phase = input clock + SEL[3:0] x unit delay

28.5.3 DLYB register map

Table 226. DLYB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

29 Analog-to-digital converter (ADC1)

29.1 Introduction

This section describes the implementation of the 14-bit ADC successive approximation analog-to-digital converter.

The ADC features up to 20 multiplexed channels. Channel A/D conversion can be performed in Single, Continuous, Scan or Discontinuous mode. The result of the ADC can be stored in a left-aligned or right-aligned 32-bit data register.

The ADC is mapped on the AHB bus to enable fast data handling.

In addition, the analog watchdog features enable the application to detect if the input voltage goes outside user-defined high or low thresholds.

The ADC features a built-in hardware oversampler that improves analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is also implemented to achieve very low consumption at low frequency.

29.2 ADC main features

- High-performance features
  - 14-, 12-, 10- or 8-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Management of single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface for fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to four injected channels (fully configurable analog input assignment to regular or injected channels)
  - Hardware assistant to prepare the injected channel context and enable fast context switching
  - Data alignment with in-built data coherency
  - Data management by general-purpose DMA for regular channel conversions with FIFO
  - Data routing to MDF for post processing
  - Four dedicated data registers for injected channels
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shift

- Data preconditioning
  - Gain compensation
  - Offset compensation
- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Support of slow bus frequency applications while keeping optimum ADC performance
  - Automatic control to avoid ADC overrun in AHB bus clock low-frequency application (auto-delayed mode)
- Up to 17 external analog input channels connected to dedicated GPIO pads
- 3 internal dedicated channels
  - One channel for internal reference voltage (V_{REFINT})
  - One channel for internal temperature sensor (V_{SENSE})
  - One channel for V_{BAT} monitoring channel ($V_{BAT}/4$)
- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions or
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Single mode: the ADC converts a single channel. The conversion is triggered by a special event.
  - Scan mode: the ADC scans and converts a sequence of channels.
  - Continuous mode: the ADC converts continuously selected inputs.
  - Discontinuous mode: the ADC converts a subset of the conversion sequence.
- Interrupt generation when the ADC is ready, at end of sampling, end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or when an overrun event occurs
- Three analog watchdogs

  The watchdogs can perform filtering to ignore out-of-range data.
- ADC input range: $V_{REF-} \leq V_{IN} \leq V_{REF+}$

Figure 147 shows the block diagram of one ADC.

29.3 ADC implementation

The tables below describe ADC implementation on STM32U575/585 devices. It also includes ADC4 for comparison.

Table 227. ADC features(1)

ADC modes/features	ADC1	ADC4
Resolution	14 bits	12 bits
Maximum sampling speed for 14-bit resolution	2.5 Msps	2.5 Msps
Hardware offset calibration	X	X

Table 227. ADC features(1) (continued)

ADC modes/features	ADC1	ADC4
Hardware linearity calibration	X	-
Extended calibration mode	X(2)	-
Single-ended inputs	X	X
Differential inputs	X	-
Injected channel conversion	X	-
Oversampling	up to x1024	up to x256
Data register	32 bits	16 bits
DMA support	X	X
Parallel data output to MDF	X	-
Dual mode	-	-
Autonomous mode	-	X
Offset compensation	X	-
Gain compensation	X	-
Number of analog watchdogs	3	3
Wakeup from Stop mode	-	X(3)

1. Note: 'X' = supported, '-'= not supported.
2. The extended calibration mode is not supported on devices revision X.
3. Wake up supported from Stop 0, Stop 1 and Stop 2 modes.

Table 228. Memory location of the temperature sensor calibration values

Name	Description	Memory address
TS_CAL1	Temperature sensor 14-bit raw data acquired by ADC1 at 30 °C (± 5 °C), $V_{DDA} = V_{REF+}$ = 3.0 V (±10 mV)	0x0BFA 0710 - 0x0BFA 0711
TS_CAL2	Temperature sensor 14-bit raw data acquired by ADC1 at 130 °C (± 5 °C), $V_{DDA} = V_{REF+}$ = 3.0 V (±10 mV)	0x0BFA 0742 - 0x0BFA 0743

Table 229. Memory location of the internal reference voltage sensor calibration value

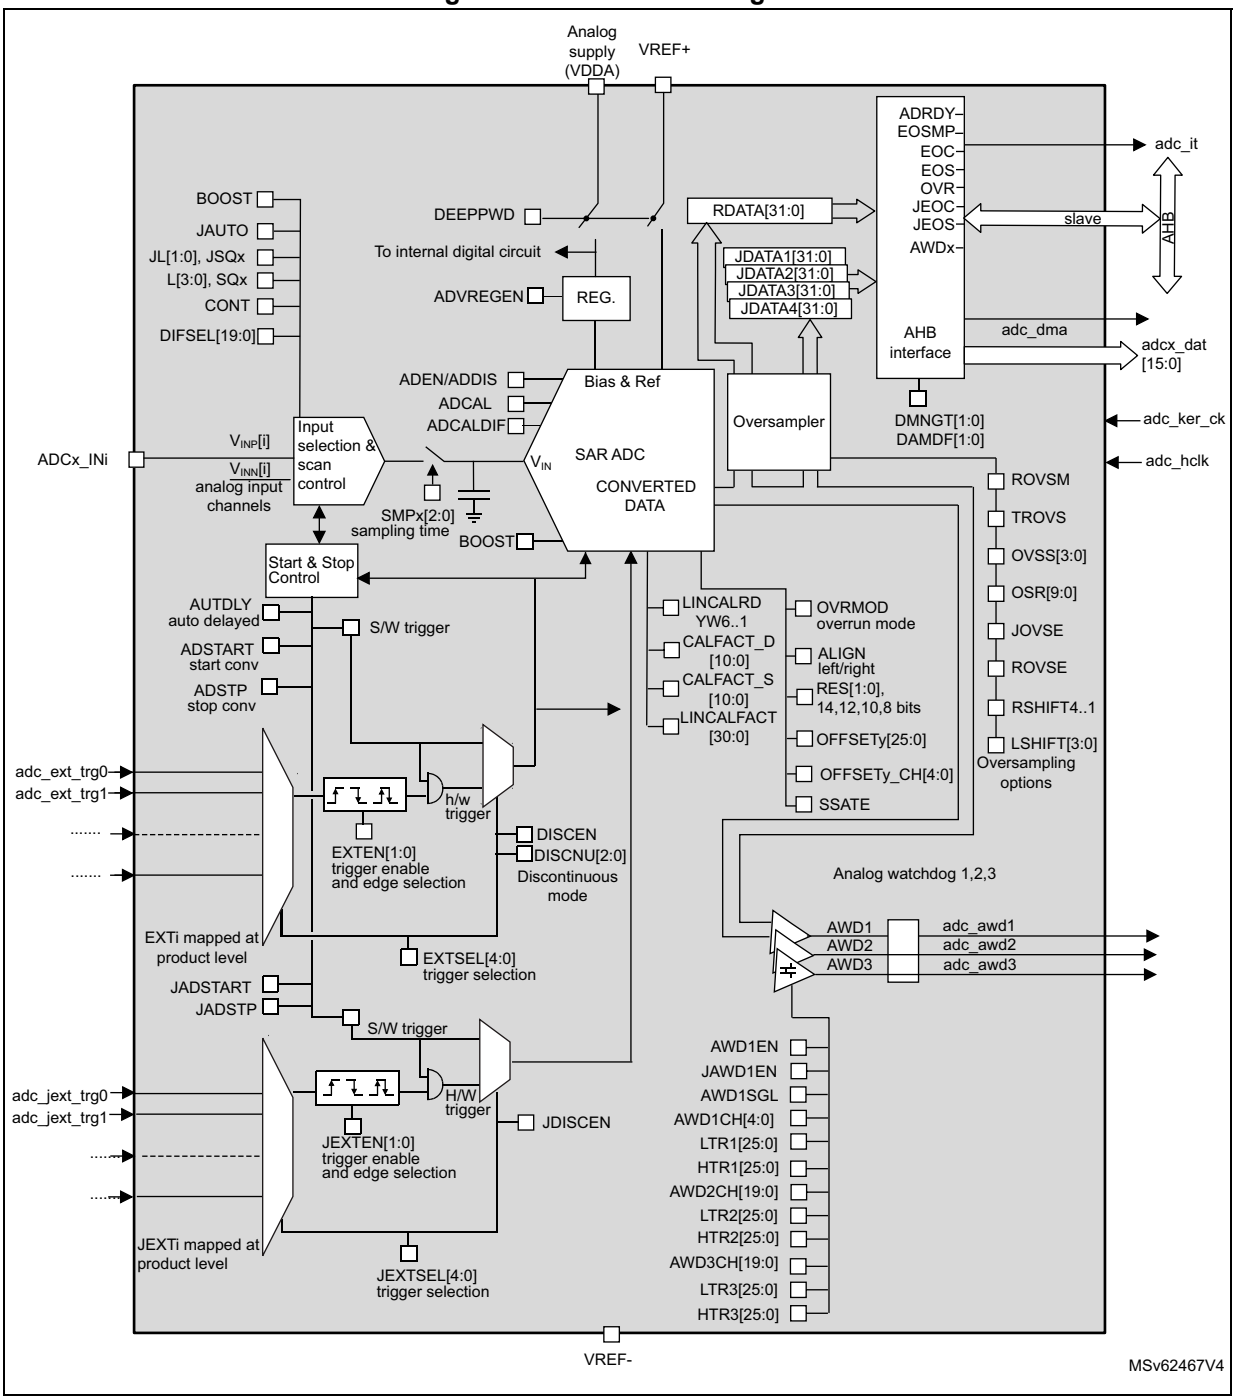
Name	Description	Memory address
VREFINT_CAL	14-bit raw data acquired by ADC1 at 30 °C (± 5 °C), $V_{DDA} = V_{REF+}$ = 3.0 V (±10 mV)	0x0BFA 07A5 - 0x0BFA 07A6

29.4 ADC functional description

29.4.1 ADC block diagram

Figure 147 shows the ADC block diagram and *Table 230* gives the ADC pin description.

Figure 147. ADC block diagram



29.4.2 ADC pins and internal signals

Table 230. ADC input/output pins

Name	Signal type	Description
VREF+	Input, analog reference positive	Higher/positive reference voltage for the ADC
VDDA	Input, analog supply	Analog power supply equal V_{DDA}
VREF–_	Input, analog reference negative	Lower/negative reference voltage for the ADC, $V_{REF-} = V_{SSA}$

29.4.3 ADC clocks

Dual clock domain architecture

Dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 148: ADC clock scheme*). This selection is done in the RCC (refer to th RCC section for more information):

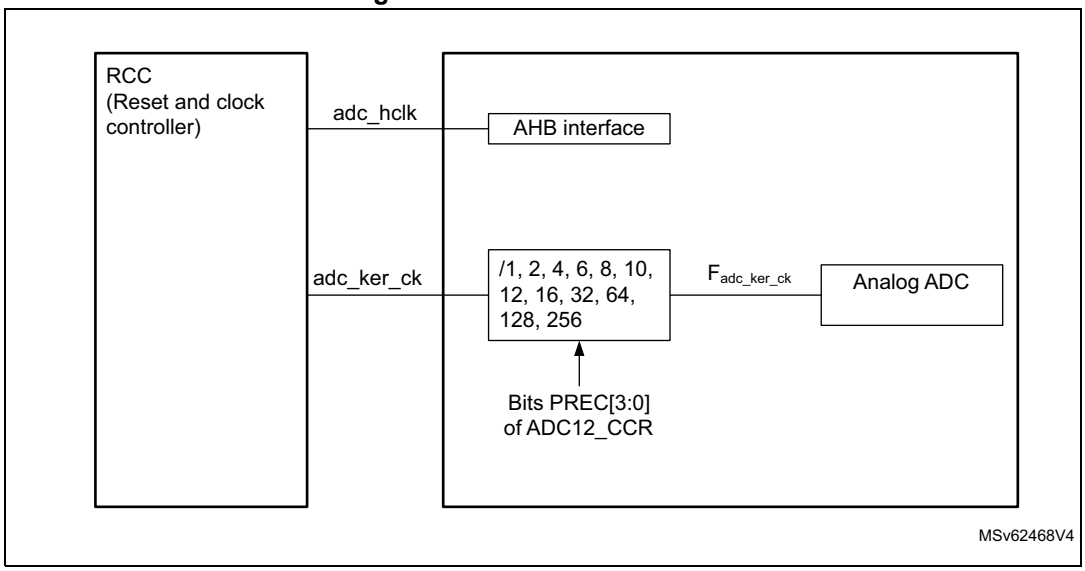
1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous with the AHB clock.
2. The ADC clock can be derived from the AHB clock.

Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by a ratio of 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256, using the prescaler configured through PRESC[3:0] bits in the ADC12_CCR register.

Option **2** enables to bypass the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through the RCC. It must be compliant with the operating frequency specified in the device datasheet.

Figure 148. ADC clock scheme



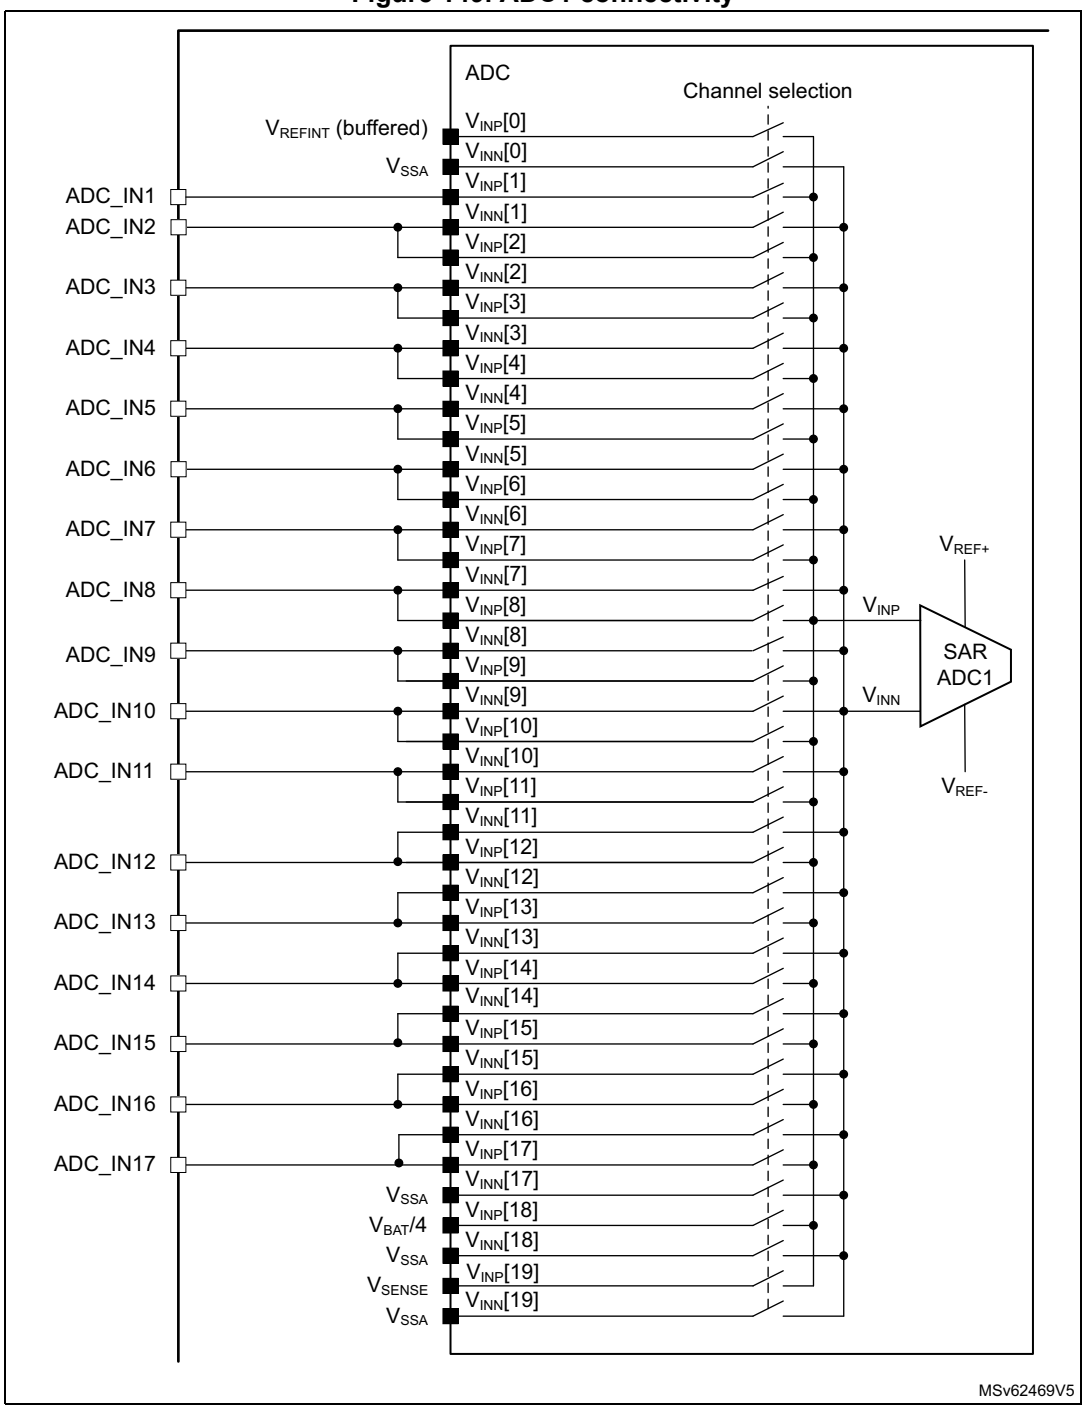
1. Refer to the RCC section for information on adc_hclk and adc_ker_ck generation.

Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock. However the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.

29.4.4 ADC connectivity

Figure 149. ADC1 connectivity



1. $V_{INN}[i]$ signal can only be used when the corresponding ADC input channel is configured as differential mode.

29.4.5 Slave AHB interface

The ADC implements an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests and never generates AHB errors.

29.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, follow the sequence below:

1. First exit Deep-power-down mode by clearing DEEPPWD bit.
2. Then, enable the ADC internal voltage regulator by setting ADVREGEN bit in the ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG\_STUP}$) before launching a calibration or enabling the ADC. This can be done by software by polling the LDORDY bit of ADC_ISR register.

After ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by clearing ADVREGEN bit. Power consumption can be further reduced by reducing the leakage currents. In addition, it is possible to enter again in ADC Deep-power-down mode by setting DEEPPWD bit in ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Setting DEEPPWD automatically disables the ADC voltage regulator and ADVREGEN bit is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration factor *is kept.*

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary either to relaunch a calibration or apply again the calibration factor which was previously saved (refer to *Section 29.4.8: Calibration (ADCAL, ADCALLIN, ADC_CALFACT)*).

29.4.7 Single-ended and differential input channels

ADC channels can be configured either as single-ended input or as differential input. This is done by writing DIFSEL[19:0] bits in the ADC_DIFSEL register. This configuration must be performed while the ADC is disabled (ADEN = 0).

In Single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and V_{REF-} (negative input).

In Differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{INN}[i]$ (negative input).

The output data in Differential mode is an unsigned data:

- When $V_{INP}[i] = V_{REF-}$: $V_{INN}[i] = V_{REF+}$and output data = 0x0000 (14-bit resolution mode),
- When $V_{INP}[i] = V_{REF+}$: $V_{INN}[i] = V_{REF-}$ and output data = 0x3FFF.

$$\text{Converted value} = \frac{\text{ADC\_Full\_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When ADC is configured as Differential mode, both inputs must be biased at V_{REF+} / 2 voltage.

For a complete description of how the input channels are connected, refer to *Section 29.4.4: ADC connectivity*

Caution: When channel “i” is configured in Differential input mode, its negative input voltage is connected to $V_{INN}[i-1]$.

29.4.8 Calibration (ADCAL, ADCALLIN, ADC_CALFACT)

The ADC provides an automatic calibration procedure that controls the whole calibration sequence including the ADC power-on/off. During the procedure, the ADC calculates an offset calibration factor for Single-ended and Differential mode. This factor includes the internal offset and the linearity that are applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until the calibration is complete.

The calibration is a prerequisite to any ADC operation. It removes the systematic errors that may vary from chip to chip and enables to compensate offset and linearity deviation.

The offset calibration is the same for single-ended or differential channels.

The linearity correction must be done only once, regardless of single / differential configuration:

- Set ADCALLIN in ADC_CR before launching a calibration that runs the linearity calibration simultaneously with the offset calibration or
- Clear ADCALLIN in ADC_CR before launching a calibration that does not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting ADCAL bit. The calibration can only be initiated when the ADC is disabled (ADEN = 0). ADCAL bit remains at 1 during all the calibration sequence. It is cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC.

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods of time, the temperature changes, or the supply voltage is modified of more than 10%, it is recommended that a new offset calibration cycle is run before enabling the ADC again.

The internal analog calibration is lost each time the ADC power is switched off (for example, when the device enters Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, the calibration factor can be written again to the ADC analog block without recalibrating, assuming that the software has previously saved the calibration factor generated during the previous calibration.

The calibration factor obtained during factory tests is programmed in a specific device option byte. To reduce the calibration time, this value can be copied to the analog ADC.

The calibration factor can be written if the ADC is enabled and no calibration is ongoing (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This operation is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate the ADC offset when V_{REF+} changes of more than 10%.

Refer to the device datasheet for the offset and linearity calibration time requirements.

Software procedure to calibrate the ADC

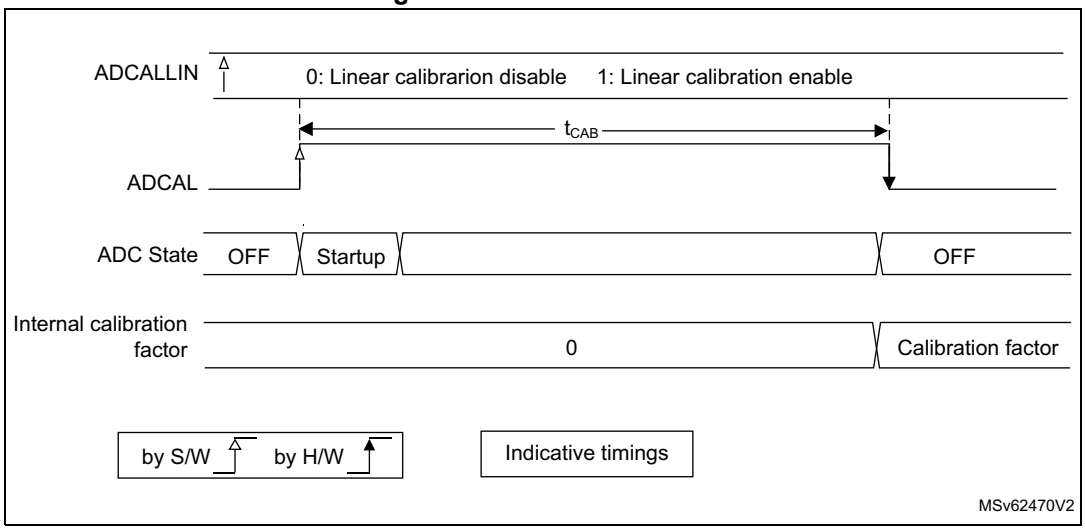
1. Make sure DEEPPWD = 0, ADVREGEN = 1 and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Make sure ADEN = 0.
3. Either enable the linearity calibration (ADCALLIN = 1) or disable it (ADCALLIN = 0).
4. Make sure CAPTURE_COEF and LATCH_COEF in ADC_CALFACT are cleared.
5. Set ADCAL in ADC_CR register and wait until ADCAL = 0.

Figure 150 shows the ADC calibration timing diagram.

Note: The software can launch the calibration only when ADEN = 0, LDORDY = 1 *(ADC disabled and LDO ready).*

Single-ended and differential channels cannot be calibrated separately. The offset calibration must be performed within the same sequence.

Figure 150. ADC calibration



Reading calibration factor procedure

Once the calibration is complete (ADCAL bit cleared by hardware), the calibration factor can be read using the ADC_CALFACT2 register. Nine read accesses are required to perform this operation:

1. Make sure DEEPPWD = 0, ADVREGEN = 1, and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Make sure that ADEN = 1.
3. Set CAPTURE_COEF and clear LATCH_COEF in ADC_CALFAC register.
4. Select the calibration factor by setting CALLINDEX[0:3] in *ADC control register (ADC_CR)*.
5. Read the calibration factor from ADC_CALFACT2 register.
6. Repeat steps **4** and **5** for each required calibration factor.
7. Clear CAPTURE_COEF bit in ADC_CALFACT register.

Note: The software can access the calibration factor only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

Software procedure to reinject the calibration factor into the ADC

1. Make sure ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Clear CAPTURE_COEF and LATCH_COEF bits in ADC_CALFACT register
3. Set CALINDEX[3:0] to the targeted calibration index to be updated, then write the calibration factor to CALFACT[31:0] in ADC_CALFACT2 register.
4. Repeat step 3 for the necessary calibration index.
5. Set LATCH_COEF bit in ADC_CALFACT register.
6. Clear LATCH_COEF bit in ADC_CALFACT register.

Note: The software is allowed to update the calibration factor only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

Calibration factor index

The calibration factors are stored in the analog block in an indexed way. Index 0b0000 and 0b1000 contains the offset calibration factor while index 0b0001 to 0b0110 contain the linearity factor. The lower two bytes of index 0b0111 contain the linearity calibration factor. The internal offset calibration factor must be programmed into the second byte of index 0b0111. However, it is read at byte 3 of index 0b1000. When programming or reinjecting the calibration factor, make sure to use the correct indexes for read and write operations.

Refer to *Table 235* for a summary.

Table 235. Calibration factor index

CALINDEX[3:0] values	Calibration factor			
	Byte location			
	Byte 3	Byte 2	Byte 1	Byte 0
0b0000	Differential offset		Single-end offset	
0b0001	Linearity factor 1			

Table 235. Calibration factor index (continued)

CALINDEX[3:0] values	Calibration factor			
	Byte location			
	Byte 3	Byte 2	Byte 1	Byte 0
0b0010	Linearity factor 2			
0b0011	Linearity factor 3			
0b0100	Linearity factor 4			
0b0101	Linearity factor 5			
0b0110	Linearity factor 6			
0b0111 (read)	Reserved	Reserved	Linearity factor 7	
0b0111 (write)	Reserved	Internal offset		
0b1000 (read)	Internal offset	Reserved	Reserved	Reserved
0b1001	Reserved	Calibration mode	Reserved	Reserved
0b1000 (write)	Reserved	Reserved	Reserved	Reserved
Other values	Reserved			

To run an offset calibration when the linearity calibration factor is programmed by software, first program the linearity calibration factor, then run the offset calibration. Running the offset calibration first would cause the offset calibration factor to be overwritten when the LATCH_COEF bit is programmed.

It is impossible to program the offset calibration alone since byte 1 and byte 0 (linearity factor 7) are overwritten when programming the offset calibration factor into byte 2 of index 0b0111. To avoid this, read the linearity calibration factor then program index 0b0111 with the read value.

Extended calibration mode

To enhance the ADC performance, the extended calibration mode is implemented on some product versions (see *Section 29.3: ADC implementation*).

Below the procedure to enable the extended calibration mode:

1. Make sure that DEEPPWD = 0 and ADVREGEN = 1, and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Set ADCCALLIN in ADC_CR register.
3. Make sure CAPTURE_COEF and LATCH_COEF of ADC_CALFACT are cleared.
4. Set ADEN and wait until ADRDY is set.
5. Set CALINDEX[3:0] = 0b1001, then write CALFACT[31:0] = 0x0002 0000 in ADC_CALFACT2 register.
6. Set LATCH_COEF bit in ADC_CALFACT register
7. Clear LATCH_COEF bit in ADC_CALFACT register
8. Set ADCAL in ADC_CR register and wait until both ADCAL and ADEN are cleared.

Note: Only this procedure is allowed to set ADCAL when ADEN is set (exception).

Once the calibration is complete, the value of CALFACT[31:0] at CALINDEX[3:0] = 0b1001 is reset.

29.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure described in *Section 29.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

Once DEEPPWD bit is cleared and ADVREGEN bit is set, the ADC can be enabled. It requires a stabilization time of t_{STAB} before staring converting accurately (see *Figure 151*). Two control bits enable or disable the ADC:

- When ADEN = 1: the ADC is enabled. The ADRDY is set as soon as the ADC is ready for operation.
- When ADDIS = 1: the ADC is disabled.

ADEN and ADDIS bits are automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to *Section 29.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])*) or when an external trigger event occurs if triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs if injected triggers are enabled.

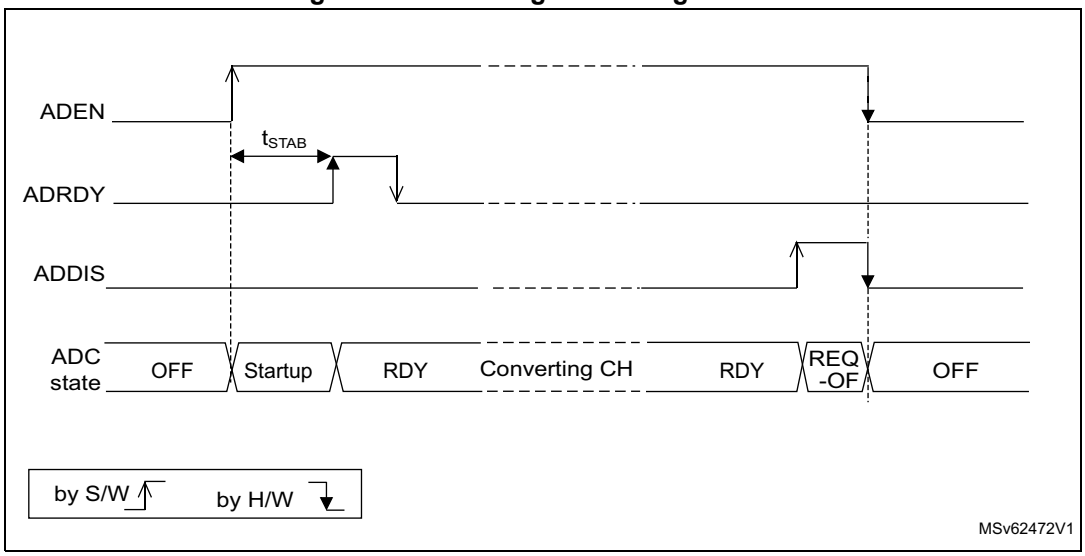
Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing 1.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to make sure that no conversion is ongoing. If required, stop any ongoing regular and injected conversion by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 151. Enabling / Disabling the ADC



29.4.10 Constraints when writing the ADC control bits

The software can program the RCC control bits to configure and enable the ADC clock (refer to the Reset and clock control section), the control DIFSEL bits in the ADC_DIFSEL register, the ADC12_CCR register and the ADCAL and ADEN control bits in the ADC_CR register, only if the ADC is disabled.

The software can program the ADCAL bit to launch the calibration when ADEN is cleared to 0. It can read or update the calibration factor if ADEN is set to 1 and no conversion is ongoing (ADSTART and JADSTART both cleared to 0).

The software is then allowed to write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable it (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRy, ADC_LTRy, ADC_HTRy, ADC_SQRy, ADC_OFRy and ADC_IER registers:

- Control bits related to configuration of regular conversions: the software is allowed to write them only if the ADC is enabled (ADEN = 1) and no regular conversion is ongoing (ADSTART must be equal to 0).
- Control bits related to configuration of injected conversions: the software is allowed to write them only if the ADC is enabled (ADEN = 1) and no injected conversion is ongoing (JADSTART must be equal to 0).
- ADC_LTRy, ADC_HTRy registers can be modified when an analog-to-digital conversion is ongoing (refer to *Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*for details).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled, a conversion is ongoing and there is no pending request to disable it (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

Note: There is no hardware protection to prevent these forbidden write accesses which may cause the ADC to enter an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN as well as all the bits of ADC_CR register).

29.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels:

- Up to 17 analog inputs coming from GPIO pads
- The ADC is connected to 3 internal analog inputs:
  - the internal temperature sensor (V_{SENSE})
  - the internal reference voltage (V_{REFINT})
  - the V_{BAT} monitoring channel ($V_{BAT}/4$)

Refer to *Table ADC interconnection* in *Section 29.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC_IN3, ADC_IN8, ADC_IN2, ADC_IN2, ADC_IN0, ADC_IN2, ADC_IN2, ADC_IN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions are ongoing. To modify ADC_SQRy registers, the ADC regular conversions must first be stopped by setting ADSTP to 1 (refer to *Section 29.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)*).

Note: To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VBATEN, VSENSESEL or VREFEN bits in the ADC12_CCR registers.

29.4.12 Channel preselection register (ADC_PCSEL)

For each channel selected through SQRx or JSQRx bits, the corresponding ADC_PCSEL bit must be configured in advance.

This ADC_PCSEL bit controls the analog switch integrated in the I/O level. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed and the analog switch integrated in the I/O cannot react as fast as ADC multiplexer does. To avoid the delay due to on analog switch control on the I/O, it is necessary to preselect the input channels which is selected through the SQRx and JSQRx. The selection is based on the $V_{INP}[i]$ of each ADC input. For example, if the ADC converts ADC_IN1, PCSEL1 bit must also be set in ADC_PCSEL.

29.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time that is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 5 ADC clock cycles
- SMP = 001: 6 ADC clock cycles
- SMP = 010: 12 ADC clock cycles
- SMP = 011: 20 ADC clock cycles
- SMP = 100: 36 ADC clock cycles
- SMP = 101: 68 ADC clock cycles
- SMP = 110: 391 ADC clock cycles
- SMP = 111: 814 ADC clock cycles

The total conversion time is calculated as follows:

$$T_{CONV} = \text{Sampling time} + \text{Conversion time}$$

Example

When converting a single data, the sampling time is 5 cycles and the conversion time is 17 cycles for 14-bit mode. With an $F_{adc\_ker\_ck}$ of 55 MHz:

T_{CONV} = (5 + 17) ADC clock cycles = 22 ADC clock cycles = 0.40 µs

The above result assumes that Rain << 1 KΩ (refer to the datasheet for additional sampling time to be added depending on the external resistance).

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

I/O analog switches voltage booster

The I/O analog switches resistance increases when the V_{DDA} voltage is too low. This requires to adapt the sampling time accordingly (see the device datasheet for electrical characteristics). This resistance can be minimized at low V_{DDA} by enabling an internal voltage booster (refer to the SYSCFG section for more details).

Bulb sampling mode

When the BULB bit is set in ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The Bulb mode is effective starting from the second conversion.

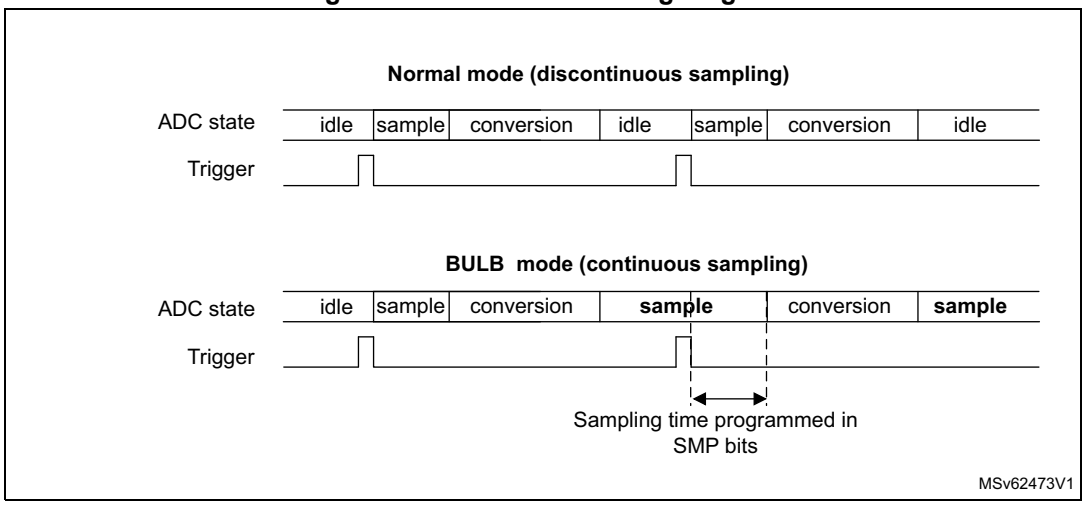
The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The Bulb mode could not be used in continuous conversion mode or with injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

When conversions in Bulb mode are stopped by setting ADSTP bit or when the DMA transfers are complete, the ADC must be disabled by setting ADDIS bit.

Figure 152. Bulb mode timing diagram



Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is not compatible with the continuous conversion mode and injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

29.4.14 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs once the conversions of all channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)

  ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

29.4.15 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically re-starts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both Discontinuous mode and Continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Section : Auto-injection mode).

29.4.16 Starting conversions (ADSTART, JADSTART)

The software starts ADC regular conversions by setting ADSTART to 1. When ADSTART is set, the conversion starts:

- immediately if EXTEN[1:0] = 0x0 (software trigger) or
- at the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 0x0

The software starts ADC injected conversions by setting JADSTART to 1. When JADSTART is set, the conversion starts:

- immediately, if JEXTEN[1:0] = 0x0 (software trigger) or
- at the next active edge of the selected injected hardware trigger if JEXTEN[1:0] is not equal to 0x0

Note: In Auto-injection mode (JAUTO = 1), use ADSTART bit to start regular conversions followed by auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both set to 0, (the ADC is idle).

ADSTART is cleared by hardware:

- In Single mode with software trigger (CONT = 0, EXTEN[1:0] = 0x0): at any end of conversion sequence (EOS = 1)
- In Discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN[1:0] = 0x0): at end of conversion (EOC = 1)
- In all other cases (CONT = x, EXTEN[1:0] = x): after executing the ADSTP assertion procedure by software.

Note: In Continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN[1:0] ≠ *0x0), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.*

JADSTART is cleared by hardware:

- In Single mode with software injected trigger (JEXTEN[1:0] = 0x0): at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN = 1
- In all other cases (JEXTEN[1:0]=x): after executing the JADSTP assertion procedure by software.

Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

29.4.17 Timing

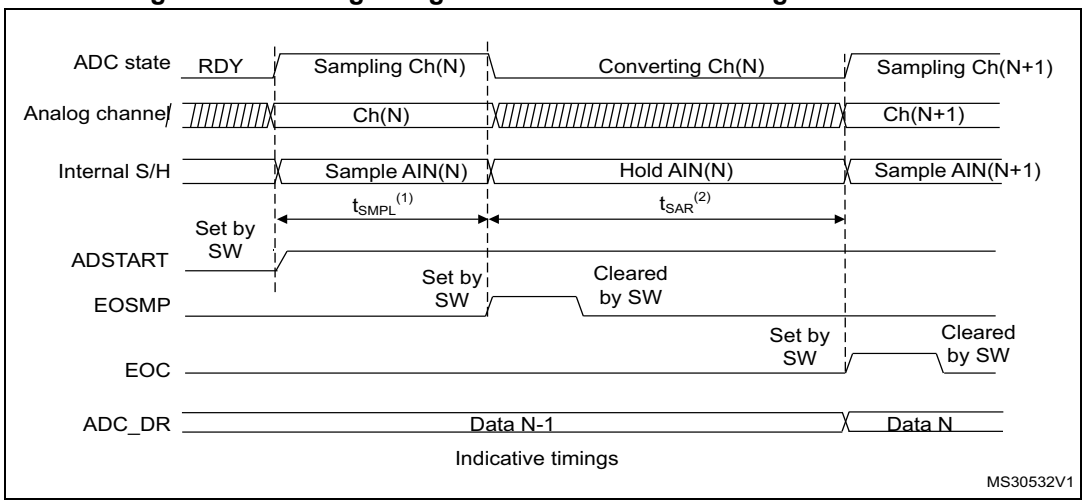
The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution for single conversion and minus the overlap time between the sampling and the previous SAR for continuous conversion.

In Single conversion mode:

$$T_{CONV} = T_{SMPL} + T_{SAR} = [5_{min} + 17_{14bits}] \times T_{adc\_ker\_ck}$$

$$T_{CONV} = T_{SMPL} + T_{SAR} = 22 \times T_{adc\_ker\_ck\ min\ for\ 14bits} = 400.0\ ns\ (for\ F_{adc\_ker\_ck} = 55\ MHz)$$

Figure 153. Analog to digital conversion time in single conversion



1. T_{SMPL} depends on SMP[2:0]
2. T_{SAR} depends on RES[1:0]

29.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP to 1, and injected conversions ongoing by setting JADSTP to 1.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice-versa. This enables, for instance, to reconfigure the injected conversion sequence and triggers while regular conversions are still ongoing (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would re-start a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (in case of regular conversion), or JADSTP/JADSTART bits (in case of injected conversion) are cleared by hardware. The software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 154. Stopping ongoing regular conversions

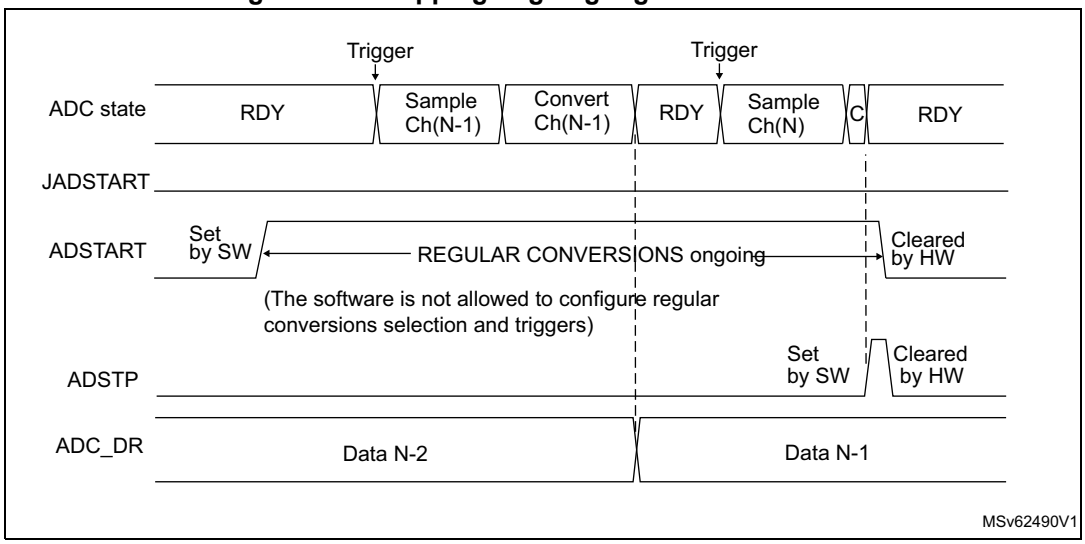


Figure 155. Stopping ongoing regular and injected conversions

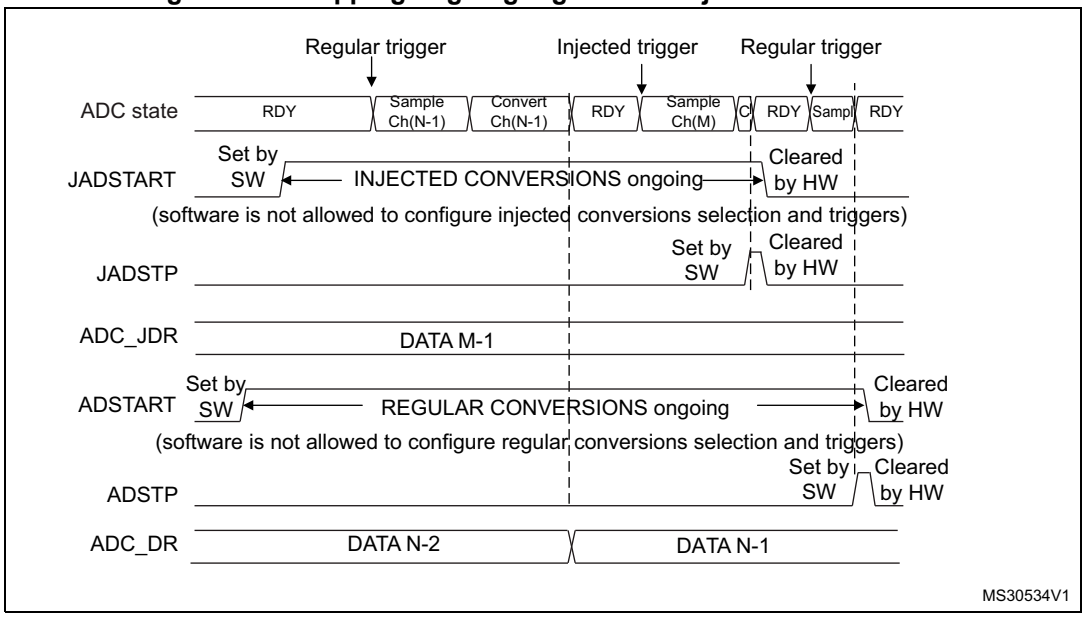


29.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware trigger which occurs while a conversion is ongoing are ignored.

- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 236 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 236. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

Table 237. Configuring the trigger polarity for injected external triggers

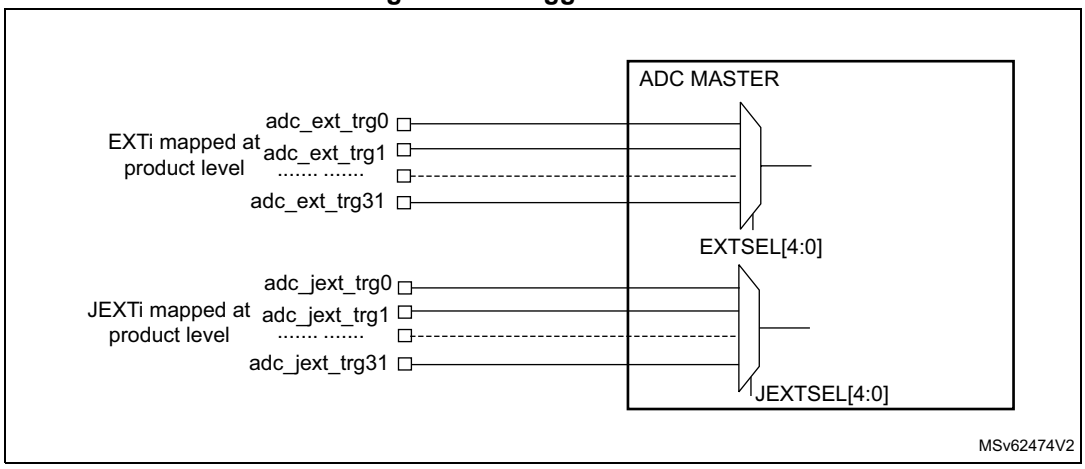
JEXTEN[1:0]	Source
00	Hardware trigger detection disabled, software trigger detection enabled
01	Hardware trigger with detection on the rising edge
10	Hardware trigger with detection on the falling edge
11	Hardware trigger with detection on both the rising and falling edges

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which events can trigger regular and injected groups conversion, out of 21 possibilities.

A regular group conversion can be interrupted by an injected trigger.

Note: The trigger selection cannot be changed on-the-fly.

Figure 156. Trigger selection



Refer to *Table ADC external triggers for regular channels and Table ADC external triggers for injected channels* in *Section 29.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to external ADC pins or internal signals.

29.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit must be cleared in the ADC_CFGR1 register:

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 157* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 44 ADC clock cycles (that is two conversions with a minimum sampling time), the minimum interval between triggers must be 45 ADC clock cycles.

Auto-injection mode

If the JAUTO bit is set in the ADC_CFGR1 register, the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

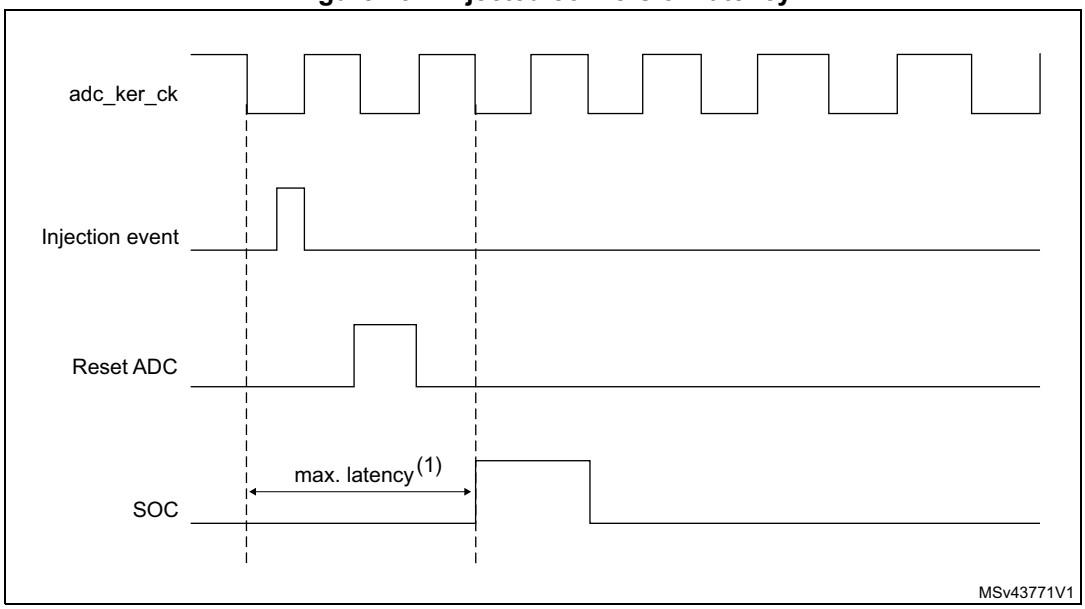
In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and Discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer's data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.

Figure 157. Injected conversion latency



1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

29.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

It is used to convert a short sequence (sub-group) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRx registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example

- DISCEN = 1, n=3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

29.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 14, 12, 10, 8 bits by programming the control bits RES[1:0]. *Figure 162*, *Figure 163*, *Figure 164* and *Figure 165* show the conversion result format with respect to the resolution as well as to the data alignment (in continuous mode assuming no added extra sampling cycle for high input resistance).

Lower resolution enables faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 238*.

Table 238. T_{SAR} timings depending on resolution

RES	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc\_ker\_ck}$ = 55 MHz	$T_{adc\_ker\_ck}$ (ADC clock cycles) with Sampling time=5 ADC clock cycles	$T_{adc\_ker\_ck}$ (ns) at $F_{adc\_ker\_ck}$ = 55 MHz
14	17 ADC clock cycles	309.1	22 ADC clock cycles	400.0
12	15 ADC clock cycles	272.7	20 ADC clock cycles	363.6
10	13 ADC clock cycles	236.4	18 ADC clock cycles	327.3
8	11 ADC clock cycles	200.0	16 ADC clock cycles	290.9

29.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

29.4.24 End of conversion sequence (EOS, JEOS)

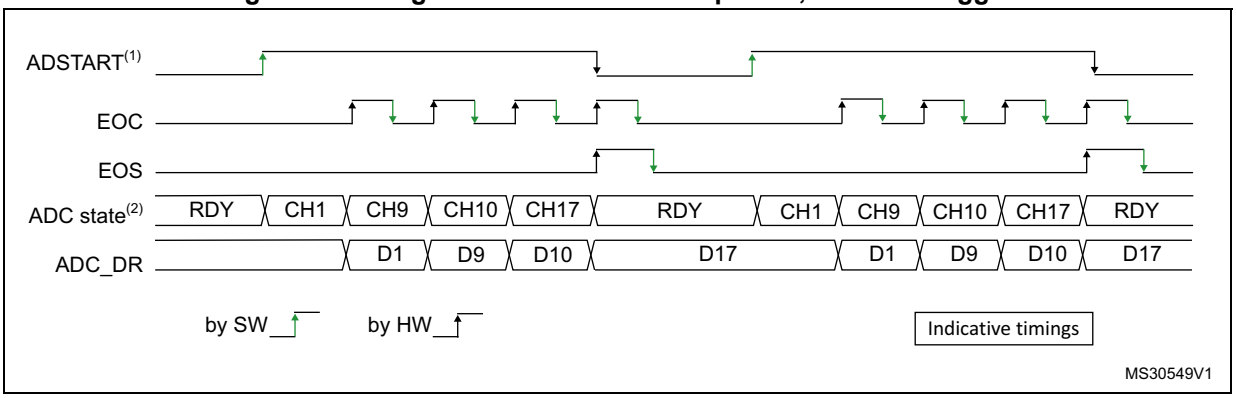
The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

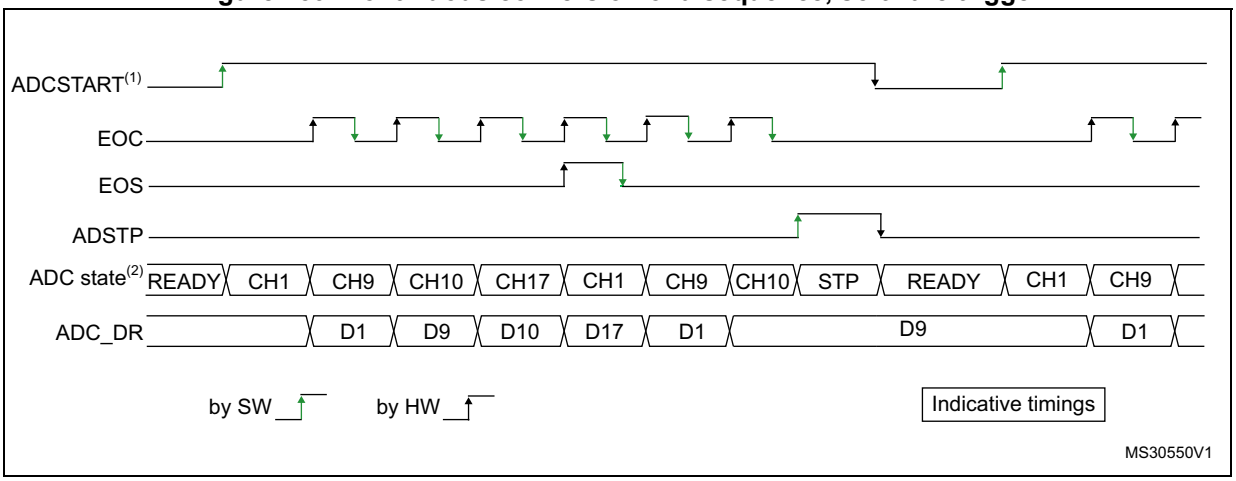
29.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers)

Figure 158. Single conversions of a sequence, software trigger



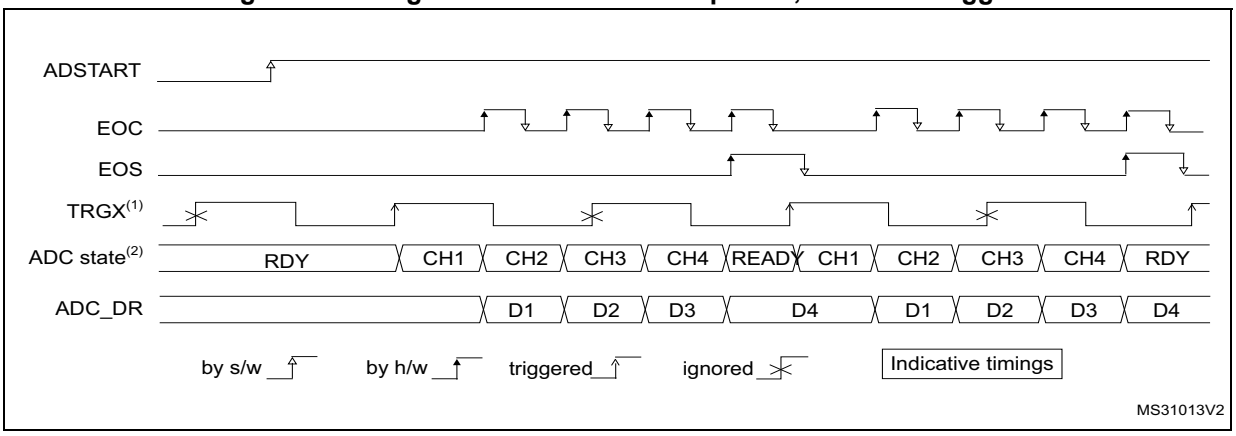
1. EXTEN[1:0] = 0x0, CONT = 0
2. Channels selected = 1,9, 10, 17; AUTDLY = 0.

Figure 159. Continuous conversion of a sequence, software trigger



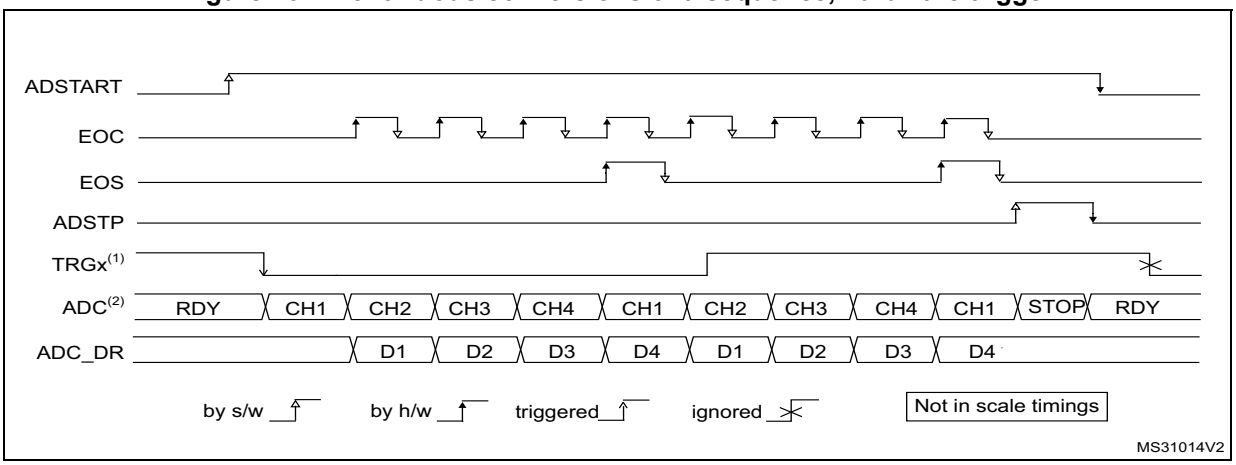
1. EXTEN[1:0] = 0x0, CONT = 1
2. Channels selected = 1,9, 10, 17; AUTDLY = 0.

Figure 160. Single conversions of a sequence, hardware trigger



1. TRGx (over-frequency) is selected as trigger source, EXTEN[1:0] = 01, CONT = 0
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

Figure 161. Continuous conversions of a sequence, hardware trigger



1. TRGx is selected as trigger source, EXTEN[1:0] = 10, CONT = 1
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

29.4.26 Low-frequency trigger mode (LFTRIG)

Once the ADC is enabled or when the last ADC conversion is complete, the ADC is ready to start the next conversion. The ADC needs to be started at a defined time (T_{idle}) otherwise the converted data can be corrupted due to transistor leakage (refer to the datasheet for the maximum value of T_{idle}).

If the user application requires a time higher than T_{idle} maximum value between one trigger to another for single conversion mode, or between ADC enable and the first conversion, then the ADC converter input multiplexer must be re initialized. This operation is selected by setting LFTRIG bit in ADC_CFGR2.

29.4.27 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register selects the alignment of the data stored after conversion. By default, data are right-aligned. Refer to *Figure 162*, *Figure 163*, *Figure 164* and *Figure 165* for examples of data alignment.

Note: The data can be re-aligned in normal and in oversampling mode.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by programming a value different from 0 in OFFSETy[23:0] bit field into ADC_OFRy register. The channel to which the offset is applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. The offset can be positive or negative depending on the value of POSOFF bit. When POSOFF is set to 0, the converted value is subtracted by the user-defined offset written in OFFSETy[23:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (eg in 14-bit mode, the maximum offset value is 0x3FFF).

The offset can be used to convert unsigned data to signed data (e.g. in 14-bit mode, the offset value is equal to 0x2000).

The offset correction is also supported in Oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 239 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

Table 239. Offset computation versus data resolution

Resolution (bits RES[1:0])	Subtraction/addition between raw converted data and offset		Result	Comments
	Raw - converted left -aligned data	Offset		
00: 14-bit	DATA[13:0]	OFFSET[13:0]	Signed or unsigned 24-bit data, right aligned to [13:0]	-
01: 12-bit	DATA[13:2],00	OFFSET[13:2]	Signed or unsigned 24-bit data, right aligned to [11:0]	The user must configure OFFSET[11:0] to 0b0000 0000 0000.

Table 239. Offset computation versus data resolution (continued)

Resolution (bits RES[1:0])	Subtraction/addition between raw converted data and offset		Result	Comments
	Raw - converted left -aligned data	Offset		
10: 10-bit	DATA[13:4],0000	OFFSET[13:4]	Signed or unsigned 24-bit data, right aligned to [9:0]	The user must configure OFFSET[3:0] to 0b0000.
11: 8-bit	DATA[13:6],000000	OFFSET[13:6]	Signed or unsigned 24-bit data, right aligned to [7:0]	The user must configure OFFSET[5:0] to 0b000000.

Figure 162, *Figure 163*, *Figure 164* and *Figure 165* show alignments for signed and unsigned data together with corresponding OVSS and LSHIFT values.

Figure 162. Right alignment (offset disabled, unsigned value)

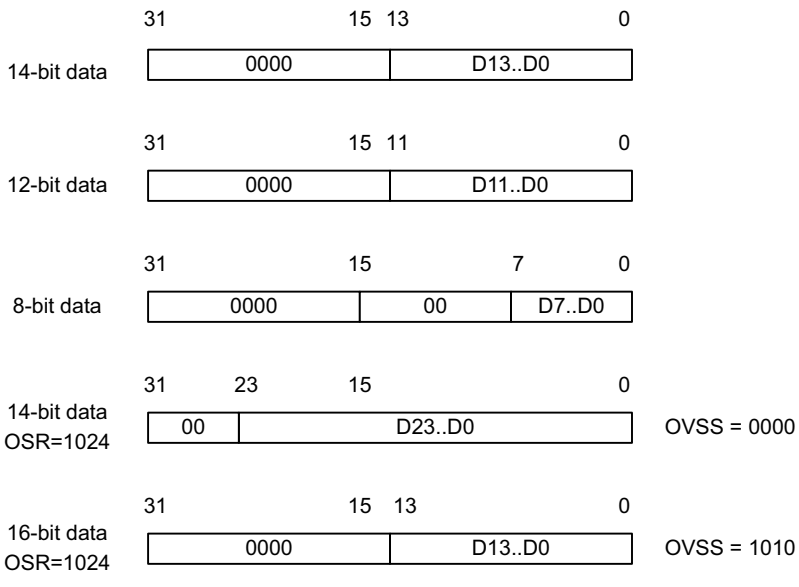


Figure 163. Right alignment (offset enabled, signed value)

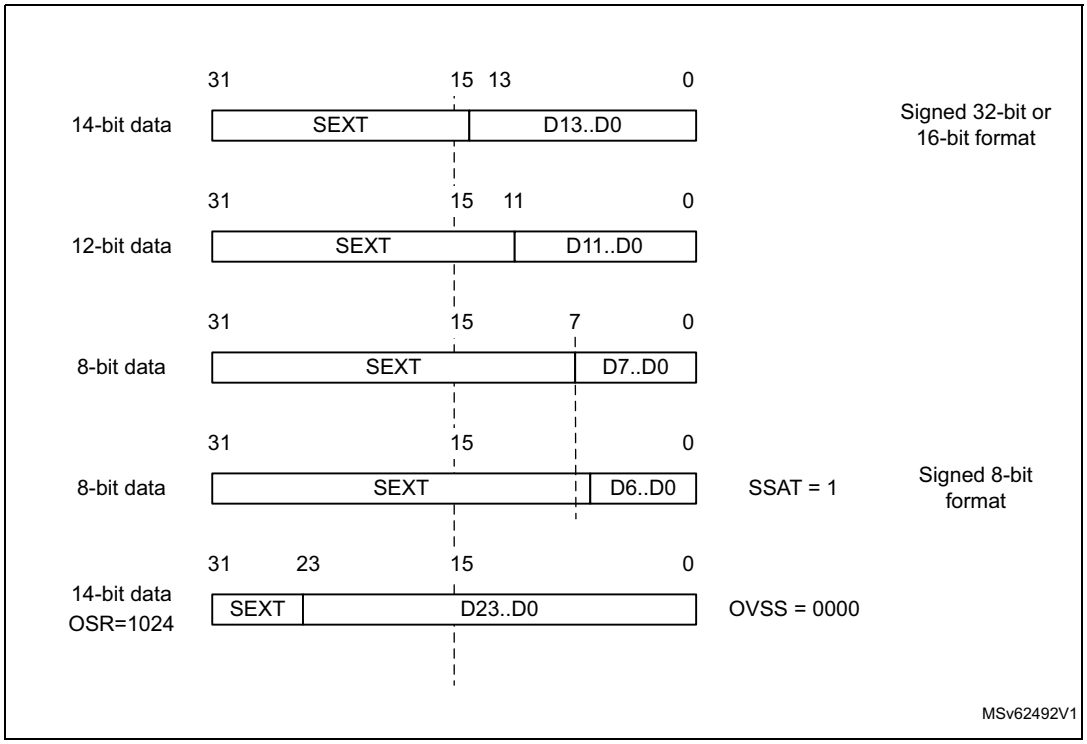

Figure 164. Left alignment (offset disabled, unsigned value)

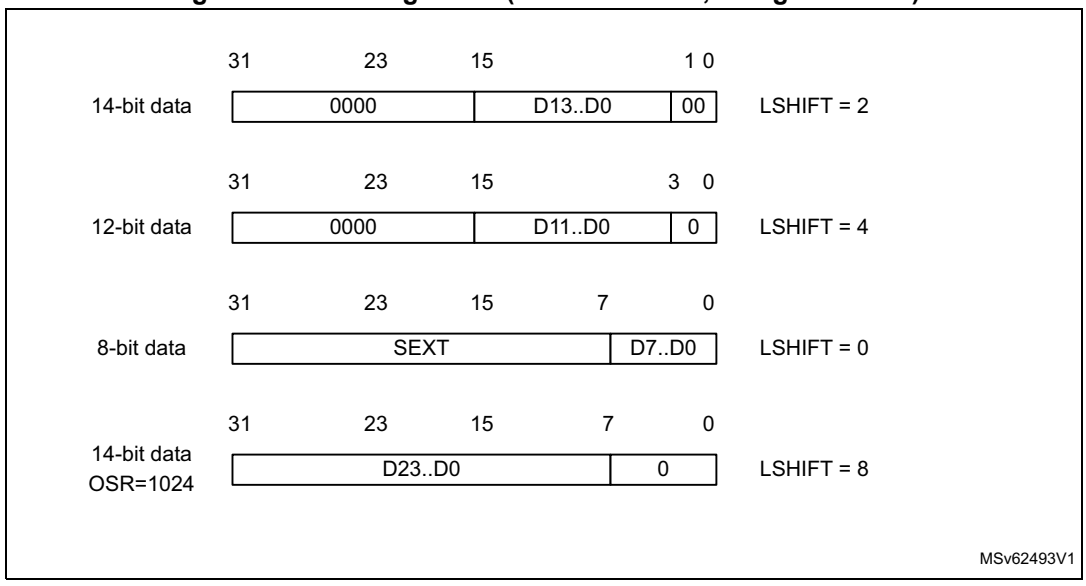

Figure 165. Left alignment (offset enabled, signed value)

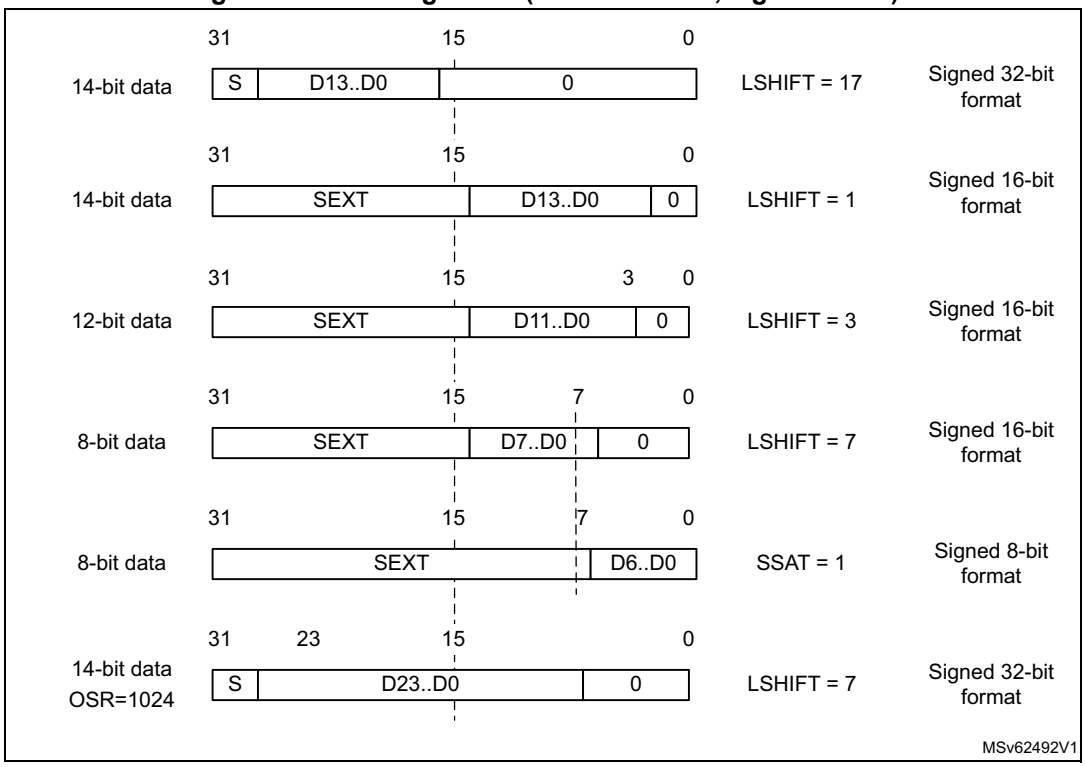

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might results in the data width to be wider than the original data.

To limit the original width, the data saturation can be enabled through SSAT and USAT bits of ADC_OFRy register.

Unsigned 14-bit data can be extended to 15-bit signed data by using an offset value different from 0x2000.

The original data width can be preserved by setting SSAT bit to 1 to limit the data width to 14 bits.

Unsigned data can be saturated to the original data width by setting USAT bit to 1.

Table 240 shows the sign-extended data format corresponding to different resolutions.

Table 240. 14-bit data formats

SSAT	USAT	Format	Data range (offset = 0x2000)
0	0	Sign-extended 15-bit significant data: SEXT[31:14] DATA[13:0]	0x0000 1FFF - 0xFFFF E000
1	0	Sign-extended 14-bit significant data: SEXT[31:13] DATA[12:0]	0x1FFF - 0xE000

Table 240. 14-bit data formats (continued)

SSAT	USAT	Format	Data range (offset = 0x2000)
0	1	Unsigned saturation14-bit significant data: DATA[13:0]	0x3FFF - 0x0000
1	1	Reserved	-

Table 241 provides numerical examples for three different offset values.

Table 241. Numerical examples for 16-bit format

Raw conversion result	Offset value	Result SSAT = 0 USAT = 0	Result SSAT = 0 USAT = 1	Result SSAT = 1 USAT = 0
0x3FFF	0x2000	0x0000 1FFF	1FFF	1FFF
0x2000		0x0000 0000	0000	0000
0x0000		0xFFFF E000	E000	E000
0x3FFF	0x2020	0x0000 1FDF	1FDF	1FDF
0x2000		0xFFFF FFE0	0000	FFE0
0x0000		0xFFFF DFE0	0000	DFE0
0x3FFF	0x1FE0	0x0000 201F	201F	1FFF
0x2000		0x0000 0020	0020	0020
0x0000		0xFFFF E020	0000	E020
0x3FFF	0x20	0x0000 3FDF	3FDF	3FDF
0x2000		0x0000 1FE0	1FE0	1FE0
0x0000		0xFFFF FFE0	0000	FFE0

Caution: SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure this recommendation is respected.

Gain compensation

When the GCOMP bit is set in ADC_CFGR2 register, the gain compensation is activated on all converted data. After each conversion, data is calculated using the following formula.

$$DATA = DATA(\text{adc result}) \times (GCOMPCOEFF) / 4096$$

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATA or JDATAx registers, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used for the oversampling mode, the gain calculation is performed after the accumulation and right-shift operations to minimize the power consumption (the gain calculation is done

only once instead of at each conversion). The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode the bit ADC_CFGR2.ROVSM bit must be set to resume the pending conversion with the correct value.

ADC overrun (OVRMOD)

The overrun flag (OVR) notifies of that a buffer overrun event occurred when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (eight stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun event occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP bit to 1.

OVR flag is cleared by software by writing 1 to it.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the OVRMOD control bit of the ADC_CFGR1 register:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (8 data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data are also discarded.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, further conversions operate normally and the ADC_DR register always contains the latest converted data.

Figure 166. Example of overrun (OVRMOD = 0)

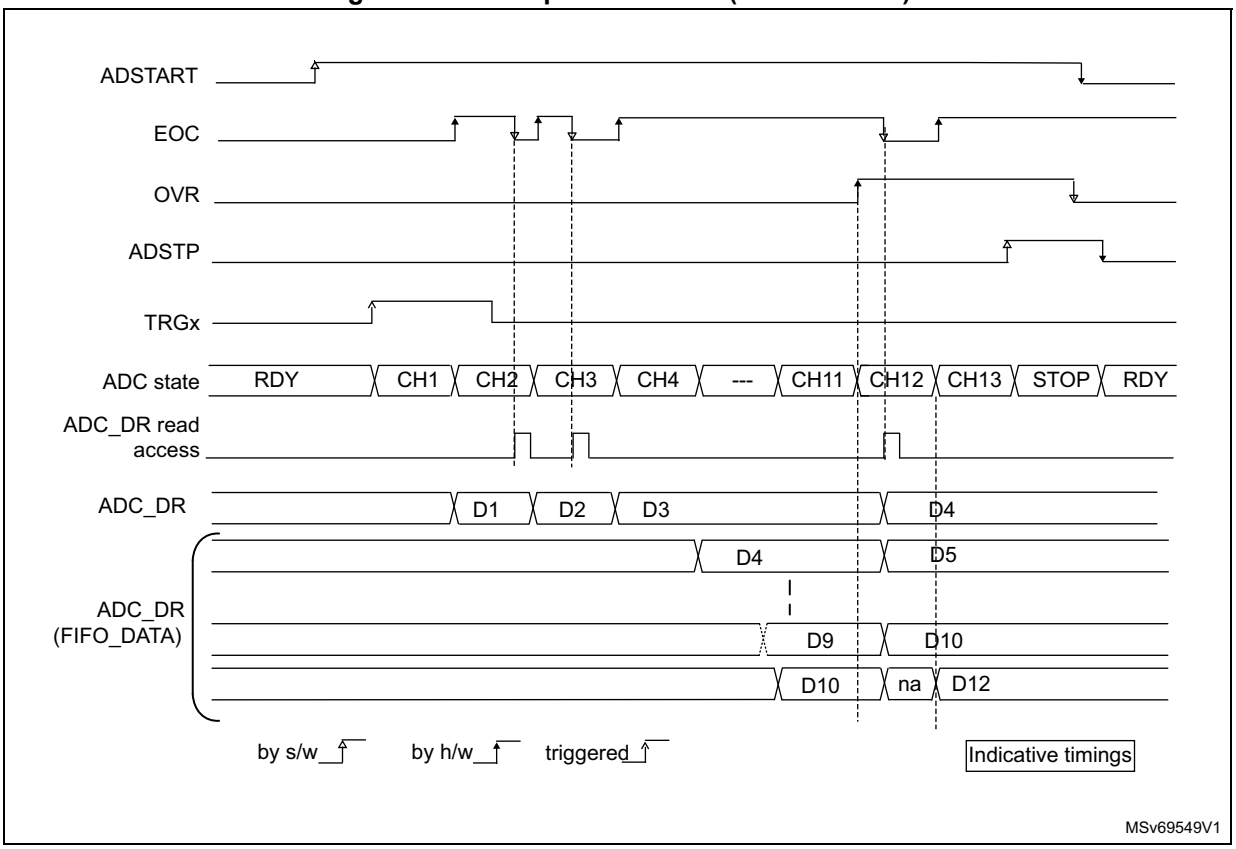

Figure 167. Example of overrun (OVRMOD = 1)

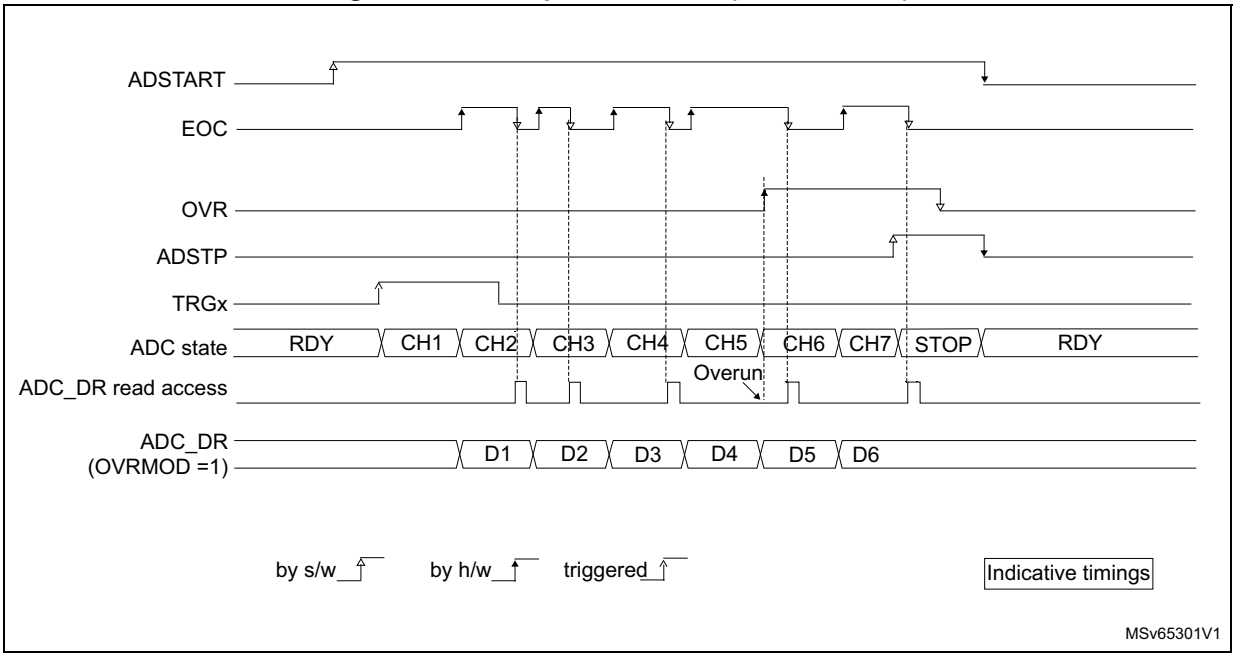

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (for example if the device features an analog watchdog). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored in a unique data register, it is useful to use DMA to convert more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR register in Single ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of the OVRMOD bit, the data is either preserved or overwritten.

The DMA transfer requests are blocked until the software clears the OSV bit.

Two different DMA modes are proposed depending on the application. They can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register, in Single ADC mode and in dual ADC mode, respectively:

- DMA one shot mode (DMNGT[1:0] = 01).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT[1:0] = 11)
  This mode is suitable when programming the DMA in Circular mode.

DMA one shot mode (DMNGT[1:0] = 01)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.

- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

DMA circular mode (DMNGT[1:0] = 11)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. DMA can be programmed either single transfer mode or incremental burst mode(4 beats), according to this mode, correct request line is selected by the DMA. Refer to the DMA chapter for further information.

29.4.28 Managing conversions using the MDF

The ADC conversion results can be transferred directly to the MDF.

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers the 16 least significant bits of the regular data register to the MDF through adcx_dat[15:0] bus, which in turn resets the EOC flag once the transfer is effective.

The data format must be in 16-bit signed format:

ADC_DR[31:16] = don’t care

ADC_DR[15] = sign

ADC_DR[14:0] = data

Any value above 16-bit signed format is truncated.

29.4.29 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see *Figure 168*).
- For an injected conversion: when the JEOS bit has been cleared (see *Figure 169*).

The Auto-delayed conversion mode enables to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 169*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 171*).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 172*).

To stop a conversion in continuous auto-injection mode combined with Auto-delay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:

1. Wait until JEOS = 1 (no more conversions are restarted).
2. Clear JEOS.
3. Set ADSTP = 1.
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

Figure 168. AUTODLY = 1, regular conversion in continuous mode, software trigger

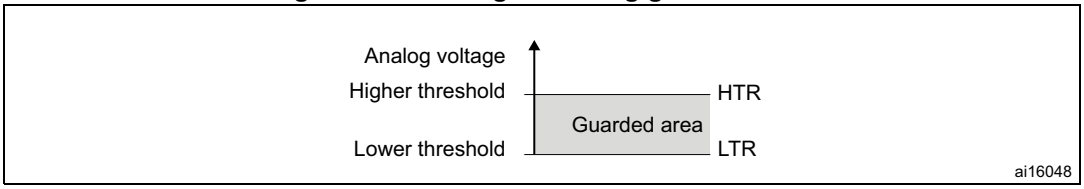
29.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 173. Analog watchdog guarded area



AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 242 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

Table 242. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed in the HTR1[24:0] bits of the ADC_HTR1 register and LTR1[24:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 25-bits (14-bit resolution with oversampling, OSR=256).

When converting data with a resolution of less than 14 bits (according to bits RES[1:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 14-bit converted data (left aligned to the half-word boundary).

Table 243 describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

Table 243. Analog watchdog 1,2,3 comparison

Resolution (bit RES[1:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
00: 14-bit	DATA[13:0]	LTR1[24:0] and HTR1[24:0]	-
01: 12-bit	DATA[13:2],00	LTR1[24:0] and HTR1[24:0]	User must configure LTR1[1:0] and HTR1[1:0] to 00
10: 10-bit	DATA[13:4],0000	LTR1[24:0] and HTR1[24:0]	User must configure LTR1[3:0] and HTR1[3:0] to 0000
11: 8-bit	DATA[13:6],000000	LTR1[24:0] and HTR1[24:0]	User must configure LTR1[5:0] and HTR1[5:0] to 000000

1. The watchdog comparison is performed when the oversampling, the gain compensation and the offset compensation are complete (the data that are compared can be either signed or unsigned).

Analog watchdog filter for watchdog 1

When the ADC is configured with only one input channel (selecting several channels in Scan mode not allowed), a valid ADC conversion data range can be configured through the ADC_LTR1 and ADC_HTR1 register:

- When converted data belong to the range defined in ADC_LTR1 and ADC_HTR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_HTR1, the AWDx flag is set an the corresponding interrupt is issued.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHy[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHy[19:0] (y=2,3) is set.

The threshold can be up to 25 bits (14-bit resolution with oversampling, OSR = 1024, and offset conversion in signed format) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 14 bits (according to bits RES[1:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 14-bit converted data (left aligned).

ADC_AWDy_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADC_AWDy_OUT (y being the watchdog number) which is directly connected to the ETR input (external trigger)

of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

Figure 174. ADCy_AWDx_OUT signal generation (on all regular channels)

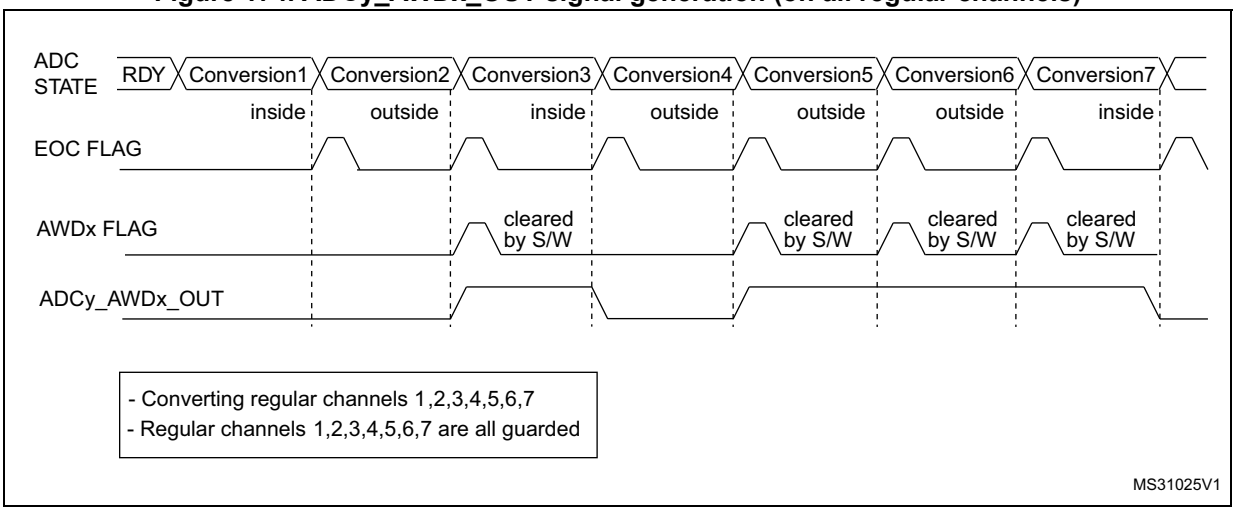


Figure 175. ADC_AWDx_OUT signal generation (AWDx flag not cleared by SW)

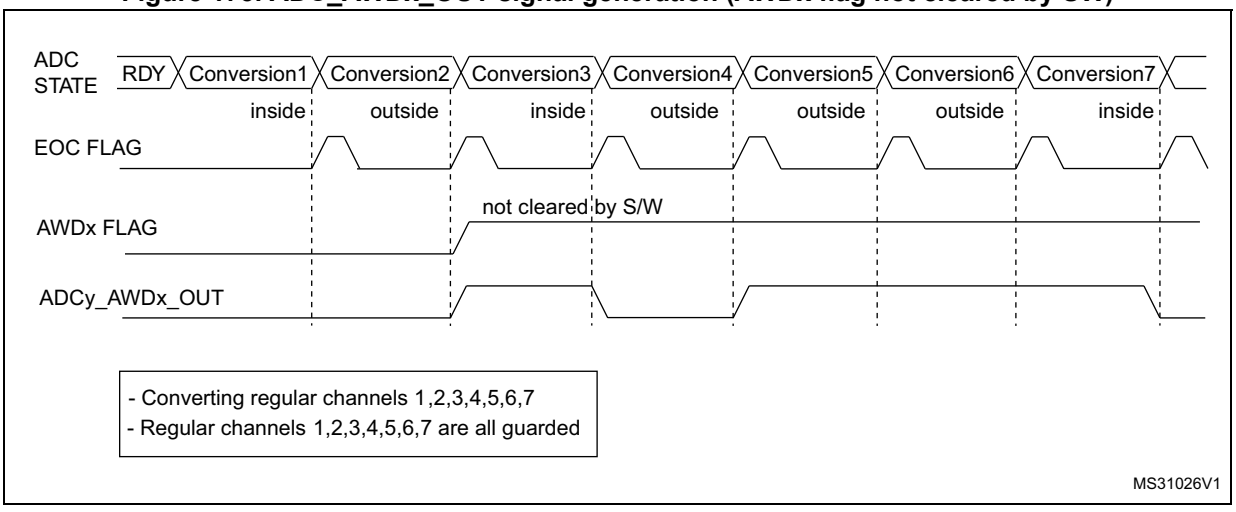

Figure 176. ADC_AWDx_OUT signal generation (on a single regular channel)

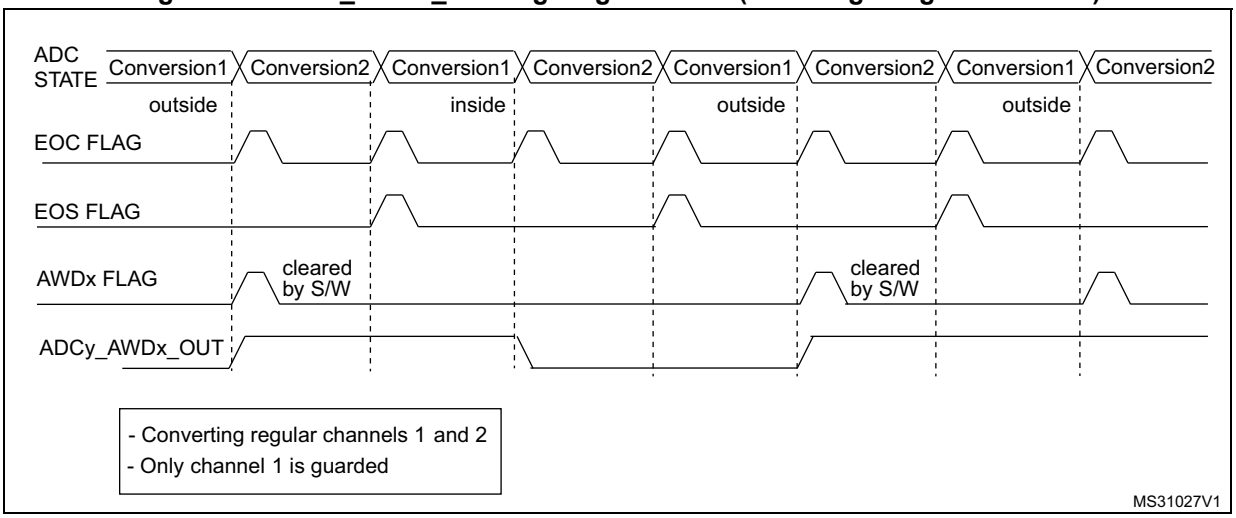

Figure 177. ADC_AWDx_OUT signal generation (on all injected channels)

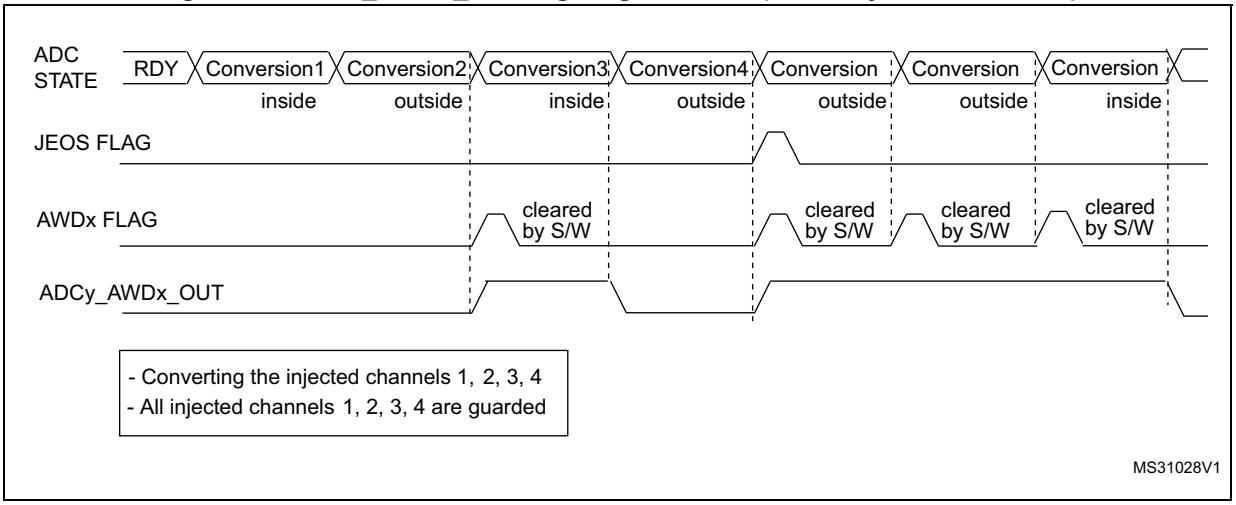


Analog watchdog threshold control

LTRx[24:0] and HTRx[24:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTRx[24:0] and HTRx[24:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in a analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWD_OUT signal.

Analog watchdog with gain and offset compensation

When gain and offset compensation are enabled, the analog watchdog compares the threshold after the compensated data.

29.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 24-bit (14-bit values and OSR = 1024).

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

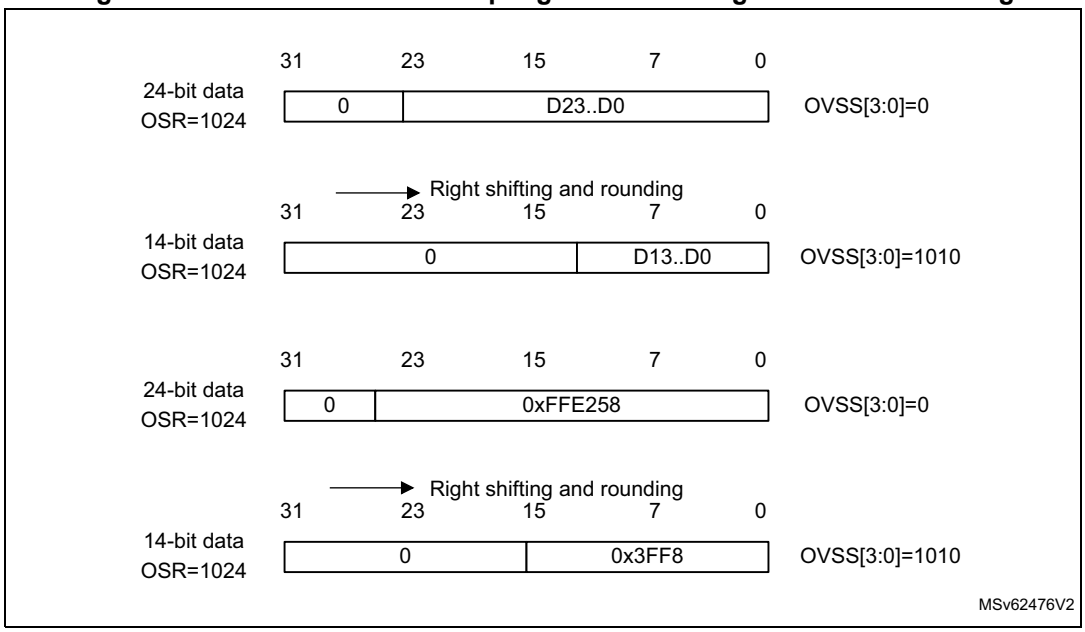
It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OSR[9:0] bits in the ADC_CFGR2 register, and can range from 2x to 1024x. The division coefficient M consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 24 bits (1024 x 14-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

Figure 178 gives a numerical example of the processing, from a raw 24-bit accumulated data to the final 14-bit result.

Figure 178. 14-bit result oversampling with 10-bits right shift and rounding



The conversion timings in Oversampled mode do not change: the sample time is maintained during the whole oversampling sequence. A new data is provided every N conversions with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase.
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total).

Operating modes supported during oversampling

In Oversampling mode, most of the ADC operating modes are maintained:

- Single or Continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (configured through RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 14-bit conversions.

Note: The Alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy_EN bit in ADC_OFRy register is ignored (considered as reset).

Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following differences:

- The RES[1:0] bits are ignored, comparison is always done using the full 25-bit values, HTRx[24:0] and LTRx[24:0].
- The comparison is performed on the oversampled accumulated value before shifting.

Note: Care must be taken when using high shifting values, since this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding an 8-bit right-aligned data, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[7:0]/LT[[7:0]. HT[11:8]/LT[11:8] must be kept reset.

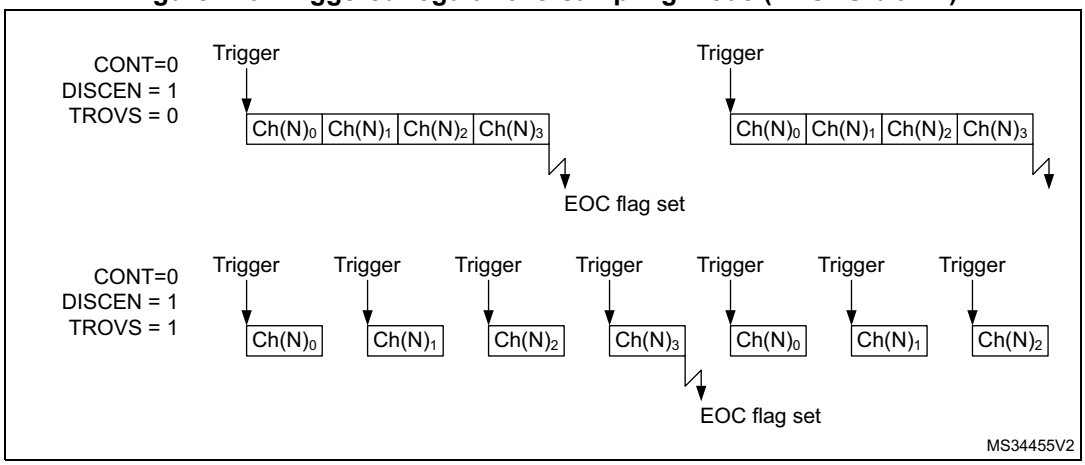
Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The *Figure 179* below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 179. Triggered regular oversampling mode (TROVS bit = 1)



Injected and regular sequencer management when oversampling

In Oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

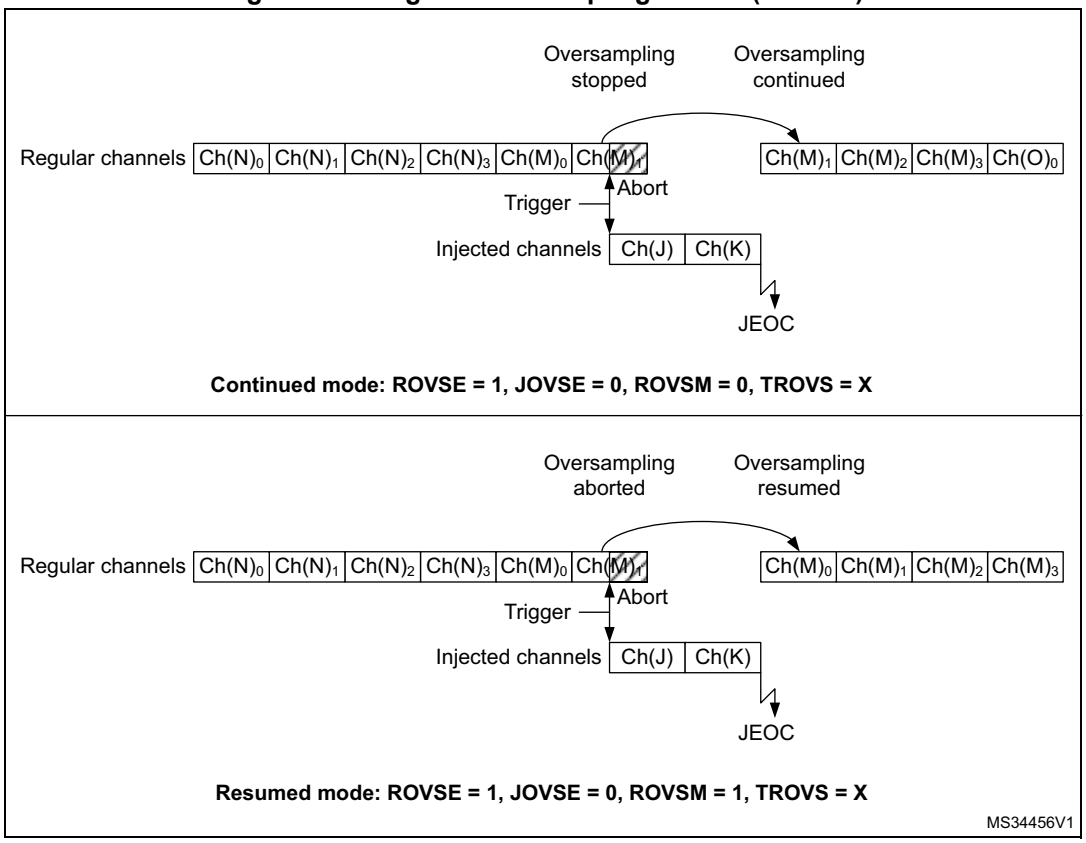
Oversampling regular channels only

The regular oversampling mode bit, ROVSM, defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In Continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- In Resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode guarantees that all data used for oversampling were converted back-to-back within a single time-slot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

Figure 180 gives examples for an oversampling ratio of 4x.

Figure 180. Regular oversampling modes (4x ratio)



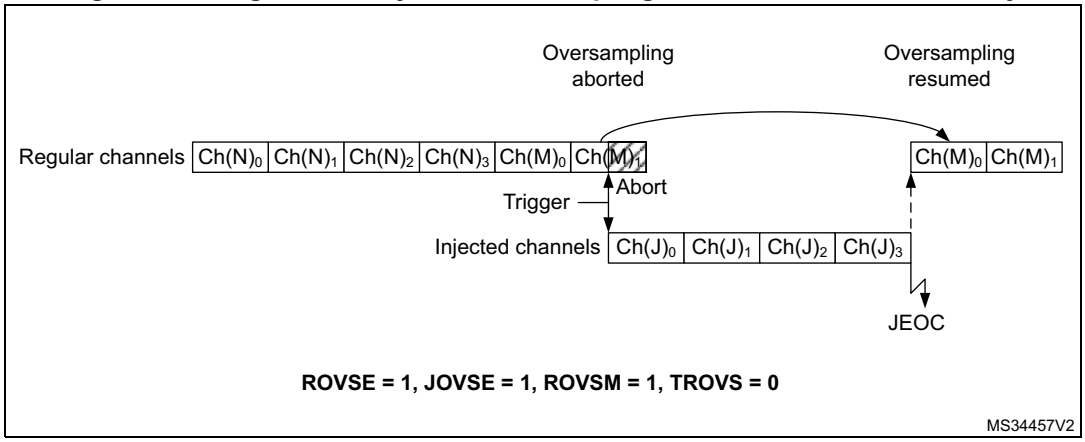
Oversampling Injected channels only

The injected oversampling mode bit, JOVSE, enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

Both ROVSE and JOVSE bits can be set simultaneously. In this case, the Regular oversampling mode is forced to Resumed mode (ROVSM bit ignored), as shown in *Figure 181*.

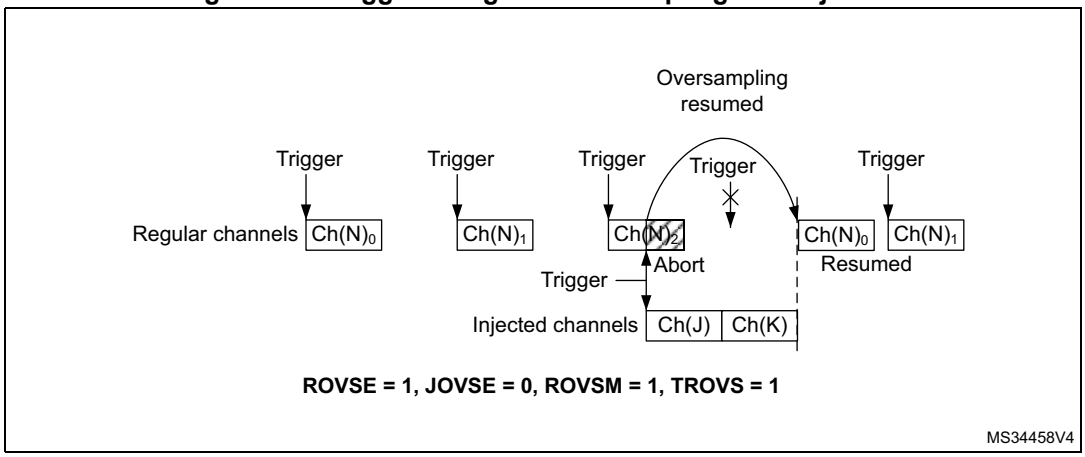
Figure 181. Regular and injected oversampling modes used simultaneously



Triggered regular oversampling with injected conversions

Injected conversions can be performed in Triggered regular mode. In this case, the Injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (Resumed mode forced). The JOVSE bit must be reset. The behavior is shown in *Figure 182*.

Figure 182. Triggered regular oversampling with injection

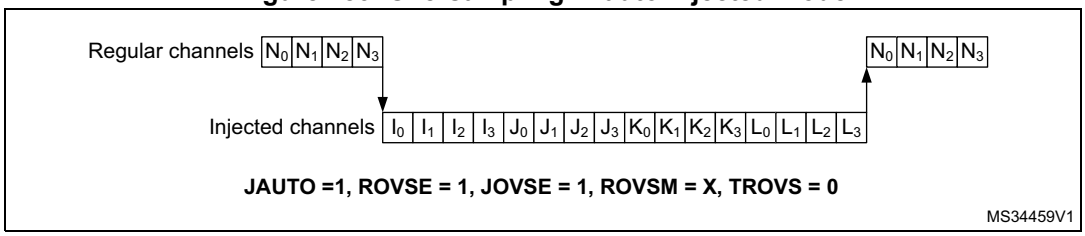


Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers. This enables to save a DMA resource. This mode is available only when both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in Auto-injected mode.

Figure 183 shows how the conversions are sequenced.

Figure 183. Oversampling in auto-injected mode



It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Summary of combined modes

Table 244 summarizes all mode combinations, including non-supported modes.

Table 244. Summary of oversampler operating modes

Regular over-sampling: ROVSE bit	Injected over-sampling: JOVSE bit	Oversampler mode: ROVSM bit 0 = continued 1 = resumed	Triggered Regular mode: TROVS bit	Comment
1	0	0 (continued)	0	Regular continued mode
1	0	0 (continued)	1	Not supported
1	0	1 (resumed)	0	Regular resumed mode
1	0	1 (resumed)	1	Triggered regular resumed mode
1	1	0 (continued)	X	Not supported
1	1	1 (resumed)	0	Injected and regular resumed mode
1	1	1 (resumed)	1	Not supported
0	1	X	X	Injected oversampling

29.4.32 Temperature sensor

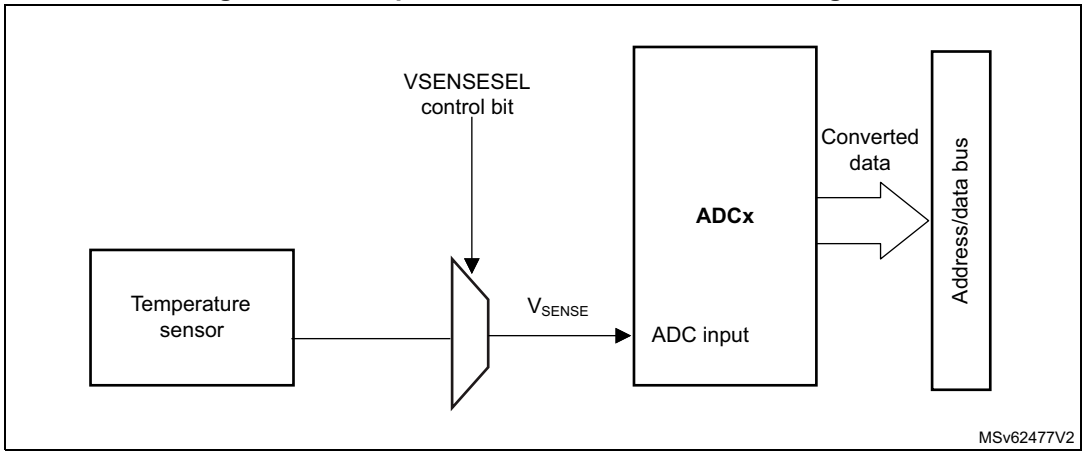
The temperature sensor can measure the device junction temperature (T_J) in the –40 to 125 °C temperature range.

The temperature sensor is internally connected ADC input channels that are used to convert the sensor output voltage to a digital value (see *Section 29.4.4: ADC connectivity* for more details). The sampling time for the temperature sensor analog pin must be greater than the stabilization time specified in the device datasheet.

When it is not in use, the sensor can be placed in power-down mode.

Figure 184 shows the block diagram of the temperature sensor.

Figure 184. Temperature sensor channel block diagram



Reading the temperature

To use the sensor:

1. Select the input channels to which the temperature sensor is connected (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the VSENSESEL bit in the ADC12_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting data in the ADC data register.
6. Calculate the actual temperature using the following formula:

$$\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30\ °\text{C}$$

   Where:

   – TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
   – TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
   – TS_DATA is the actual temperature sensor output value converted by ADC

   Refer to *Section 29.3: ADC implementation* for more information on TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode and before it can output at the correct level. The ADC also has a startup time after power-on. As a result, to minimize the delay, the ADEN and VSENSESEL bits must be set simultaneously.

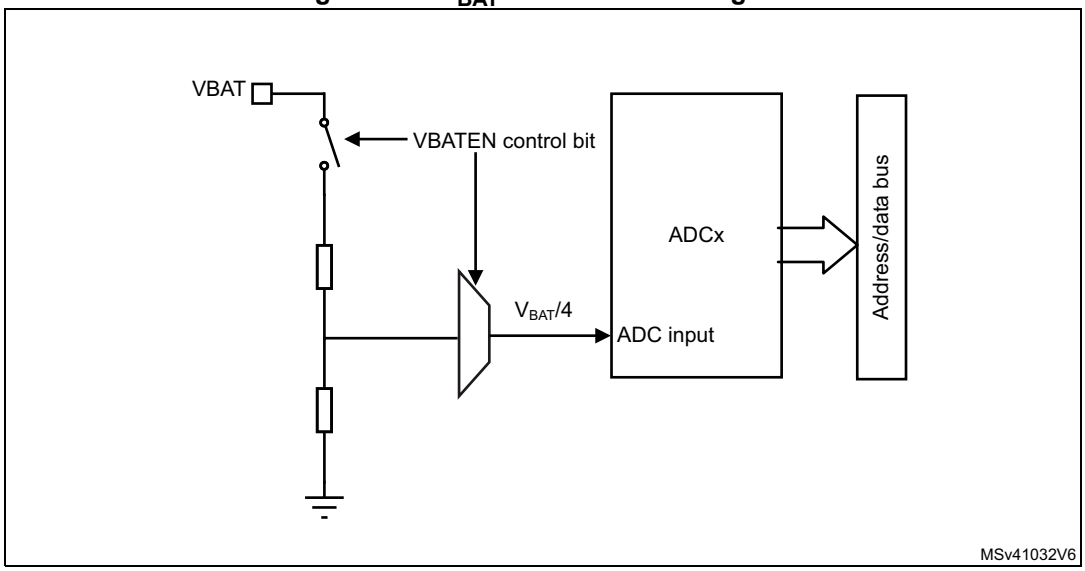
29.4.33 V_{BAT} supply monitoring

The VBATEN bit in the ADC12_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage could be higher than V_{DDA}, the VBAT pin is internally connected to a bridge divider by 4 to ensure the correct operation of the ADC. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}/4$ to the corresponding ADC input channels (see *Section 29.4.4: ADC connectivity* for more details). As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/4$ voltage.

Figure 185 shows the block diagram of the V_{BAT} sensing feature.

Figure 185. V_{BAT} channel block diagram



Note: The VBATEN bit of the ADC12_CCR register must be set to enable the conversion of the ADC internal channels to which VBAT is connected (see Section 29.4.4: ADC connectivity for more details).

29.4.34 Monitoring the internal voltage reference

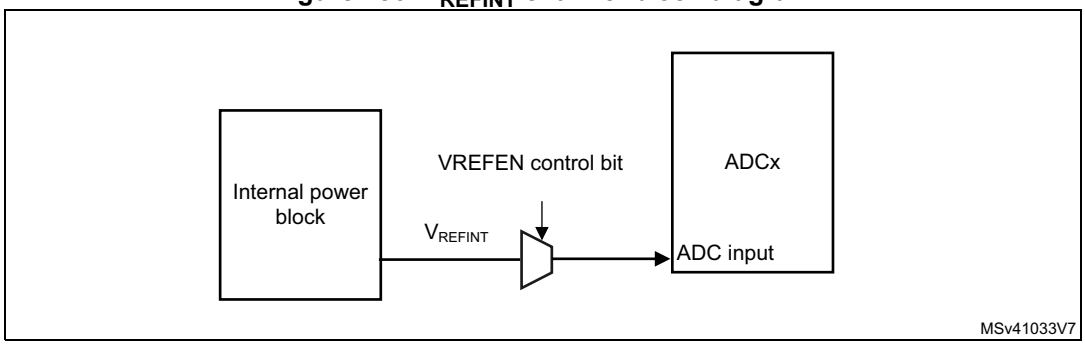
The internal voltage reference can be monitored to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to *Section 29.4.4: ADC connectivity* for details on the ADC input channels to which the internal voltage reference is internally connected.

The sampling time for this channel must be greater than the stabilization time specified in the device datasheet.

Figure 185 shows the block diagram of the V_{REFINT} sensing feature.

Figure 186. V_{REFINT} channel block diagram



Note: The VREFEN bit of the ADC12_CCR register must be set to enable the conversion of the ADC internal channels to which VREFINT is connected (see Section 29.4.4: ADC connectivity for more details).

Calculating the actual V_{REF+} voltage using the internal reference voltage

The V_{DDA} power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference (V_{REFINT}) and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} = 3.0 V can be used to evaluate the actual V_{REF+} voltage level, if VREF+ pin is connected to a variable V_{DDA} power supply.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = 3.0\ V \times VREFINT\_CAL / VREFINT\_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value (refer to *Section 29.3: ADC implementation* for the value of VREFINT_CAL).
- VREFINT_DATA is the actual VREFINT output value converted by ADC.

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the voltage reference V_{REF+} and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent of V_{DDA}. For applications where V_{DDA} is known and ADC converted values are right-aligned, the following formula can be used to calculate this absolute value:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL\_SCALE} \times ADC\_DATA$$

For applications where V_{DDA} value is not known, the internal voltage reference and V_{DDA} can be replaced by the expression provided in *Section : Calculating the actual V_{REF+} voltage using the internal reference voltage*, resulting in the following formula:

$$V_{CHANNELx} = \frac{3.0\ V \times VREFINT\_CAL \times ADC\_DATA}{VREFINT\_DATA \times FULL\_SCALE}$$

Where:

VREFINT_CAL is the VREFINT calibration value (refer to *Section 29.3: ADC implementation* for the value of VREFINT_CAL).

ADC_DATA is the value measured by the ADC on channel x (right-aligned)

VREFINT_DATA is the actual VREFINT output value converted by the ADC

FULL_SCALE is the maximum digital value of the ADC output. For example with 14-bit resolution, it is 2^{14} - 1 = 16383 or with 8-bit resolution, 2^8 - 1 = 255.

Note: If ADC measurements are done using an output format other than 14-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

29.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)

Separate interrupt enable bits are available for flexibility.

Table 245. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop 0, Stop 1 and Stop 2 modes	Exit from Stop 3, Standby modes
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No	No
	End of conversion of a regular group	EOC	EOCIE				
	End of conversion sequence of a regular group	EOS	EOSIE				
	End of conversion of an injected group	JEOC	JEOCIE				
	End of conversion sequence of an injected group	JEOS	JEOSIE				
	Analog watchdog 1 status bit is set	AWD1	AWD1IE				
	Analog watchdog 2 status bit is set	AWD2	AWD2IE				
	Analog watchdog 3 status bit is set	AWD3	AWD3IE				
	End of sampling phase	EOSMP	EOSMPIE				
	Overrun	OVR	OVRIE				

29.6 ADC registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

29.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDO RDY	Res.	Res.	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
			r			rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY**: ADC voltage regulator ready

This bit is set by hardware. It indicates that the ADC internal supply is ready. The ADC is available after $t_{ADCVREG\_SETUP}$ time.
0: ADC voltage regulator disabled
1: ADC voltage regulator enabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_LTR3 & ADC_HTR3 register. It is cleared by software writing 1 to it.
0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_LTR2 & ADC_HTR2 register. It is cleared by software writing 1 to it.
0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_LTR1, & ADC_HTR1 register. It is cleared by software. writing 1 to it.
0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

29.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	AWD3 IE	AWD2 IE	AWD1 IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMP IE	ADRDY IE
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: Software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: Software is allowed to write this bit only when JADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.3 ADC control register (ADC_CR)

Address offset: 0x08

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the ADC calibration.
It is cleared by hardware after calibration is complete.
0: Calibration complete
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.
0: ADC not in deep-power down
1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bits is set by software to enable the ADC voltage regulator.
Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.
0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.
For more details about the ADC voltage regulator enable and disable sequences, refer to *Section 29.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*.
The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:24 **CALINDEX[3:0]**: Calibration factor

This bitfield controls the calibration factor to be read or written.
Calibration index 0 is dedicated to single-ended and differential offsets, calibration index 1 to 7 to the linearity calibration factors, and index 8 to the internal offset:
0000: Offset calibration factor
0001: linearity calibration factor 1
0010: linearity calibration factor 2
0011: linearity calibration factor 3
0100: linearity calibration factor 4
0101: linearity calibration factor 5
0110: linearity calibration factor 6
0111: linearity calibration factor 7 and internal offset (write access only)
1000: internal offset (read access only)
1001: Calibration mode selection
Others: Reserved, must not be used

Note: ADC_CALFACT2[31:0] correspond to the location of CALINDEX[3:0] calibration factor data (see Section 29.4.8: Calibration (ADCAL, ADCALLIN, ADC_CALFACT) for details).

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **ADCALLIN**: Linearity calibration

This bit is set and cleared by software to enable the linearity calibration.
0: Writing ADCAL launches a calibration without the linearity calibration.
1: Writing ADCAL launches a calibration with he linearity calibration.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).

In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in Single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the end of injected conversion sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time as JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In Auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in Single conversion mode (CONT = 0, DISCEN = 0) when software trigger is selected (EXTEN[1:0] = 0x0): at the assertion of the end of regular conversion sequence (EOS) flag.

– In Discontinuous conversion mode (CONT = 0, DISCEN = 1), when the software trigger is selected (EXTEN[1:0] = 0x0): at the end of conversion (EOC) flag.

– in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)

In Auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

29.6.4 ADC configuration register (ADC_CFGR1)

Address offset: 0x0C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	Res.	JDISCEN	DISCNUM[2:0]			DISCEN
	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					Res.	RES[1:0]		DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel-0 monitored by AWD1

00001: ADC analog input channel-1 monitored by AWD1

.....

10011: ADC analog input channel-19 monitored by AWD1

Others: Reserved, must not be used

Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.

Software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 Reserved, must be kept at reset value.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off

1: Auto-delayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 **OVRMOD**: Overrun Mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:
00000: adc_ext_trg0
00001: adc_ext_trg1
...
Refer to the ADC external trigger for regular channels in *Section 29.4.2: ADC pins and internal signals* for details on trigger mapping.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.
00: 14 bits
01: 12 bits
10: 10 bits
11: 8bits

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data management configuration

This bit is set and cleared by software to select how the ADC interface output data are managed.
00: Regular conversion data stored in DR only
01: DMA One -shot mode selected
10: MDF mode selected
11: DMA Circular mode selected

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSHIFT[3:0]				LFTRIG	Res.	OSR[9:0]									
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw			rw	rw	rw	rw	rw	rw				rw	rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 27 **LFTRIG**: Low-frequency trigger

This bit is set and cleared by software
0: Low-frequency trigger mode disabled
1: Low-frequency trigger mode enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:16 **OSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.
0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.
0: Sampling time control trigger mode disabled
1: Sampling time control trigger mode enabled
The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.
EXTEN[1:0] bits must be set to 01. BULB bit must not be set when the SMPTRIG bit is set.
When EXTEN[1:0] bits is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Software trigger starts the conversion for sampling time control trigger mode

1: Software trigger starts the sampling for sampling time control trigger mode.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to select the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of the conversion.

SMPTRIG bit must not be set when the BULB bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular Oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 9 **TROVS**: Triggered Regular Oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling right shift

This bit field is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No right shift

0001: 1-bit right shift

0010: 2-bit right shift

0011: 3-bit right shift

0100: 4-bit right shift

0101: 5-bit right shift

0110: 6-bit right shift

0111: 7-bit right shift

1000: 8-bit right shift

1001: 9-bit right shift

1010: 10-bit right shift

1011: 11-bit right shift

Others: Reserved, must not be used.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected Oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected oversampling disabled

1: Injected oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ROVSE**: Regular Oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular Oversampling disabled

1: Regular Oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

29.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 5 ADC clock cycles

001: 6 ADC clock cycles

010: 12 ADC clock cycles

011: 20 ADC clock cycles

100: 36 ADC clock cycles

101: 68 ADC clock cycles

110: 391 ADC clock cycles

111: 814 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 5 ADC clock cycles
001: 6 ADC clock cycles
010: 12 ADC clock cycles
011: 20 ADC clock cycles
100: 36 ADC clock cycles
101: 68 ADC clock cycles
110: 391 ADC clock cycles
111: 814 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCSEL19	PCSEL18	PCSEL17	PCSEL16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **PCSEL[19:0]**: Channel i (V_{INP}[i]) preselection

These bits are written by software to preselect the input channel I/O instance to be converted.

0: Input channel i (V_{INP}[i]) is not preselected for conversion, the ADC conversion of this channel shows a wrong result.

1: Input channel i (V_{INP}[i]) is preselected for conversion

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.9 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ4[4:0]					Res.	SQ3[4:0]					Res.	SQ2[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the regular conversion sequence.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

29.6.10 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

29.6.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SQ12[3:0]				Res.	SQ11[4:0]					Res.	SQ10[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 12th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 11th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 10th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

29.6.12 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 16th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 15th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

29.6.13 ADC regular data register (ADC_DR)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 29.4.27: Data management*.

29.6.14 ADC injected sequence register (ADC_JSQR)

Address offset: 0x4C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

...

Refer to the ADC external trigger for injected channels in *Section 29.4.2: ADC pins and internal signals* for details on trigger mapping.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bits 1:0 **JL[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

29.6.15 ADC offset y register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y-1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_CH[4:0]					SSAT	USAT	POSOFF	OFFSET[23:16]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed into OFFSETy[25:0] bits applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If OFFSETy_EN bit is set, it is not allowed to select the same channel in different ADC_OFRy registers.

Bit 26 **SSAT:** Signed saturation enable

This bit is written by software to enable or disable the Signed saturation feature.

(see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT)* for details).

0: Offset is subtracted maintaining data integrity and extending converted data size (9-bit and 15-bit signed format).

1: Offset is subtracted and result is saturated to maintain converted data size.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **USAT**: Unsigned saturation enable

This bit is written by software to enable or disable the unsigned saturation feature.

0: Offset is subtracted maintaining data integrity and keeping converted data size

1: Offset is subtracted and result is saturated to maintain converted data size.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: offset sign

This bit is set and cleared by software to enable the positive offset.

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 **OFFSET[23:0]:** Data offset y for the channel programmed into OFFSETy_CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (regular or injected). The channel to which the data offset y applies must be programmed to the OFFSETy_CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

When OFFSETy[21:0] bitfield is reset, the offset compensation is disabled.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If several offsets (OFFSETy) point to the same channel, only the offset with the lowest y value is considered for the subtraction.

For example, if OFFSET1_CH[4:0] = 4 and OFFSET2_CH[4:0] = 4, this is OFFSET1[25:0] that is subtracted when converting channel 4.

29.6.16 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x70

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GCOMP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	GCOMPCOEFF[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GCOMP**: Gain compensation mode

This bit is set and cleared by software to enable the gain compensation mode.

0: Regular ADC operating mode

1: Gain compensation enabled and applied on all channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 **GCOMPCOEFF[13:0]**: Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.
00 1000 0000 0000: gain factor of 0.5
...
01 0000 0000 0000: gain factor of 1
10 0000 0000 0000: gain factor of 2
11 0000 0000 0000: gain factor of 3
...
The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.999756.

Note: This gain compensation is only applied when GCOMP bit of ADCx_CFGR2 register is 1.

29.6.17 ADC injected data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y-1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

AWD2CH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2

AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2

When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWD2CH must be also selected into the SQRi or JSQRi registers. Software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.19 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0xA4

Reset value: 0x0000 0000

AWD3CH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD3CH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWD3CH[i] = 0: ADC analog input channel-i is not monitored by AWD3

AWD3CH[i] = 1: ADC analog input channel-i is monitored by AWD3

When AWD3CH[19:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.20 ADC watchdog threshold register 1 (ADC_LTR1)

Address offset: 0xA8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

HTR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT1[2:0]**: Analog watchdog filtering parameter

This bit is set and cleared by software.

000: No filtering

001: two consecutive detection generates an AWDx flag or an interrupt

...

111: Eight consecutive detection generates an AWDx flag or an interrupt

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:25 Reserved, must be kept at reset value.

Bits 24:0 **HTR1[24:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1.

Refer to *Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*.

29.6.22 ADC watchdog lower threshold register 2 (ADC_LTR2)

Address offset: 0xB0

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **HTR2[24:0]**: Analog watchdog 2 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 2.
Refer to *Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*.

29.6.24 ADC watchdog lower threshold register 3 (ADC_LTR3)

Address offset: 0xB8

Reset value: 0x0000 0000

LTR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **LTR3[24:0]**: Analog watchdog 3 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 3.
Refer to *Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*.

29.6.25 ADC watchdog higher threshold register 3 (ADC_HTR3)

Address offset: 0xBC

Reset value: 0x01FF FFFF

HTR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **HTR3[24:0]**: Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3.
Refer to *Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*.

29.6.26 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0xC0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DIFSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]**: Differential mode for channels 19 to 0

These bits are set and cleared by software. They allow selecting if a channel is configured as single ended or differential mode.
DIFSEL[i] = 0: ADC analog input channel-i is configured in single ended mode
DIFSEL[i] = 1: ADC analog input channel-i is configured in differential mode

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

29.6.27 ADC user control register (ADC_CALFACT)

Address offset: 0xC4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

I_APB_DATA[7:0]								I_APB_ADDR[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CAPTURE_COEF**: Calibration factor capture enable bit
This bit enables the internal calibration factor capture.
0: Calibration factor not captured
1: Calibration factor available in CALFACT[31:0] bits, the calibration factor index being defined by CALINDEX[3:0] bits

Bit 24 **LATCH_COEF**: Calibration factor latch enable bit
This bit latches the calibration factor in the CALFACT[31:0] bits.
0: No effect
1: Calibration factor latched in the analog block on LATCH_COEF bit transition from 0 to 1. Prior to latching the calibration factor, CALFACT[31:0] bits must be programmed with the content of CALINDEX[3:0] bits.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **VALIDITY**: Delayed write access status bit
This bit indicates the communication status between the ADC digital and analog blocks.
0: Operation still in progress
1: Operation complete

Bits 15:8 **I_APB_DATA[7:0]**: Delayed write access data
This bitfield contains the data that are being written during delayed write accesses.

Bits 7:0 **I_APB_ADDR[7:0]**: Delayed write access address
This bitfield contains the address that is being written during delayed write accesses.

29.6.28 ADC calibration factor register (ADC_CALFACT2)

Address offset: 0xC8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CALFACT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CALFACT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CALFACT[31:0]**: Linearity or offset calibration factor

These bits can be written either by hardware or by software.

They contain the 32-bit offset or linearity calibration factor.

When CAPTURE_COEF is set to 1, the calibration factor of the analog block is read back and stored in CALFACT[31:0], indexed by CALINDEX[3:0] bits.

When LATCH_COEF is set to 1, the calibration factor of the analog block is updated with the value programmed in CALFACT[31:0], indexed by CALINDEX[3:0] bits.

To read all calibration factors, perform nine accesses to the ADC_CALFACT2 register.

To write all calibration factors, perform eight accesses to the ADC_CALFACT2 register.

Note: The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

29.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

29.7.1 ADC system control register (ADC12_CCR)

Address offset: 0x08

Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC12_CCR is common to ADC1 and ADC2. ADC2 is not available on all devices (refer to *Section 29.3: ADC implementation*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	VSENSE SEL	VREFEN	PRESC[3:0]				Res.	Res.
							rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable

This bit is set and cleared by software to control the V_{BAT} channel.

0: V_{BAT} channel disabled

1: V_{BAT} channel enabled

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 23 **VSENSESEL**: Temperature sensor voltage selection

This bit is set and cleared by software to control the temperature sensor channel.

0: Temperature sensor channel disabled

1: Temperature sensor channel enabled

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 22 **VREFEN**: V_{REFINT} enable

This bit is set and cleared by software to enable/disable the V_{REFINT} buffer.

0: V_{REFINT} channel disabled

1: V_{REFINT} channel enabled

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 21:18 **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the ADC clock. The clock is common to all ADCs.

0000: input ADC clock not divided

0001: input ADC clock divided by 2

0010: input ADC clock divided by 4

0011: input ADC clock divided by 6

0100: input ADC clock divided by 8

0101: input ADC clock divided by 10

0110: input ADC clock divided by 12

0111: input ADC clock divided by 16

1000: input ADC clock divided by 32

1001: input ADC clock divided by 64

1010: input ADC clock divided by 128

1011: input ADC clock divided by 256

Others: Reserved, must not be used

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 17:0 Reserved, must be kept at reset value.

30 Analog-to-digital converter (ADC4)

30.1 Introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 25 multiplexed channels enabling it to measure signals from 19 external and 6 internal sources. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The analog watchdog feature enables the application to detect if the input voltage goes outside the user-defined higher or lower thresholds.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

30.2 ADC main features

- High performance
  - 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
  - ADC conversion time: 0.4 µs for 12-bit resolution (2.5 Msps), faster conversion times can be obtained by lowering resolution.
  - Self-calibration
  - Programmable sampling time
  - Data alignment with built-in data coherency
  - DMA support
- Low-power
  - The application can reduce the bus clock frequency for low-power operation while still keeping optimum ADC performance. For example, 0.4 µs conversion time is kept, whatever the bus clock frequency
  - Wait mode: prevents ADC overrun in applications with low bus clock frequency
  - Auto off mode: ADC is automatically powered off except during the active conversion phase. This dramatically reduces the power consumption of the ADC.
- Autonomous mode
  - Conversion and DMA transfers supported in Stop mode
  - Wakeup from Stop on ADC interrupts
  - Enter and exit from Deep-power-down mode managed automatically
- Analog input channels
  - 19 external analog inputs
  - 1 channel for the internal temperature sensor (V_{SENSE})
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for the internal digital core voltage (V_{CORE})
  - 1 channel for monitoring the external VBAT power supply pin

  - Connection to DAC internal channels
- Start-of-conversion can be initiated:
  - By software
  - By hardware triggers with configurable polarity (timer events or GPIO input events)
- Conversion modes
  - Can convert a single channel or can scan a sequence of channels.
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at the end of sampling, end of conversion, end of sequence conversion, and in case of analog watchdog or overrun events
- Analog watchdog
- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256x
  - Programmable data shift up to 8 bits
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

30.3 ADC implementation

Table 248. ADC features(1)

ADC modes/features	ADC1	ADC4
Resolution	14 bits	12 bits
Maximum sampling speed for 14-bit resolution	2.5 Msps	2.5 Msps
Hardware offset calibration	X	X
Hardware linearity calibration	X	-
Single-ended inputs	X	X
Differential inputs	X	-
Injected channel conversion	X	-
Oversampling	up to x1024	up to x256
Data register	32 bits	16 bits
DMA support	X	X
parallel data output to MDF	X	-
Dual mode	-	-
Autonomous mode	-	X
Offset compensation	X	-
Gain compensation	X	-

Table 248. ADC features(1) (continued)

ADC modes/features	ADC1	ADC4
Number of analog watchdogs	3	3
Wakeup from Stop mode	-	X(2)

1. Note: 'X' = supported, '-'= not supported.
2. Wake up supported from Stop 0, Stop 1 and Stop 2 modes.

Table 249. Memory location of the temperature sensor calibration values

Name	Description	Memory address
TS_CAL1	Temperature sensor 14-bit raw data acquired by ADC1 at 30 °C (± 5 °C), $V_{DDA} = V_{REF+}$ = 3.0 V (±10 mV)	0x0BFA 0710 - 0x0BFA 0711
TS_CAL2	Temperature sensor 14-bit raw data acquired by ADC1 at 130 °C (± 5 °C), $V_{DDA} = V_{REF+}$ = 3.0 V (±10 mV)	0x0BFA 0742 - 0x0BFA 0743

adc_trg6	lptim3_ch2
adc_trg7	exti15

30.4.3 ADC voltage regulator (ADVREGEN)

The ADC has a specific internal voltage regulator which must be enabled and stable before using the ADC.

The ADC internal voltage regulator can be enabled by setting ADVREGEN bit to 1 in the ADC_CR register. The software must wait for the ADC voltage regulator startup time ($t_{ADCVREG\_SETUP}$) before launching a calibration or enabling the ADC. The LDO status can be verified by checking the LDORDY bit in ADC_ISR register.

After ADC operations are complete, the ADC can be disabled (ADEN = 0). It is then possible to save additional power by disabling the ADC voltage regulator (refer to *Section : ADC voltage regulator disable sequence*).

Note: When the internal voltage regulator is disabled, the internal analog calibration factor is reset, and a new calibration must be performed.

ADC voltage regulator enable sequence

To enable the ADC voltage regulator, follow the sequence below:

1. Clear the LDORDY bit in ADC_ISR register by programming this bit to 1.
2. Set the ADVREGEN bit to 1 in ADC_CR register.
3. Wait until LDORDY = 1 in the ADC_ISR register (LDORDY is set after the ADC voltage regulator startup time). This can be handled by interrupt if the interrupt is enabled by setting the LDORDYIE bit in the ADC_IER register.

ADC voltage regulator disable sequence

To disable the ADC voltage regulator, follow the sequence below:

1. Make sure that the ADC is disabled (ADEN = 0).
2. Clear ADVREGEN bit in ADC_CR register.
3. Clear the LDORDY bit in ADC_ISR register by programming this bit to 1(optional),

30.4.4 Calibration (ADCAL)

The ADC has a calibration feature. During the procedure, the ADC calculates a calibration factor which is internally applied to the ADC until the next ADC power-off. The application must not use the ADC during calibration and must wait until it is complete.

The calibration must be performed before starting analog-to-digital conversion. It removes the offset error which may vary from chip to chip due to process variation, supply voltage and temperature.

The calibration is initiated by software by setting bit ADCAL to 1. It can be initiated only when all the following conditions are met:

- the ADC voltage regulator is enabled (ADVREGEN = 1 and LDORDY = 1),
- the ADC is disabled (ADEN = 0), and
- the Auto-off mode is disabled (AUTOFF = 0).

ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. After this, the calibration factor can be read from the ADC_DR register (from bits 6 to 0).

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). When the ADC operating conditions change (V_{DDA} changes are the main contributor to ADC offset variations and temperature change to a lesser extend), it is recommended to re-run a calibration cycle. It is recommended to recalibrate when V_{REF+} voltage changed more than 10%.

The calibration factor is lost in the following cases:

- The power supply is removed from the ADC (for example when the product enters Standby or V_{BAT} mode).
- The ADC peripheral is reset.

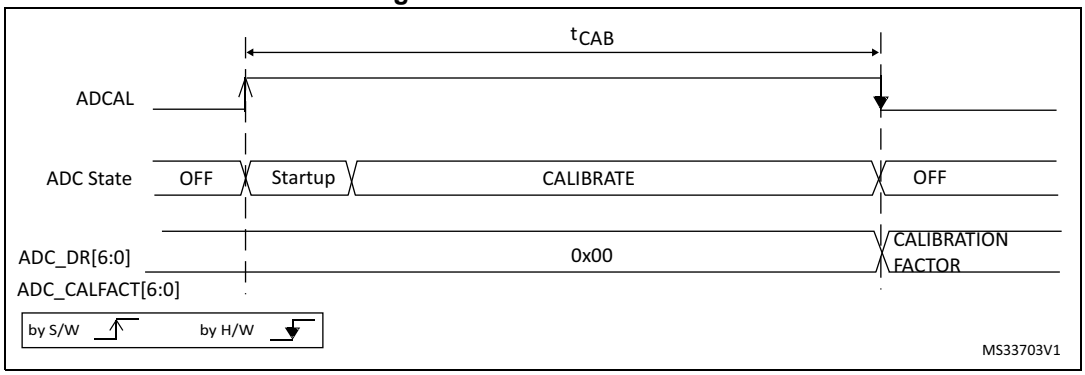
The calibration factor is lost each time power is removed from the ADC (for example when the product enters Standby or V_{BAT} mode). Still, it is possible to save and restore the calibration factor by software to save time when re-starting the ADC (as long as temperature and voltage are stable during the ADC power-down).

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion.

Software calibration procedure

1. Ensure that ADEN = 0, ADVREGEN = 1, AUTOFF = 0, DPD = 0, and DMAEN = 0.
2. Set ADCAL = 1.
3. Wait until ADCAL = 0 (or until EOCAL = 1). This can be handled by interrupt if the interrupt is enabled by setting the EOCALIE bit in the ADC_IER register
4. The calibration factor can be read from bits 6:0 of ADC_DR or ADC_CALFACT registers.

Figure 188. ADC calibration

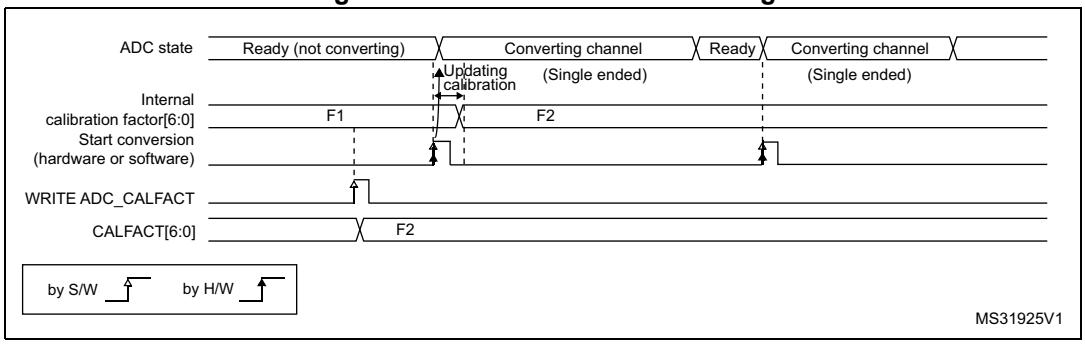


1. Refer to the device datasheet for the value of t_{CAB}.

Calibration factor forcing software procedure

1. Ensure that ADEN = 1 and ADSTART = 0 (ADC started with no conversion ongoing).
2. Write ADC_CALFACT with the saved calibration factor.
3. The calibration factor is used as soon as a new conversion is launched.

Figure 189. Calibration factor forcing



30.4.5 ADC on-off control (ADEN, ADDIS, ADRDY)

At power-up, the ADC is disabled and put in power-down mode (ADEN = 0).

As shown in *Figure 190*, the ADC needs a stabilization time of t_{STAB} before it starts converting accurately.

Two control bits are used to enable or disable the ADC:

- Set ADEN = 1 to enable the ADC. The ADRDY flag is set as soon as the ADC is ready for operation.
- Set ADDIS = 1 to disable the ADC and put the ADC in Power-down. The ADEN and ADDIS bits are then automatically cleared by hardware as soon as the ADC is fully disabled.

Conversion can then start either by setting ADSTART to 1 (refer to *Section 30.4.16: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN) on page 1099*) or when an external trigger event occurs if triggers are enabled.

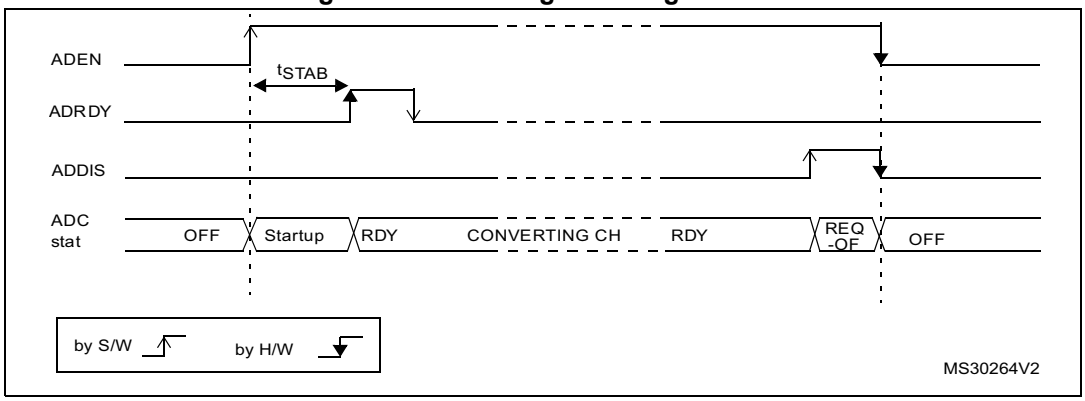
Follow the procedure below to enable the ADC:

1. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1.
2. Set ADEN = 1 in the ADC_CR register.
3. Wait until ADRDY = 1 in the ADC_ISR register (ADRDY is set after the ADC startup time). This can be handled by interrupt if the interrupt is enabled by setting the ADRDYIE bit in the ADC_IER register.

Follow the procedure below to disable the ADC:

1. Check that ADSTART = 0 in the ADC_CR register to ensure that no conversion is ongoing. If the Software trigger mode was used, stop the Software trigger mode by writing 1 to the ADSTP bit of the ADC_CR register and waiting until this bit is read at 0.
2. Set ADDIS = 1 in the ADC_CR register.
3. If required by the application, wait until ADEN = 0 in the ADC_CR register, indicating that the ADC is fully disabled (ADDIS is automatically reset once ADEN = 0).
4. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1 (optional).

Figure 190. Enabling/disabling the ADC

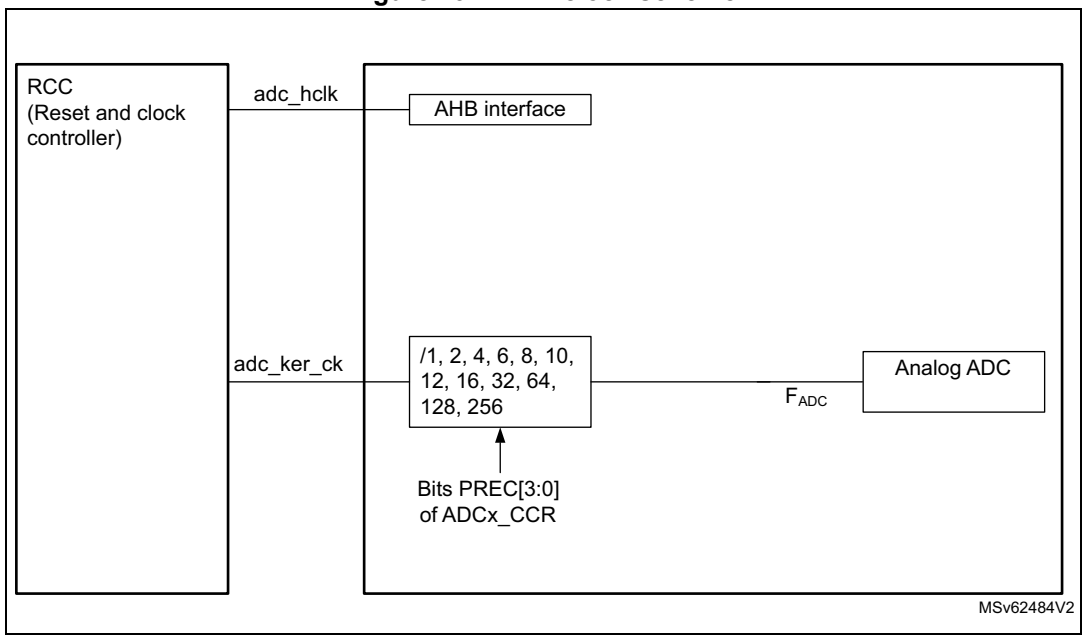


Note: In Auto-off mode (AUTOFF = 1) the power-on/off phases are performed automatically, by hardware and the ADRDY flag is not set.

30.4.6 ADC clock (PRESC[3:0])

The ADC has a dual clock-domain architecture, so that the ADC can be fed with a clock (ADC asynchronous clock) independent from the bus clock.

Figure 191. ADC clock scheme



1. Refer to *Section Reset and clock control (RCC)* for how the bus clock and ADC asynchronous clock are enabled.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 191: ADC clock scheme*). This selection is done in the RCC (refer to th RCC section for more information):

a) The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous with the bus clock.

b) The ADC clock can be derived from the bus clock.

Option a) has the advantage of reaching the maximum ADC clock frequency whatever the clock scheme selected. The ADC clock can eventually be divided by a programmable ratio of 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256, configured through PRESC[3:0] bits in the ADCx_CCR register.

Option b) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

Table 254. Latency between trigger and start of conversion(1)

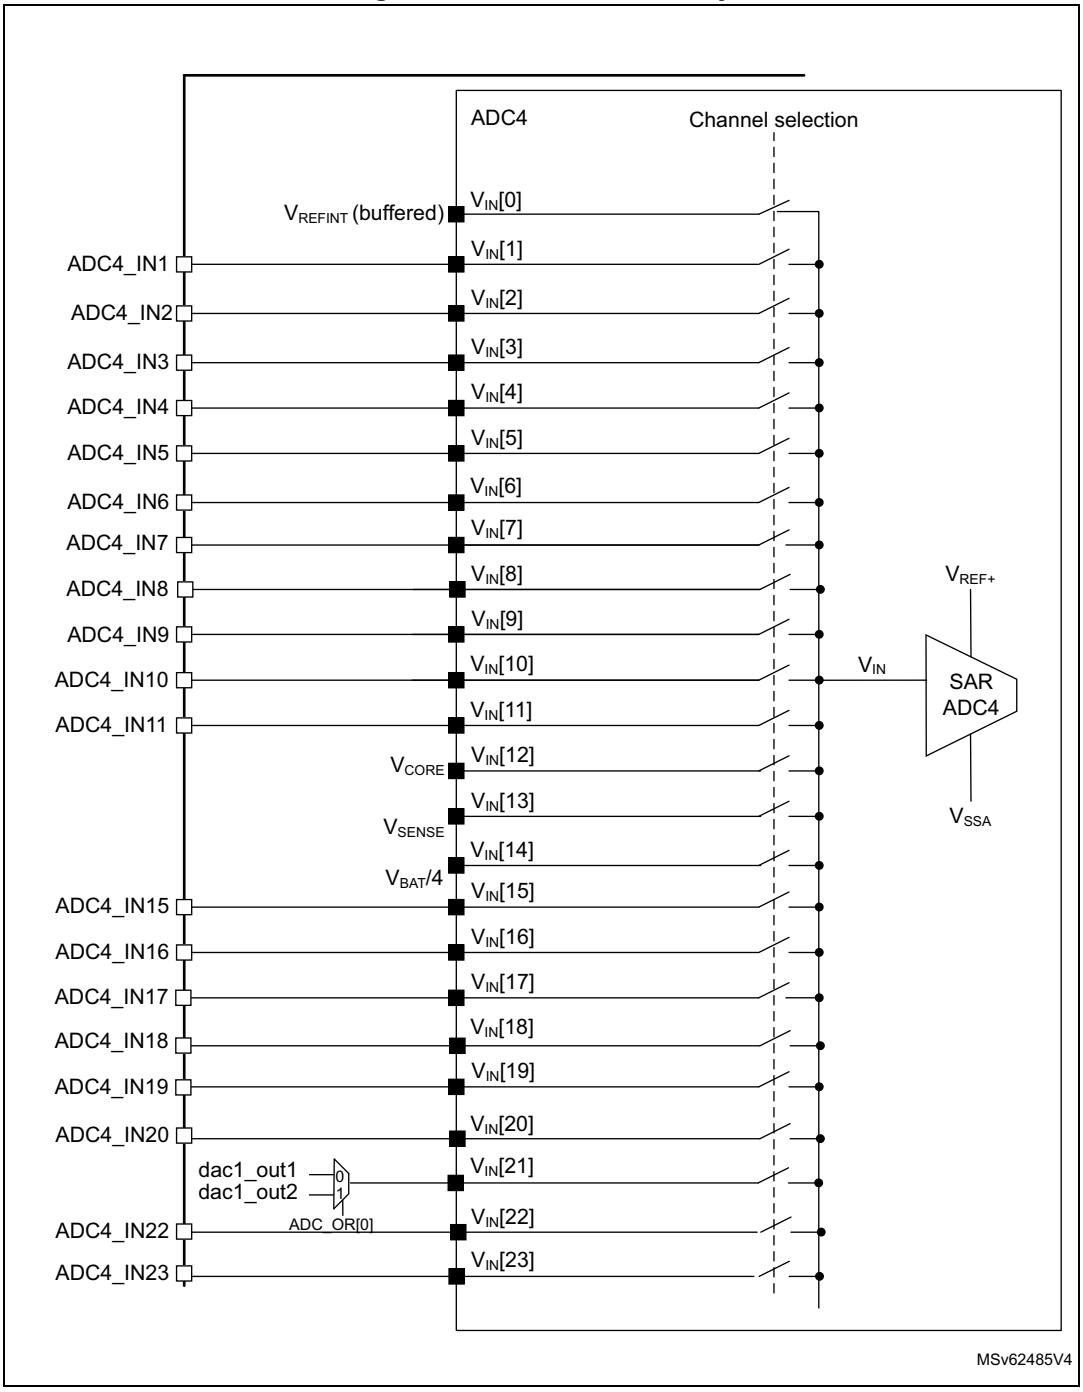
ADC clock source	Latency between the trigger event and the start of conversion
Clock different from bus clock	Latency is not deterministic (jitter)
Bus clock divided by 2	Latency is deterministic (no jitter) and equal to 4 ADC clock cycles
Bus clock divided by 4	Latency is deterministic (no jitter) and equal to 3.75 ADC clock cycles
Bus clock divided by 1	Latency is deterministic (no jitter) and equal to 4 ADC clock cycles

1. Refer to the device datasheet for the maximum F_{ADC} frequency.

30.4.7 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described in *Figure 192*.

Figure 192. ADC4 connectivity



30.4.8 Configuring the ADC

The software can write to the ADCAL and ADEN bits in the ADC_CR and ADC_PWRR register if the ADC is disabled (ADEN must be 0).

The software must only write to the ADSTART and ADDIS bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN = 1 and ADDIS = 0).

For all the other control bits in the ADC_IER, ADC_CFGRi, ADC_SMPR, ADC_CHSELR and ADC_CCR registers, refer to the description of the corresponding control bit in *Section 30.7: ADC registers*. If the ADC operates in Software trigger mode, set the ADSTP bit in ADC_CR register, then wait until ADSTP bit become 0 before reconfiguring the above registers.

ADC_AWDTRi registers can be modified when a conversion is ongoing.

The software must only write to the ADSTP bit in the ADC_CR register if the ADC is enabled (and possibly converting) and there is no pending request to disable the ADC (ADSTART = 1 and ADDIS = 0).

Note: There is no hardware protection preventing software from making write operations forbidden by the above rules. If such a forbidden write access occurs, the ADC may enter an undefined state. To recover correct operation in this case, the ADC must be disabled (clear ADEN = 0 and all the bits in the ADC_CR register).

30.4.9 Channel selection (CHSEL, SCANDIR, CHSELRMOD)

There are up to 25 multiplexed channels:

- 19 analog inputs from GPIO pins (ADC_INx)
- 6 internal analog inputs: temperature Sensor, internal reference voltage, V_{CORE}, V_{BAT} channel, DAC internal channels

It is possible to convert a single channel or a sequence of channels.

The sequence of the channels to be converted can be programmed in the ADC_CHSELR channel selection register: each analog input channel has a dedicated selection bit (CHSELx).

The ADC scan sequencer can be used in two different modes:

- Sequencer not fully configurable:

  The order in which the channels are scanned is defined by the channel number (CHSELRMOD bit must be cleared in ADC_CFGR1 register):
  - Sequence length configured through CHSELx bits in ADC_CHSELR register
  - Sequence direction: the channels are scanned in a forward direction (from the lowest to the highest channel number) or backward direction (from the highest to the lowest channel number) depending on the value of SCANDIR bit (SCANDIR = 0: forward scan, SCANDIR = 1: backward scan)

  - Any channel can belong to in these sequences
- Fully-configurable sequencer

  The CHSELRMOD bit is set in ADC_CFGR1 register.
  - Sequencer length is up to eight channels
  - The order in which the channels are scanned is independent from the channel number. Any order can be configured through SQ1[3:0] to SQ8[3:0] bits in ADC_CHSELR register.
  - Only 15 channels can be selected in this sequence (refer to *Section 30.7.10: ADC channel selection register [alternate] (ADC_CHSELR)*.
  - If the sequencer detects SQx[3:0] = 0b1111, the following SQx[3:0] registers are ignored.
  - If no 0b1111 is programmed in SQx[3:0], the sequencer scans full eight channels.

The software is allowed to program the CHSEL, SCANDIR and CHSELRMOD bit only when ADSTART bit is cleared in ADC_CR register. This ensures that no conversion is ongoing. If the ADC operated in Software trigger mode, set ADSTP bit then wait until ADSTP bit become 0 before reconfiguring these registers. This sequence must be respected even if ADSTART bit is cleared to 0 after the conversion,

Temperature sensor, DAC output, V_{REFINT}, V_{BAT}, and V_{CORE} internal channels

The temperature sensor, the internal DAC channels, the internal reference voltage (V_{REFINT}), V_{BAT}, and V_{CORE} are connected to ADC internal channels. Refer to *Table ADC interconnection* in *Section 30.4.2: ADC pins and internal signals* for details.

30.4.10 Programmable sampling time (SMPx[2:0])

Before starting a conversion, the ADC needs to establish a direct connection between the voltage source to be measured and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the sample and hold capacitor to the input voltage level.

Having a programmable sampling time allows the conversion speed to be trimmed according to the input resistance of the input voltage source.

The ADC samples the input voltage for a number of ADC clock cycles that can be modified using the SMP1[2:0] and SMP2[2:0] bits in the ADC_SMPR register.

Each channel can choose one out of two sampling times configured in SMP1[2:0] and SMP2[2:0] bitfields, through SMPSELx bits in ADC_SMPR register.

The total conversion time is calculated as follows:

t_{CONV} = Sampling time + 12.5 x ADC clock cycles

Example:

With ADC_CLK = 16 MHz and a sampling time of 1.5 ADC clock cycles:

t_{CONV} = 1.5 + 12.5 = 14 ADC clock cycles = 0.875 µs

The ADC indicates the end of the sampling phase by setting the EOSMP flag.

30.4.11 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs a single sequence of conversions, converting all the channels once. This mode is selected when CONT is cleared in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then the ADC stops until a new external trigger event occurs or the ADSTART bit is set again.

Note: To convert a single channel, program a sequence with a length of 1.

30.4.12 Continuous conversion mode (CONT = 1)

In continuous conversion mode, when a software or hardware trigger event occurs, the ADC performs a sequence of conversions, converting all the channels once and then automatically re-starts and continuously performs the same sequence of conversions. This mode is selected when CONT is set to 1 in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 *and CONT* = 1*.*

30.4.13 Starting conversions (ADSTART)

Software starts ADC conversions by setting ADSTART to 1.

When ADSTART is set, the conversion:

- Starts immediately if EXTEN = 00 (software trigger)
- At the next active edge of the selected hardware trigger if EXTEN ≠ 00

The ADSTART bit is also used to indicate whether an ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART remains at 0, indicating that the ADC is idle.

The ADSTART bit is cleared by hardware:

- In single mode with software trigger (CONT = 0, EXTEN = 00)
  - At any end of conversion sequence (EOS = 1)
- In discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN = 00)
  - At end of conversion (EOC = 1)
- In all cases (CONT = x, EXTEN = XX)
  - After execution of the ADSTP procedure invoked by software (see *Section 30.4.15: Stopping an ongoing conversion (ADSTP) on page 1099*).

When the ADC operates in Autonomous mode (DPD bit transition from 1 to 0, see *Section : Autonomous mode (AUTOFF, DPD)*), the ADSTART bit can be set only when the ADC is powered on. (both LDORDY = 1 and ADRDY = 1). In Continuous mode (CONT = 1), the ADSTART bit is not cleared by hardware when the EOS flag is set because the sequence is automatically relaunched.

Note: When hardware trigger is selected in single mode (CONT = 0 and EXTEN = 01), ADSTART is not cleared by hardware when the EOS flag is set. This avoids the need for software having to set the ADSTART bit again and ensures the next trigger event is not missed.

It is necessary to set ADSTP to 1 and wait until ADSTP is cleared before reconfiguring or disabling the ADC, even if ADSTART bit is cleared to after the software triggered ADC conversion mode.

30.4.14 Timings

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$t_{CONV} = t_{SMPL} + t_{SAR} = [1.5\ _{|min} + 12.5\ _{|12bit}] \times t_{ADC\_CLK}$

$t_{CONV} = t_{SMPL} + t_{SAR} = 42.9\ ns\ _{|min} + 357.1\ ns\ _{|12bit} = 0.400\ \mu s\ _{|min}$ (for $f_{ADC\_CLK} = 35$ MHz)

Figure 193. Analog to digital conversion time

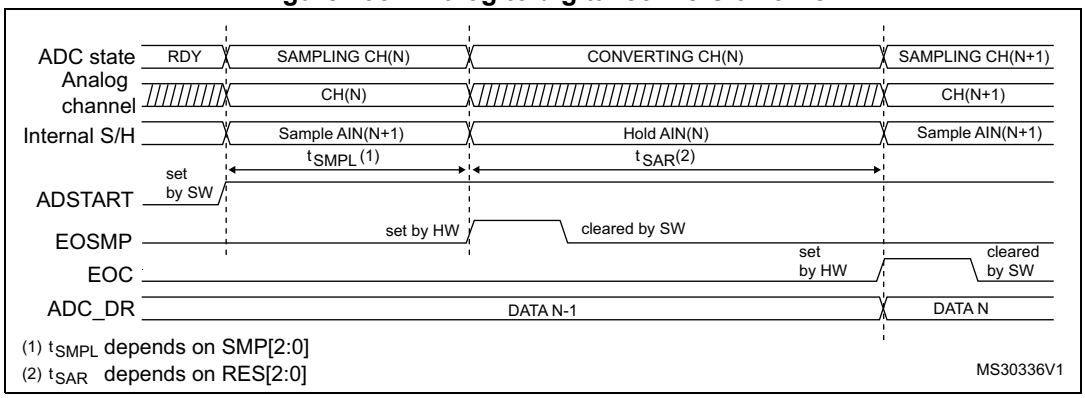


Figure 194. ADC conversion timings

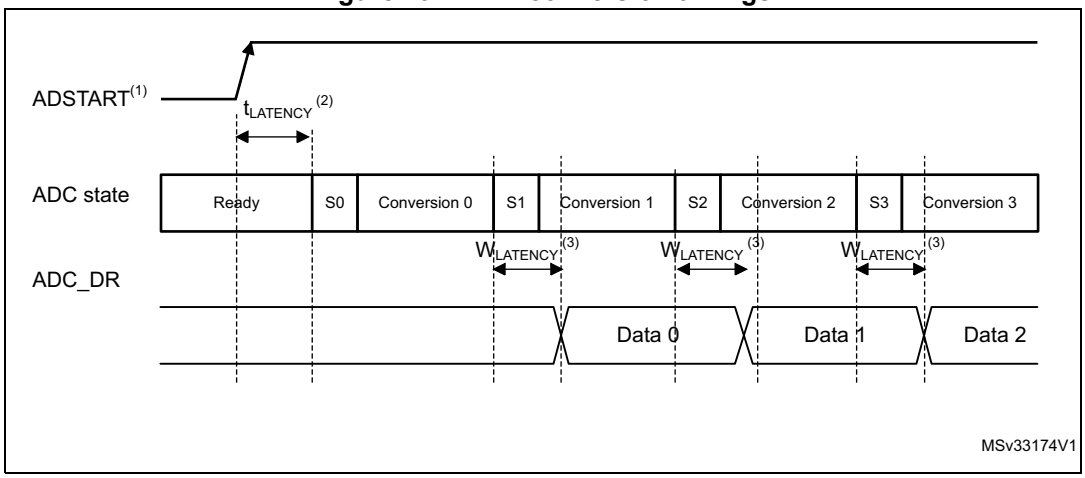


1. EXTEN = 00 or EXTEN ≠ 00.
2. Trigger latency (refer to datasheet for more details).
3. ADC_DR register write latency (refer to datasheet for more details).

30.4.15 Stopping an ongoing conversion (ADSTP)

The software can decide to stop any ongoing conversions by setting ADSTP to 1 in the ADC_CR register.

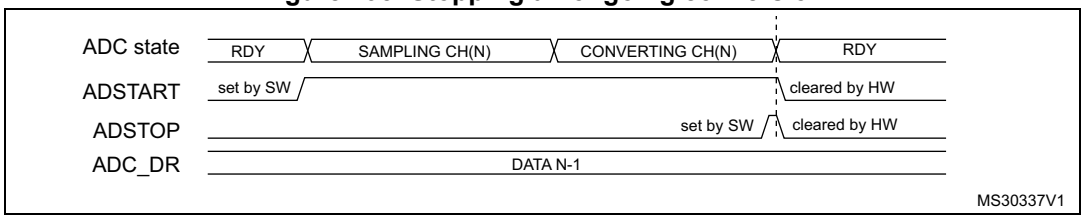
This resets the ADC operation and the ADC is idle, ready for a new operation.

When the ADSTP bit is set by software, any ongoing conversion is aborted and the result is discarded (ADC_DR register is not updated with the current conversion).

The scan sequence is also aborted and reset (meaning that restarting the ADC would re-start a new sequence).

Once this procedure is complete, the ADSTP and ADSTART bits are both cleared by hardware and the software must wait until ADSTART is cleared to 0 before starting new conversions.

Figure 195. Stopping an ongoing conversion



30.4.16 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)

A conversion or a sequence of conversion can be triggered either by software or by an external event (for example timer capture). If the EXTEN[1:0] control bits are not equal to “0b00”, then external events are able to trigger a conversion with the selected polarity. The trigger selection is effective once software has set bit ADSTART to 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

If bit ADSTART is cleared, any hardware triggers which occur are ignored.

Table 255 provides the correspondence between the EXTEN[1:0] values and the trigger polarity.

Table 255. Configuring the trigger polarity

Source	EXTEN[1:0]
Trigger detection disabled	00
Detection on rising edge	01
Detection on falling edge	10
Detection on both rising and falling edges	11

Note: The polarity of the external trigger can be changed only when the ADC is not converting (ADSTART = 0).

The EXTSEL[2:0] control bits are used to select which of 8 possible events can trigger conversions.

Refer to Table ADC interconnection in *Section 30.4.2: ADC pins and internal signals* for the list of all the external triggers that can be used for regular conversion.

The software source trigger events can be generated by setting the ADSTART bit in the ADC_CR register.

Note: The trigger selection can be changed only when the ADC is not converting (ADSTART = 0).

30.4.17 Discontinuous mode (DISCEN)

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

In this mode (DISCEN = 1), a hardware or software trigger event is required to start each conversion defined in the sequence. On the contrary, if DISCEN is cleared, a single hardware or software trigger event successively starts all the conversions defined in the sequence.

Example:

- DISCEN = 1, channels to be converted are channels 0, 3, 7 and 10
  - 1st trigger: channel 0 is converted and an EOC event is generated
  - 2nd trigger: channel 3 is converted and an EOC event is generated
  - 3rd trigger: channel 7 is converted and an EOC event is generated
  - 4th trigger: channel 10 is converted and both EOC and EOS events are generated.
  - 5th trigger: channel 0 is converted an EOC event is generated
  - 6th trigger: channel 3 is converted and an EOC event is generated
  - ...
- DISCEN = 0, channels to be converted are channels 0, 3, 7 and 10
  - 1st trigger: the complete sequence is converted: channel 0, then 3, 7 and 10. Each conversion generates an EOC event and the last one also generates an EOS event.
  - Any subsequent trigger events restarts the complete sequence.

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

30.4.18 Programmable resolution (RES) - fast conversion mode

It is possible to obtain faster conversion times (t_{SAR}) by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] bits in the ADC_CFGR1 register. Lower resolution allows faster conversion times for applications where high data precision is not required.

Note: The RES[1:0] bit must only be changed when the ADEN bit is reset.

The result of the conversion is always 12 bits wide and any unused LSB bits are read as zeros.

Lower resolution reduces the conversion time needed for the successive approximation steps as shown in *Table 256*.

Table 256. t_{SAR} timings depending on resolution

RES[1:0] bits	t_{SAR} (ADC clock cycles)	t_{SAR} (ns) at f_{ADC} = 35 MHz	$t_{SMPL\ (min)}$ (ADC clock cycles)	t_{CONV} (ADC clock cycles) (with min. $t_{SMPL)}$	t_{CONV} (ns) at f_{ADC} = 35 MHz
12	12.5	357	1.5	14	400
10	10.5	300	1.5	12	343
8	8.5	243	1.5	10	286
6	6.5	186	1.5	8	229

30.4.19 End of conversion, end of sampling phase (EOC, EOSMP flags)

The ADC indicates each end of conversion (EOC) event.

The ADC sets the EOC flag in the ADC_ISR register as soon as a new conversion data result is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set in the ADC_IER register. The EOC flag is cleared by software either by writing 1 to it, or by reading the ADC_DR register.

The ADC also indicates the end of sampling phase by setting the EOSMP flag in the ADC_ISR register. The EOSMP flag is cleared by software by writing1 to it. An interrupt can be generated if the EOSMPIE bit is set in the ADC_IER register.

The aim of this interrupt is to allow the processing to be synchronized with the conversions. Typically, an analog multiplexer can be accessed in hidden time during the conversion phase, so that the multiplexer is positioned when the next sampling starts.

Note: As there is only a very short time left between the end of the sampling and the end of the conversion, it is recommenced to use polling or a WFE instruction rather than an interrupt and a WFI instruction.

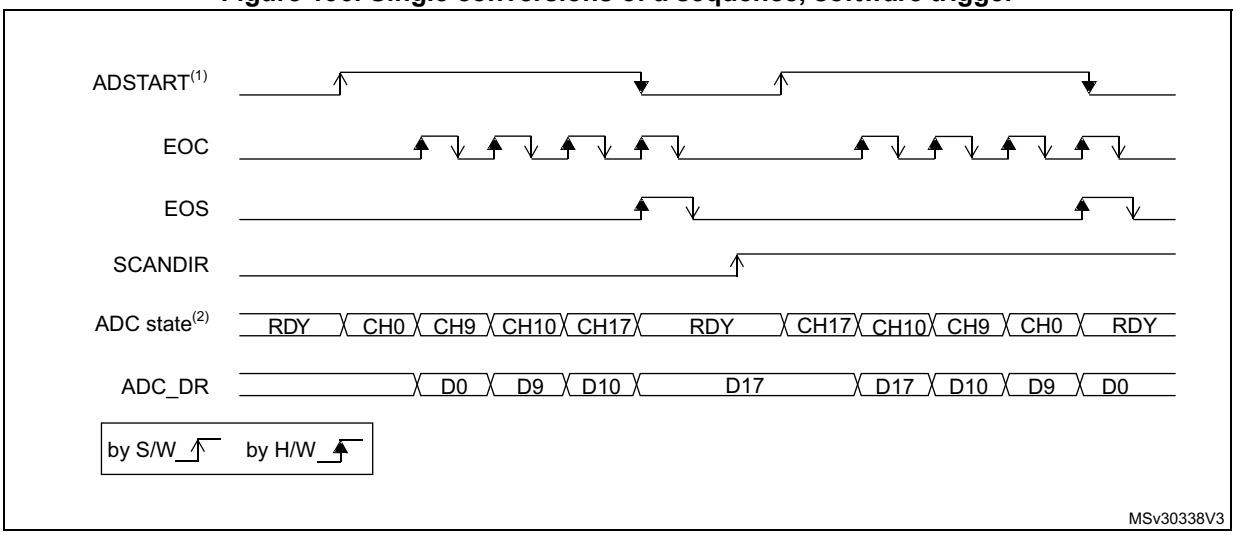
30.4.20 End of conversion sequence (EOS flag)

The ADC notifies the application of each end of sequence (EOS) event.

The ADC sets the EOS flag in the ADC_ISR register as soon as the last data result of a conversion sequence is available in the ADC_DR register. An interrupt can be generated if the EOSIE bit is set in the ADC_IER register. The EOS flag is cleared by software by writing 1 to it.

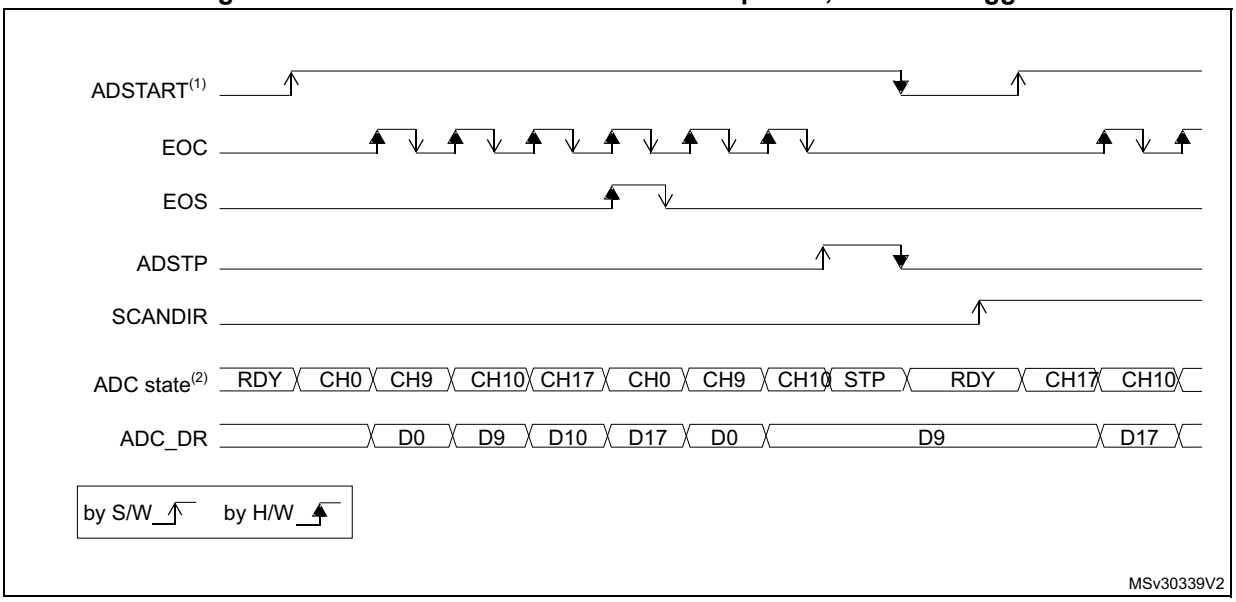
30.4.21 Example timing diagrams (single/continuous modes hardware/software triggers)

Figure 196. Single conversions of a sequence, software trigger



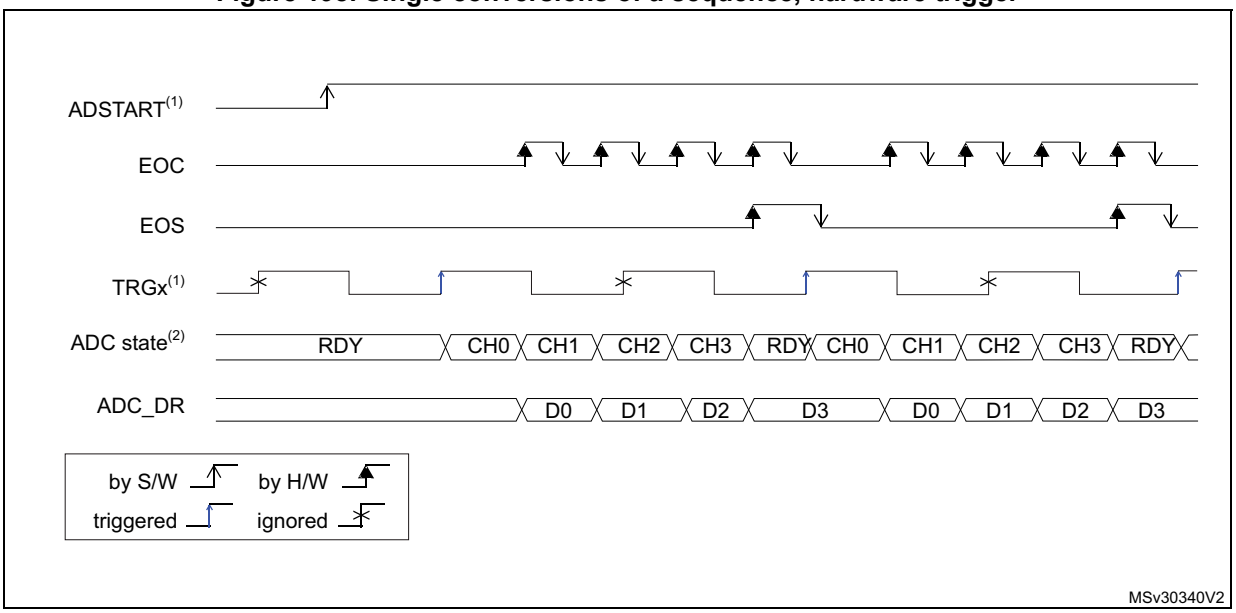
1. EXTEN = 00, CONT = 0.
2. CHSEL = 0x20601, WAIT = 0, AUTOFF = 0.

Figure 197. Continuous conversion of a sequence, software trigger



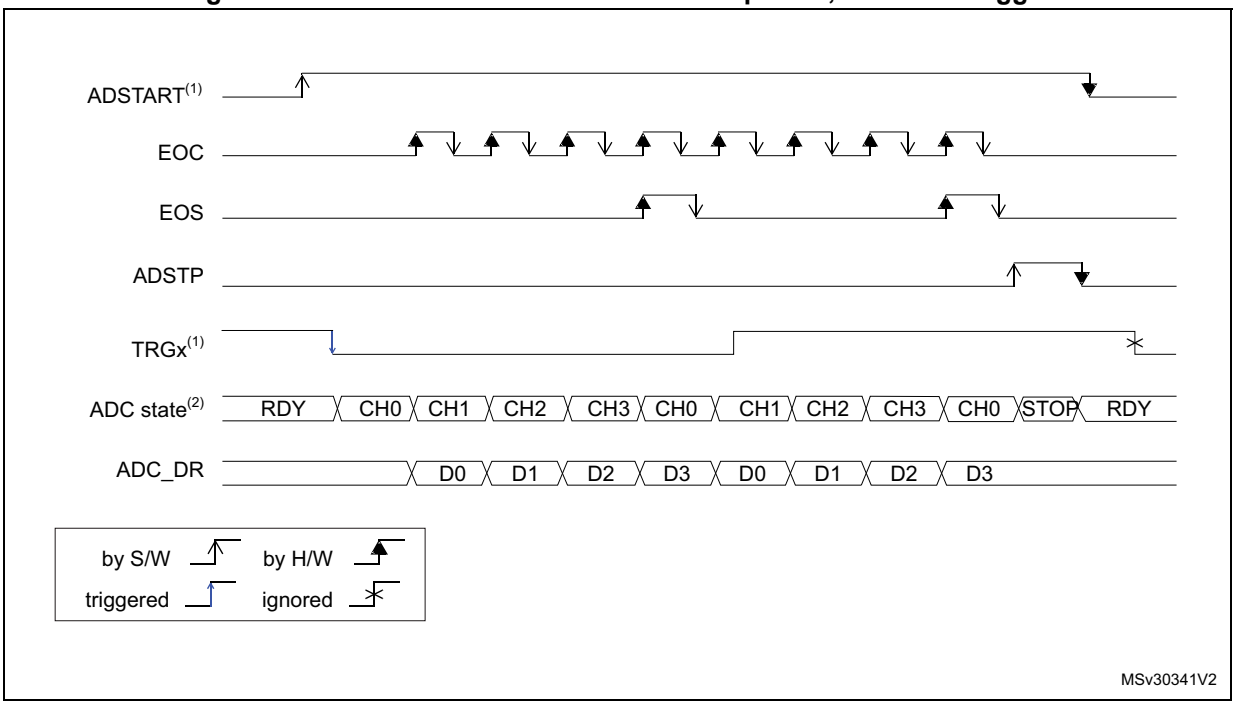
1. EXTEN = 00, CONT = 1.
2. CHSEL = 0x20601, WAIT = 0, AUTOFF = 0.

Figure 198. Single conversions of a sequence, hardware trigger



1. EXTSEL = TRGx (over-frequency), EXTEN = 01 (rising edge), CONT = 0.
2. CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 0.

Figure 199. Continuous conversions of a sequence, hardware trigger



1. EXTSEL = TRGx, EXTEN = 10 (falling edge), CONT = 1.
2. CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 0.

30.4.22 Low frequency trigger mode

If the application has to support a time longer than the maximum t_{IDLE} value (between one trigger to another for single conversion mode or between the ADC enable and the first ADC conversion), then the ADC internal state needs to be rearmed. This mechanism can be enabled by setting LFTRIG bit to 1 in ADC_CFGR2 register. By setting this bit, any trigger (software or hardware) sends a rearm command to ADC. The conversion is started after a two ADC clock cycle delay compared to LFTRIG set to 0.

It is not necessary to use this mode when AUTOFF bit is set to 1. For Wait mode, only the first trigger generates an internal rearm command.

30.4.23 Data management

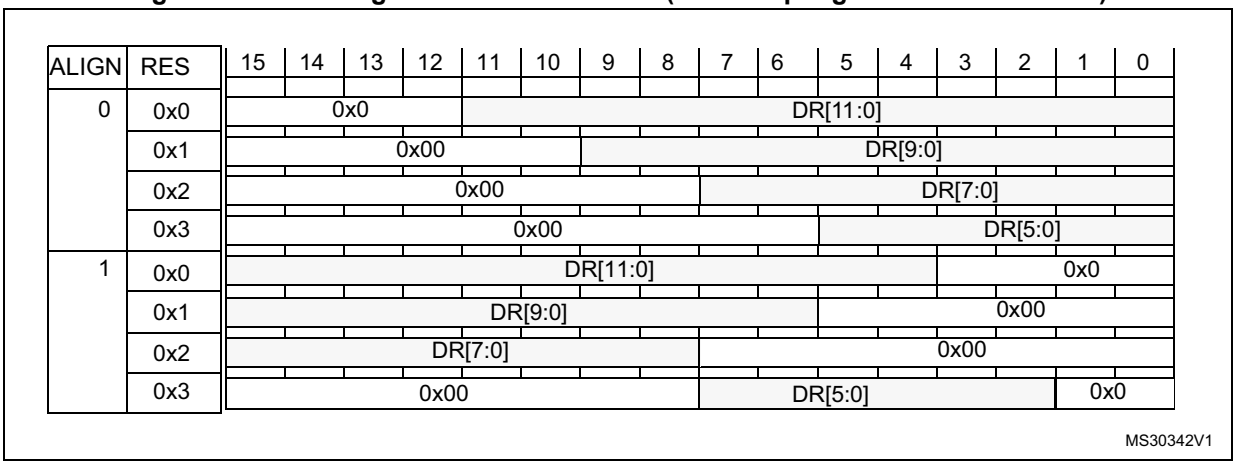
Data register and data alignment (ADC_DR, ALIGN)

At the end of each conversion (when an EOC event occurs), the result of the converted data is stored in the ADC_DR data register which is 16-bit wide.

The format of the ADC_DR depends on the configured data alignment and resolution.

The ALIGN bit in the ADC_CFGR1 register selects the alignment of the data stored after conversion. Data can be right-aligned (ALIGN = 0) or left-aligned (ALIGN = 1) as shown in *Figure 200*.

Figure 200. Data alignment and resolution (oversampling disabled: OVSE = 0)



ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) indicates a data overrun event, when the converted data was not read in time by the CPU or the DMA, before the data from a new conversion is available.

The OVR flag is set in the ADC_ISR register if the EOC flag is still at 1 at the time when a new conversion completes. An interrupt can be generated if the OVRIE bit is set in the ADC_IER register.

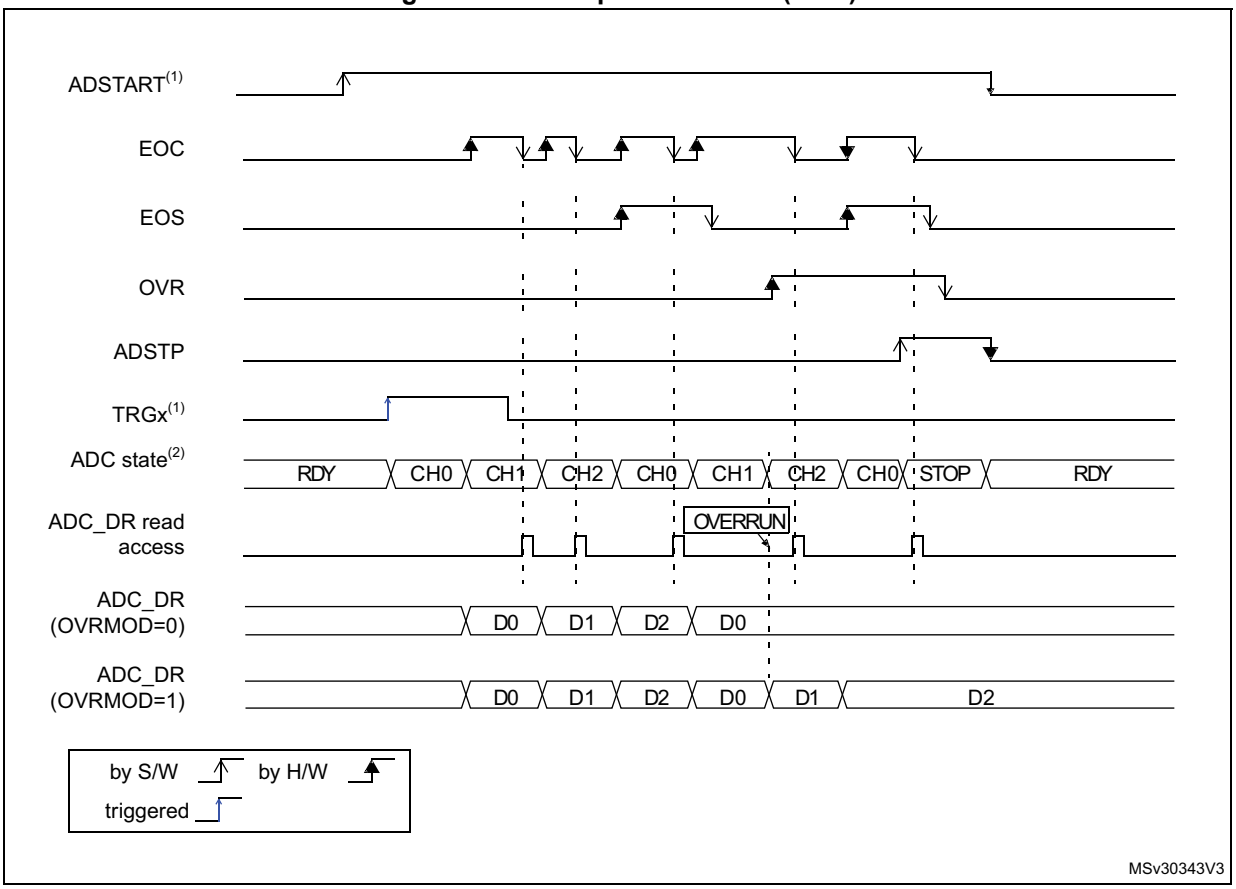
When an overrun condition occurs, the ADC keeps operating and can continue to convert unless the software decides to stop and reset the sequence by setting the ADSTP bit in the ADC_CR register.

The OVR flag is cleared by software by writing 1 to it.

It is possible to configure if the data is preserved or overwritten when an overrun event occurs by programming the OVRMOD bit in the ADC_CFGR1 register:

- OVRMOD = 0
  - An overrun event preserves the data register from being overwritten: the old data is maintained and the new conversion is discarded. If OVR remains at 1, further conversions can be performed but the resulting data is discarded.
- OVRMOD = 1
  - The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, further conversions can be performed and the ADC_DR register always contains the data from the latest conversion.

Figure 201. Example of overrun (OVR)



Managing a sequence of data converted without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by software. In this case the software must use the EOC flag and its associated interrupt to handle each data result. Each time a conversion is complete, the EOC bit is set in the ADC_ISR register and the ADC_DR register can be read. The OVRMOD bit in the ADC_CFGR1 register must be configured to 0 to manage overrun events as an error.

Managing converted data without using the DMA without overrun

It may be useful to let the ADC convert one or more channels without reading the data after each conversion. In this case, the OVRMOD bit must be configured at 1 and the OVR flag must be ignored by the software. When OVRMOD is et to 1, an overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion data.

Managing converted data using the DMA

Since all converted channel values are stored in a single data register, it is efficient to use DMA when converting more than one channel. This avoids losing the conversion data results stored in the ADC_DR register.

When DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR1 register), a DMA request is generated after the conversion of each channel. This allows the transfer of the

converted data from the ADC_DR register to the destination location selected by the software.

Note: The DMAEN bit in the ADC_CFGR1 register must be set after the ADC calibration phase.

Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD) on page 1105*).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG in the ADC_CFGR1 register:

- DMA one shot mode (DMACFG = 0).

  This mode must be selected when the DMA is programmed to transfer a fixed number of data words.
- DMA circular mode (DMACFG = 1)

  This mode must be selected when programming the DMA in circular mode or double buffer mode.

DMA one shot mode (DMACFG = 0)

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section), even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted and its partial result discarded
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- The scan sequence is stopped and reset
- The DMA is stopped

DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available in the data register, even if the DMA has reached the last DMA transfer. This allows the DMA configuration in circular mode in order to handle a continuous analog input data stream.

30.4.24 Low-power features

Wait conversion mode (WAIT)

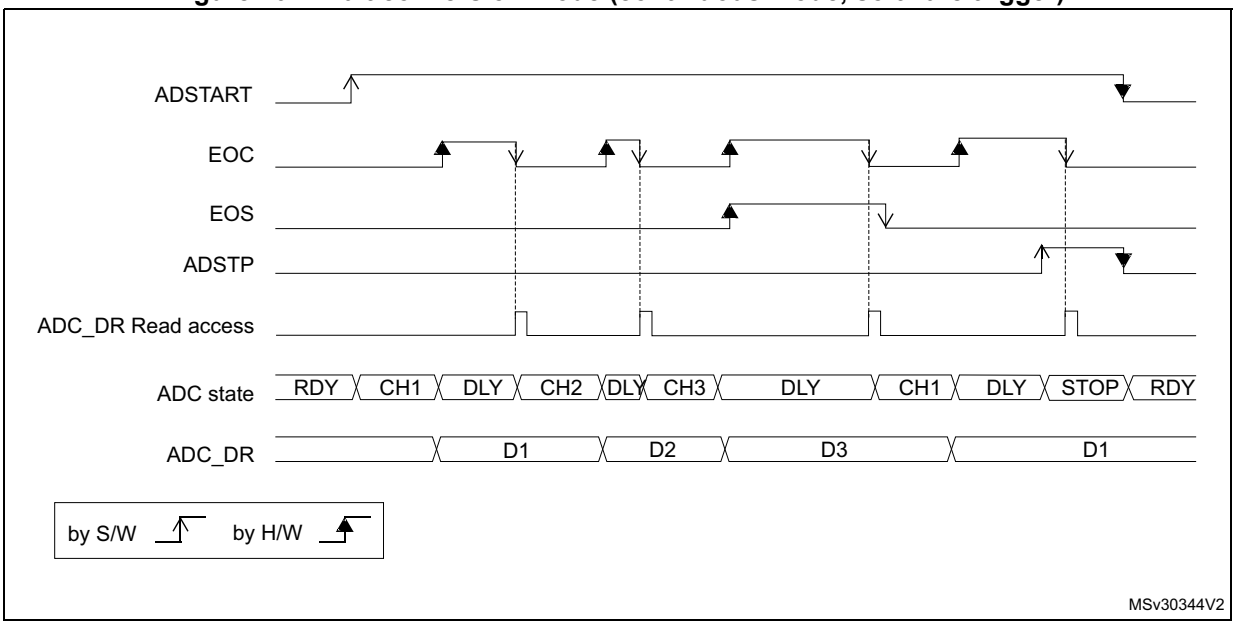
Wait conversion mode can be used to simplify the software as well as optimizing the performance of applications clocked at low frequency where there might be a risk of ADC overrun occurring.

When the WAIT bit is set to 1 in the ADC_CFGR1 register, a new conversion can start only if the previous data has been treated, once the ADC_DR register has been read or if the EOC bit has been cleared.

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

Note: Any hardware triggers which occur while a conversion is ongoing or during the wait time preceding the read access are ignored.

Figure 202. Wait conversion mode (continuous mode, software trigger)



1. EXTEN = 00, CONT = 1.
2. CHSEL = 0x3, SCANDIR = 0, WAIT = 1, AUTOFF = 0.

ADC power-saving modes

The ADC embeds two power-saving modes, the Auto-off and the Autonomous modes.

Auto-off mode (AUTOFF)

The Auto-off mode is enabled by setting the AUTOFF bit to 1 in the ADC_PWRR register.

Below the Auto-off mode operating sequence:

1. When AUTOFF is set to 1, the ADC is always powered off when no conversion is ongoing.
2. It then automatically wakes up when a conversion is triggered by software or by hardware, and a startup time is inserted between the trigger event and the ADC sampling time.
3. The ADC is then automatically disabled once the conversion or sequence of conversions is complete.
4. When consecutive hardware or software triggers occur, the ADC is automatically enabled and the conversion is processed.

Refer to *Figure 203* for a description of Auto-off mode state diagram.

The Auto-off mode dramatically reduces power consumption in applications requiring a limited number of conversions or conversion requests far between enough (for example with a low frequency hardware trigger) to justify the extra power and time used for switching the ADC on and off.

Auto-off mode can be combined with Wait mode (WAIT = 1) for applications clocked at low frequency. This combination can achieve significant power saving if the ADC is automatically powered off during the wait phase and restarted as soon as the ADC_DR register is read by the application (see *Figure 204: ADC behavior with WAIT = 0 and AUTOFF = 1* and *Figure 205: ADC behavior with WAIT = 1 and AUTOFF = 1*).

The Auto-off mode is compatible with the low-power background autonomous mode (LPBAM).

Note: Refer to the Section Reset and clock control (RCC) for the description of how to manage the dedicated internal oscillators. The ADC interface can automatically switch on/off these internal oscillators to save power.

Figure 203. Auto-off mode state diagram

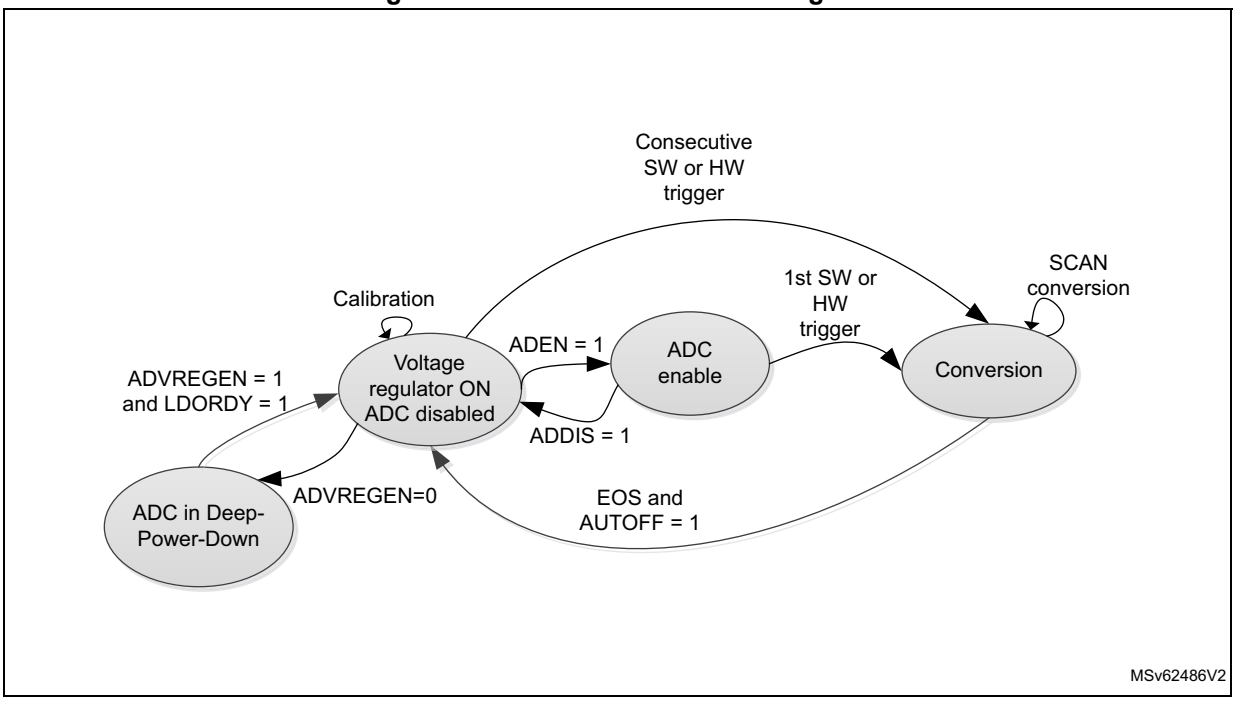


Figure 204. ADC behavior with WAIT = 0 and AUTOFF = 1

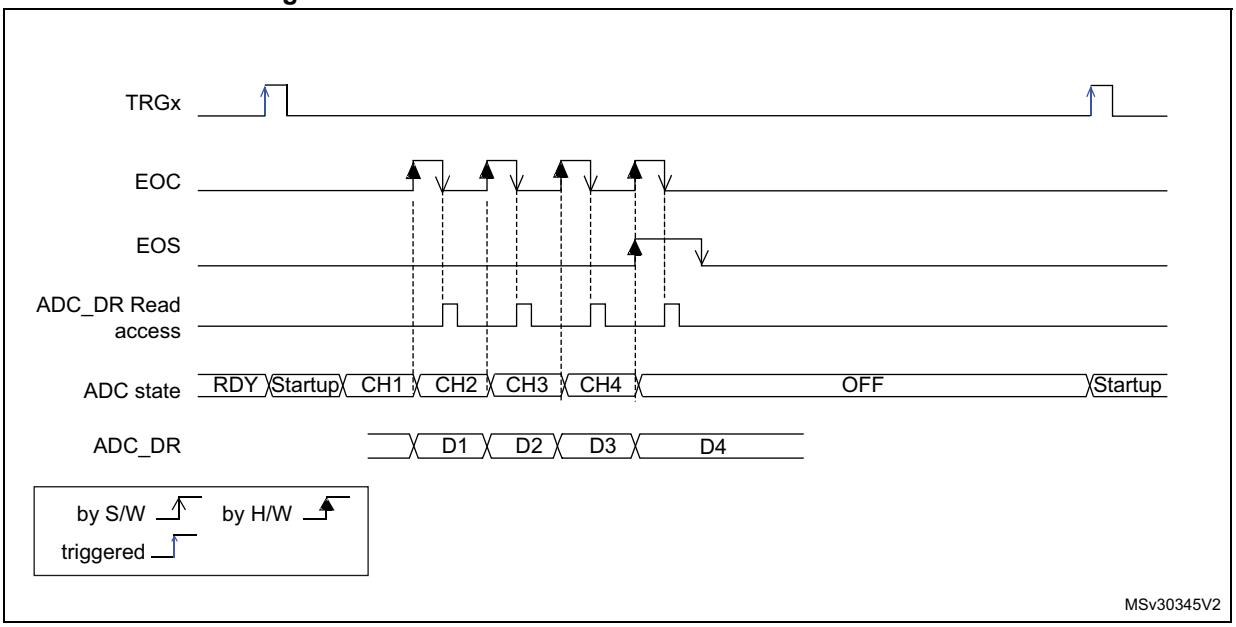
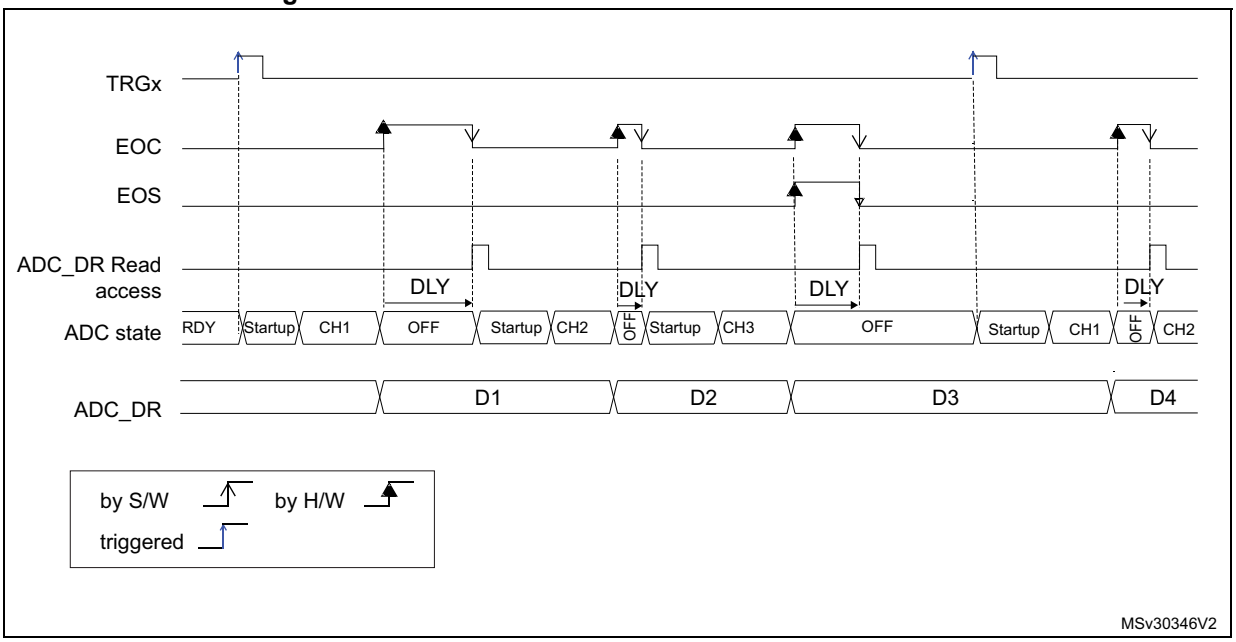


1. EXTSEL = TRGx, EXTEN = 01 (rising edge), CONT = x, ADSTART = 1, CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 1.

Figure 205. ADC behavior with WAIT = 1 and AUTOFF = 1



1. EXTSEL = TRGx, EXTEN = 01 (rising edge), CONT = x, ADSTART = 1, CHSEL = 0xF, SCANDIR = 0, WAIT = 1, AUTOFF = 1.

Autonomous mode (AUTOFF, DPD)

The Autonomous mode is enabled by setting both AUTOFF and DPD bits to 1 in ADC_PWRR register. In addition, the Autonomous mode must be enabled in the RCC.

Below the Autonomous mode operating sequence:

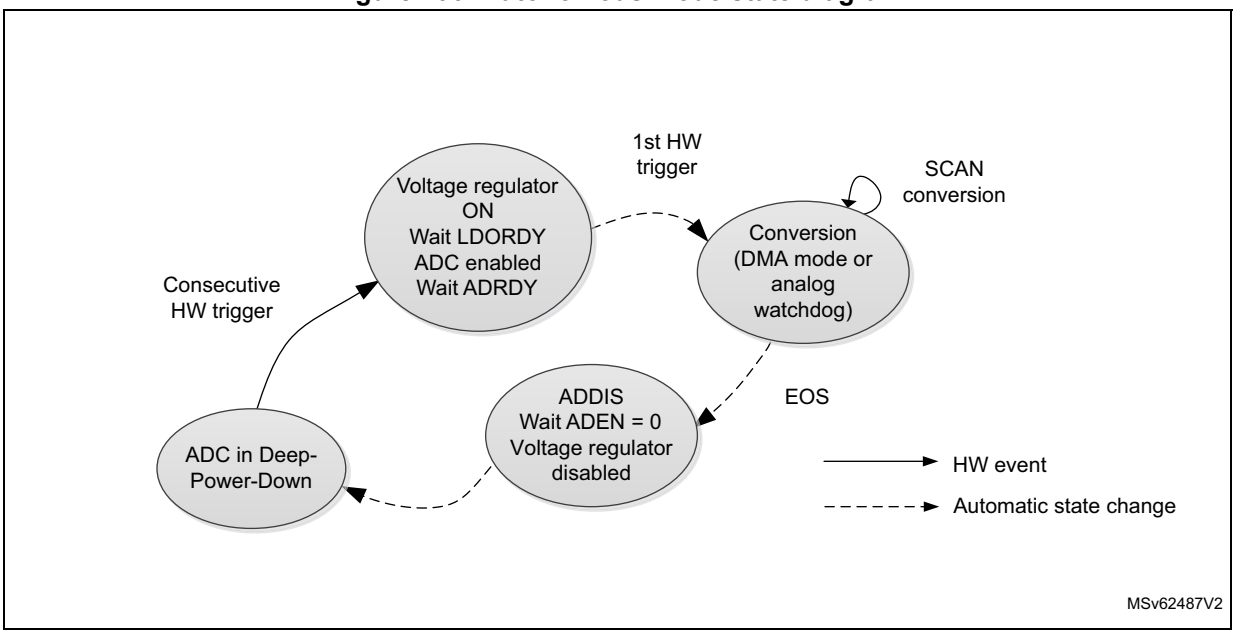
1. When AUTOFF and DPD are both set to 1, the ADC is powered off when no conversion is ongoing.
2. Upon hardware trigger reception, the ADC requests the adc_ker_ck and adc_hclk clocks to the RCC, the ADC voltage regulator is enabled, the calibration factor is loaded, the ADC is enabled and the conversion starts.
3. Once the ADC conversion is complete, the ADC can either generate an AWDx interrupt or a DMA request, depending on peripheral configuration:
   - When DMA mode is enabled, the ADC generates a DMA request to transfer data to memory or to another peripherals.
   - When an analog watchdog is enabled, ADC data do not need to be transferred. The analog watchdog compares the data to the threshold value and generates an AWDx interrupt to wake up the device if the data is under or over the programmed threshold.
4. When the ADC conversion/sequence or conversion is complete, the ADC and the ADC voltage regulator are automatically disabled as well as V_{REFINT} buffer and the temperature sensor, and further clock requests are deasserted. This allows the minimization of current consumption.
5. When consecutive hardware triggers occur, the ADC is automatically enabled and the conversion is processed.

Refer to *Figure 206* for a description of Autonomous mode state diagram.

The Autonomous mode enables the ADC peripheral to operate when the device is in Stop mode. However it can also be used in Run or Sleep mode.

It is compatible with the low-power background autonomous mode (LPBAM).

Figure 206. Autonomous mode state diagram



30.4.25 Analog window watchdog

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Description of analog watchdog 1

AWD1 analog watchdog is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. It is used to monitor that either one selected channel or all enabled channels (see *Table 258: Analog watchdog 1 channel selection*) remain within a configured voltage range (window) as shown in *Figure 207*.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in HT1[11:0] and LT1[11:0] bits of ADC_AWD1TR register. An interrupt can be enabled by setting the AWD1IE bit in the ADC_IER register.

The AWD1 flag is cleared by software by programing it to 1.

When converting data with a resolution of less than 12-bit (according to bits DRES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

Table 257 describes how the comparison is performed for all the possible resolutions.

Table 257. Analog watchdog comparison

Resolution bits RES[1:0]	Analog Watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
00: 12-bit	DATA[11:0]	LTx[11:0] and HTx[11:0]	-
01: 10-bit	DATA[11:2],00	LTx[11:0] and HTx[11:0]	The user must configure LTx[1:0] and HTx[1:0] to “00”
10: 8-bit	DATA[11:4],0000	LTx[11:0] and HTx[11:0]	The user must configure LTx[3:0] and HTx[3:0] to “0000”
11: 6-bit	DATA[11:6],000000	LTx[11:0] and HTx[11:0]	The user must configure LTx[5:0] and HTx[5:0] to “000000”

1. The watchdog comparison is performed on the raw converted data before any alignment calculation.

Table 258 shows how to configure the AWD1SGL and AWD1EN bits in the ADC_CFGR1 register to enable the analog watchdog on one or more channels.

Figure 207. Analog watchdog guarded area

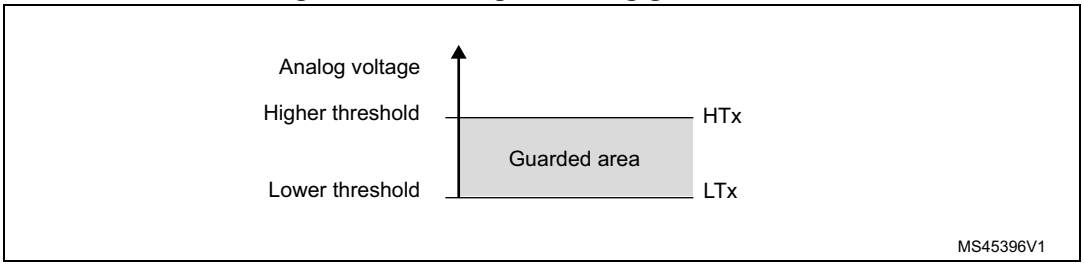


Table 258. Analog watchdog 1 channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit
None	x	0
All channels	0	1
Single(1) channel	1	1

1. Selected by the AWD1CH[4:0] bits

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the AWDxCHy in ADC_AWDxCR (x = 2, 3).

The corresponding watchdog is enabled when any AWDxCHy bit (x = 2,3) is set in ADC_AWDxCR register.

When converting data with a resolution of less than 12 bits (configured through DRES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

Table 257 describes how the comparison is performed for all the possible resolutions.

The AWD2/3 analog watchdog status bit is set if the analog voltage converted by the ADC is below a low threshold or above a high threshold. These thresholds are programmed in

HTx[11:0] and LTx[11:0] of ADC_AWDxTR registers (x = 2 or 3). An interrupt can be enabled by setting the AWDxIE bit in the ADC_IER register.

The AWD2 and AWD3 flags are cleared by software by programming them to 1.

ADC_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal, ADC_AWDx_OUT (x being the watchdog number) that is directly connected to the ETR input (external trigger) of some on-chip timers (refer to the timers section for details on how to select the ADC_AWDx_OUT signal as ETR).

ADC_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds. It remains at 1 if the next guarded conversions are still outside the programmed thresholds.
- ADC_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS to 1). Note that stopping conversions (ADSTP set to 1), might clear the ADC_AWDx_OUT state.
- ADC_AWDx_OUT state does not change when the ADC converts the none-guarded channel (see *Figure 210*)

AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADC_AWDx_OUT (as an example, ADC_AWDx_OUT can toggle while AWDx flag remains at 1 if the software has not cleared the flag).

The ADC_AWDx_OUT signal is generated by the ADC_CLK domain. This signal can be generated even the bus clock is stopped.

The AWD comparison is performed at the end of each ADC conversion. The ADC_AWDx_OUT rising edge and falling edge occurs two ADC_CLK clock cycles after the comparison.

As ADC_AWDx_OUT is generated by the ADC_CLK domain and AWD flag is generated by the bus clock domain, the rising edges of these signals are not synchronized.

Figure 208. ADC_AWDx_OUT signal generation

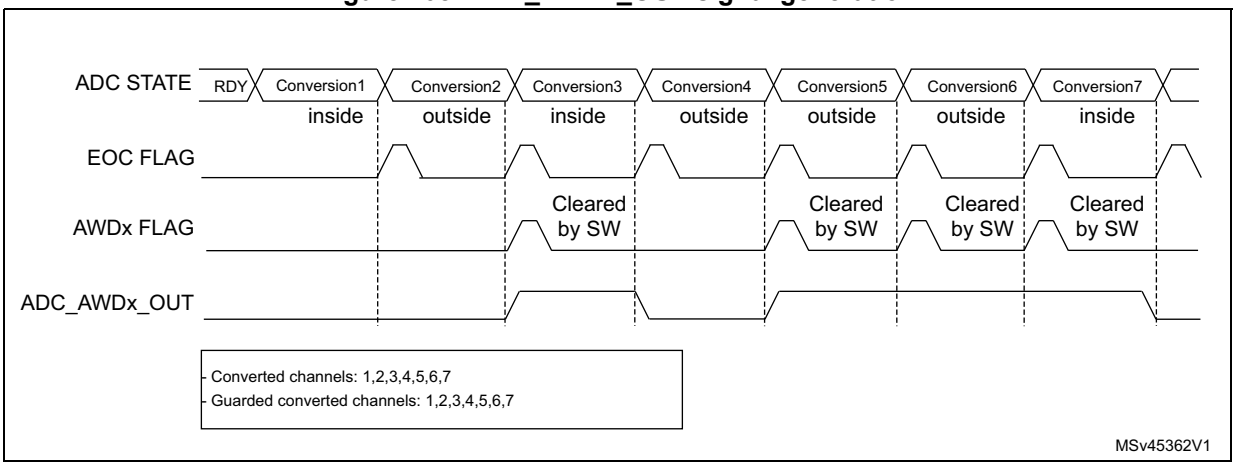

Figure 209. ADC_AWDx_OUT signal generation (AWDx flag not cleared by software)

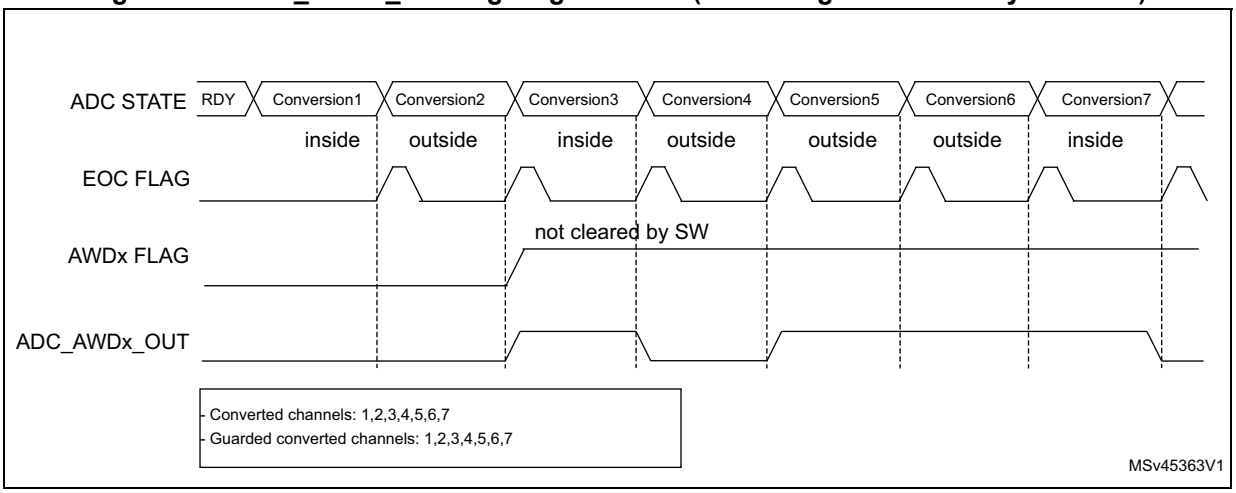

Figure 210. ADC_AWDx_OUT signal generation (on a single channel)

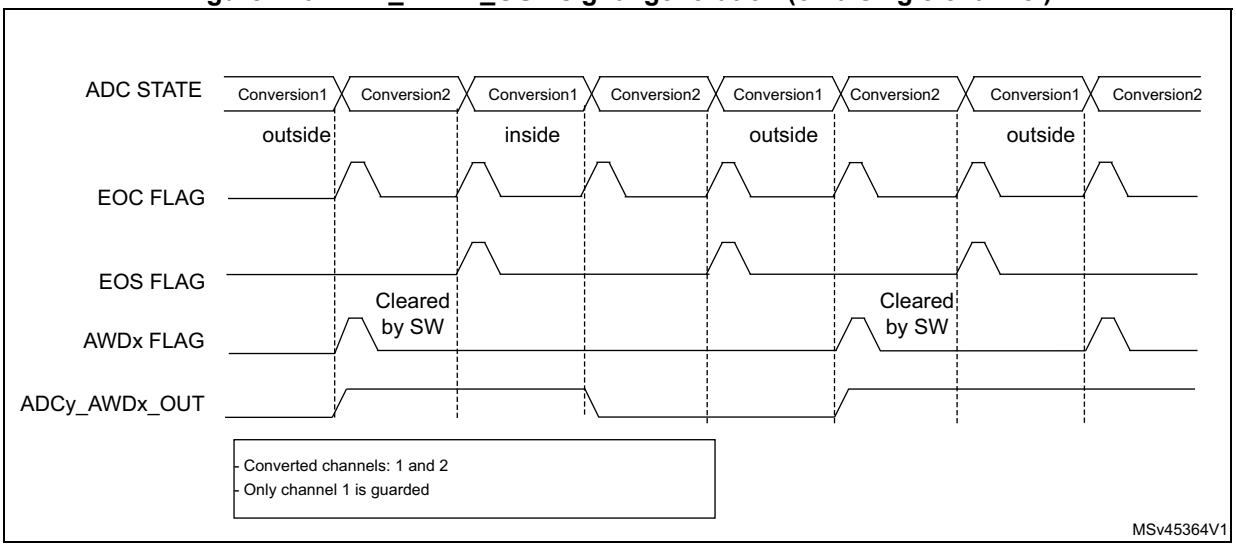
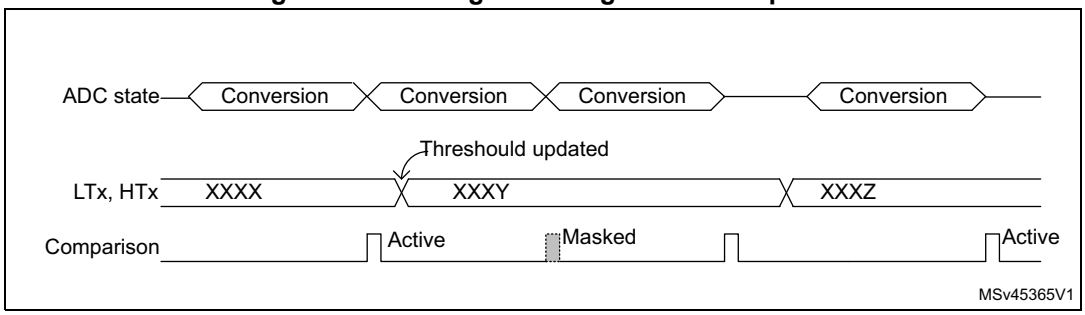


Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed during an analog-to-digital conversion (that is between the start of the conversion and the end of conversion of the ADC internal state). If HTx and LTx bits are programmed during the ADC guarded channel conversion, the watchdog function is masked for this conversion. This mask is cleared when starting a new conversion, and the resulting new AWD threshold is applied starting the next ADC conversion result. AWD comparison is performed at each end of conversion. If the current ADC data are out of the new threshold interval, this does not generated any interrupt or an ADC_AWDx_OUT signal. The Interrupt and the ADC_AWDx_OUT generation only occurs at the end of the ADC conversion that started after the threshold update. If ADC_AWDx_OUT is already asserted, programming the new threshold does not deassert the ADC_AWDx_OUT signal.

Figure 211. Analog watchdog threshold update



30.4.26 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It can handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

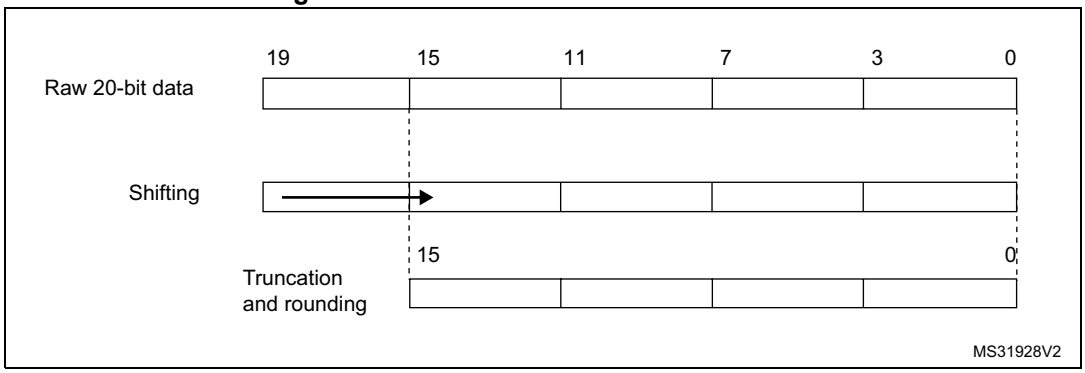
It allows the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register. It can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits. It is configured through the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256 x 12-bit), which is first shifted right. The lower bits of the result are then truncated, keeping only the 16 least significant bits rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

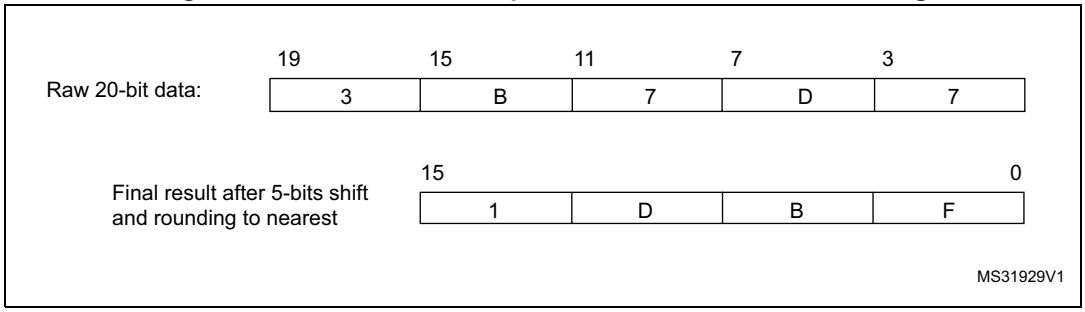
Note: If the intermediate result after the shifting exceeds 16 bits, the upper bits of the result are simply truncated.

Figure 212. 20-bit to 16-bit result truncation



The *Figure 213* gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 213. Numerical example with 5-bits shift and rounding



The *Table 259* below gives the data format for the various N and M combination, for a raw conversion data equal to 0xFFF.

Table 259. Maximum output results vs N and M. Grayed values indicates truncation

Oversampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS = 0111	8-bit shift OVSS = 1000
2x	0x1FFE	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040	0x0020
4x	0x3FFC	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040
8x	0x7FF8	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080

128x	0x7FF80	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800
256x	0xFFF00	0xFF00	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF

The conversion timings in oversampled mode do not change compared to standard conversion mode: the sample time is maintained equal during the whole oversampling sequence. New data are provided every N conversion, with an equivalent delay equal to N x t_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags features are raised as following:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- the end of sequence (EOCSEQ) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total)

ADC operating modes supported when oversampling

In oversampling mode, most of the ADC operating modes are available:

- Single or continuous mode conversions, forward or backward scanned sequences and up to 8 channels programmed sequence
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (WAIT, AUTOFF)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

Note: The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR1 is ignored and the data are always provided right-aligned.

Analog watchdog

The analog watchdog functionality is available (AWDxSGL, AWD1EN and AWDxCH bits), with the following differences:

- the RES[1:0] bits are ignored, comparison is always done on using the full 12-bits values HTx[11:0] and LTx[11:0]
- the comparison is performed on the most significant 12 bits of the 16 bits oversampled results ADC_DR[15:4]

Note: Care must be taken when using high shifting values. This reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[[7:0], and HTx[11:8] / LTx[11:8] must be kept reset.

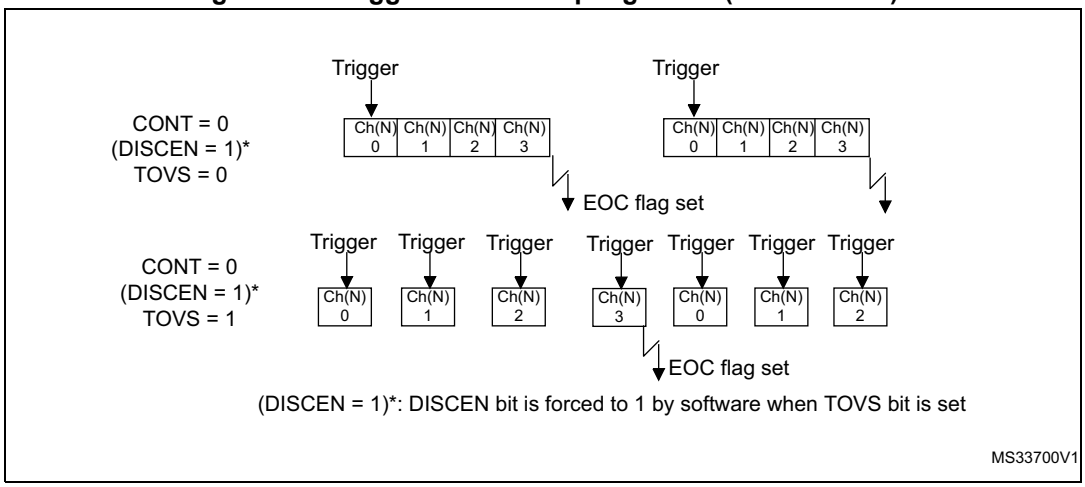
Triggered mode

The averager can also be used for basic filtering purposes. Although not a very efficient filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TOVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

Figure 214 below shows how conversions are started in response to triggers in discontinuous mode.

If the TOVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 214. Triggered oversampling mode (TOVS bit = 1)



30.4.27 Temperature sensor and internal reference voltage

The temperature sensor can be used to measure the junction temperature (T_J) of the device. The temperature sensor is internally connected an ADC internal input channel which is used to convert the sensor's output voltage to a digital value. The sampling time for the temperature sensor analog pin must be greater than the minimum T_{S_temp} value specified in the datasheet. When not in use, the sensor can be put in Power-down mode.

The internal voltage reference (V_{REFINT}) provides a stable (bandgap) voltage output for the ADC and the comparators.

Refer to Table *ADC interconnection* in *Section 30.4.2: ADC pins and internal signals* for details on the ADC internal input channel to which the above voltages are connected.

Figure 215 shows the block diagram of connections between the temperature sensor, the internal voltage reference and the ADC.

The VSENSESEL bit must be set to enable the conversion of V_{SENSE} while VREFEN bit must be set to enable the conversion of V_{REFINT}.

When the ADC operates in Autonomous mode, these signals are controlled automatically to reduce power consumption (VSENSESEL and VREFEN must be set to measure the voltage in Autonomous mode).

The temperature sensor output voltage linearly changes with the temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by STMicroelectronics during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference. Refer to the datasheet for additional information.

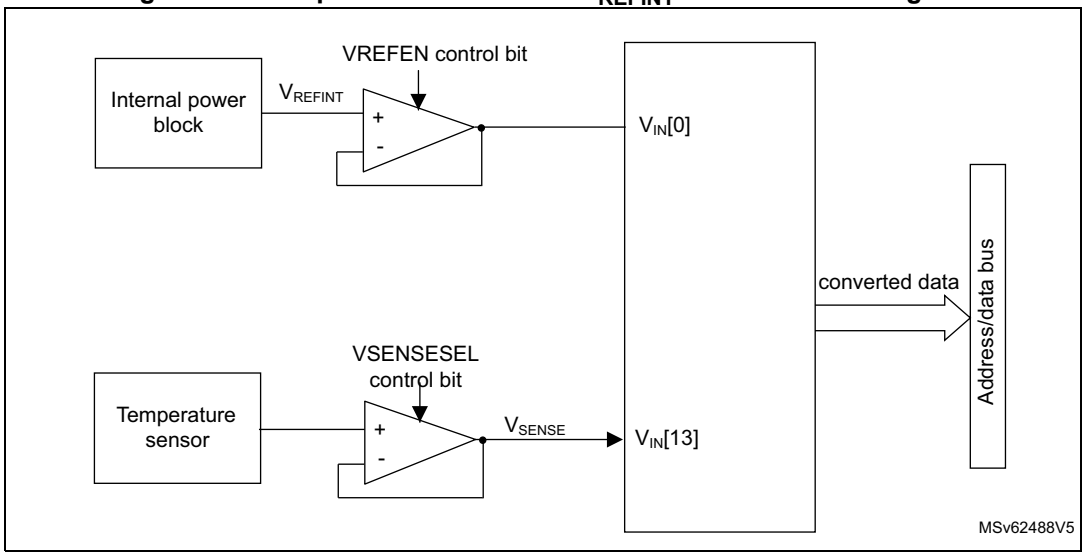
During the manufacturing process, the calibration data of the internal voltage reference are stored in the system memory area. The user application can then read them and use them

to improve the accuracy of the internal reference. Refer to the electrical characteristics section of the device datasheet for additional information.

Main features

- Linearity: ±2 °C max., precision depending on calibration

Figure 215. Temperature sensor and V_{REFINT} channel block diagram



Reading the temperature

1. Select the input channel connected to V_{SENSE} (refer to Table *ADC interconnection* in *Section 30.4.2: ADC pins and internal signals*).
2. Select an appropriate sampling time specified in the device datasheet (T_{S_temp}).
3. Set the VSENSESEL bit in the ADC_CCR register to wake up the temperature sensor from Power-down mode and wait for its stabilization time (t_{START}).
4. Start the ADC conversion by setting the ADSTART bit in the ADC_CR register (or by external trigger)
5. Read the resulting V_{SENSE} data in the ADC_DR register
6. Calculate the temperature using the following formula

$$\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + \text{TS\_CAL1\_TEMP}$$

Where:

– TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.

– TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.

– TS_DATA is the actual temperature sensor output value converted by the ADC.

Refer to *Section 30.3: ADC implementation* for more information on TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking up from Power-down mode before it can output V_{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and VSENSESEL bits must be set at the same time.

Calculating the actual V_{REF+} voltage using the internal reference voltage

The V_{DDA} power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference (VREFINT) and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} = 3.0 V can be used to evaluate the actual V_{REF+} voltage level, if VREF+ pin is connected to a variable V_{DDA} power supply.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = 3.0\ V \times VREFINT\_CAL / VREFINT\_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value
- VREFINT_DATA is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the voltage reference V_{REF+} and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent from V_{REF+}. For applications where V_{REF+} is known and ADC converted values are right-aligned, the following formula can be used to calculate this absolute value:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL\_SCALE} \times ADC\_DATA_x$$

For applications where V_{REF+} value is not known, the internal voltage reference and V_{REF+} can be replaced by the expression provided in *Section : Calculating the actual V_{REF+} voltage using the internal reference voltage*, resulting in the following formula:

$$V_{CHANNELx} = \frac{3.0\ V \times VREFINT\_CAL \times ADC\_DATA_x}{VREFINT\_DATA \times FULL\_SCALE}$$

Where:

- VREFINT_CAL is the VREFINT calibration value (refer to *Section 30.3: ADC implementation* for the value of VREFINT_CAL).
- ADC_DATA_x is the value measured by the ADC on channelx (right-aligned).
- VREFINT_DATA is the actual VREFINT output value converted by the ADC.
- FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, it is 2^{12} - 1 = 4095 or with 8-bit resolution, 2^8 - 1 = 255.

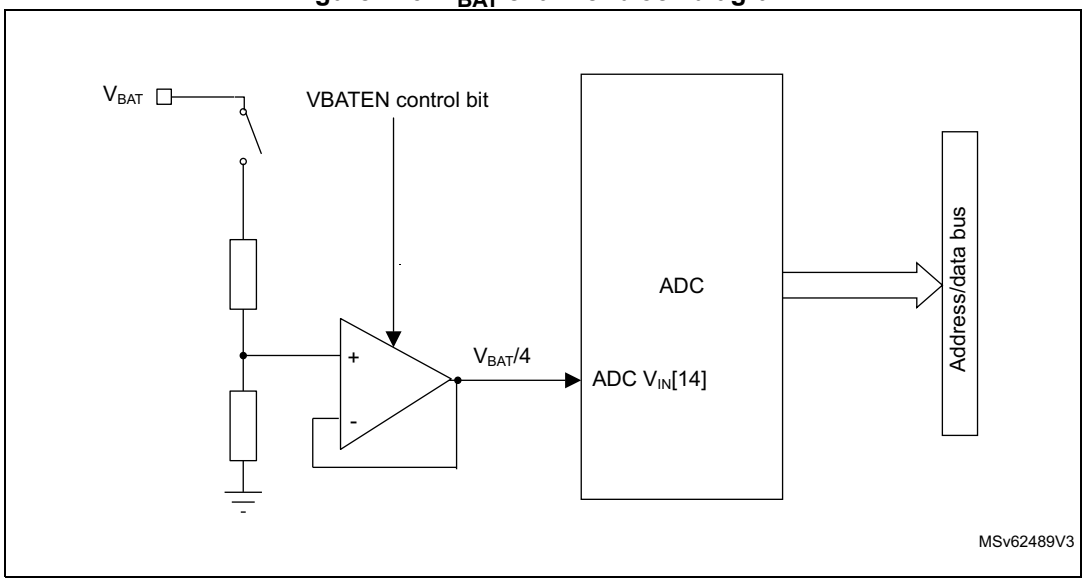
Note: If ADC measurements are done using an output format other than 12 bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

30.4.28 Battery voltage monitoring

The VBATEN bit in the ADC_CCR register allows the application to measure the battery voltage on the VBAT pin. As the V_{BAT} voltage could be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4.

This bridge is automatically enabled when VBATEN is set, to connect V_{BAT}/4 to the corresponding ADC input channel (refer to Table ADC interconnection in *Section 30.4.2: ADC pins and internal signals*). As a consequence, the converted digital value is half the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only during ADC conversion.

Figure 216. V_{BAT} channel block diagram



30.4.29 Concurrent operation with another ADC

When ADC4 is used simultaneously with another ADC (let us call it ADCx, x being different from 4), ADCx operation might generate noise on V_{REF+} voltage. Since V_{REF+} is also ADC4 reference voltage, this might cause conversion errors. To prevent this issue from happening, set VREFPROTEN bit in ADC_PWRR register. As soon as ADCx sampling phase starts, ADC4 is put on hold during one ADC4 clock cycle, thus resulting in ADC4 conversion time to be longer of one clock cycle.

In addition, ADCx might have two sampling phases during ADC4 conversion. This is due to the injected conversion function of ADCx. By setting VREFSECSMP to 1 in ADC_PWRR, ADC4 operation can be held twice during the conversion phase. When VREFSECSMP bit is set, ADC4 conversion time is longer of two clock cycles.

VREFSECSMP and VREFPROTEN bits must be set simultaneously.

ADCx and ADC4 must use the same clock source to be able to use the concurrent operation feature.

It is recommended to use this function when ADC4 works at a frequency greater or equal than ADCx.

30.5 ADC low-power modes

Table 260. Effect of low-power modes on the ADC

Mode	Description
Sleep	No effect, DMA requests are functional. ADC interrupts cause the device to exit Sleep mode.
Stop	The content of the ADC register is kept. ADC can be functional. DMA request are functional, and the interrupt cause the device to exit Stop mode.
Standby	The ADC peripheral is powered down and must be reinitialized after exiting Standby mode.

30.6 ADC interrupts

An interrupt can be generated by any of the following events:

- End of calibration (EOCAL flag)
- ADC power-up, when the ADC is ready (ADRDY flag)
- End of any conversion (EOC flag)
- End of a sequence of conversions (EOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2, AWD3 flags)
- When the end of sampling phase occurs (EOSMP flag)
- when a data overrun occurs (OVR flag)
- LDO ready, when LDO output is stabilized (LDORDY flag)

Separate interrupt enable bits are available for flexibility.

Table 261. ADC wakeup and interrupt requests

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop mode(1)	Exit from Standby mode
ADC	LDO ready	LDORDY	LDORDYIE	Program LDORDY to 1	Yes	Yes	No
	End of calibration	EOCAL	EOCALIE	Program EOCAL to 1		Yes	
	ADC ready	ADRDY	ADRDYIE	Program ADRDY to 1		Yes	
	End of conversion	EOC	EOCIE	Program EOC to 1 and red ADC_DR		Yes	
	End of sequence of conversions	EOS	EOSIE	Program EOS to 1		Yes	
	Analog watchdog 1 status bit is set	AWD1	AWD1IE	Program AWD1 to 1		Yes	
	Analog watchdog 2 status bit is set	AWD2	AWD2IE	Program AWD2 to 1		Yes	
	Analog watchdog 3 status bit is set	AWD3	AWD3IE	Program AWD2 to 1		Yes	
	End of sampling phase	EOSMP	EOSMPIE	Program EOSMP to 1		No	
	Overrun	OVR	OVRIE	Program OVR to 1		Yes	

1. The ADC can wake up the device from Stop mode only if the peripheral instance supports the Wakeup from Stop mode feature. Refer to *Section 30.3: ADC implementation* for the list of supported Stop modes.

30.7 ADC registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

30.7.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDO RDY	EOCAL	Res.	AWD3	AWD2	AWD1	Res.	Res.	OVR	EOS	EOC	EOSMP	ADRDY
			rc_w1	rc_w1		rc_w1	rc_w1	rc_w1			rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY**: LDO ready
This bit is set by hardware. It indicates that the ADC internal LDO output is ready.
It is cleared by software by writing 1 to it.
0: ADC voltage regulator disabled
1: ADC voltage regulator enabled and stabilized

Bit 11 **EOCAL**: End of calibration flag
This bit is set by hardware when calibration is complete. It is cleared by software writing 1 to it.
0: Calibration is not complete
1: Calibration is complete

Bit 10 Reserved, must be kept at reset value.

Bit 9 **AWD3**: Analog watchdog 3 flag
This bit is set by hardware when the converted voltage crosses the values programmed in ADC_AWD3TR and ADC_AWD3TR registers. It is cleared by software by writing 1 to it.
0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag
This bit is set by hardware when the converted voltage crosses the values programmed in ADC_AWD2TR and ADC_AWD2TR registers. It is cleared by software writing 1 to it.
0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag
This bit is set by hardware when the converted voltage crosses the values programmed in ADC_TR1 and ADC_HR1 registers. It is cleared by software by writing 1 to it.
0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog event occurred

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs, meaning that a new conversion has complete while the EOC flag was already set. It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of sequence flag

This bit is set by hardware at the end of the conversion of a sequence of channels selected by the CHSEL bits. It is cleared by software writing 1 to it.

0: Conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Conversion sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each conversion of a channel when a new data result is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.

0: Channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion, at the end of the sampling phase.It is cleared by software by writing 1 to it.

0: Not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

30.7.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDYIE	EOCALIE	Res.	AWD3IE	AWD2IE	AWD1IE	Res.	Res.	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
			rw	rw		rw	rw	rw			rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDYIE**: LDO ready interrupt enable

This bit is set and cleared by software. It is used to enable/disable the LDORDY interrupt.

0: LDO ready interrupt disabled

1: LDO ready interrupt enabled. An interrupt is generated when the LDO output is ready.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensure that no conversion is ongoing).

Bit 11 **EOCALIE**: End of calibration interrupt enable

This bit is set and cleared by software to enable/disable the end of calibration interrupt.

0: End of calibration interrupt disabled

1: End of calibration interrupt enabled

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt.

0: Analog watchdog interrupt disabled

1: Analog watchdog interrupt enabled

Note: The Software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt.

0: Analog watchdog interrupt disabled

1: Analog watchdog interrupt enabled

Note: The Software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt.

0: Analog watchdog interrupt disabled

1: Analog watchdog interrupt enabled

Note: The Software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the overrun interrupt.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 3 **EOSIE**: End of conversion sequence interrupt enable

This bit is set and cleared by software to enable/disable the end of sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 2 **EOCIE**: End of conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of conversion interrupt.

0: EOC interrupt disabled

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled.

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

30.7.3 ADC control register (ADC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	Res.	Res.	ADVREGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs			rw												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADSTP	Res.	ADSTART	ADDIS	ADEN
											rs		rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the calibration of the ADC.

It is cleared by hardware after calibration is complete.

0: Calibration complete

1: Write 1 to calibrate the ADC. Read at 1 means that a calibration is in progress.

Note: The software is allowed to set ADCAL only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0, AUTOFF = 0, and ADEN = 0).

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN is set to 1 and ADSTART is cleared to 0 by writing ADSTP to 1 (ADC enabled and no conversion is ongoing).

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bit is set by software, to enable the ADC internal voltage regulator. The voltage regulator output is available after $t_{ADCVREG\_SETUP}$.

It is cleared by software to disable the voltage regulator. It can be cleared only if ADEN is et to 0.

0: ADC voltage regulator disabled

1: ADC voltage regulator enabled

Note: The software is allowed to program this bit field only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:5 Reserved, must be kept at reset value.

Bit 4 **ADSTP**: ADC stop conversion command

This bit is set by software to stop and discard an ongoing conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC is ready to accept a new start conversion command.

0: No ADC stop conversion command ongoing

1: Write 1 to stop the ADC. Read 1 means that an ADSTP command is in progress.

Note: To clear the A/D converter state, ADSTP must be set to 1 even if ADSTART is cleared to 0 after the software trigger A/D conversion. It is recommended to set ADSTP to 1 whenever the configuration needs to be modified.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ADSTART**: ADC start conversion command

This bit is set by software to start ADC conversion. Depending on the EXTEN [1:0] configuration bits, a conversion either starts immediately (software trigger configuration) or once a hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– In single conversion mode (CONT = 0, DISCEN = 0), when software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion Sequence (EOS) flag.

– In discontinuous conversion mode(CONT=0, DISCEN = 1), when the software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion (EOC) flag.

– In all other cases: after the execution of the ADSTP command, at the same time as the ADSTP bit is cleared by hardware.

0: No ADC conversion is ongoing.

1: Write 1 to start the ADC. Read 1 means that the ADC is operating and may be converting.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: No ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: Setting ADDIS to 1 is only effective when ADEN = 1 and ADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable command

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, ADSTP = 0, ADSTART = 0, ADDIS = 0 and ADEN = 0)

30.7.4 ADC configuration register 1 (ADC_CFGR1)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AWD1CH[4:0]					Res.	Res.	AWD1EN	AWD1SGL	CHSELRMOD	Res.	Res.	Res.	Res.	DISCEN
	rw	rw	rw	rw	rw			rw	rw	rw					rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	WAIT	CONT	OVRMOD	EXTEN[1:0]		Res.	EXTSEL[2:0]			ALIGN	SCANDIR	RES[1:0]		DMACFG	DMAEN
	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input Channel 0 monitored by AWD

00001: ADC analog input Channel 1 monitored by AWD

.....

10001: ADC analog input Channel 17 monitored by AWD

10110: ADC analog input Channel 22 monitored by AWD

10111: ADC analog input Channel 23 monitored by AWD

Others: Reserved

Note: The channel selected by the AWDCH[4:0] bits must be also set into the CHSELR register. The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 25:24 Reserved, must be kept at reset value.

Bit 23 **AWD1EN**: Analog watchdog enable

This bit is set and cleared by software.

0: Analog watchdog **1** disabled

1: Analog watchdog **1** enabled

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWDCH[4:0] bits or on all the channels

0: Analog watchdog **1** enabled on all channels

1: Analog watchdog **1** enabled on a single channel

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 21 **CHSELRMOD**: Mode selection of the ADC_CHSELR register

This bit is set and cleared by software to control the ADC_CHSELR feature:

0: Each bit of the ADC_CHSELR register enables an input

1: ADC_CHSELR register is able to sequence up to 8 channels

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **DISCEN**: Discontinuous mode

This bit is set and cleared by software to enable/disable discontinuous mode.

0: Discontinuous mode disabled

1: Discontinuous mode enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WAIT**: Wait conversion mode

This bit is set and cleared by software to enable/disable wait conversion mode.

0: Wait conversion mode off

1: Wait conversion mode on

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 13 **CONT**: Single / continuous conversion mode

This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 12 **OVRMOD**: Overrun management mode

This bit is set and cleared by software and configure the way data overruns are managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection

These bits are set and cleared by software to select the external trigger polarity and enable the trigger.

00: Hardware trigger detection disabled (conversions can be started by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 9 Reserved, must be kept at reset value.

Bits 8:6 **EXTSEL[2:0]**: External trigger selection

These bits select the external event used to trigger the start of conversion (refer to table *ADC interconnection* in *Section 30.4.2: ADC pins and internal signals* for details):

000: adc_trg0
001: adc_trg1
010: adc_trg2
011: adc_trg3
100: adc_trg4
101: adc_trg5
110: adc_trg6
111: adc_trg7

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 5 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to *Figure 200: Data alignment and resolution (oversampling disabled: OVSE = 0) on page 1105*

0: Right alignment
1: Left alignment

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 4 **SCANDIR**: Scan sequence direction

This bit is set and cleared by software to select the direction in which the channels is scanned in the sequence. It is effective only if CHSELRMOD bit is cleared to 0.

0: Upward scan (from CHSEL0 to CHSEL23)
1: Backward scan (from CHSEL23 to CHSEL0)

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12 bits
01: 10 bits
10: 8 bits
11: 6 bits

Note: The software is allowed to write these bits only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 1 **DMACFG**: Direct memory access configuration

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.

0: DMA one shot mode selected

1: DMA circular mode selected

For more details, refer to *Section : Managing converted data using the DMA on page 1106*

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 0 **DMAEN**: Direct memory access enable

This bit is set and cleared by software to enable the generation of DMA requests. This allows the automatic management of the converted data by the DMA controller. For more details, refer to *Section : Managing converted data using the DMA on page 1106*.

0: DMA disabled

1: DMA enabled

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

30.7.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	TOVS	OVSS[3:0]				OVSR[2:0]			Res.	OVSE
						rw	rw	rw	rw	rw	rw	rw	rw		rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **LFTRIG**: Low frequency trigger mode enable

This bit must be set by software.

0: Reserved

1: Low frequency trigger mode enabled.

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 28:10 Reserved, must be kept at reset value.

Bit 9 **TOVS**: Triggered *Oversampling*

This bit is set and cleared by software.

0: All oversampled conversions for a channel are done consecutively after a trigger

1: Each oversampled conversion for a channel needs a trigger

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: *Oversampling shift*

This bit is set and cleared by software.

0000: No shift

0001: Shift 1-bit

0010: Shift 2-bits

0011: Shift 3-bits

0100: Shift 4-bits

0101: Shift 5-bits

0110: Shift 6-bits

0111: Shift 7-bits

1000: Shift 8-bits

Others: Reserved

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1(which ensures that no conversion is ongoing).

Bits 4:2 **OVSR[2:0]**: *Oversampling ratio*

This bit filed defines the number of oversampling ratio.

000: 2x

001: 4x

010: 8x

011: 16x

100: 32x

101: 64x

110: 128x

111: 256x

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bit 1 Reserved, must be kept at reset value.

Bit 0 **OVSE**: *Oversampler Enable*

This bit is set and cleared by software.

0: Oversampler disabled

1: Oversampler enabled

Note: Software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

30.7.6 ADC sampling time register (ADC_SMPR)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SMPSEL23	SMPSEL22	SMPSEL21	SMPSEL20	SMPSEL19	SMPSEL18	SMPSEL17	SMPSEL16	SMPSEL15	SMPSEL14	SMPSEL13	SMPSEL12	SMPSEL11	SMPSEL10	SMPSEL9	SMPSEL8
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPSEL7	SMPSEL6	SMPSEL5	SMPSEL4	SMPSEL3	SMPSEL2	SMPSEL1	SMPSEL0	Res.	SMP2[2:0]			Res.	SMP1[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw		rw	rw	rw

Bits 31:8 **SMPSELx:** Channel-x sampling time selection (x = 23 to 0)

These bits are written by software to define which sampling time is used.

0: Sampling time of CHANNELx use the setting of SMP1[2:0] register.

1: Sampling time of CHANNELx use the setting of SMP2[2:0] register.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SMP2[2:0]:** Sampling time selection 2

These bits are written by software to select the sampling time that applies to all channels.

000: 1.5 ADC clock cycles

001: 3.5 ADC clock cycles

010: 7.5 ADC clock cycles

011: 12.5 ADC clock cycles

100: 19.5 ADC clock cycles

101: 39.5 ADC clock cycles

110: 79.5 ADC clock cycles

111: 814.5 ADC clock cycles

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SMP1[2:0]:** *Sampling time selection 1*

These bits are written by software to select the sampling time that applies to all channels.

000: 1.5 ADC clock cycles

001: 3.5 ADC clock cycles

010: 7.5 ADC clock cycles

011: 12.5 ADC clock cycles

100: 19.5 ADC clock cycles

101: 39.5 ADC clock cycles

110: 79.5 ADC clock cycles

111: 814.5 ADC clock cycles

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

30.7.7 ADC watchdog threshold register (ADC_AWD1TR)

Address offset: 0x20

Reset value: 0x0FFF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HT1[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	LT1[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT1[11:0]**: Analog watchdog 1 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog.
Refer to *Section 30.4.25: Analog window watchdog on page 1112*.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **LT1[11:0]**: Analog watchdog *1* lower threshold
These bits are written by software to define the lower threshold for the analog watchdog.
Refer to *Section 30.4.25: Analog window watchdog on page 1112*.

30.7.8 ADC watchdog threshold register (ADC_AWD2TR)

Address offset: 0x24

Reset value: 0x0FFF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HT2[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	LT2[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT2[11:0]**: Analog watchdog 2 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog.
Refer to *Section 30.4.25: Analog window watchdog on page 1112*.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **LT2[11:0]**: Analog watchdog 2 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog.
Refer to *Section 30.4.25: Analog window watchdog on page 1112*.

30.7.9 ADC channel selection register [alternate] (ADC_CHSELR)

Address offset: 0x28

Reset value: 0x0000 0000

The same register can be used in two different modes:

– Each ADC_CHSELR bit enables an input (CHSELRMOD = 0 in ADC_CFGR1). Refer to the current section.

– ADC_CHSELR is able to sequence up to 8 channels (CHSELRMOD = 1 in ADC_CFGR1). Refer to next section.

CHSELRMOD = 0 in ADC_CFGR1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CHSEL 23	CHSEL 22	CHSEL 21	CHSEL 20	CHSEL 19	CHSEL 18	CHSEL 17	CHSEL 16
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CHSEL 15	CHSEL 14	CHSEL 13	CHSEL 12	CHSEL 11	CHSEL 10	CHSEL 9	CHSEL 8	CHSEL 7	CHSEL 6	CHSEL 5	CHSEL 4	CHSEL 3	CHSEL 2	CHSEL 1	CHSEL 0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **CHSELx**: Channel x selection (x = 23 to 0)

These bits are written by software and define which channels are part of the sequence of channels to be converted.

0: Input Channel-x is not selected for conversion

1: Input Channel-x is selected for conversion

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

30.7.10 ADC channel selection register [alternate] (ADC_CHSELR)

Address offset: 0x28

Reset value: 0x0000 0000

The same register can be used in two different modes:

– Each ADC_CHSELR bit enables an input (CHSELRMOD = 0 in ADC_CFGR1). Refer to the current previous section.

– ADC_CHSELR is able to sequence up to 8 channels (CHSELRMOD = 1 in ADC_CFGR1). Refer to this section.

CHSELRMOD = 1 in ADC_CFGR1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SQ8[3:0]				SQ7[3:0]				SQ6[3:0]				SQ5[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **SQ8[3:0]**: 8th conversion of the sequence

These bits are programmed by software with the channel number assigned to the 8th conversion of the sequence. 0b1111 indicates the end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

0000: CH0

0001: CH1

...

1010: CH10

1011: CH11

1100: CH12

1101: CH13

1110: CH14

1111: No channel selected (End of sequence)

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 27:24 **SQ7[3:0]**: 7th conversion of the sequence

These bits are programmed by software with the channel number assigned to the 7th conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 23:20 **SQ6[3:0]**: 6th conversion of the sequence

These bits are programmed by software with the channel number assigned to the 6th conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 19:16 **SQ5[3:0]**: 5th conversion of the sequence

These bits are programmed by software with the channel number assigned to the 5th conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 15:12 **SQ4[3:0]**: 4th conversion of the sequence

These bits are programmed by software with the channel number assigned to the 4th conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1(which ensures that no conversion is ongoing).

Bits 11:8 **SQ3[3:0]**: 3rd conversion of the sequence

These bits are programmed by software with the channel number assigned to the 3rd conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 7:4 **SQ2[3:0]**: 2nd conversion of the sequence

These bits are programmed by software with the channel number assigned to the 2nd conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 3:0 **SQ1[3:0]**: 1st conversion of the sequence

These bits are programmed by software with the channel number assigned to the 1st conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

30.7.11 ADC watchdog threshold register (ADC_AWD3TR)

Address offset: 0x2C

Reset value: 0x0FFF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HT3[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	LT3[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT3[11:0]**: *Analog watchdog 3 higher threshold*

These bits are written by software to define the higher threshold for the analog watchdog.

Refer to *Section 30.4.25: Analog window watchdog on page 1112*.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **LT3[11:0]**: Analog watchdog *3*lower threshold

These bits are written by software to define the lower threshold for the analog watchdog.

Refer to *Section 30.4.25: Analog window watchdog on page 1112*.

30.7.12 ADC data register (ADC_DR)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA[15:0]**: Converted data

These bits are read-only. They contain the conversion result from the last converted channel. The data are left- or right-aligned as shown in *Figure 200: Data alignment and resolution (oversampling disabled: OVSE = 0) on page 1105*.

Just after a calibration is complete, DATA[6:0] contains the calibration factor.

30.7.13 ADC power register (ADC_PWRR)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VREFSECSMP	VREFPROT	DPD	AUTOFF
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **VREFSECSMP**: V_{REF+} second sample bit

This bit is set and cleared by software. It is used to enable/disable the second V_{REF+} protection when multiple ADCs are working simultaneously and a clock divider of 1 is used.

0: V_{REF+} second sample disabled

1: V_{REF+} second sample enabled

Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).

Bit 2 **VREFPROT**: V_{REF+} protection bit

This bit is set and cleared by software. It is used to enable/disable V_{REF+} protection when multiple ADCs are working simultaneously and a clock divider is used.

0: V_{REF+} protection disabled

1: V_{REF+} protection enabled

Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).

Bit 1 **DPD**: Deep-power-down mode bit

This bit is set and cleared by software. It is used to enable/disable Deep-power-down mode in Autonomous mode when the ADC is not used.

0: Deep-power-down mode disabled

1: Deep-power-down mode enabled

Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).

Setting DPD in Auto-off mode automatically disables the LDO.

Bit 0 **AUTOFF**: Auto-off mode bit

This bit is set and cleared by software. it is used to enable/disable the Auto-off mode.

0: Auto-off mode disabled

1: Auto-off mode enabled

Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).

30.7.14 ADC Analog Watchdog 2 Configuration register (ADC_AWD2CR)

Address offset: 0xA0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWD2 CH23	AWD2 CH22	AWD2 CH21	AWD2 CH20	AWD2 CH19	AWD2 CH18	AWD2 CH17	AWD2 CH16
								rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **AWD2CHx:** Analog watchdog channel selection (x = 23 to 0)

These bits are set and cleared by software. They enable and select the input channels to be guarded by analog watchdog 2 (AWD2).

0: ADC analog channel-x is not monitored by AWD2

1: ADC analog channel-x is monitored by AWD2

Note: The channels selected through ADC_AWD2CR must be also configured into the ADC_CHSELR registers. Refer to SQ8[3:0] for a definition of channel selection. The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

30.7.15 ADC Analog Watchdog 3 Configuration register (ADC_AWD3CR)

Address offset: 0xA4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWD3 CH23	AWD3 CH22	AWD3 CH21	AWD3 CH20	AWD3 CH19	AWD3 CH18	AWD3 CH17	AWD3 CH16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **AWD3CHx:** Analog watchdog channel selection (x = 23 to 0)

These bits are set and cleared by software. They enable and select the input channels to be guarded by analog watchdog 3 (AWD3).

0: ADC analog channel-x is not monitored by AWD3

1: ADC analog channel-x is monitored by AWD3

Note: The channels selected through ADC_AWD3CR must be also configured into the ADC_CHSELR registers. Refer to SQ8[3:0] for a definition of channel selection. The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

30.7.16 ADC Calibration factor (ADC_CALFACT)

Address offset: 0xC4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT[6:0]**: Calibration factor

These bits are written by hardware or by software.

– Once a calibration is complete, they are updated by hardware with the calibration factors.

– Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new calibration is launched.

– Just after a calibration is complete, DATA[6:0] contains the calibration factor.

Note: Software can write these bits only when ADEN = 1 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

30.7.17 ADC option register (ADC_OR)

Address offset: 0xD0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CHN21 SEL
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **CHN21SEL**: Channel 21 selection bit

This bit is set and cleared by software. It is used to select the internal source connected to ADC input channel 21:

0: dac1_out1 selected

1: dac1_out2 selected

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 = 0 (which ensures that no conversion is ongoing).

30.7.18 ADC common configuration register (ADC_CCR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBAT EN	VSENSE SEL	VREF EN	PRESC[3:0]				Res.	Res.
							rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: V_{BAT} enable

This bit is set and cleared by software to enable/disable the V_{BAT} channel.

0: V_{BAT} channel disabled

1: V_{BAT} channel enabled

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing)

Bit 23 **VSENSESEL**: Temperature sensor selection

This bit is set and cleared by software to enable/disable the temperature sensor.

0: Temperature sensor disabled

1: Temperature sensor enabled

Note: Software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bit 22 **VREFEN**: V_{REFINT} enable

This bit is set and cleared by software to enable/disable the V_{REFINT} buffer.

0: V_{REFINT} disabled

1: V_{REFINT} enabled

Note: Software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 21:18 **PRESC[3:0]:** ADC prescaler

Set and cleared by software to select the frequency of the clock to the ADC.

0000: input ADC clock not divided
0001: input ADC clock divided by 2
0010: input ADC clock divided by 4
0011: input ADC clock divided by 6
0100: input ADC clock divided by 8
0101: input ADC clock divided by 10
0110: input ADC clock divided by 12
0111: input ADC clock divided by 16
1000: input ADC clock divided by 32
1001: input ADC clock divided by 64
1010: input ADC clock divided by 128
1011: input ADC clock divided by 256
Other: Reserved

Note: Software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 17:0 Reserved, must be kept at reset value.

30.8 ADC register map

The following table summarizes the ADC registers.

Table 262. ADC register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 115* for the register boundary addresses.

31 Digital-to-analog converter (DAC)

31.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, V_{REF+} (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to *voltage reference buffer (VREFBUF)* section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

31.2 DAC main features

The DAC main features are the following (see *Figure 217: Dual-channel DAC block diagram*)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Autonomous mode to reduce the power consumption for the system
- Input voltage reference from V_{REF+} pin or internal VREFBUF reference

Figure 217 shows the block diagram of a DAC channel and *Table 264* gives the pin description.

31.3 DAC implementation

Table 263. DAC features

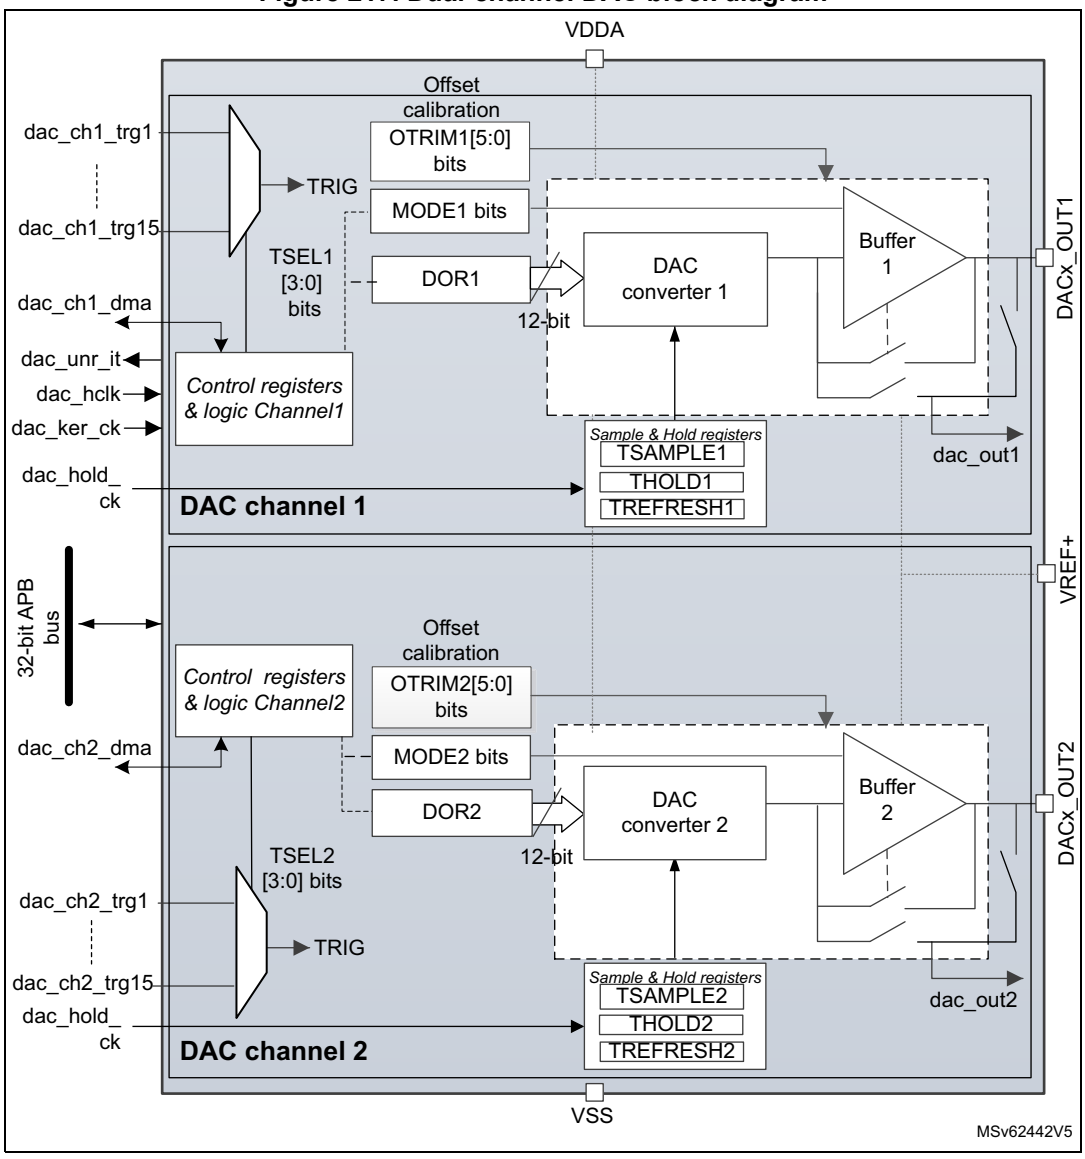
DAC features	DAC1
Dual channel	X
Output buffer	X
I/O connection	DAC1_OUT1 on PA4, DAC1_OUT2 on PA5
Maximum sampling time	1 MSPS
Autonomous mode(1)	X
VREF+ pin	X

1. The Autonomous mode is supported in Stop 0, Stop 1 and Stop 2 modes.

31.4 DAC functional description

31.4.1 DAC block diagram

Figure 217. Dual-channel DAC block diagram



1. MODEx bits in the DAC_MCR control the output mode and the switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.
2. Refer to *Section 31.3: DAC implementation* for channel2 availability.

31.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI or LSE clock source (dac_hold_ck).

Table 264. DAC input/output pins

Pin name	Signal type	Remarks
VREF+	Input, analog reference positive	The higher/positive reference voltage for the DAC, $V_{REF+} \leq V_{DDAmax}$ (refer to datasheet)
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply
DACx_OUTy	Analog output signal	DACx channely analog output

Table 265. DAC internal input/output signals

Internal signal name	Signal type	Description
dac_ch1_dma	Bidirectional	DAC channel1 DMA request/acknowledge
dac_ch2_dma	Bidirectional	DAC channel2 DMA request/acknowledge
dac_ch1_trgx (x = 1 to 15)	Inputs	DAC channel1 trigger inputs
dac_ch2_trgx (x = 1 to 15)	Inputs	DAC channel2 trigger inputs
dac_unr_it	Output	DAC underrun interrupt
dac_hclk	Input	DAC peripheral clock
dac_ker_ck	Input	DAC kernel clock
dac_hold_ck	Input	DAC low-power clock used in Sample and hold mode
dac_out1	Analog output	DAC channel1 output for on-chip peripherals
dac_out2	Analog output	DAC channel2 output for on-chip peripherals

Table 266. DAC interconnection

Signal name	Source	Source type
dac_hold_ck	ck_lsi or ck_lse	LSI or LSE clock selected in the RCC
dac_chx_trg1 (x = 1, 2)	tim1_trgo	Internal signal from on-chip timers
dac_chx_trg2 (x = 1, 2)	tim2_trgo	Internal signal from on-chip timers
dac_chx_trg3 (x = 1, 2)	tim4_trgo	Internal signal from on-chip timers
dac_chx_trg4 (x = 1, 2)	tim5_trgo	Internal signal from on-chip timers
dac_chx_trg5 (x = 1, 2)	tim6_trgo	Internal signal from on-chip timers
dac_chx_trg6 (x = 1, 2)	tim7_trgo	Internal signal from on-chip timers
dac_chx_trg7 (x = 1, 2)	tim8_trgo	Internal signal from on-chip timers
dac_chx_trg8 (x = 1, 2)	tim15_trgo	Internal signal from on-chip timers
dac_chx_trg11 (x = 1, 2)	lptim1_ch1	Internal signal from on-chip timers
dac_chx_trg12 (x = 1, 2)	lptim3_ch1	Internal signal from on-chip timers
dac_chx_trg13 (x = 1, 2)	exti9	External pin

31.4.3 DAC clocks

Two clock sources can be used to update the DAC:

- dac_hclk: DAC peripheral clock (AHB clock)
- dac_ker_ck: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- dac_hold_ck: low-power clock used in Sample and hold mode

The DAC clock is selected in the RCC.

31.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a t_{WAKEUP} startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

31.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:

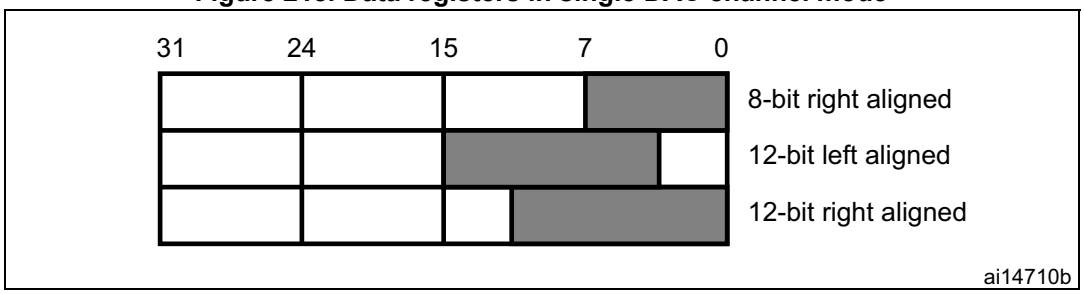
  – 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)

  – 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)

  – 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

Figure 218. Data registers in single DAC channel mode



- Dual DAC channels (when available)

  There are three possibilities:

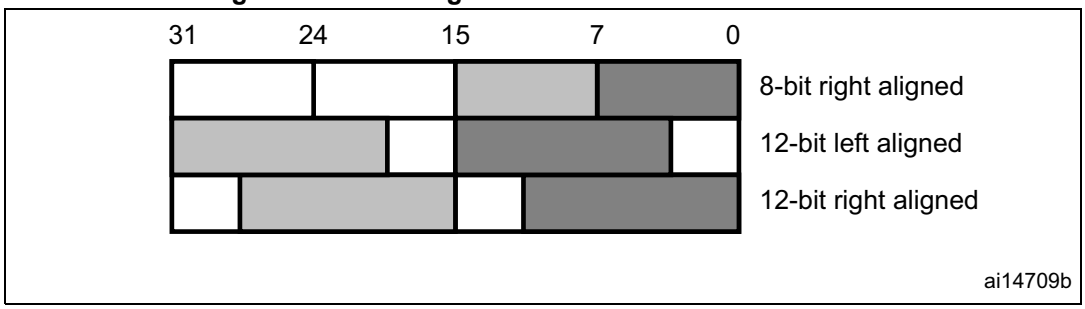
  – 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

  – 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

  – 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 219. Data registers in dual DAC channel mode



Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2's complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB bit of the data written to DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB bit is inverted. The four LSBs are simply ignored.

Table 267. Data format (case of 12-bit data)

SINFORMATx bit	DATA written to DHRx register	DATA transfered to DORx register
0	0x000	0x000
0	0xFFF	0xFFF
1	0x7FF	0xFFF
1	0x000	0x800
1	0xFFF	0x7FF
1	0x800	0x000

31.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{SETTLING}$ that depends on the power supply voltage and the analog output load.

To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_hclk or dac_ker_ck clock speed is faster than 80 MHz. It adds an extra delay to the transfer from DAC_DHRx register to DAC_DORx register.

Refer to Table *HFSEL description* below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

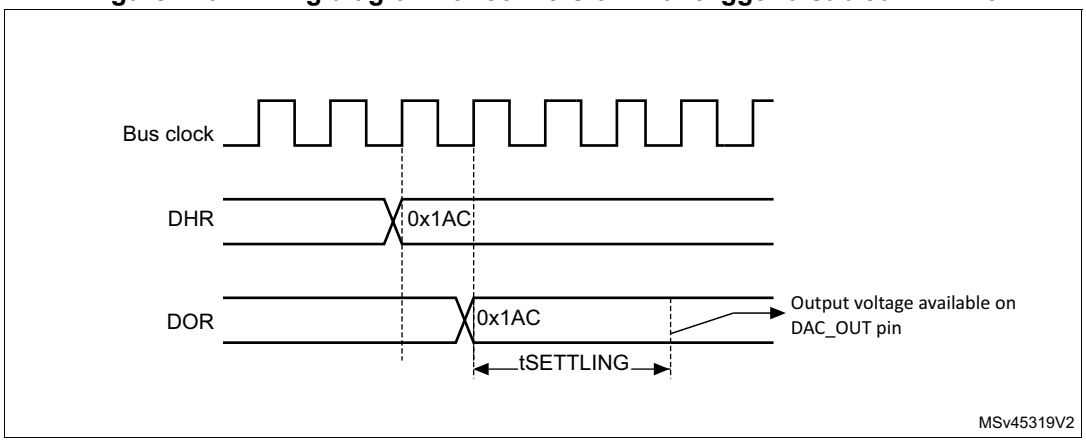
The above timing is only related to the limitation of the DAC interface. Refer also to the $t_{SETTLING}$ parameter value in the product datasheet.

Table 268. HFSEL description

HFSEL [1:0]	AHB frequency	Latency using AHB clock (dac_hclk)	Latency using dac_ker_ck clock	Function
00	≤ 80 MHz	3	4	DAC_DOR update rate up to 3 AHB clock cycles or 4 dac_ker_ck cycles.
01	>80 MHz(1)	5	5	DAC_DOR update rate up to 5 AHB clock or dac_ker_ck cycles.
10	>160 MHz	7	6	DAC_DOR update rate up to 7 AHB clock cycles or 6 dac_ker_ck cycles.
11	Reserved	-	-	-

1. Refer to the device datasheet for the value of the maximum AHB frequency.

Figure 220. Timing diagram for conversion with trigger disabled TEN = 0



31.4.7 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and V_{REF+}.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DACoutput} = V_{REF} \times \frac{DOR}{4096}$$

31.4.8 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in *Section 31.4.2: DAC pins and internal signals*.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

31.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA

workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

DMA Double data mode

When the DMA controller is used in Normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.
2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA Double data mode.

In DMA Double mode, DMA requests can only handle one DAC channel. To use two channel outputs in DMA Double mode, each DMA channel has to be configured separately.

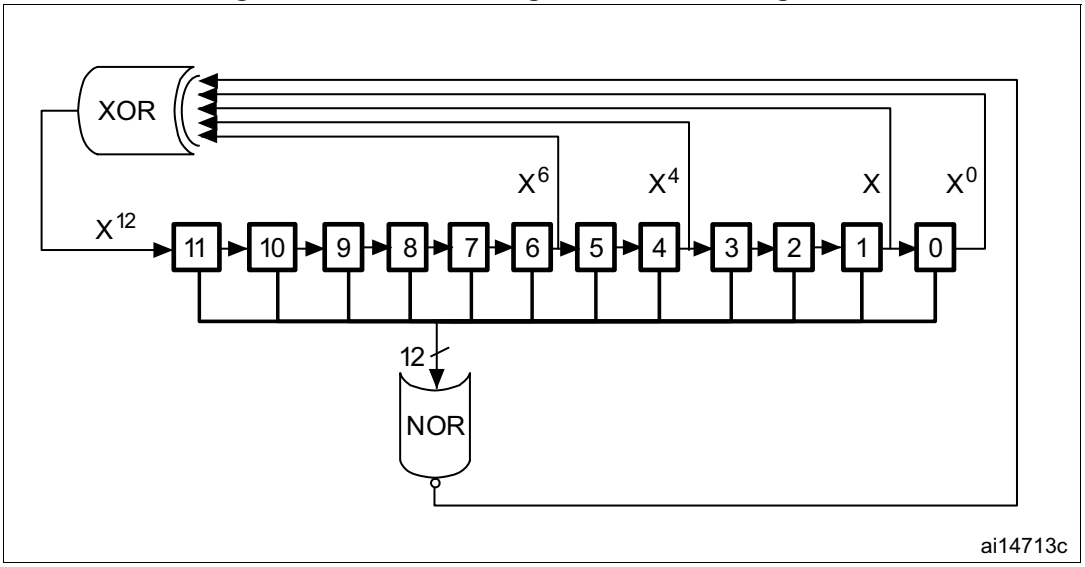
The following conditions must be met to change from Double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

31.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.

Figure 221. DAC LFSR register calculation algorithm

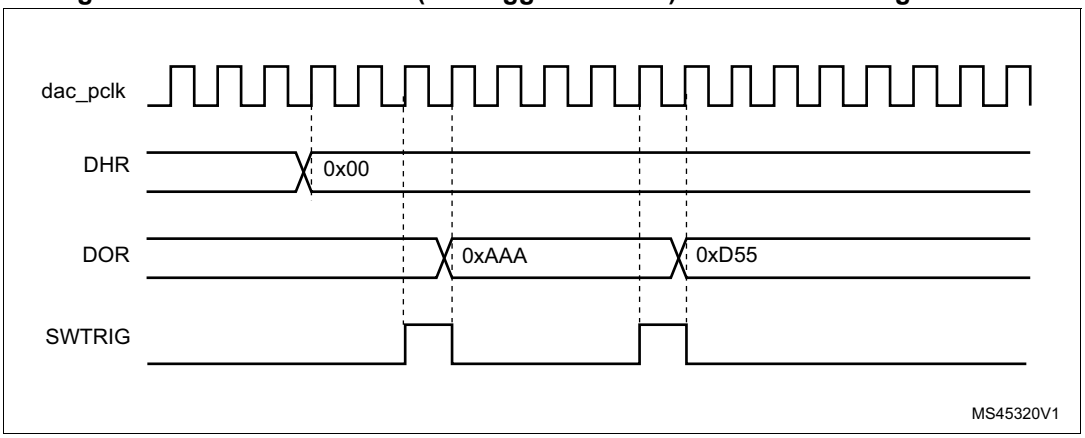


The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 222. DAC conversion (SW trigger enabled) with LFSR wave generation



Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

31.4.11 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10”. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 223. DAC triangle wave generation

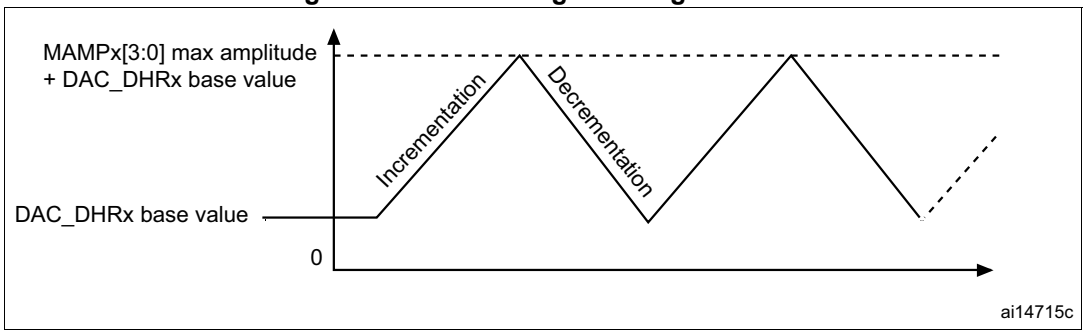


Figure 224. DAC conversion (SW trigger enabled) with triangle wave generation

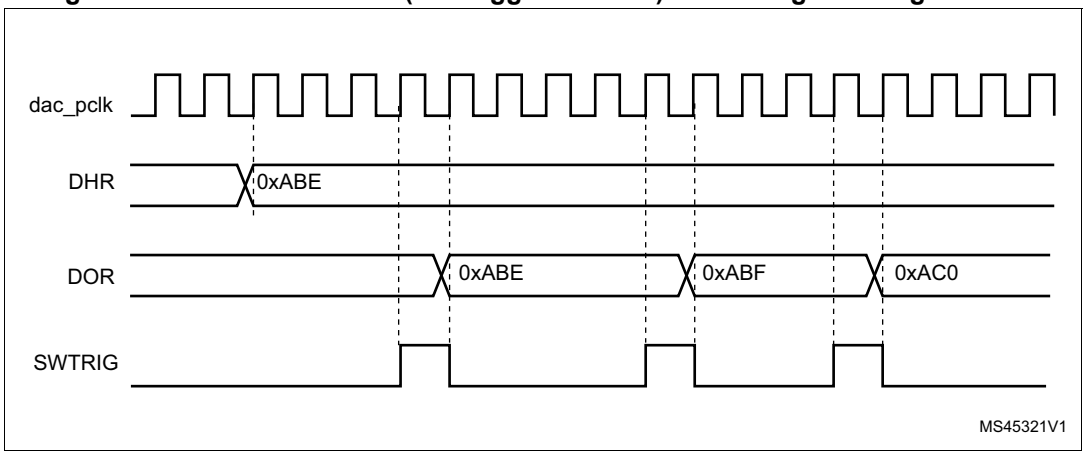


Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.

31.4.12 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI or LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing the DAC channels to be used in deep low power modes such as Stop mode.

The LSI or LSE low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register
3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,

62 cycles are required for hold phase: THOLDx[9:0] = 62,

and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 269. Sample and refresh timings

Buffer State	t_{SAMP} (1)(2)	$t_{REFRESH}$ (2)(3)
Enable	7 µs + (10*R_{BON}*C_{SH})	7 µs + (R_{BON}*C_{SH})*ln(2*N_{LSB})
Disable	3 µs + (10*R_{BOFF}*C_{SH})	3 µs + (R_{BOFF}*C_{SH})*ln(2*N_{LSB})

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. C_{SH} is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*Nlsb) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

C_{SH} = 100 nF

V_{REF+} = 3.0 V

Sampling phase:

t_{SAMP} = 7 µs + (10 * 2000 * 100 * 10^{-9}) = 2.007 ms

(where R_{BON} = 2 kΩ)

Refresh phase:

$t_{REFRESH}$ = 7 µs + (2000 * 100 * 10^{-9}) * ln(2*10) = 606.1 µs

(where N_{LSB} = 10 (10 LSB drop during the hold phase)

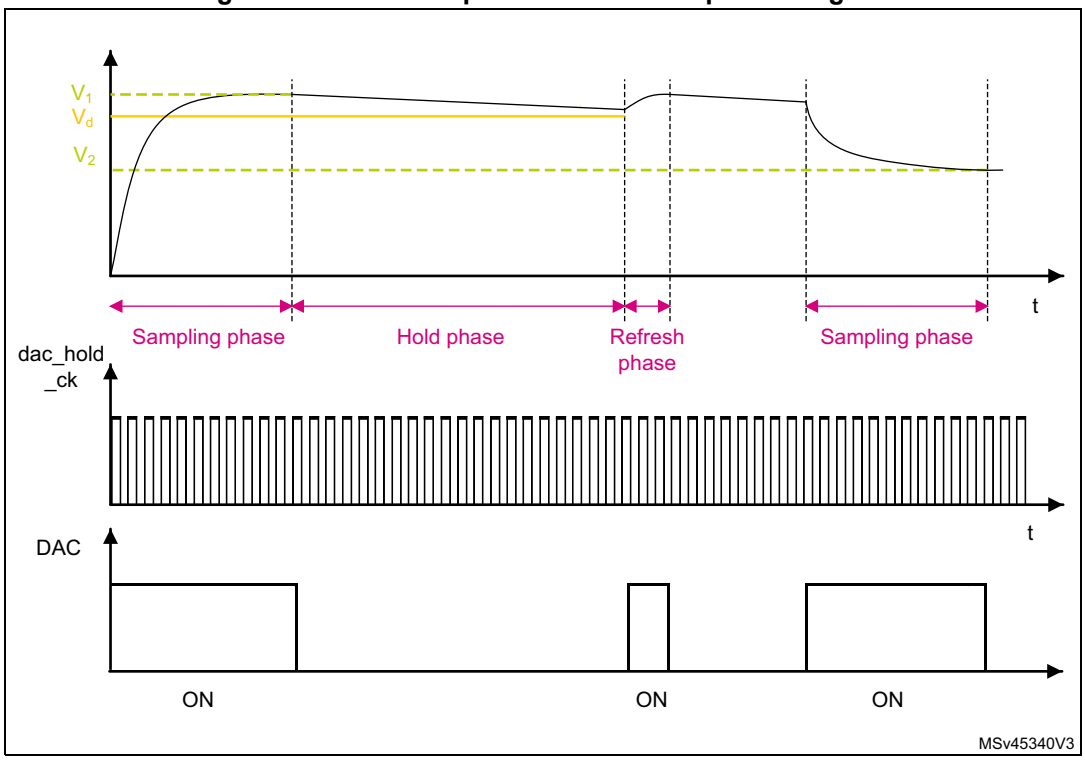
Hold phase:

D_v = i_{leak} * t_{hold} / C_{SH} = 0.0073 V (10 LSB of 12bit at 3 V)

i_{leak} = 150 nA (worst case on the IO leakage on all the temperature range)

t_{hold} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 ms

Figure 225. DAC Sample and hold mode phase diagram



Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

  When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{Lint}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

Table 270. Channel output modes summary

MODEx[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	0	1			Connected to external pin and to on chip-peripherals (such as comparators)
0	1	0		Disabled	Connected to external pin
0	1	1			Connected to on chip peripherals (such as comparators)

Table 270. Channel output modes summary (continued)

MODEx[2:0]			Mode	Buffer	Output connections
1	0	0	Sample and hold mode	Enabled	Connected to external pin
1	0	1			Connected to external pin and to on chip peripherals (such as comparators)
1	1	0		Disabled	Connected to external pin and to on chip peripherals (such as comparators)
1	1	1			Connected to on chip peripherals (such as comparators)

31.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = ((D/2^N) \times G \times V_{ref}) + V_{OS}$$

Where V_{OUT} is the analog output, D is the digital input, G is the gain, V_{ref} is the nominal full-scale voltage, and V_{os} is the offset voltage. For an ideal DAC channel, G = 1 and V_{os} = 0.

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the V_{os}, a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to VREF+/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)

  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming

  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when V_{DDA} voltage, temperature, VREF+ values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when V_{DD} is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 00000b.
   b) Wait for t_{TRIM} delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during *device* operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

Note: A t_{TRIM} delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value.This parameter is specified into datasheet electrical characteristics section.

If V_{DDA}, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

31.4.14 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

Simultaneous trigger with single LFSR generation

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated.
At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

31.4.15 DAC Autonomous mode

The Autonomous mode can be used to update the DAC output voltage in Stop mode. This allows DMA transfers to be performed when the device operates in Run, Sleep or Stop mode. The Autonomous mode is supported AUTOMODE only when the DAC is in Sample and hold mode. It is enabled by setting the bit in the DAC_AUTOCR register. DMA requests must also be enabled (DMAEN = 1).

When the AUTOMODE bit is set, each hardware trigger signal generates an AHB clock request to the RCC. Once the peripheral receives the AHB clock, the content of the DHRx register is loaded into DAC_DOR register and a DMA request is generated. When the DMA transaction is complete, the DAC deasserts the AHB clock request and waits for a new trigger event.

When the Sample and hold mode is selected, the dac_ker_ck low-power clock must be enabled by the RCC.

DMA transfers in Autonomous mode are performed following the sequence described below:

1. The DAC outputs the voltage on a GPIO or on an on-chip peripheral (dac_ker_ck and dac_hclk are not required).
2. The DAC receives a hardware trigger from another peripheral.
3. The DAC asserts the clock request.
4. The DAC loads DHRx register into DAC_DOR register.
5. The DAC generates a DMA request.
6. The DMA transfers the new data from memory to DHRx registers.
7. The DAC deasserts the clock request.

To initialize the DAC to operate autonomously in Stop mode, follow the sequence below:

1. Enable the DAC clock Autonomous mode in the RCC.
2. Select the DAC kernel clock in the RCC.
3. Enable dac_hold_ck clock for the DAC in the RCC.
4. Select a Sample and hold mode through MODEx bit.
5. Configure the Sample and hold mode by setting TSAMPLEx[9:0], THOLDx[9:0], TREFRESHx[7:0] bits.
6. Load the target value into DHRx register.
7. Set TENx bit to output the DAC value.
8. Configure the trigger setting through TSEL[3:0] bits.
9. Set DMAENx bit and configure the DMA interface.
10. Set the AUTOMODE bit.

Timing uncertainty of DHRx to DAC_DOR transfer

After each trigger event, the data contained in DHRx register is transferred to the DAC_DOR register. Since this transfer is based on AHB clock, the transfer timing depends on the clock availability.

When the AHB clock is stopped, a minimum time is required to restart it. This time depends on the clock source.

31.5 DAC in low-power modes

Table 271. Effect of low-power modes on DAC

Mode	Description
Sleep	No effect, DAC used with DMA.
Stop(1)	The DAC remains functional and can perform DMA transfers in Sample and hold mode.
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby or Shutdown mode.
Shutdown	

1. Refer to *Section 31.3: DAC implementation* for information on the Stop modes supported by the DAC peripheral.

31.6 DAC interrupts

Table 272. DAC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
DAC	DMA underrun	DMAUDRx	DMAUDRIEx	Write DMAUDRx = 1	Yes	No	No

31.7 DAC registers

Refer to *Section 1 on page 104* for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

31.7.1 DAC control register (DAC_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CEN2	DMAUDRIE2	DMAEN2	MAMP2[3:0]				WAVE2[1:0]		TSEL2[3]	TSEL2[2]	TSEL2[1]	TSEL2[0]	TEN2	EN2
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CEN1	DMAUDRIE1	DMAEN1	MAMP1[3:0]				WAVE1[1:0]		TSEL1[3]	TSEL1[2]	TSEL1[1]	TSEL1[0]	TEN1	EN1
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in Normal operating mode

1: DAC channel2 in calibration mode

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Note: These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)
These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15

Refer to the trigger selection tables in *Section 31.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.

Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).
These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

Note: When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.
These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled

1: DAC channel2 enabled

Note: These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel1 calibration enable

This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel1 in Normal operating mode

1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.

00: wave generation disabled

01: Noise wave generation enabled

1x: Triangle wave generation enabled

Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bits 5:2 **TSEL1[3:0]**: DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
Refer to the trigger selection tables in *Section 31.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.
Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1**: DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
